

1 Volume I

Regional Biosecurity Plan for Micronesia and Hawaii

Volume I

Prepared by:

University of Guam and the Secretariat of the Pacific Community 2014

This plan was prepared in conjunction with representatives from various countries at various levels including federal/national, state/territory/commonwealth, industry, and non-governmental organizations and was generously funded and supported by the Commander, Navy Installations Command (CNIC) and Headquarters, Marine Corps.

Attachment O: Models

Attachment P: Biosecurity Officer Qualifications

Attachment Q: List of Consultancy Trips

Attachment R: List of Implementation Strategy Workshop Attendees

Volume II: Executive Summary to the Risk Assessments and the Freshwater Systems Risk Assessment

Volume III: Marine Systems Risk Assessment and Supplement to the Regional Biosecurity Plan for Micronesia and Hawaii Marine Risk Assessment

Volume IV: Terrestrial Systems Risk Assessment

1. Forward

This document, the Regional Biosecurity Plan for Micronesia and Hawaii or RBP, is the work of many, in fact hundreds of individuals. Various government agencies, organizations, and individuals have contributed either through preparing texts that have become elements of this overall document and/or by supplying detailed comments and suggestions which have been used to build the implementation strategy. The concept of building this plan with such extensive input was felt to be the appropriate mechanism to insure that biosecurity needs for the region were comprehensively documented and it is to be hoped that any errors which do exist in this document are minimal and that any existing errors can over time be identified and corrected for future editions of this living document.

The RBP was originally termed the Micronesia Biosecurity Plan or MBP. Since the inception of the plan the term MBP has been used for a variety of subcomponents as well as to reference the overall project and the term can be found in earlier documents and components including the risk assessments which are part of the RBP. The risk assessment sections of this document are by far the largest components. These assessments contain a vast array of useful information and details and end users are encouraged to explore them in order to benefit fully from these assessments.

Given the extensive size of the risk assessments, an attempt was made to keep the strategic implementation component of the plan as streamlined as feasible to assist end users. The implementation section hinges on the recommendation tables, one table for each jurisdiction, plus additional tables for the U.S. (covering its three jurisdictions within the region) and for the U.S. Department of Defense (DoD). In this regard, the U.S. regional and DoD are treated as jurisdictions, although strictly speaking they are not. The three jurisdictions which fall under U.S. federal oversight and are part of this plan are only a part of the area covered by the U.S. federal jurisdiction. DoD is a department of the U.S. federal government with facilities, personnel, and materials in many areas around the globe. This plan only covers those DoD elements which are within the region or which are either entering or departing the region.

The preparers of the RBP have agreed that the task at hand was not to write a biosecurity plan for the region per se, but rather to serve as compilers, editors, and synthesizers working to produce a regional biosecurity strategy from the input of experts and stakeholders from throughout the region as well as supplementing this core input with additional material from experts from beyond the region as appropriate. Ultimately, what the reader of this document will find is what local, regional, and global experts and stakeholders have suggested should be included in this document. Some jurisdictions provided much more input than others. It is hoped that the information provided in this plan will assist each and every jurisdiction as well as the region in moving forward with improving biosecurity across the board (within jurisdictions, between jurisdictions, and for the region, as well as for linkages outside the region).

This plan was drafted and developed with the intention that it should remain a living document and that once the final product has been delivered to the jurisdictions, the jurisdictions themselves would

determine how best to move forward with recommendations, implementation, and updating their elements of the plan as needed in order to insure that it remains current and ultimately functional. It is hoped that updates both in regards to advancements towards meeting specific recommendations as well as to the plan itself will be shared between jurisdictions and supported by the region, ultimately ensuring that the plan remains a regional concept with a regional focus but driven by the individual jurisdictions via regional agreements and continued planning, development, and implementation.

2. Mission Statement

The concept of the RBP is visionary in its scope. The transfer of invasive species or invasive alien species (IAS) to the region and within the region is real, ongoing, and an increasing problem that must be addressed. The spatial scale for this plan is extremely broad, encompassing most of Micronesia and the archipelago of Hawaii. The plan attempts to cover the broadest possible extent of habitats and taxonomic groups including terrestrial, freshwater, and marine systems. This overall approach is unprecedented due to the broad geographic and taxonomic scope, as well as inclusion of multiple countries and cultures.

The primary entities covered by the RBP are listed below. These entities are often referred to as jurisdictions within the RBP, as most of them are government jurisdictions.

- The U.S. Federal Government, as it relates to its jurisdictions within the region
- The U.S. Territory of Guam, commonly referred to as Guam
- The U.S. Commonwealth of the Northern Mariana Islands or CNMI
- The U.S. state of Hawaii, commonly referred to as Hawaii
- The Federated States of Micronesia or FSM
- The FSM state of Chuuk
- The FSM state of Kosrae
- The FSM state of Pohnpei
- The FSM state of Yap
- The Republic of Palau, commonly referred to as Palau
- The Republic of the Marshall Islands or RMI
- The DoD

The approach used to develop the RBP explicitly considers multiple vectors and environments (marine, freshwater, and terrestrial systems) together, using an appropriate spatial scale at which invasions operate. The implementation of this large-scale, integrative, and cross-cutting strategy should result in improved biosecurity protection, efficiency, and consistency, compared to advancing many individual activities in isolation. By cross-cutting we refer to the fact that invasive species negatively affect most major concerns within the region such as climate change adaptation, human health, green economy development, natural resources conservation, economic stability and growth, food security, etc. and that by addressing invasive species via appropriate biosecurity we are in fact positively affecting all of

these major concerns. The implementation guidance within the RBP supports establishment of a coordinated and consistent strategy internationally, across multiple countries and cultures. Most current understanding and management of invasions come from temperate latitudes and continents, but this plan aims to address invasions on tropical islands ecosystems. Even though Micronesia and Hawaii encompass a large area including multiple countries, current levels of trade and the number of points of entry are few relative to many other global regions. This suggests that understanding transfers of vessels and goods is more feasible here than it is for many other areas and should make developing appropriate and functional biosecurity mechanisms feasible. This underscores the value of Micronesia and Hawaii as a model. It is important to recognize that current capacity and resources limit present day biosecurity activities throughout the region and overcoming these deficiencies needs to be part of the implementation plan for the region. By implementing a cohesive regional plan and developing appropriate mechanisms to address IAS, Micronesia and Hawaii could become world leaders in advancing biosecurity, especially in tropical ecosystems. Coordinated biosecurity within the region could effectively become a global model.

Cooperation among nations in the western Pacific, whereby preventive measures are enacted to reduce the probability of exporting or importing invasive species, will benefit each nation by reducing the probability of such species becoming established (McNeely et al. 2001). A somewhat similar approach has been implemented for northern Australia and is known as the North Australian Quarantine Strategy (NAQS). NAQS has helped address many biosecurity concerns for northern Australia by coordinating efforts between northern ports of entry and Australia's northern neighbors including Indonesia, Papua New Guinea and Timor-Leste (Pheloung 2003). A proactive, precautionary approach is preferred for regional biosecurity development and this will require effective and coordinated efforts together with sufficient resources and networking (Henderson and Bomford 2011). Such cooperation is essential to the development of biosecurity for the western Pacific and it is encouraged between jurisdictions covered by the RBP as well as others.

Advancing a uniform and consistent approach to biosecurity throughout the region is desirable, as it would be the most likely way to reduce overall effort and costs associated with IAS control and management for the entire region and it would serve to increase clarity and possibly compliance. Thus, communication, coordination, and participation among all member countries and jurisdictions in the region are critical elements in regards to reaching the desired outcome of a better protected region.

The RBP, including both the risk assessments and implementation strategy, provides planning and in some cases execution level information. Each jurisdiction within the region will need to review the implementation guidance and in some cases may be required to further tailor the guidance to meet unique needs. Direct details such as timelines, particular costs, and specific personnel and equipment lists are in large part left out unless supplied specifically by the jurisdictions. Each jurisdiction will need to develop specific details for action items they determine are practical, warranted, and feasible to enact. The RBP does not set laws or regulations nor define the responsibilities or obligations of any jurisdictions, agencies, or offices. Again these elements are left for the appropriate authorities to determine. The RBP is a guidance document which is to be utilized to strengthen biosecurity.

3. Executive Summary

The Micronesia Chief Executives (MCEs) and their council on invasive species, known as the Regional Invasive Species Council or RISC, have been in the forefront of regional IAS work for almost a decade. The current effort to develop a regional biosecurity plan originated with the RISC and the MCEs as early as 2005. In 2007, DoD formally announced its intentions to prepare an Environmental Impact Statement (EIS) to address environmental impacts associated with the relocation of military forces from their current location in Okinawa to Guam, as well as the expansion of training in the Mariana Islands (Federal Register Volume 72 No 44, March 7, 2007). The announcement elicited concerns about the unintentional movement of invasive species associated with the relocation effort. In response to regional concerns, the U.S. Department of the Navy (DON) contracted the U.S. Geological Survey (USGS), the Smithsonian Environmental Research Center (SERC), and the U.S. Department of Agriculture Animal and Plant Health Inspection Service (USDA APHIS) to produce three risk assessments, one each for freshwater systems (Volume II), marine systems (Volume III), and terrestrial systems (Volume IV). These risk assessments were to address invasive species whose introduction to, or spread within, the region might compromise human health and safety, animal and plant health, economic viability and/or biodiversity values in the region. These DON funded risk assessments were the first concrete steps in developing this regional biosecurity plan. While DON funded the development of the regional biosecurity plan, the plan itself is not restricted to DON or even only DoD related activities but rather encompasses (or attempts to encompass) biosecurity concerns throughout the region for all levels of society.

Guam is the main transport hub for the rest of Micronesia and Hawaii is a major hub for much of the Pacific Region, including Micronesia. Entry of any pest or disease into either hub could lead to a rapid movement of the same pests into the surrounding region. For this reason, biosecurity within these jurisdictions is of immense regional importance.

Some species' risks are well known but many are unknown and unpredictable. Therefore a comprehensive strategy needs to have both specificity to manage the known high-risk present threats (e.g. brown treesnake (BTS) (*Boiga irregularis*) and coconut rhinoceros beetle (CRB) (*Oryctes rhinoceros*)) and generality or precautionary processes for the unknown or infrequent threats.

The means by which the threats arrive or leave a jurisdiction or region can be classified according to their physical vector and/or pathway (ships, aircraft, or people), as diseases brought with incursions of risk species or of non-risk species allowed into each island, and/or in relation to some human derived process (legal, illegal, or accidental introduction). Ultimately how each jurisdiction will handle planning and developing their biosecurity capacity will in part depend on current and future anticipated vectors and pathways and it is essential that a well formed pathways analysis be part of any biosecurity planning efforts.

Mitigation or intervention to manage these high risk species can be done pre-border at a source, along the pathways and/or on the vectors, at the border, or post-border – with generally increasing costs and

potential adverse outcomes as the intervention point is delayed. Identifying the costs of intervention at different points along the risk chain, and also the resulting costs to environment, economy, and health if sub-optimal interventions are used, is essential to managing a biosecurity system and allocating responsibilities.

There is a common belief that intervention all along the risk chain is optimal (e.g. Russell et al. 2008). This is true across the whole biosecurity process, and probably true for high, medium and low risk species when funds are not constrained, but as funds are usually constrained it is not true for each invasive species or class of species generally speaking. Therefore, most biosecurity systems allocate resources to the most effective points in the risk chain. This point varies with the nature of the risk species, the predicted frequency of the event, the cost to detect it, the cost of dealing with an event at the most effective point in the chain, and the consequence and cost of failure to detect and manage the event at that point in the chain. This complexity makes biosecurity planning difficult by requiring a combination of precautionary and reactive management commensurate with the likelihoods of events, and the costs and feasibility of action, and costs of failure. Plans need to focus more on processes than on the specifics of risky species.

A question faced by all agencies developing biosecurity plans is whether to focus activities around particular species or around generic processes designed to cover all eventualities or perhaps more likely, how to determine the optimal mixture of the two. Clear and present hazards (e.g. BTS) tend to focus effort at the species level, but uncertain or rare events need to be managed by more systematic biosecurity approaches. The compromise approach is to ask, "What collateral reduction of risks might be covered by a focus on high-risk species?"

Each of the risk assessments, presented in volumes II, III, and IV, has addressed these considerations in various degrees of detail, especially for those with Guam as an endpoint. However, sources, pathways, and vectors have only been identified and linked to the assessments for some risks. The focus of the assessments on sources and endpoints (the freshwater component), pathways and endpoints (the terrestrial component), pathways alone (the marine component), or vectors (the phytosanitary and disease parts of the terrestrial component) appears to have been determined by the assumed best points of intervention along the risk chains.

Terrestrial, marine and freshwater risk species are all transported from a source (within or outside Micronesia) to an island (or its littoral zone) in Micronesia or Hawaii but, of course, the nature of this transportation differs with the risk species. Terrestrial species can be transported by anything that floats or flies, marine species can float but are transported mostly on ships via biofouling or in ballast or waste water, and freshwater species are mostly deliberately moved in 'fish tanks'. The terrestrial and marine components concentrate on inbound pathways for Guam and have less detail of intra-Micronesia risks. Future updates of the plan will need to refine and enhance the definitions of intra-Micronesia risks for the terrestrial and marine environments.

A focus on pathways is critical (since it is not possible to focus on each and every species), but along with a focus on pathways, it is equally important to also focus on a few key species, as appropriate management of these key species will also reduce the risk of invasion by other species.

The three risk assessments and the implementation strategy are a plan or framework and no matter how well developed and comprehensive they are, until there is effective action taken within the jurisdictions, by the jurisdictions, biosecurity will remain sub-standard for the region. Implementation of this plan by the jurisdictions is the anticipated next step in this process. This is the critical step and it is anticipated that implementation will be a multi-tiered effort, or efforts, undertaken by the leadership and agencies of the individual jurisdictions, in partnership with other jurisdictions as well as external partners. It should be recognized, however, that the RBP does not create any right, obligation, or legal responsibility on the part of any of the jurisdictions discussed herein to fund or execute the recommendations set forth in the plan.

The purpose of this regional biosecurity plan is to act as a tool with which to help enhance the coordination of current management efforts, identify remaining problem areas and gaps, and recommend additional actions that are needed to effectively address IAS issues within jurisdictions as well as regionally. The focus of this plan is the identification of feasible, cost-effective management practices to be implemented by appropriate authorities for the environmentally sound prevention and control of IAS in a coordinated fashion.

The goal of the plan is to provide recommendations that, if appropriately implemented, will minimize the harmful ecological, social, cultural, and economic impacts of IAS through the prevention and management of their introduction, expansion, and dispersal into, within, and from the region and the jurisdictions of the region. Objectives that need to be addressed in order to advance towards the goal include: securing funding, coordination and collaboration, prevention, monitoring, early detection and rapid response, management and eradication (where feasible), education and outreach, research, policy, and restoration.

4. Introduction

4-1. Background

Invasive species pose a constant and costly threat to Pacific islands' native ecosystems, ecosystem functions, biodiversity, watersheds, economies (including tourism, agriculture, aquaculture, importation, exportation, and transportation), public health, cultures, and the quality of life of residents and visitors.

Oceanic islands throughout the world are notoriously vulnerable to biological invasions. Islands experience long periods of evolution in isolation from those forces faced routinely by plants and animals on continents. This isolation also contributes to the vulnerability of islands to biological invasion (Loope and Mueller-Dombois 1989). The relatively small, restricted populations of native species on isolated islands and the intensity of human impacts on the small land areas of islands have clearly made the situation worse by increasing most islands' susceptibility to invasion.

The MCEs and their council on invasive species for years have advocated a regional approach to biosecurity in Micronesia. DON agreed to fund the development of this regional biosecurity plan in part to assist with minimizing the risk of introduction and spread of invasive species to and within the region in response to the proposed U.S. military relocation from Okinawa to Guam and the CNMI (hereafter referred to simply as "the build-up"). This regional plan has been termed the RBP. A critical component of the RBP is its proposed framework for regional biosecurity found within the RBP's implementation strategy (Section 11).

Biosecurity strategies or plans have been formulated for many countries, including island states such as New Zealand (Anon 2003) and the Bahamas

www.best.bs/Documents/Bahamas_Biosecurity_Strategy.pdf, July 2014). There have also been efforts to develop biosecurity strategies that involve multiple countries or regions of countries such as the NAQS. The RBP differs in its scope and ambition in several respects. First, the geographic area being considered is enormous (covering up to 5000 miles east-west and up to 1700 miles north-south), and it includes multiple countries, unique cultures, and diverse activities and institutional structures. Second, the approach adopted here includes all human-mediated mechanisms (vectors) of alien species introductions, attempting to evaluate their operational characteristics and the status of current management practices in the region. Third, the RBP attempts to address biosecurity in a holistic sense considering pre-border, border, and post-border elements for each jurisdiction. Although addressing these dimensions presents obvious challenges, it also represents an important opportunity and step forward in integrating information across vectors at a regional scale. This integration is vital to advance coordinated and effective action for invasion management across countries as well as the military, government, and public and private sectors.

An appropriate definition for biosecurity would be a strategic and integrated approach that encompasses policy and regulatory framework for analyzing and managing relevant risks to human, animal and plant life and health, and associated risks to the environment. Therefore, a regional

biosecurity plan may be considered a set of proposed actions that a group of end users with common goals implement to prevent the incursion and establishment of potential IAS into a region. A strategic implementation plan is a proactive management tool that should be used as a guide that illustrates critical steps in the capacity building process and addresses existing challenges and gaps.

While biosecurity can include post-border responses to new incursions and management of established invasive species, such as eradication, containment, and control, extra emphasis is usually placed on pre-border efforts that aim to prevent invasions from occurring in the first place. Prevention, or minimizing the probability and number of new invasions, is usually viewed as the most cost-effective and desirable strategy to pursue, because it can be extremely difficult to eradicate or control species once they have established (Wittenberg and Cock 2001). Even though prevention may be the best approach to minimizing impacts from potential IAS, other elements should not be neglected, such as early detection and rapid response for post-border situations. No border security can be 100% effective all of the time and, therefore, a good biosecurity plan will incorporate pre-border, border, and post-border elements to insure the best possible protection from potential IAS.

Efforts to prevent the transport or import of potentially harmful species are usually directed at specific vectors and aim to reduce the magnitude (concentration or abundance) and frequency of species transfers to a target area. Such measures may be aimed at entire communities (e.g., ballast water of ships, as discussed in the marine risk assessment) or particular species of concern, and vectors are an explicit focal point for evaluation and management action(s) in most cases. Thus, vector management is a central aspect of most efforts to prevent invasions, whether on land or in water.

4-2. Overview of Invasive Alien Species

In order for an organism to be considered an IAS, it must meet all of the following criteria:

- Non-native
- Able to establish in a new location (start an incipient population or at least seems likely to be able to do this based on life history traits and/or examples of establishment in similar locations)
- Cause harm (to environment and/or directly or indirectly to humans and/or their endeavors or at least seems likely that it would cause harm if permitted to establish based on life history traits and/or examples from other locations)

Non-native species refer to plants, animals, and micro-organisms transported or established outside of their natural range due to the activities of humans, regardless of whether these actions are intentional or not. Non-native species are sometimes referred to as non-indigenous, alien or exotic species. Not all non-native species will become invasive, and not all non-native species cause unacceptable harm. Some intentional introductions are considered beneficial (at least to humans), such as some crops (e.g. rice) and livestock (e.g. cattle and poultry). In fact, many of the species used for agricultural purposes within Micronesia are non-native plants. Introduced species form the basis of the more than \$800-billion food

system in the United States (Pimentel et al. 2000). Some species, either purposely or accidentally introduced, fail to become established or remain restricted in numbers or geographical range, and may be of negligible economic or ecological significance. As an example, many of the bird species currently established on the island of Guam (e.g. blue quail (*Coturnix chinensis*), black francolin (*Francolinus francolinus*)) were introduced during the 1800s and early 1900s as sources of food and while these non-native species have established, they do not currently appear to have extensive negative impacts, although it should be pointed out that their potential impacts to native systems of Guam have not been closely examined and their populations are most likely kept in check by the presence of the BTS. While not all species have the potential to become invasive if introduced to a new location, some do and when they do become established these species have the potential to cause serious harm. There are numerous examples of non-native species having become invasive and causing major disruptions in agriculture, other economic sectors, to people and the natural environment. Examples of such species are numerous and would include organisms such as miconia (*Miconia calvescens*), strawberry guava (*Psidium guajava*), and little fire ant (LFA) (*Wasmannia auropunctata*).

Invasive species are sometimes referred to simply as pest or nuisance species. These terms are misleading as both can also be applied to native species where they cause conflicts with human activities. Therefore it should be clear that not all pest or nuisance species are necessarily non-native and it is better to use the term invasive when discussing IAS.

While the specific biology of invasive species varies enormously, some or all of the following general characteristics apply to many invasive species (both terrestrial and aquatic) worldwide:

- Adaptable to, and capable of thriving in different habitats and a wide range of conditions;
- Have rapid growth rates of individuals, thereby able to displace other plants or animals;
- Are easily dispersible to new localities; and
- Have reproductive characteristics that allow for rapid population growth.

Invasive species often tend to relatively easily surmount geographical and environmental barriers, establish themselves quickly, and then expand their numbers and ranges, often rapidly, in the new habitat (Ehrlich 1986; Mack et al. 2000; Richardson et al. 2000), frequently displacing or extirpating populations of native species in the process (Vitousek et al. 1997). Most of the highly successful invaders have been those introduced into new regions, either inadvertently or deliberately, by human agency (e.g., Baker 1986; Mack et al. 2000; Ruiz et al. 2000; Mack and Lonsdale 2001; Naylor et al. 2001; Reichard and White 2001; Fuller 2003; Kraus 2003).

The establishment and spread of species introduced to regions where they are not native is commonly cited as second only to habitat loss as a cause of global biodiversity decline (Wilson 1992; Wilcove et al. 1998). There is evidence that invasive species are a leading cause of animal extinctions (Clavero and García-Berthou 2005). Reduced diversity and abundance of native species resulting from the widespread

establishment of non-native invasive species has also led to biotic homogenization, a human-mediated phenomenon whereby the species composition of different ecosystems become more similar (McKinney and Lockwood 1999; Lockwood and McKinney 2001; Rahel 2002; Olden and Poff 2004; Olden et al. 2004; Helfman 2007; Rooney et al. 2007). Some scientists have referred to the present as the “Homogocene” era to highlight the unprecedented global redistribution of species and associated alterations to ecosystems (Rosenzweig 2001; Didham et al. 2005). Invasion success depends on the characteristics of introduced organisms and the physical and biological makeup of the environment to which they are introduced. The mechanisms and results of invasions vary widely. Highly invasive species may exploit native species directly, such as through predation or hybridization, may be superior competitors, or may have ecological or economic effects of a more subtle nature.

Although the biological fragility of islands has been debated, evidence suggests that many introduced species are more likely to establish on islands than in mainland areas, and are more likely to have major ecological effects (Simberloff 1995). The vulnerability of islands to invasion has been attributed to a variety of factors. In general, biological communities on islands have evolved and diversified in relative isolation (with limited gene exchange) over many millennia. As a result, islands typically exhibit high species endemism, low numbers of top predators, and species and communities that are highly specialized. These characteristics, combined with other factors, make island floras and faunas especially vulnerable to impacts from the introduction of non-indigenous species (Vermeij 1991; Paulay 1994).

Islands in the Pacific Ocean are among the most biologically diverse in the world, yet also face some of the highest extinction rates and threats to endemic species (CI-MCBC 2007). On Pacific islands the estimated minimum numbers of native species for different biotic groups (percent endemic in parentheses) are: vascular plants 5,330 (57%); birds 242 (68%); reptiles 61 (49%); mammals (all bats) 15 (73%); and amphibians 3 (100%). Data for fish are not as well documented, but at least 100 species, many endemic, occur as adults in freshwater habitats of western and central Pacific islands. The invertebrate fauna is even less well known, but diversity is high; for example, land snails may number over 750 species in Hawaii alone, possibly with as many as 4,000 species throughout the insular tropical Pacific (CI-MCBC 2007).

Although habitat loss may be the primary threat to many insular ecosystems, introduced species on tropical islands of the Pacific play a major role due in part to the vulnerability of a native biota that evolved with less or no exposure to terrestrial predators, grazing herbivores, and pathogens that are typical of larger land masses. For some islands, IAS may currently be the single greatest threat to native wildlife. In Hawaii alone, the large number and diversity of introduced species has resulted in a myriad of impacts to the native flora and fauna. For example, the impacts on the native bird fauna of the Hawaiian Islands by invasive species such as the Indian mongoose (*Herpestes edwardsii*) and mosquitos (and associated pathogens) has been extensive.

There are also cases of widespread harm resulting from the introduction of one or only a few invasive species. One of the most infamous examples in the western Pacific is that of the BTS. The introduction of this snake to Guam has resulted in the extinction or dramatic decline of a variety of native birds, bats

and reptiles (Rodda et al. 1997; Fritts and Rodda 1998). In addition to the ecological threats posed to native species and ecosystems, the economic impact of invasive species can be enormous (NRC 2000; Pimentel et al. 2000; Finnoff et al. 2005; Lovell and Stone 2005; Pimentel et al. 2005; Shogren and Tschirhart 2005). Such impacts can be especially burdensome to island economies.

Biological invasions by non-native species have the potential to cause significant environmental, genetic, economic, social, and cultural impacts as well as effects on human health (Mack et al. 2000; Carlton 2001; Millennium Ecosystem Assessment 2005; Charles and Dukes 2007). Invasions and associated effects are known to occur across diverse global regions and habitats, representing a major force of change. It appears that no area is immune from invasions, which are occurring from the poles to the tropics in terrestrial, freshwater, and marine environments.

Range expansions occur when species establish self-sustaining populations beyond their historical range. While range expansions may result from natural dispersal, in recent times human-aided dispersal has resulted in introductions of harmful non-native species. This includes the unintentional transfer of organisms associated with trade and transportation, as well as intentional introductions for aquaculture and related activities. Human activities have substantively altered invasion dynamics in two major ways. First, the observed rate of new invasions has increased dramatically in recent time, driven primarily by human introductions (Ruiz et al. 2000; Ruiz and Carlton 2003). Second, the geographic scale of invasions has changed, because global commerce moves biota across historical dispersal barriers such as continents and ocean basins, creating connectivity among geographic regions that would not otherwise exist. In addition to the key role of transportation, invasion dynamics are also responding to climate change, which affects the probability of establishment as well as the possible consequences (Stachowicz et al. 2002; Harley et al. 2006; Hellmann et al. 2008). As Hulme (2012) suggests, climate change “may lead to an increase or decrease in susceptibility of ecosystems to invasion such that past patterns of establishment may not hold in the future.”

As a result of the rapid expansion in international travel and trade over recent decades, more people and goods are moving throughout the world than ever before. This increased traffic has been undeniably of great benefit, fostering greater contact and communication and raising living standards. However, the pace and extent of modern global travel also have engendered significant risks, one of the most serious of which is the increased chance of introduction of non-native species that may become invasive (Bright 1998; McNeely 2006).

In their impact on human society, invasive species impose economic, social, cultural and medical costs in a variety of ways. They feed on or infect valued plants (food and fiber crops, ornamentals, timber) or, in the case of weeds, compete with them for nutrients and sunlight, thus reducing yields or causing post-harvest losses; increase crop production costs through increases in mechanical and chemical controls; increase crop protection costs directly or by harboring other pests (arthropods, nematodes, plant pathogens); reduce the quality of farm products (e.g., through contamination of crop seed with weed seed, reduction in the area of useful forage for livestock in pastures and rangelands); damage fisheries and aquaculture; reduce the quality of livestock or game through infection, parasitization, or toxicity,

leading to death or failure to thrive, lowered quality of animal products (milk, fleece, or hides), or reproductive failure; increase processing costs incurred in cleaning contaminated products; interfere with water management in agriculture by infesting irrigation ditches and other waterways; increase utility costs; damage commercial and residential structures; increase costs to maintain rights-of-way for railroads, highways, and power and telephone transmission lines; endanger human health and decrease labor productivity through allergies and poisonings, and the transmission of pathogens; reduce revenues from recreational hunting and fishing, and from tourism; restrict access to foreign markets; and decrease land values (OTA 1993; Westbrooks 1998; Mullin et al. 2000; Huber et al. 2002; Monaco et al. 2002).

Biotic invasions have enormous economic consequences. Worldwide, the annual economic impact of invasive species (losses or damages combined with control costs) is estimated to exceed \$1 trillion, nearly 5% of the global economy (Pimentel et al. 2001). Costs to the U.S. economy alone total approximately \$137 billion annually (Pimentel et al. 2000).

Economic losses due to introduced plants surpass those caused by any other class of invasive species. For example, the annual economic impact of invasive weeds is estimated to be approximately \$39 billion in India, \$34 billion in the United States, \$17 billion in Brazil, \$1.4 billion in the United Kingdom (Pimentel et al. 2001), \$12 billion in South Africa (van Wilgen et al. 2001), \$3 billion in Australia (Sinden et al. 2004), and \$1 billion in New Zealand (Williams and Timmins 2002). Losses to the Canadian economy resulting from invasion by four weeds, Canada thistle (*Cirsium arvense* (L.) Scopoli (Asteraceae)), leafy spurge (*Euphorbia esula* L. (Euphorbiaceae)), diffuse knapweed (*Centaurea diffusa* Lam.), and spotted knapweed (*C. maculosa* Lam. (Asteraceae)), exceed \$250 million annually (Claudi 2002). Rockwell (2003) estimated that the total costs imposed solely by invasive aquatic weeds in the United States ranged from \$900 million to \$14 billion annually. In the United States, invasive plants currently infest an estimated 40 million hectares, and continue to spread into an additional 1.2 million hectares every year (NISC 2001). They have badly degraded more than 15 million hectares of grazing lands and natural ecosystems in Australia (Glanznig 2003). Noxious weeds have invaded an estimated 10 million hectares in South Africa (van Wilgen et al. 2001), where they are appropriating as many as 3.3 billion cubic meters (7%) of mean annual surface water runoff from catchments, riparian zones, and wetlands (Olckers 1999).

Invasive species, in their capacity to modify community structure and ecosystem processes, also impose a heavy toll on natural environments. They impact ecosystems by reducing biodiversity through predation, grazing, competition, or hybridization; simplifying food webs; initiating epizootics or epiphytotics; altering fire regimes and hydrological cycles; changing soil chemistry and biology through, for example, changes in pH and nutrient cycling, salt accumulation, nitrogen fixation, or altering the composition of the soil fauna and flora; affecting normal geomorphologic processes by promoting siltation or erosion; altering the activity of pollinators; and modifying evolutionary trajectories in native species (Mooney and Drake 1989; OTA 1993; Cronk and Fuller 1995; Woods 1997; Mack and D'Antonio 1998; Westbrooks 1998; Mooney and Cleland 2001; Huber et al. 2002; Levine et al. 2003; Zedler and Kercher 2004; Mooney 2005). So large has been the negative impact of some invasive species that they

have been described as “ecosystem engineers” (Crooks 2002). Biotic invasions have been implicated as major actors driving global environmental change (Vitousek et al. 1996; Sala et al. 2000), rivaling habitat loss as a contributor to species extinctions (Vitousek et al. 1997; Wilcove et al. 1998). In turn, the causes and consequences of global change (e.g., increased atmospheric pollution, shifting climatic zones, and habitat disruption) may provide new opportunities for invasions, increasing their frequency and severity (e.g., Huenneke 1997).

4-3. Pathways and Vectors Definitions

Pathways describe the processes or means by which a nonindigenous or alien species is introduced from one location to another (Hulme et al. 2008). According to Ruiz and Carlton (2003), a vector is how a species is transported—the physical means or agent. In this sense, an individual pathway may consist of multiple vectors, with each vector composed of: (1) a carrier (either in the form of a living organism, such as a plant or animal, or a nonliving inorganic or organic item, such as a shipping crate, soil, or volume of water, such as ballast), and; (2) one or more introduced organisms that are transported (or “vectored”) by the carrier. The two authors also identify other terms closely associated with pathways, including “routes” (the geographic path over which a species is transported), and “corridors” (the physical conduit over or through which the vector moves within the route, such as roads and railroad beds) (Ruiz and Carlton 2003).

Non-human mediated colonization of remote oceanic islands by life is a rare event. The modes of long-distance dispersal available to potential colonizers include: 1) direct dispersal, for which flying animals such as birds, bats, and large insects are best equipped for reaching isolated areas under their own power, and are usually well represented in island biotas; 2) windborne dispersal, via which tiny seeds and invertebrates are carried passively on air currents; 3) waterborne dispersal, a mechanism responsible for transporting propagules, such as large seeds capable of floating in seawater for extended periods, or small animals, as well as seeds rafting on trees or mats of vegetation washed into the ocean; and 4) dispersal by birds, who may serve as inadvertent carriers of plant and animal “hitchhikers” adhering to feathers or feet, or, in the case of some seeds, passing through the digestive system to be deposited with feces in a suitable site for germination (Juvik 1998).

5. Limitations to the Scope of the Regional Biosecurity Plan

Though this plan is meant to be comprehensive, there are limitations to its scope that were realized at various stages in its development. Significant aspects that are not fully addressed in the RBP include biosecurity considerations and IAS within the following groups: micro-organisms, terrestrial plants, algae, and arthropods. Micro-organisms (bacteria, viruses, diseases, protists) are certainly part of the invasive species problem, and though they are alluded to in various parts of this plan, the scope of the issues potentially associated with micro-organisms was deemed overly extensive to readily facilitate detailed inclusion within this document. Each of the existing risk assessments does cover some aspects

of the taxon groups mentioned above, but this information should not be considered comprehensive. To properly address each of these taxon groups, an extensive amount of additional work will need to be completed. While the amount of effort needed to complete risk assessments for the region in all taxon groups is extensive, it is hoped that as part of the efforts, which evolve from the recommendations of this plan, work can begin to address these current short comings. All of these taxon groups are known to contribute to biosecurity concerns; in fact, terrestrial plants and arthropods are probably the two IAS taxon groups that currently receive the highest level of funding and management both globally as well as within the region. The lack of detailed coverage of these taxon groups within the RBP was necessitated in part in order to be realistic in where efforts could be initially focused, and in no way is meant to indicate that these groups are not just as important in terms of their threats. Some of the major recommendations coming from this document will be for the region to complete risk assessments and recommendations for each of these groups in order to insure that biosecurity concerns receive full coverage for the region as soon as feasible.

6. Overview of the region

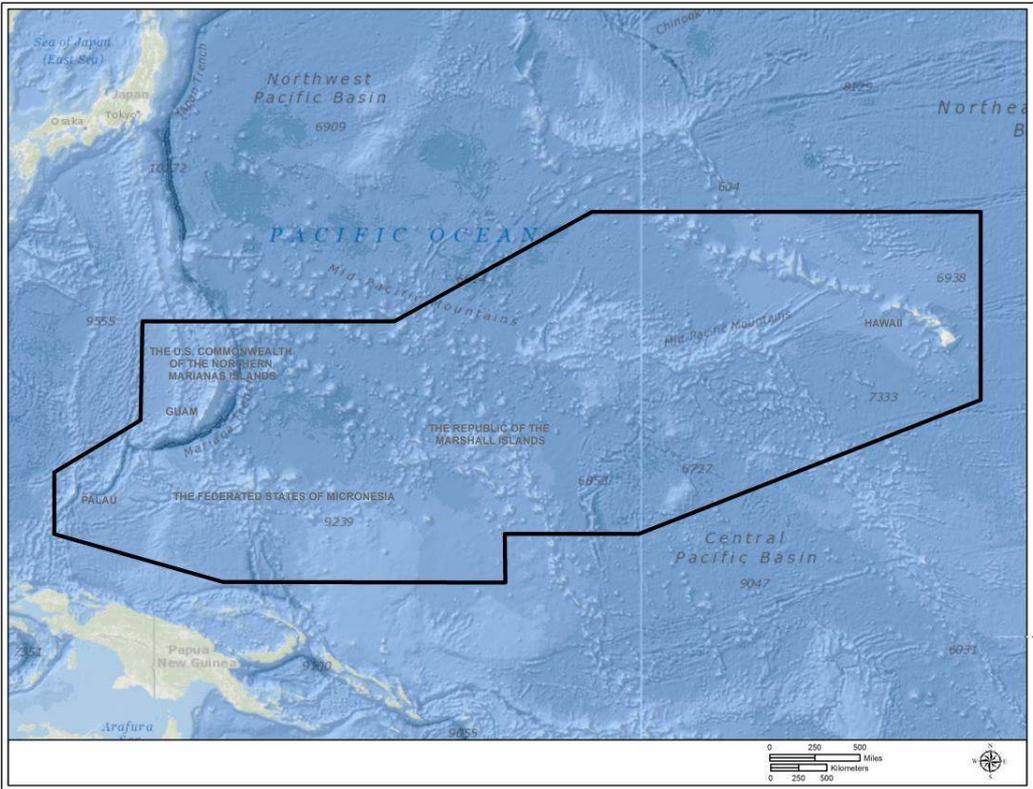

The region of focus for this biosecurity plan includes most of the islands of the global region known as Micronesia and the archipelago of Hawaii (Figure 1). Overviews of the individual jurisdictions can be found in Attachment A of this document. The islands of this region are all located in the tropical or sub-tropical north Pacific.

Micronesia is a sub region of Oceania that is comprised of four main island groups or archipelagos (three of which are covered by this plan: Marianas, Carolines, and Marshalls) as well as numerous outer islands. Overall, Micronesia encompasses thousands of individual islands and is approximately 7,400,000 square kilometers (2,900,000 square mi) in size, with both high islands and atolls. The region has a tropical maritime climate with little annual variation in temperature and a slightly more variable rainfall within parts of the region. Most islands experience wet and dry seasonality, although the dry season may not be very pronounced depending on location.

Guam and the Hawaiian island of Oahu serve as the two main hubs of human activity and shipping for the region, with most goods transshipped through Oahu to Guam with some goods then going from Guam to other islands within the region. Various countries within Southeast Asia are also important trade partners with both the Micronesian jurisdictions and Hawaii.

The Mariana islands are situated about 1,700 km (1,060 mi) south of Japan, 2,100 km (1,300 mi) east of the Philippines, and 1,800 km (1,100 mi) north of New Guinea. There are 15 islands, all of volcanic origin. The archipelago runs more or less north-south. The Mariana archipelago is composed of two jurisdictions, the CNMI and Guam. The CNMI is composed of the 14 northern islands. Guam consists of the single southernmost island.

Figure 1: Republic of the Marshall Islands, Republic of Palau, Federated States of Micronesia, Territory of Guam, Commonwealth of the Northern Mariana Islands, and the State of Hawaii

The Caroline Islands are a widely scattered archipelago north of New Guinea, east of the Philippines, and south of the Mariana archipelago. This archipelago runs more or less east-west. Politically the islands of the archipelago are divided between the Federated States of Micronesia and the Republic of Palau. Palau encompasses the westernmost section of the archipelago and the FSM the central and eastern sections. The archipelago is composed of approximately 500 islands, which include several large high islands and many low atolls.

The Marshall Islands are divided into two island chains, Ratak and Ralik. There are a total of 29 atolls and five isolated islands. The Marshall Islands lie to the east of the Caroline Islands and north of the equator.

7. Pertinent Regulatory Drivers

The regulatory drivers for the region provide requirements and justification for planning, compliance, and development in regards to biosecurity. Regulatory guidance is essential for developing appropriate biosecurity standards for the region. All jurisdictions have existing regulations that support some level of biosecurity. In large part the existing regulations are based on the U.S. system. The U.S. has a quarantine system, which continues to evolve, but which was mainly established to address agricultural concerns on the U.S. mainland. To a large extent these regulations do not adequately address freshwater and marine concerns, nor do they always take the best approach for relatively small tropical islands or island groups. While some regulatory improvements have occurred in most jurisdictions within the past 10 to 20 years, all of the jurisdictions still have gaps in their existing regulations that should be addressed. An overview of the existing regulations for each jurisdiction can be found in Attachment B of this document.

8. Overview of the Proposed U.S. Department of Defense Build-up

The U.S. military has various resources in the Micronesia-Hawaii region and utilizes these and others areas within the region for training purposes. The current DoD facilities and training locations within the region include: Guam Bases (Andersen Air Force Base- AAFB, Naval Base Guam, and the various naval annexes and properties), Tinian training facilities, Palau Civic Action Teams (CAT) Camp Katuu, U.S. Army Kwajalein Atoll (USAKA), Wake Island, and Hawaii based facilities.

The concept of the RBP, or more precisely, the interest in regional biosecurity, existed well before planning for the military build-up in the Marianas was announced, but the actual development of such a framework went unfunded and the concept therefore remained only a concept. Funding to develop the RBP was initiated to assist with planning and environmental impact analysis related to the potential for IAS introduction in the region due in part to the military build-up. Linkages between Micronesia and the State of Hawaii were also added to the overall coverage of the RBP only once the military build-up had been proposed.

The proposed military build-up on Guam has been reduced in size from its original scope. The draft risk assessments relied upon the definition of the build-up as depicted within the 2010 FEIS for the Guam and CNMI Military Relocation (DON 2010). Some of the figures and statistics used in the risk assessments, specifically in regards to the amount of military traffic entering and leaving via military ports may reflect the original larger build-up concept and not reflect build-up planning as of 2014. Similarly, the military build-up statistics considered in the risk assessments date from 2006 and do not reflect current DoD planning.

As of 2014, the number of personnel to be relocated to the region has been reduced from the originally planned 8,600 Marines and 9,000 family members, to a force of approximately 5,000 Marines and 1,300 family members on Guam. Approximately two-thirds of the Marines relocated to Guam will be rotational with the remaining one-third permanent. In addition, the timeline to complete the build-up was extended from 5 to 12 years. As a result of the reduced and more gradual scope of the build-up, peak and steady-state population numbers on Guam will be much less than previously anticipated (see Figure 2.2-1 in Chapter 2 of the Draft Supplemental Environmental Impact Statement (Joint Guam Program Office 2014): <http://guammarines.s3.amazonaws.com/static/draftSEIS/Chapter2.pdf>). Associated with this, the number of off-island workers and amount of commercial port throughput will be substantially less than under the 2010 ROD. More information regarding the proposed military build-up can be found at <http://www.guambuildupeis.us/>.

9. Risk Assessments

9-1. Overview of the risk assessment process

Risk analysis is commonly used for management of IAS because pragmatic decisions can be made that provide a balance between competing environmental and socio-economic interests, despite limited availability of information (e.g., Hayes and Hewitt 1998; Hewitt et al. 2006; Barry et al. 2008; Campbell and Hewitt 2008, 2011).

In a biosecurity context, conventional risk assessment methodology consists of five steps:

1. Identifying endpoints (within biosecurity common endpoints are a breach in quarantine or a subsequent impact)
2. Identifying hazards
3. Determining likelihood
4. Determining consequences; and
5. Calculating risk

This process is similar (following the five step process) to the risk management standard used in Australia and New Zealand and the risk framework agreed on by the U.S. Aquatic Nuisance Species Task Force and U.S. National Invasive Species Council (2007). Biosecurity risk endpoints are typically (a) inoculation (breaking the quarantine barrier), (b) establishment, and (c) spread. Additionally, some would also consider mitigating impacts as an endpoint.

The terms of reference for the development of the RBP risk assessments were set by DoD and are as follows:

The deliverables will cover/discuss three periods; 1) current steady state, 2) during the military build-up, and 3) post military build-up steady state.

1. List of priority species and potential pathways that are not established in the Micronesian region and Hawaii that could pose a high risk to the local economies, environments, and human health.

2. Map of ports of origin for the Micronesian region:

- Rank high/medium/low risk for each port based on priority species previously identified.
- Rank high/medium/low risk for each pathway based on priority species previously identified.

3. Rank high/medium/low risk for the top import and export commodities for each island group based on priority species previously identified.

4. List of priority species established in the region that require pre-departure mitigation measures to reduce the risk of their movement within and outside the Micronesian region:

- Prioritized list of pathways associated with the previously identified locally established species that will be targeted for pre-departure quarantine measures.

5. Ranked list of highest risk regional and trade partner ports based on lists of both locally established priority species and species not yet established within the Micronesian Region:

- Prioritized list of pre-departure mitigation measures for immediate implementation.
- Development of regional monitoring strategy.

9-2. Caveats to the Risk Assessments

1. A major weakness of the risk assessments is that all threat analyses (or attempts at analyses) are measured by intercept data or basically the frequency that organisms are detected at the border. This approach fails to measure slippage (failure to detect an organism during an inspection), and varies in respect of the speed with which actual entry and establishment of new organisms are detected. For example, a dozen or so very serious pests of agriculture and the environment have successfully become established in Hawaii in the past 10 years alone. They include the LFA, varroa mite (*Varroa destructor*), coffee berry borer (*Hypothenemus hampei*), small hive beetle (*Aethina tumida*), coqui frog (*Eleutherodactylus coqui*), ohia rust (*Puccinia psidii*), and several others. These organisms have rarely if ever been recorded in any intercept data prior to their detection as established pests. Another concern with this approach is that not all detections/intercepts are identified.
2. The RBP risk assessments fail to adequately consider the movement of established pests already in the region within jurisdictions and to surrounding jurisdictions. This flaw appears to arise from a notion that once a pest is established it is no longer important to target it for detection

on goods leaving one jurisdiction for another. This assumption of course is not appropriate. The Pacific Region is a complex network of independent nations, nation-states, islands, and island-states. Often the political boundaries do not reflect cultural boundaries and these may overlap considerably. This factor complicates biosecurity activities and needs to be recognized.

3. The RBP marine risk assessment authors did not utilize the term invasive species in their document but rather relied on the term non-native to denote invasive species or potentially invasive species. This is regrettable as not all non-natives should be considered invasive species e.g. many food crops are non-native. The reader should be aware of this anomaly when reading elements of the RBP marine risk assessment.
4. USAKA and the Palau CAT Camp Katuu were not covered in the RBP risk assessments. Wake Island Airfield was mentioned on several occasions in the terrestrial risk assessment but information pertaining to Wake Island was not extensive. Additional information regarding these three facilities and their current biosecurity measures could not be obtained for usage during the strategic implementation development phase, thus these specific locations are not adequately covered by this plan.
5. The RBP terrestrial risk assessment extensively covers Guam, the BTS, and the possible role of USDA-APHIS for U.S. jurisdictions. While much of the information provided is of value, by focusing on these key elements the document minimizes the regional aspect of this effort, other critical IAS or potential IAS, and the roles of other agencies and offices especially in regards to non-U.S. jurisdictions where presumably USDA-APHIS as a U.S. agency cannot provide the same support which they suggest for Guam. While the RBP terrestrial risk assessment addresses BTS issues, it seems to inadequately address the need for surveillance, detection, and rapid response to other potentially invasive species, including ants, aphids, wood-borers, spiders, and microbiological pathogens to name just a few. Invaders from these (and other) taxon groups have enormous capacity to do harm, and little is being done currently to address the imminent threat and their coverage in the RBP terrestrial risk assessment is regrettably insufficient.
6. The RBP terrestrial risk assessment does not adequately cover the concept of stowaway or hitchhiker organisms. Stowaways are a very big concern and should be addressed equally with other invasive species pathways. It was anticipated that the RBP risk assessments would provide information on what each jurisdiction had in terms of established invasive species that others in the region did not. It was also anticipated that there would be some information on potential invasive species found in areas outside of the region (such as southeast Asia) that are linked to the region through shipping and other transportation routes. This information is essential for each jurisdiction in developing adequate and appropriate biosecurity measures. Much of this basic information was regrettably not identified within the RBP risk assessments and, therefore, should be developed in the near future to support and fine tune regional biosecurity efforts.

7. In 2012 the National Oceanic and Atmospheric Administration (NOAA) nominated 66 species of coral for listing under the Endangered Species Act. The proposed action of listing these species as endangered in the U.S. occurred after the RBP risk assessments were drafted and therefore is not covered by the risk assessments. Some coral species are potentially biofoulers. It is unclear if there is evidence of biofouling by any of the 66 nominated species, but presumably the possibility exists. It is unclear what if any impact the potential listing of these marine organisms could have in regards to biosecurity. Would a biofouled vessel arriving at a U.S. port need to be sampled to determine the species composition of the attached biofouling community? Or would it simply fall under recommended regulations which support zero biofouling and immediate remedial action could be taken, potentially including hull cleaning, if biofouling is detected. If sampling of the community would be required prior to treatment, determinations on how and where this would be accomplished are needed. Additionally, if an endangered species or even proposed species were detected, how would treatment of the hull proceed? Regular sampling of biofouling communities to determine species composition is currently not a feasible action within the region covered by this plan. Do any of these 66 nominated species have ranges that overlap with the region? If not, then presumably if they did arrive they could be treated as non-native organism and potentially an invasive species and, therefore, would most likely not be afforded ESA protection. But if the native range of one or more of these species does or is thought might overlap with any portion of the region, then again this situation should be further explored.
8. The original authors of the three sets of risk assessments also proposed recommendations regarding how to improve biosecurity within the region. Many of the recommendations listed within the risk assessments refer directly to Guam but could equally be applied to the other jurisdictions covered by the RBP. Most of the recommendations within the risk assessments are also covered in the implementation strategy recommendation tables, a single section within the implementation strategy that lists all recommendations so that the end user can readily locate them.
9. The assessment of invasive terrestrial plants is limited in scope while invasive plants are a major concern for the region. It would be helpful to have this work completed for the region. Minimally the region should work towards establishing a weeds risk assessment.
10. Arthropods are generally poorly covered in the risk assessments; even though arthropods are one of the largest groups of organisms known to have potential as IAS. This gap should be addressed.
11. The emergency response plans, actions, and capacities listed throughout the terrestrial risk assessment are very USDA-specific. It is doubtful USDA could or should be the lead entity responding in all cases. Additionally, many Micronesian nations may not have capacity or desire to be led under the auspices of USDA. This section of the plan is overly "mono-agency" specific and does not adequately address leadership and capacity beyond USDA programs.

12. No risk assessment was completed for marine algae. This should be addressed for the region.
13. Risk assessments placed disproportionate focus on Guam. For example, air transport is only considered in detail for aircraft arrivals to Guam. The remainder of the region is poorly addressed and follow up work should be conducted including keeping updated details on changes to plane arrivals and locations with direct linkages to the region.
14. Micro-organisms are not adequately covered in the risk assessments. This should be addressed for the region.

To fully explore the risk assessments, refer to Volume II (Executive Summary to the Risk Assessments and the Freshwater Systems Risk Assessment); Volume III (Marine Systems Risk Assessment); and Volume IV (Terrestrial Systems Risk Assessment)

10. Example Species of Concern

Lists of IAS of concern are interesting but can be counterproductive if they are perceived as complete – which in the RBP risk assessments they are not. Within the region it is recognized that one island’s natives or established species might be another island’s invasive species. All islands within the region have at least some species (exotic and native) not found on any other particular island or at least not all islands, and are therefore a proximal source for those species if a pathway or vector exists to move them. Species present on all islands are not necessarily a priority biosecurity issue, unless they pose a disease or health risk that is not present on all islands or if overall impacts from these species are extensively high.

The most devastating invasive ant species to establish to date in both Hawaii and Guam is the LFA. This species is established on the Big Island of Hawaii and several smaller populations are known to exist elsewhere within the state. Surveys for this species have not been completed on Guam but it seems likely that it is wide spread and well established. The LFA if unchecked has the potential to cause significant impacts native ecosystems as well as agricultural production.

The CRB is established in Palau and Guam. Eradication efforts on Guam have not been successful. In December 2013, this same species was detected at on Oahu with numerous individuals being found, including multiple life stages (suggesting it has been there for some time).

The BTS has been established on Guam since at least the early 1950s. To date, no other populations of this species have been confirmed outside of its native range. However, the snake continues to be a major pest on Guam and it threatens the rest of the region.

Dengue virus, zika virus, chikungunya virus, and melioidosis (caused by a bacterium) have all been reported for Yap State in the last few years. These organisms are all non-native to the region and cause or may cause serious human health issues. Some of these organisms are found elsewhere within the region.

Kosrae has been battling a white fly (*Aleurocanthus spiniferus*) outbreak for more than a year now. The larvae of these flies are feeding on the food crops and forestry biomass of the state. In 2013 Kosrae also learned that coconut termites (*Neotermes rainbowi*) have established. These termites have infested coconut trees, which in turn will likely need to be destroyed if there is any hope of containing this pest species.

Attempts to list species of concern have met with limited success, the reason being that there are so many known species of concern. Perhaps, even more important is the understanding that what we don't know is likely or should likely be an even bigger concern. The potential for harmful species to arrive within the region from outside grows every year. Asia is probably the biggest growing influence on the region and regional knowledge of established species within Asian countries that pose a serious risk to Micronesia and/or Hawaii is limited. Some jurisdictions provided a list of species that they currently consider top level concerns and these can be found in the jurisdictional overviews. Trying to determine which IAS pose the biggest threat to a given location given incomplete knowledge is an interesting exercise. When such lists of worst IAS are produced, they should be treated as working lists and not conclusive.

11. Implementation Strategy

11-1. Challenges

For the region, biosecurity risks are high for both marine and terrestrial habitats and are less well defined, but still significant, for freshwater. Many vectors moving within or entering the region transit through the marine environment. Almost all vectors eventually end up on terrestrial habitats or unloaded into terrestrial habitats. Freshwater habitats are generally well protected from IAS due mainly to their limited existence within the region. On the other hand, the limited existence of freshwater habitats also makes them extremely vulnerable, and easily impacted by IAS if and when incursions into these systems do occur. While the likelihood of additional freshwater introductions are relatively low when compared to marine and terrestrial systems, any IAS introductions that do occur within the freshwater systems of the region are likely to have broader impacts on these systems than additional marine or terrestrial introductions would have. In reality, the impacts potentially caused by IAS incursions are in large part dependent on the organism(s) themselves and how these organisms react with the systems they are invading. It is difficult to predetermine exactly what impacts any introduced organism will have, but risk analysis can provide some insight. All systems are at risk and any introduced non-native organisms have the potential to become established, create viable populations, and cause impacts, therefore fitting the definition of an invasive species.

It has been clearly established both globally and within each jurisdiction of the region that some non-native organisms, if permitted to establish, will cause harm. Numerous harmful organisms are already known to be established within parts of the region. Specific examples of non-native organisms that are established within the region, that are causing harm, and that are likely to cause further serious impacts if their current distributions are permitted to expand include some of the same organisms that have

been exemplified time and again throughout the RBP such as the BTS, CRB, and LFA. These are stand out organisms due to the impacts they have already caused, but there are many non-native organisms already established within the region that are less well known and surely others not yet within the region that are relatively unknown but could cause serious damage if they were to become established. Appropriate biosecurity systems once in place can reduce the risk posed by established high risk threats within the region as well as relatively unknown threats from elsewhere.

Within the non-U.S. jurisdictions of the region, inspections are typically carried out by local agricultural quarantine officers. Inspections of cargo are made following reviews of bills of lading and of baggage, based on customs declarations or when there is reason to suspect smuggling (usually based on the inspector's judgment). All inspections are visual, as X-ray machines and other methods (such as trained dogs) are currently not available. As with Guam and CNMI, there is little to no capacity to do random inspections or to carry out investigations beyond entry points.

There are large gaps in the current biosecurity systems in place within the region. In some jurisdictions, these gaps go right to the core of the biosecurity system. One such gap is the almost complete lack of marine system biosecurity regulations and capacity, resulting in a minimal likelihood of intercepting marine risk organisms at ports of entry. This lack of marine system oversight is perhaps one of the most serious gaps identified since the region is composed of relatively small islands separated by large tracts of marine environment. Most materials and commodities arriving in the region arrive via ocean-going vectors. Resolving the current lack of attention to marine system biosecurity across the region should be a high priority for the region and each of the individual jurisdictions. Other gaps are further addressed below.

Another clear example of a major biosecurity gap for some jurisdictions is the lack of biosecurity legislation formulated specifically to address IAS. Where such legislation does exist, it is generally not comprehensive. The inability to collect sufficient revenue and to utilize this revenue to support biosecurity regulations needs to be addressed and in fact should be a high priority for all jurisdictions. Laws are needed to support regulations, regulations need to be improved across the board, and revenue streams to support biosecurity efforts need to be better developed.

Other major gaps that need to be addressed for most if not all jurisdictions include: improved outreach and education improvements enabling citizens and visitors to actively participate in supporting biosecurity efforts; enhanced regulations based on established biosecurity legislation (several of the jurisdictions currently have pending bills); better development, implementation, and enforcement of border quarantine/biosecurity elements; increased pre-border sanitation; and moving beyond the conceptual stages of post-border early detection and response capacity to having solidly developed response capacity including established funding mechanisms that permit truly rapid response to new incursions by appropriately trained responders directed by an incident commander.

11-2. Needs

All jurisdictions within the region have basic infrastructure and staffing needs that should be met in order to address current levels of vector arrivals, on the ground management of established IAS, response to new incursions, and restorative efforts once appropriate management levels (or eradications) have been achieved. Future increases in both vector arrivals and additional IAS becoming established will require more resources than currently exist within the region. With or without the proposed military build-up, the numbers of pathways and vectors both within the region and arriving to the region is likely to continue to increase. Various invasive species are already well established in each and every jurisdiction of the region. Without improved biosecurity, additional invasive species will likely become established and established species will likely expand their current distributions.

11-3. Recommendations

The core of the implementation strategy is the biosecurity recommendations. The recommendations are organized into tables by jurisdiction. The jurisdictional recommendation tables can be found in the following attachments:

- Chuuk State Biosecurity Recommendations, See Attachment C
- Kosrae State Biosecurity Recommendations, See Attachment D
- Pohnpei State Biosecurity Recommendations, See Attachment E
- Yap State Biosecurity Recommendations, See Attachment F
- Federated States of Micronesia National Biosecurity Recommendations, See Attachment G
- Republic of the Marshall Islands Biosecurity Recommendations, See Attachment H
- Republic of Palau Biosecurity Recommendations, See Attachment I
- Commonwealth of the Northern Mariana Islands Biosecurity Recommendations, See Attachment J
- State of Hawaii Biosecurity Recommendations, See Attachment K
- Territory of Guam Biosecurity Recommendations, See Attachment L
- United States Department of Defense Biosecurity Recommendations, See Attachment M
- United States Regional Biosecurity Recommendations, See Attachment N

Recommendations for each jurisdiction include a variety of action items, each with its own time line, lead, resources, and prioritization. Many of the recommendations fall into what could be termed topical areas, which vary from jurisdiction to jurisdiction depending on needs, although many of the same

topical areas or recommendations occur in more than one jurisdiction. Recommendations that are common to all jurisdictions include improvements to pre-border, border, and post-border biosecurity as well as improving the coordinating of outreach efforts.

Recommendations for each jurisdiction have been categorized as one of the following: support, coordination and collaboration, prevention, early detection and rapid response, management and eradication, awareness, research, policy, and restoration. Some recommendations could easily fit into more than one of these categories and where this is the case, an attempt has been made to place the recommendation under the most fitting category with the understanding that categories should not be viewed as exclusive. Not all categories have been used for every jurisdiction.

Action items in the recommendation tables have been ranked into one of three priority levels: high, medium, and low. All listed action items are potentially important, irrespective of prioritization. While the priority ranking should be considered when determining what action items to address and in what order, other considerations should also be taken into account, including what action items, regardless of priority ranking, are readily achievable; or for which items dedicated funding or other resources may be available, or potential could be established relatively quickly.

During the development of the jurisdictional recommendations common themes were identified:

- 1) Current biosecurity measures throughout the region have gaps at all levels including pre-border, border and post-border.
- 2) Pre-border sanitation policies are minimal at best and lacking in many cases.
- 3) Current biosecurity efforts are inadequate largely because of a lack of funding resulting in inadequate staff numbers, inadequate or lacking equipment, and insufficient training (See Attachment P for basic training considerations). There are exceptions; for example, current biosecurity efforts by DoD or funded by DoD within the region are perhaps the most up to date in terms of capacity.
- 4) Other biosecurity gaps include: lack of regulatory support, lack of linkages between trade policy and biosecurity elements, insufficient communication at all levels within jurisdictions and between jurisdictions in regards to biosecurity, and in some cases the inability of offices and agencies at different levels of government to fully support each other due to restrictive policies and operational standards.
- 5) Education and awareness efforts in regards to IAS, while existing throughout the region, have been insufficient in most cases and often focused only on specific species and/or activities. More comprehensive planning and follow through with IAS awareness in regards to educating, changing behavior, and engaging the public are absolutely essential for improving both jurisdictional and regional biosecurity. Again, there are exceptions and various well thought out and functional awareness components do exist, such as the Joint Region Marianas education program for construction workers and military workforce. Hawaii also has a variety of well thought out awareness efforts. Overall coordination of various educational efforts and tools could still be improved, especially at the jurisdictional and regional levels.

6) Early detection and rapid response capacity development has been insufficient, resulting in the lack of capacity or in a few cases the existence of a minimal capacity, which is often focused on specific organisms and not well developed as a true response capacity to IAS in general. This is true at both the jurisdictional and regional levels.

7) The military build-up is going to place an increased strain on some these already inadequate biosecurity measures.

8) Commerce, trade, and visitation are all likely to continue to increase throughout the region (regardless of the military build-up), again resulting in increased strain on existing biosecurity measures.

None of the Micronesia jurisdictions have the capacity to carry out thorough inspections of luggage or cargo in terms of trained personnel and equipment. Many lack equipment such as X-ray machines and computers that could make biosecurity enforcement more efficient and effective. None of the jurisdictions has adequate capacity to carry out investigations or effective enforcement beyond ports of entry. In some cases, this is due to discrepancies between import regulations and other laws, as in the case of Guam, where it is not illegal to possess certain species that are prohibited for import. U.S. domestic mail is not routinely inspected, providing a potentially important (but poorly documented) pathway for trade in non-native species between the continental U.S. and Hawaii, Guam, and CNMI.

Even for declared or permitted live imports, species-level identification; labels and any certification (of disease-free status or absence of associated organisms) are often missing or inadequate, making assessment and pre-screening difficult at best. Little to no screening of outgoing cargo occurs in the region (with the exception of the USDA BTS program on Guam). Anecdotal information, as well as established records from various agencies, indicates that smuggling of live species is occurring throughout the region, including terrestrial, estuarine, and marine organisms. There is currently little capacity to address this situation.

There is clearly a need for additional capacity at most if not all ports in the region in regards to quarantine/biosecurity staff, equipment, and facilities. While numbers of potential organisms and sources that threaten each jurisdiction can never be completely known, it is certain that the amount of goods and personnel moving into and within the region will continue to increase. It appears that the short term anticipated increases will strain the available capacity to inspect and control the flow of these organisms, especially given the current limitations.

There is a regional early detection and rapid response program specifically for BTS incursions, which could be extended to support detection and removal throughout the region of alien reptiles and amphibians and might serve as a model on which to fabricate a truly regional response capacity for IAS. The program is headed by the USGS and since 2002 has provided the region with response training, networking, and limited outreach capacity in regards to alien snakes and on a more limited basis IAS in general (Stanford and Rodda 2007). The program is based around incident command structure principles and utilizes key skilled individuals to lead response actions with a mix of both trained and untrained personnel (Stanford and Rodda 2007). Ultimately, each jurisdiction would need to develop its own early

detection and rapid response capabilities, but a regional office, at least in part based on this existing model, could assist with supporting/supplementing local response capacity as requested.

By and large, the jurisdictional recommendations have been vetted by local stakeholders via extensive consultations conducted both onsite and remotely. A list of jurisdictional consultancy trips is provided in Attachment Q. Draft recommendation tables for each jurisdiction were provided to stakeholders in each jurisdiction during January 2014. In most locations stakeholders held round table workshops to facilitate stakeholder review and comment on the draft recommendations, with these comments being returned to UOG and SPC to support improvement of the draft recommendations. In early May 2014, the draft implementation strategy (including the updated recommendation tables) was provided to registered attendees of a regional workshop scheduled to be held later in the same month. The regional workshop was held on Guam from 18-21 May of 2014 and was facilitated by SPC and UOG with the purpose of reviewing these recommendations. During this workshop the jurisdictions came together to review and comment on the biosecurity implementation strategy. Representatives from all jurisdictions as well as key stakeholder organizations and offices participated in the workshop. A list of workshop participants is provided in Attachment R.

Regional implementation of the biosecurity recommendations will be challenging as the recommendations are extensive and full implementation will require significant increases in funding and other resources to be made available for biosecurity activities. In this regard, it is important to note that the RBP does not create any right, obligation or legal responsibility on the part of any of the jurisdictions discussed herein to fund or execute the recommendations set forth in the plan. In addition, for many of the recommendations to be appropriately developed and implemented, supporting legislation will need to be developed and enacted. What is more, many of the recommendations are linked and can, therefore, best be addressed by first prioritizing recommendations for each jurisdiction and then building on initial successes to achieve additional improvements ultimately resulting in a holistic approach to biosecurity both within jurisdictions but also across the region. Prioritization needs to be carried out at the jurisdictional level by internal stakeholders. Prioritization suggestions are offered for many of the recommendations (where specifics were not previously provided by the jurisdictions). These suggestions as well as suggestions on lead offices, time lines, and resources should be fully reviewed internally and adjustments made as needed.

11-4. Strategies

Finalization of the implementation strategy does not imply a commitment to implement any or all of the recommendations within the plan, but rather it represents that all jurisdictions accept the plan as written and understand it is a tool to be used by each jurisdiction as they move forward with improvement to their respective biosecurity measures. Jurisdictions, if they so choose, may decide to officially endorse the plan and/or their recommendations. It is important to remember that the RBP should remain a living document and that jurisdictions can and should update their elements as needed, checking off completed actions, providing more specific information as possible, and developing recommendations to address new circumstances as they arise.

In regards to the implementation strategy, the overarching goal for the region and each individual jurisdiction is the same, improvement of biosecurity mechanisms leading to better protection from IAS. How this goal is to be achieved within the context of the jurisdictions varies specifically but in large part the needs are similar across the various jurisdictions.

The recommendation tables document specific recommendations for the region and for each jurisdiction. These recommendations and their associated action items are important and extensive. Perhaps a practical way to begin with enhancing regional biosecurity is to outline what could be considered the highest priority recommendations. Given the size and complexity of the region, developing a consensus on what should be the top priorities may be difficult, but it is essential to focus resources and capacity, as spreading efforts over many elements will reduce overall effectiveness. A list of critical elements that need to be addressed in much if not all of the region follows. This list includes items that need to happen, that are likely achievable (at least in part), and that once achieved would greatly enhance the region's biosecurity capacity.

1. All political jurisdictions in the region should have well developed biosecurity legislation. In turn, this legislation should support appropriate and comprehensive biosecurity regulations, policies, and guidelines. Once comprehensive regulations, policies, and guidelines are established, clear standard operating procedures (SOPs) for front line agencies/staffs need to be developed and implemented. All of these items should be clearly and concisely documented and made readily available for interested parties.
2. All jurisdictions should consider developing a cost recovery biosecurity system where users via fees and penalties fund the system, if not completely, then at least in large part (see information regarding cost recovery within the New Zealand biosecurity system model in Attachment O: Models). Jurisdictions need to be realistic in estimating how much revenue such systems can ultimately provide. As an example it has been suggested that for New Zealand, the cost-recovery system which is currently in place probably provides about 30 % of the total funding needs (Pers. Comm. P. Cowan 2014). Ultimately cost-recovery systems will need to be paired with other funding streams in order to insure adequate financial support for comprehensive biosecurity.
3. All jurisdictions need to ensure that biosecurity support and invasive species awareness via outreach and education programs are raised to a level where citizens and visitors are clearly aware of IAS issues, support biosecurity efforts, and willingly contribute to IAS management, control, and prevention activities. Without the support and engagement of the citizenry, biosecurity efforts will remain only partially effective. Once the citizenry is fully engaged and has a deep awareness of invasive species concerns including how invasive species affect them directly, then they and the various governing bodies will effectively support biosecurity. The lack of effective support is currently one of the biggest gaps the region faces in regards to improving biosecurity efforts.

4. Communication and cooperation at all levels needs to be significantly improved. The basic framework for a functional biosecurity effort, including appropriate communication, is established in some jurisdictions but not all. And in no jurisdiction does this framework currently function adequately. Minimally, each jurisdiction should have each of the following:
 - A. An invasive species taskforce (or the equivalent: council, committee, working group, etc.);
 - B. RISC representatives who provide a direct linkage between governance and the various IAS elements within each jurisdiction.
 - C. A jurisdictional invasive species coordinator (or the equivalent) with the capacity and authority to support both coordination of biosecurity and invasive species efforts within the jurisdiction and to facilitate regional (and beyond) two way communication and support of biosecurity and invasive species issues. Ideally this position would work directly with the jurisdictional leadership, play a major role in the invasive species taskforce, and work closely with the RISC.

Each element above should be endorsed and supported by the jurisdictional leadership. The second element above should be retained and reviewed with each change in jurisdictional leadership, to ensure its continued functionality.

In addition to the elements above, the region as a whole should support, develop, create, fund, and utilize a regional invasive species coordination office to support regional and jurisdictional biosecurity and invasive species work. The concept is similar to that of a cooperative invasive species management area or CISMA but on a regional scale and with a central coordinating office. There are various potential ways to establish and support a regional invasive species coordination office, all of which provide specific benefits but each of which also presents specific hurdles. The specifics on how such an office would be established and operate will require consultation throughout the region to ensure that if developed, the office is truly a regional office that all of the jurisdictions support and benefit from.

The Pacific currently has various groups that at least in part are working to address invasive species concerns, including the Secretariat of the Pacific Community (SPC) and the Secretariat of the Pacific Region Environmental Program (SPREP). Both of these groups have a Pacific wide mandate, it may be feasible for one or the other to establish a specific invasive species coordination office, which could support Micronesia and Hawaii. Additionally, there are other organizations working regionally that might also be able to host such an office, including The Nature Conservancy (TNC) and The Micronesia Conservation Trust (MCT). The U.S. via various agencies and offices, both civilian and military, might also be able to support such a regional office. For all of the examples above, another level of consideration would be whether to fund such an office fully as a long term endeavor, fund fully for a few years and then anticipate that the office would begin to function largely on grant support; fund, at least minimally, with support from all of the jurisdictions; or fund and support via some combination of the above

mentioned methods. Such an office could also conceivably be linked with the Micronesia Center for a Sustainable Future and/or one of the land grant institutions within the region.

On a broad scale, the office conceptually should be able to support the region as well as the jurisdictions of the region with biosecurity and IAS issues. The office should be able to work across the region and not be restricted to focusing on U.S. jurisdictions nor non-U.S. jurisdictions, but cover both adequately.

5. All jurisdictions currently have some type of biosecurity mechanism in place for terrestrial risks, although no jurisdiction has a fully comprehensive program. The region as a whole, has little biosecurity in place for aquatic risks. Each jurisdiction needs to determine how best to improve existing biosecurity elements and to ensure that biosecurity activities are adequately covering terrestrial, freshwater, and marine systems. Marine systems are by far the most lacking in regards to current biosecurity efforts regionally. Since the region is encompassed by marine ecosystems most of the region's resources are marine system based and most vectors and pathways are marine system based. Therefore, it seems reasonable that marine systems should have a higher level of biosecurity attention than is currently the case. Each jurisdiction needs to determine how to address this anomaly where the conceivably most important system is receiving the lowest level of protection in regards to biosecurity. Initial steps that should be taken are to insure that legislation adequately covers biosecurity for marine systems, ensure that front line agencies/offices are provided with the training, infrastructure, resources, and capacity to conduct marine biosecurity inspections and management actions, and implement and enforce marine system biosecurity elements such as ballast water discharge, ballast water treatment, and hull cleanliness standards.

For each jurisdiction, it is clear that there are pressing biosecurity system gaps. Addressing these gaps should be a major focus. For example, all jurisdictions have existing regulations that address elements of biosecurity but none are fully adequate. Specific issues include:

1. Guam has a biosecurity law and, therefore, should be considered a model for the other jurisdictions, but it has yet to fully implement this law, as the funding mechanism described in that legislation is still being debated. Guam is currently exploring options regarding how to move forward with the law's implementation.
2. The Republic of Palau, the Republic of the Marshall Islands, and the Federated States of Micronesia each have pending biosecurity legislation and each country needs to review, debate, and final determination of these bills a high priority with decisions forthcoming on whether or not the pending bills can be supported or if these countries need to go back and develop new biosecurity bills.
3. Hawaii has reasonably comprehensive biosecurity regulations, but needs to increase support for aquatic biosecurity capacity.

4. The CNMI has no specific biosecurity legislation and should as a first step hold jurisdiction wide consultations to determine if such legislation is needed and if needed, begin the process of bill development with the expectation of having a biosecurity law in place within the next 2-3 years. As part of the consideration on biosecurity legislation, the CNMI should also consider establishing a government endorsed invasive species taskforce. The taskforce could be extremely helpful in the consultation process and, if warranted, with drafting the biosecurity legislation.

Looking at the bigger picture and moving forward with developing mechanisms to address the top recommendations will not only enhance the region's capacity but will also effectively support buy-in from local and regional as well as international partners. This will in turn support funding and regional cohesion, ultimately further advancing biosecurity efforts.

All jurisdictions in the region should develop and implement a mixed model approach to biosecurity, focusing on pre-arrival sanitation with high levels of inspection for all vectors from all pathways on arrival at dedicated entry locations. While the focus should be on these elements, specific policies should also be put in place to address concerns from high priority threats, such as those posed by the potential by BTS and CRB incursions. As part of the planning and development to address high level threats, policies and procedures should be established that while addressing the high level threat also improve overall biosecurity protection from all non-native taxa, i.e., focusing on specific threats should in theory assist with overall protection, not just protection from the specific threats.

Pre-border sanitation, as noted previously, is generally lacking within the region but has the potential to provide the best return per resources engaged. The fact that pre-border sanitation is minimal or lacking for the region, is due in large part to how biosecurity systems have evolved, which typically involved end users trying to reduce the impacts associated with arriving or established pests. While these efforts are worthy of attention, increasing efforts with pre-border sanitation could stop many potential pest species from entering the transportation chain, in effect stopping these species from being transported and potentially establishing. Reductions in pest arrivals and introductions would ultimately be the best way to protect end points from the impacts of invasive species as well as requiring lower levels of resources to intercept pests on arrival and to establish and support management and eradication programs. Greater focus on stopping the transport of unwanted organisms via pre-border sanitation efforts is needed throughout the region.

To improve pre-border sanitation will require expanding the traditional biosecurity role to include working with trade partners (both private and governmental) to develop appropriate sanitation mechanisms such as biosecure staging areas, pre-departure inspection and certification, awareness training for shippers, forwarders, and others working at departure ports and freight consolidation areas, and possibly focusing on specific businesses or practices when required. A developing model of potential effective pre-border sanitation that should be considered is the on-going efforts by DoD on Guam to utilize Hazard Analysis and Critical Control Point (HACCP) planning to reduce the potential of invasive species arriving on Guam with materials, equipment, and personnel. The United States Fish and

Wildlife Service (USFWS) has provided support and training for DoD, civilian agencies, and contractors in regards to utilizing HACCP as a strategic tools to reduce pest arrivals. Jurisdictions and agencies throughout the region should consider utilizing the HACCP process to improve overall biosecurity.

Some recommendations are easily recognizable as high priority items that need to be addressed early on in the biosecurity development process. A clear example of one such recommendation is improved buy-in from citizens as well as other elements of society, including the military, with supporting biosecurity and IAS work. This can best be achieved through a variety of outreach and educational activities, some of which are already either running or being planned but others still need to be developed and implemented (See Attachment O for examples of recent IAS awareness videos). Awareness and buy-in by both local communities and governance is essential to developing appropriate biosecurity for the region. Achieving sufficient levels of awareness should be considered a long term commitment as it will not be achieved overnight or even in a few years. One element that would support long term invasive species and biosecurity awareness is to formalize it as a standardized part of the educational systems throughout the region. Awareness efforts need to be highly coordinated (both within jurisdictions but also throughout the region), broad based, well supported, and improved and expanded over time. By developing such awareness efforts citizens, visitors, businesses, foreign workers, military and all elements of society can be engaged in supporting biosecurity systems through an understanding of IAS, their potential impacts, and the need for biosecurity programs to reduce the risk associated with IAS.

Improving awareness and buy-in will take time and efforts to engage the public and the military should already be underway. Other efforts to improve biosecurity need to move forward concurrently. Outreach to improve buy-in is essential and while efforts for this are being improved and expanded, jurisdictions will also need to determine what other recommendations they can move forward with.

Awareness of IAS and biosecurity within all levels of society, including the military, must be improved. Various groups are currently working within the region to improve environmental awareness. One such program is facilitated by RARE, an NGO which supports localized capacity building in various locations around the globe, including the Pacific Region. The RARE program perhaps should be considered as a model for awareness campaigns. This model utilizes social marketing techniques to change knowledge, attitudes and behaviors in specified target audiences. Building pride for the uniqueness of local natural resources is the foundation and motivation for change, adoption and maintenance of stakeholder support for conservation projects. RARE campaigns are discussed in more detail in the models attachment (Attachment O).

11-5. Costs

Funding and other resources to support biosecurity development, improvements, and maintenance should be supplied from a mixed model approach that relies on cost recovery for services provided, penalty assessment and collection for infractions to established laws, regional collaboration, and the interjection of funds and other resources from external sources. While biosecurity systems should

depend on a variety of funding streams, each jurisdiction should be looking to maximize funding self-sufficiency by engaging full participation by the citizenry and by instituting biosecurity cost-recovery systems.

Primarily all jurisdictions should be operating a cost recovery system where biosecurity fees and penalties are appropriately assessed, instituted, and enforced across the board (and ideally are harmonized as much as is feasible throughout the region to reduce the potential for competition between jurisdictions in regards to user fees). Funds collected via fees and penalties in regards to biosecurity should go directly into government sanctioned revolving funds that are explicitly set up to support biosecurity agencies and activities.

In addition to establishing cost recovery biosecurity systems in all jurisdictions, it is understood that support from external funding sources will continue to be needed and engagement of external donors to support biosecurity must be improved. Funding from external sources should be used to better develop capacities through items such as training and resource development including facilities, fleets, and workspace tools. Each jurisdiction (perhaps working together regionally) should develop long term planning for the acquisition and use of external funds. There are numerous and varied funding and support opportunities available for IAS efforts including donor country aid funds, international programs, NGOs, regional programs, agencies, offices, council, and committees. A short list of possible support sources follows:

- The U.S. Agency for International Development (US AID): <http://www.usaid.gov>
- The Australian Agency for International Development (AusAID): <http://aid.dfat.gov.au/Pages/home.aspx>
- The United Nations Development Programme - Global Environmental Facility (UNDP-GEF): <http://web.undp.org/gef/>
- Birdlife International: <http://www.birdlife.org/>
- Conservation International: <http://www.conservation.org/Pages/default.aspx>
- Island Conservation: <http://www.islandconservation.org/>
- SPC: <http://www.spc.int/>
- SPREP: <http://www.sprep.org/>
- USDA: <http://www.usda.gov/>. The USDA has a helpful website for managers looking for funding to support invasive species work: <http://www.invasivespeciesinfo.gov/toolkit/grants.shtml>
- USFWS: <http://www.fws.gov/>; The USFWS also has webpages to assist with granting opportunities: <http://www.fws.gov/grants/>

- The U.S. Department of Health and Human Services also has a helpful website listing current grants within the U.S. Federal Government: <http://www.grants.gov/web/grants/home.html>

Government buy-in and support will be essential to insuring long term funding. Clearly demonstrating the cost-benefits of improved biosecurity utilizing local, regional, and broader scale examples should be a basic concept that all jurisdictions promote. Improving biosecurity systems is going to require funding. Demonstrating how improved biosecurity can lead to overall cost savings and quality of life improvements utilizing real world examples should become a standard practice. Improved biosecurity versus steady-state or even reductions in current capacity is essential. Support should be sought from governance, local communities and cultural leadership.

11-6. Conclusions

For the RBP to be successfully implemented at its fullest level, each jurisdiction needs to have the capacity to track and manifest passengers and cargo and have an adequate number of professionally trained personnel capable of inspecting cargo, passengers and associated baggage, and vectors at all ports of entry (both internal and external). Legislation and regulations must be in place and enforceable to ensure pre-border, border, and post-border actions biosecurity actions are carried out and enforced. Cost recovery systems must be instituted and managed to help ensure that biosecurity programs are appropriately funding and can expand if the need for services increases. Animal & Plant Health Inspection Service/Plant Protection & Quarantine (APHIS/PPQ) and Customers & Border Protection (CBP) models offer good examples of training and organizational structure. It is highly recommended for all partners in the RBP to receive training using the Hawaii, APHIS/PPQ, CBP programs, or similar programs in New Zealand or Australia.

Suitable inspection facilities must be in place and equipped with the required technical tools and trained staff to identify suspected invasive plants, animals, diseases, and micro-organisms posing threats to terrestrial, freshwater, and marine systems. Access to taxonomic expertise and knowledge of and ability to quickly implement items such as response procedures are also essential. Equipment to look inside cargo containers, to inspect the hulls of watercraft, to identify pests, to implement treatments, etc. are needed and once obtained must be maintained and replaced as needed. Examples include fork lifts, microscopes, sniffing dogs, fumigation equipment, etc. Such facilities should be constructed in a manner that if an invasive pest is found in cargo, the cargo can be quarantined and species appropriate corrective actions implemented (e.g. fumigation) at the shipper's expense. Otherwise, the cargo should be immediately resealed and returned to the ship from which it was off-loaded and the reason for rejection noted electronically along with all pertinent container information. Suspect cargo should be quarantined until it can be properly inspected. Cargo confirmed to contain invasive species should remain quarantined and either be returned to sender or species appropriate corrective actions implemented (e.g. fumigation) with 24 hours of confirmed pest identification.

Biosecurity systems, no matter how advanced, no matter how well funded, no matter how well implemented are never going to stop 100% of all incursions. But a good system that is supported with

ample resources is likely going to prevent most incursions and hence reduce the potential damage that would have been caused if most incursions were not prevented. There are no biosecurity models that function perfectly; they all have troublesome elements, but the system utilized in New Zealand appears to work relatively well. But, what works in one location may or may not be transferrable to another location, and even if transferrable, implementation does not always equate with success. The jurisdictions of Micronesia and Hawaii should review various biosecurity models and through internal consultations determine the best pathway forward in regards to improving their own overall biosecurity strategies.

Whatever initial improvements are made and whatever systems ultimately are developed, detailed monitoring, data collection, and data analysis should become a standard part of all biosecurity systems. These and other elements (such as surveys) should be utilized as feedback mechanisms providing input and details back into the system highlighting what elements of these systems are functional and which continue to need improvement. This information will in turn permit more focused direction and better use of limited resources to address any remaining gaps.

As recommendations are fully implemented, inclusive of feedback follow through, each jurisdiction will have a fully functional biosecurity system, the region will have coordinated biosecurity, and ultimately Micronesia and Hawaii will be better protected from invasive species. The region's commitment towards developing the RBP has made the region a global leader in biosecurity and through its implementation will insure that the region is protected and continues to serve as a model for other areas within the Pacific as well as globally in regards to island biosecurity.

12. Concluding Remarks

For the islands of Micronesia and Hawaii, a stable and sustainable economy is dependent upon a healthy natural resource base. Efforts to enhance food security, develop opportunities for economic prosperity and protect cultures, natural environments and biodiversity are increasingly and fundamentally impacted by a wide range of invasive plants, animals and disease organisms. IAS threaten the way of life for many Pacific islanders. IAS degrade oceans, destroy crops, smother reefs and forests, and kill unique endemic species. IAS impact traditional practices and cultures, as well as, the health of Pacific islanders. Aside from climate change, IAS are the single greatest long-term threat to Pacific Island economies, environments, cultures, people and sustainable livelihoods. IAS undermine ecosystem resilience and the ability to adapt to climate change and develop sustainably.

At the same time, Pacific islands offer some of the greatest opportunities for the successful prevention, eradication, and control of IAS due to their relatively small size, limited number of ports of entry, and isolation from the continental sources of most known IAS. Furthermore, the region is a global leader in IAS expertise and has years of successful collaborative efforts and prevention, eradication and control experience.

It is with this knowledge in mind that the region has enthusiastically joined with partners in the United States Government, the Secretariat of the Pacific Community, Landcare Research and many other Pacific and international biosecurity experts to develop this Regional Biosecurity Plan for Micronesia and Hawaii. This comprehensive plan provides an unprecedented blueprint for effective prevention, management, and control of invasive species within and into the region.

***This list encompasses most, but possibly not all, acronyms used throughout the four volumes of the Regional Biosecurity Plan.**

15. Key Terms*

Animal Contamination: Something that comes in contact or association with animal secretion.

Antifouling paint: Any coating (generally applied as a paint) specifically designed to prevent or deter the settlement and growth of biofouling organisms on a submerged surface (e.g., vessel hull) including biocidal coatings and fouling-release coatings.

APHIS Compliance Agreement: Written agreement that demonstrates understanding between or among parties agreeing to follow APHIS procedures.

Ballast water: Any water (including associated sediments) taken on board a vessel for the express purpose of managing the trim and stability during a voyage.

Ballast water exchange: Emptying and refilling a ballast water tanks typically conducted in order to reduce the potential number of coastal organisms within the holding tank.

Benthic: Pertaining to the flora and fauna found on (or associated with) the bottom of the ocean.

Biofouling: Marine organisms attached to any submerged artificial structure, including wharves, jetties and any part of a vessel hull (including the hulls, rudders, propellers and other hull appendages) or internal seawater systems (including sea-chests and pipe work), or to any equipment or equipment spaces attached to or onboard the vessel (including mooring devices, anchor wells, cable lockers, cargo spaces, bilges, etc).

Bioinvasion or biological invasion: The movement of a living organism to an area outside its natural range, potentially resulting in the establishment or spread of the organism.

Bioregion: An area constituting a natural ecological community with characteristic flora, fauna, and environmental conditions, and bounded by natural rather than artificial borders.

Biosecurity: The management of the risks to animal, plant, human, and environmental health posed by pests and diseases. Managing the risks associated with pests, diseases, genetically modified organisms (GMOs), and other live organisms entering, emerging, establishing or spreading which would potentially cause harm to: human, animal or plant health, the environment or the economy.

Biotic resistance: The hypothesized intrinsic resistance to new species entering a community by the existing members. Elton (1957) suggested that well-connected, species rich communities would naturally resist new species entering by predation, parasitism, and direct and indirect competition.

Build-up:The United States Department of Defense proposed relocation of US Marine Corps forces from Okinawa to Guam and the CNMI.

Bulk Cargo: Cargo not enclosed in a container

Colonize: Refers to larvae or propagules that successfully settle and establish on a submerged substrata.

Dry and semi-dry ballast: The largely historic (though some vessels still use dry ballast) use of rocks, cobble, sand and other dry substances to help maintain the trim and stability of a vessel, semi-dry refers to the wet nature of the bilge, providing a humid environment.

Dunnage: Wood packaging material used to secure or support a commodity during transport, but which does not remain associated with the commodity.

Epibenthic species: Species found living on the surface of the benthic substrata on the bottom of the ocean or estuary.

Endemic species: A species unique to a defined geographic area, such as an island or group of islands.

Exotic: Not native to the specified region or country.

Fomite: An inanimate object or substance, such as a tool, clothing, packing or bedding materials, capable of carrying infectious organisms and thus transmitting from animal to animal (or human to human).

Fumigation: Treatment with a chemical agent that reaches the commodity wholly or primarily in a gaseous state.

Garbage: All waste material derived in whole or in part from fruits, vegetables, meats, or other plant or animal (including poultry) material, and other refuse of any character whatsoever that has been associated with any such material aboard any means of conveyance and includes food scraps, table refuse, galley refuse, food wrappers or packaging materials, and other waste material from stores, food preparation areas, passengers' or crews' quarters, dining rooms, or any other areas on vessels, aircraft, or other means of conveyances.

Hitchhiker: Species unintentionally moved to a different location in cargo, packing material, a shipping container used for transport, or on/in the conveyance of transport.

Inoculate/inoculation: Refers to the release of a non-indigenous species into the surrounding environment. This includes the release of offspring, fragments and/or direct transfer of individuals, but does not infer successful establishment.

Indigenous or native: Species that are naturally occurring in a region, having evolved or migrated into a region without human intervention.

Infestation: The occurrence of one or more pest species in an area or location where their numbers and impact are currently or potentially at unacceptable levels. A sudden increase in destructiveness or population numbers of a pest species in a given area.

Introduced species: Species that have been transported by human activities – intentionally or unintentionally – into a region in which they did not occur in historical time. See also ‘invasive’, ‘non-indigenous’, and ‘non-native species’.

Invasive species (or invasive alien species): Exotic species, including animal and plant disease agents, microbes, and pests, whose introduction does or is likely to cause economic, environmental, social, and/or cultural harm and/or harm to human health.

LLOYDS MIU: Lloyds compiles and provides data on the global fleet of commercial vessel, including vessel characteristics and traffic patterns (www.lloydslistintelligence.com).

Meroplankton: The category of organisms that spend a part of their life cycle in the water column as plankton. For invertebrates and many fishes, the planktonic stage is usually the larval stage.

Micronesian Region: Guam, the Republic of Palau, the Federated States of Micronesia, the Commonwealth of the Northern Mariana Islands, and the Republic of the Marshall Islands.

Niche area or vessel niche area: The wetted (submerged) surfaces of a vessel that are distinct from the contiguous hull, usually sheltered from laminar flow, including propulsion and steering gear, internal cooling circuits, sea strainers, sea chests, bow and stern thrusters, transducers, log probes, anchors, anchor chains, anchor lockers and bilge.

Non-indigenous or non-native species: see exotic species definition

Pest: Any species, strain or biotype of plant, animal or pathogenic agent considered injurious.

Phytosanitary Certificate: Official document which attests to the phytosanitary status of any consignment affected by phytosanitary regulations.

Propagative plant material: Plant material which may include nursery stock, plants, and other propagative parts such as bulbs, seeds, roots, rhizomes, tubers, corms, etc.

Recruitment: The post-settlement survival of an individual or species within a defined time period.

Reproductive phenology: The timing and period (duration) of reproductive activity for an individual species.

Sea-chests: Recesses built into a vessel’s hull below the waterline that house the seawater intake pipes used for ballast uptake, engine cooling, firefighting and other onboard functions.

Sessile: Species that are firmly attached to the hard substratum (e.g., sponges, corals, barnacles).

Transport pressure: Refers to the numbers of vessels that arrive from a particular bioregion and multiplied by a port duration weighting.

Species richness: The number of species represented in an ecological community.

Wood Packaging Material (WPM): Wood or wood products used in supporting, a commodity to protect it during transport (includes dunnage).

Vector: The physical means, agent or mechanism which facilitates the transfer of organisms or their propagules from one place to another.

Zoonoses: Any disease or infection that is naturally transmissible from animals to humans.

***This list encompasses key terms used throughout the four volumes of the Regional Biosecurity Plan.**

16. Acknowledgments

The plan was created by a truly collaborative effort, as over 150 individuals had direct input into its development. This includes resource managers, policy makers, researchers, educators, representatives from the shipping, aquaculture, aquarium, and tourism industries, active ocean and inland water users, as well as other stakeholders throughout the region and from further afield.

The concept of the plan came originally from the RISC and the Micronesia Chief Executives. Personnel from NISC and the DOI were instrumental in further developing the concept and bringing the concept to the attention of the DoD. The DoD funded both the development of the risk assessments and the final RBP product and in addition has been extremely supportive throughout the developmental process.

The risk assessments were drafted by U.S. federal agencies including the Smithsonian Institute, USGS, and USDA. The risk assessments were reviewed by LandCare New Zealand as well as dozens of independent and agency level reviewers.

The University of Guam, SPC, and LandCare updated the risk assessments in regards to review of comments and worked synergistically on developing the other components of the RBP including the implementation strategy.

Development of the implementation strategy involved numerous consultations with thematic experts and government officials throughout the region with various feedback mechanisms incorporated into the process with the outlook of insuring the most effective and efficient end product possible for each of the jurisdictions.

Large components of the original risk assessments completed for this project by USDA, USGS, and the Smithsonian Institute, element of the peer review completed by LandCare, and hundreds of comments and remarks from stakeholders throughout the region have been incorporated into this body of work.

As in many collaborative projects, the list of names to be thanked is long and it is not possible to list everyone who has contributed to this plan. The contributions and participation of all involved is much appreciated and played a large part in the success of development of this plan.

Attachment A: Overview of the Island Jurisdictions Included in the Regional Biosecurity Plan

Territory of Guam

Guam is the largest and southernmost island in the Mariana archipelago as well as being the largest island within Micronesia (Figure A-1). The surface geology of the southern half of the island is primarily volcanic rock and the northern half is limestone (Gingerich 2003). Guam has extensive coastal reefs, eroded volcanic hills in the south and a raised limestone plateau in the north. Elevations range from sea level to the summit of Mount Lamlam at 406 meters (1,332 feet). The climate is warm tropical maritime, generally warm and humid; temperature varies little during the year, averaging 26°C (Western Regional Climate Center: <http://www.wrcc.dri.edu/cgi-bin/cliMAIN.pl?pigum>). Mean annual precipitation ranges from 216 to 292 cm (85 to 115 inches) (Gingerich 2003). A dry season occurs from January to June with a rainy season from July to December. The exact timing and extent of the dry season varies annually. About 40 watersheds are present on Guam, mostly on the southern half of the island. Artificial freshwater habitats on Guam consist primarily of small to large impoundments, the largest being Fena Reservoir. Since precolonial times, the island of Guam has been a center of trade and travel. Guam laid on the colonial trade route between the Philippines and Mexico and more recently was of strategic importance during World War II (WWII) and the Cold War and continues to play a major role in U.S. military strategy. Guam has been a U.S. territory since 1898, and about a third of the island is currently devoted to military installations. Guam has 544 square kilometers of land with a 125.5-km (78-mile) coastline and a population of approximately 154,805 in 2010. Located about three-quarters of the way from Hawaii to the Philippines, Guam occupies a strategic location for the U.S. military in the western North Pacific, and it is the primary focus of the proposed military relocation of U.S. forces currently located in Okinawa, Japan.

According to data from the Guam Bureau of Statistics and Plans for 2009, the major suppliers for imported commodities were the United States (50%), Japan (14%), Western Europe (13%), and Asia (China, Korea, Taiwan, Hong Kong, Singapore, Thailand, and the Philippines) (16%). Food commodities and non-alcoholic beverages represented the largest commodity group, making up more than 30% of all imports in 2009 (Guam BSP 2009).

Guam's economy depends largely on U.S. military spending and tourism. Over the past 30 years, the tourism business has grown to become the largest income source following national defense. The Guam economy continues to expand in both tourism and military sectors. As military expansion continues, environmental protection and aesthetics should continue to be a primary focus for the protection and development of Guam's tourist industry. Most visitors to Guam arrive by air from Japan (78%) and Korea (10%).

Natural resources include the marine environment, agricultural products, and the terrestrial environment. Aquatic wildlife from the marine environment supports tourism and some recreational

and subsistence fishing. Guam's agricultural production is extremely limited and what does exist are mainly fruits and vegetables produced for local consumption. The terrestrial environment of Guam has been fairly heavily impacted by various elements including major battles during WWII, extensive and long term human habitation, and various established and highly detrimental invasive species.

Guam has a history of invasive species problems, including the establishment of the Brown Treesnake, Coconut Rhinoceros Beetle, and Little Fire Ant (*Wasmannia auropunctata*). Guam is a major transportation hub for the Micronesia region and could also be a hub for dispersal of IAS within the region. DoD, GDOA, GCQA, Guam Port Authority, UOG, USDA, USFWS, Guam Invasive Species Council (GISC) and Guam Invasive Species Advisory Committee (GISAC) are all involved in IAS control and management on Guam.

Figure A-1: The Territory of Guam

Summary details of the Territory of Guam:

1. Location: latitude 13°28'N and longitude 144°45'E
2. Number of islands: 1
3. Size: 544 km²
4. Population: 154,805
5. Examples of native species that are imperiled: Guam Rail (*Gallirallus owstoni*), Mariana Fruit Bat (*Pteropus mariannus*), Guam subspecies of the Micronesian Kingfisher (*Todiramphus cinnamomina cinnamomina*), Mariana Crow (*Corvus kubaryi*), Mariana Common Moorhen (*Gallinula chloropus guami*), Mariana Swiftlet (*Aerodramus bartschi*), Green Sea Turtle (*Chelonia mydas*), Hawksbill Sea Turtle (*Eretmochelys imbricata*), *Serianthes nelsonii* (organisms listed are only those considered at the federal level, local experts may want to expand this to include species of local concern)
6. Examples of established IAS of significant concern: Brown Treesnake, Coconut Rhinoceros Beetle, Little Fire Ant, various rat species (*Rattus* spp.), numerous plant species and arthropods
7. Example of an IAS with significant threat of establishing: Coqui Frog (*Eleutherodactylus coqui*)
8. Main economic drivers: Tourism, DoD, and local businesses
9. Main trade partners: U.S. mainland
10. Import examples
 - a. Food stuffs and beverages
 - b. White leg shrimp also known as Pacific white shrimp (*Litopenaeus vannamei*) post larvae and broodstock (Arthur et al. 2012). Adults were imported in 2007 from Hawaii and Kentucky.
 - c. Mangrove Crab (*Scylla serrata*) annually imported from the FSM and the Philippines (Arthur et al. 2012)
 - d. Mozambique Tilapia (*Oreochromis mossambicus*) fry annually imported from the Philippines and Taiwan POC (Arthur et al. 2012)
 - e. Freshwater and Marine aquarium fish imported from Malaysia, Singapore, Taiwan POC, and US (Arthur et al. 2012). Pet shops import aquatic organisms on a monthly basis
11. Export example: Guam has a live export trade of the aquatic species *Litopenaeus vannamei* which is exported to China and the United Arab Emirates as brood stock (Arthur et al. 2012).
12. Ports and post offices points of entry
 - a. Air
 1. Won Pat International Airport: Guam's Antonio B. Won Pat International Airport (A.B. Won Pat Airport), also known as Guam International Airport, serves as the hub for regional air travel, international cargo, and passenger transport. Fiscal Year (FY) 2006-2007 had an average of 756 aircraft operations/week and numbers of aircraft operating averaged 1,610/month (approximately 400/week). Several international airlines operate from Guam: United, Northwest, Japan, Korean Air, Philippine Airlines, China Airlines, and Asia Pacific. The airport has 21 aircraft parking positions with 18 common-use terminal gates. U.S. Customs and Border Protection (CBP) personnel provide immigration services, and Guam Customs and Quarantine Agency (GCQA) personnel conduct

customs and agriculture clearance during scheduled aircraft operations and on prior arrangements with field supervisors.

2. AAFB
- b. Sea
 1. Guam commercial port
 2. Naval Base Guam
- c. Post offices
 1. Barrigada
 2. DoD

Commonwealth of the Northern Mariana Islands

The 14 northern islands of the Mariana Archipelago make up the CNMI (Figure A-2). The three largest of these islands are currently the only ones with permanent human settlements. The three inhabited islands are Saipan, Tinian, and Rota. Saipan is the seat of the commonwealth government and also the island where most of the population resides. On Saipan, tourism is a main economic activity, while manufacturing which was an important economic resource has all but closed down in recent years. Rota and Tinian are primarily dependent on agricultural activities. Visitation to the CNMI is mainly from Southeast Asian countries with most visitors arriving and staying on Saipan and only a few visiting Tinian or Rota.

Several international airlines fly to the CNMI, mainly Saipan, while Tinian and Rota are generally accessed by Mariana Islands based commuter planes. Delta flies 21 times a week into Saipan with three flights daily from Nagoya and Narita, Japan. Asiana has 11 flights a week from Incheon, South Korea, four flights a week from Pusan, South Korea, and four flights a week from Osaka, Japan. Charters include China Southern, Air China, and Shanghai Airlines; China Southern and Shanghai Airlines bring two charter flights twice weekly from Guangzhou. Air China only occasionally operates (holidays, special occasions) from Beijing (Deposa 2010).

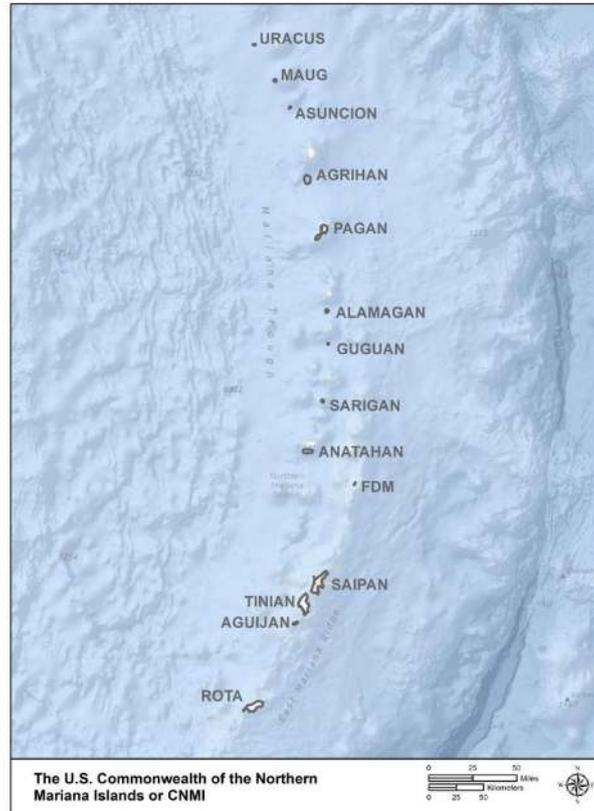

The climate of the CNMI is similar to that of Guam, with pronounced wet and dry seasons.

Saipan: Saipan is located between latitude 15°5'30" to 15°17'30" N and longitude 145°41'30" to 145°50'00"E. The island is about 21 km (13 mi) long and about 6.4 km (4 mi) wide, with a surface area of about 124 km² (48 mi²), making it the largest island in the CNMI. Saipan also has the largest human population among all of the CNMI islands. A ridge extends centrally through the island and there is a wide coastal area to the west. The highest point is Mount Tapochau, with a maximum elevation of 466 m (1,530 ft.). Annual rainfall averages about 203 cm (80 inches) (van der Brug 1985).

Tinian: Tinian is located at 15°N and 145°E. With a surface area of about 101 km² (39 mi²) it is the second largest island in the CNMI, and measures about 19 km (12 mi) long and 9.7 km (6 mi) wide. The surface topography is divided into five physiographic areas, with the southern part of the island having the greatest elevation; the highest point is Mt. Kastiyu (Lasso Hill), at 187 m (614 ft.) (Gingerich 2002).

Rota: Rota is located between latitude 14°06' to 14°12'N and longitude 145°07' to 145°17'E. It is the southernmost island of the CNMI and lies about 72 km (45 mi) north-northeast of Guam. The island is oriented east-west and is about 18.5 km (11.5 mi) long and 4.8 km (3 mi) wide. Including two small islands along its west shore, the surface area of Rota is approximately 85.5 km² (33 mi²).

Figure A-2: The Commonwealth of the Northern Mariana Islands

Summary details of the Commonwealth of the Northern Mariana Islands:

1. Location: the western Pacific between latitudes 14°08 and 20°33'N and between longitude 144°54' and 146°04'E
2. Number of islands: 14 islands, including 3 which are inhabited (Saipan, Tinian, and Rota)
3. Size: 475 km²
4. Population: 53,883 (2010 census); 90% of population lives on the island of Saipan
5. Examples of native species that are imperiled: Mariana Fruit Bat, Micronesian Megapode (*Megapodius laperouse*), Mariana Crow, Mariana Common Moorhen, Mariana Swiftlet, Nightingale Reed Warbler (*Acrocephalus luscinius*), Rota Bridled White-eye (*Zosterops rotensis*), Green Sea Turtle, Hawksbill Sea Turtle, *Serianthes nelsonii*, *Nesogenes rotensis*, *Osmoxylon mariannense*

6. Examples of established IAS of concern: Giant African Snail (*Achatina fulica*) and Melon Fruit fly (*Bactrocera cucurbitae*)
7. Examples of IAS of significant concern of establishing: Coconut Rhinoceros Beetle, Brown Treesnake, Coconut Termite (*Neotermes rainbowi*)
8. Main economic drivers: Tourism, Services
9. Main trade partners: USA and Japan
10. Import examples: food, construction material and equipment, and petroleum products
11. Export examples: Garment production was a major revenue earner for the island of Saipan prior to 2010. Garments were exported to USA mainland. The industry has closed. At present exports are mainly sweet potato, yam and taro. These agricultural products are exported to Guam.
12. Ports
 - a. Air
 1. Saipan International Airport: A Port of Entry responsible for enforcing the Immigration and Nationality Act (INA) for arriving aliens and establishing departure control for certain flights as part of the “Northern Mariana Islands Immigration, Security, and Labor Act.” Officers perform admission of aliens; travel control of citizens and aliens; inspections; apprehensions; examinations; exclusions and removals. It is the gateway to the CNMI, serving Saipan, Rota and Tinian. It can accommodate wide-bodied aircraft, i.e. DC 10's and 747's. The runway is 8,700 feet long with a parallel taxiway and connecting taxiways. The main terminal accommodates international passengers with six jet ways and houses the Immigration and Customs processing areas. Major airlines operating include: United Airlines, All Nippon Airlines, Delta Airlines, Asiana Airlines, Shanghai Airlines, Sichuan Airlines, China Eastern and Fly Guam. Flights arrive direct from cities in Japan, Korea, Hong Kong, Philippines, China and Guam. Saipan International Airport operates mainly inter-island flights. In FY 2006–2007, the number of plane operations per week equaled those at Guam over roughly the same FY period with the majority (71%) from commuter traffic compared to 18% for commercial traffic. The commuter terminal serves as feeder for a Tinian and Rota. The airport operates 24 hours 7 days a week with 24-hour availability of aircraft rescue personnel and equipment (CPA 2007b). Ground handling is by POI Aviation Services affiliated with Tan Holdings Company (POI 2010). Immigration and customs are available during scheduled operations, otherwise by prior arrangements with the chief of Immigration in Saipan (CPA 2007b). DoD also utilizes this airport.
 2. Tinian International Airport: Tinian International Airport hosted approximately 252 plane operations in FY 2008–2009 with 99% commuter and fewer than 1% commercial (CPA 2007c). Tinian has multiple daily commuter flights from Saipan and is also utilized by privately chartered Star Marianas Airlines which provides services for the Tinian Dynasty Hotel & Casino customers originating primarily from China. Passenger traffic is mainly inter-island from Saipan, Rota, and Guam. The airport has accommodations for aircraft with capacities of up to 36 passengers. The current runway is 8,600 feet in length with a parallel taxiway and two connecting taxiways at each end. Construction of a high-speed taxiway has been advertised for bid and the runway expansion is expected to increase traffic. The airport is equipped for night operation with night flights from Saipan

and Guam transporting passengers destined mainly for the hotel and casino. DoD also utilizes this airport.

3. Rota International Airport: Rota International Airport hosts primarily inter-island traffic from Saipan and Guam. An average of 18 aircraft operations/day occurred in FY 2007-2008, 72% commuter and 27% commercial. In FY 2005-2006, a total of 6,550 aircraft operations averaging 17/day ranged from 94% air taxi to 4% general aviation. The airport can accommodate aircraft with capacities of up to 39 passengers. The airport is equipped for nighttime operations. U.S. Immigration (conducted by CBP) and CNMI Customs and Quarantine services are available during scheduled aircraft operations and on prior arrangements with field supervisors. Airlines operating include Freedom Air, Cape Air, and Arctic Circle Air Company. DoD also utilizes this airport.

b. Sea

1. Port of Saipan: The commercial seaport has 2,600 linear feet of berthing space and a 22-acre container yard. The channel, turning basin, and berthing areas have been widened and deepened to a uniform -40 feet in order to accommodate medium to deep draft vessels into port. The port has two fuel storage facilities and shares space with a bulk cement company, three freight forwarding companies and three shipping agents. Sunset Cruises, a private concession, also utilizes the port. The U.S. Coast Guard recently assisted with improved navigational aids and repositioned harbor buoys to mark the safest route into port. There is a quarantine zone established at the Saipan seaport which is enclosed in a snake proof barrier where suspect materials including multiple sea containers can be placed until appropriately investigated.
2. Port of Rota: One stevedoring company is available and two storage companies. Quarantine, Customs, and Immigration services are also available at the seaport. The port has sixteen 22-foot Boat Slips.
3. Port of Tinian: There are two stevedoring companies available at the Tinian harbor and a bulk fuel plant operated by Mobil Oil. Three finger piers are available for berthing including a small boat ramp. The port has a quarantine area enclosed with a snake repellent barrier.

State of Hawaii

Elevations range from sea level to over 4,000 m (Loope and Mueller-Dombois 1989). The climate is tropical at sea level, although freezing conditions occasionally occur at high elevations (Juvik and Juvik 1998). Mean monthly temperatures in Honolulu range from 23° C (73° F) in January to 28° C (82° F) in August, and mean annual precipitation in Hawaii ranges from 38 to 1,016 cm (15 to 400 inches) (Juvik and Juvik 1998). The major islands of Hawaii have a wide diversity of inland and coastal aquatic habitats, including about 400 reservoirs and other artificial impoundments, 360 perennial streams, and 30 stream-mouth estuaries, as well as many irrigation ditches, a few natural lakes, and numerous fresh and saline wetlands (Maciolek 1984; Yamamoto and Tagawa 2000). Parham et al. (2008) provided detailed information about all of Hawaii's watersheds, including distributions of nonindigenous species. Streams in Hawaii tend to be steep with widely-varying flow rates.

1. Location: The Hawaiian archipelago is a series of volcanic islands in the central Pacific Ocean between latitudes 18°55' and 28°27'N and longitudes 154°48' and 178°22'W. The island group is over 3,000 km (1,864 mi) from the nearest continent.
2. Number of islands: There are eight major high islands
3. Size: The eight major high islands have a total land area of 16,500 km²

The Hawaiian archipelago comprises eight main, or high, islands and a series of leeward atolls, banks, reefs, and shoals, extending southeast to northwest for about 2,400 kilometers (km) (1,491 miles) in the north Pacific Ocean, from approximately 19° to 28° north latitude (Loope 1998) (Figure A-3).

Figure A-3: The Hawaiian Archipelago

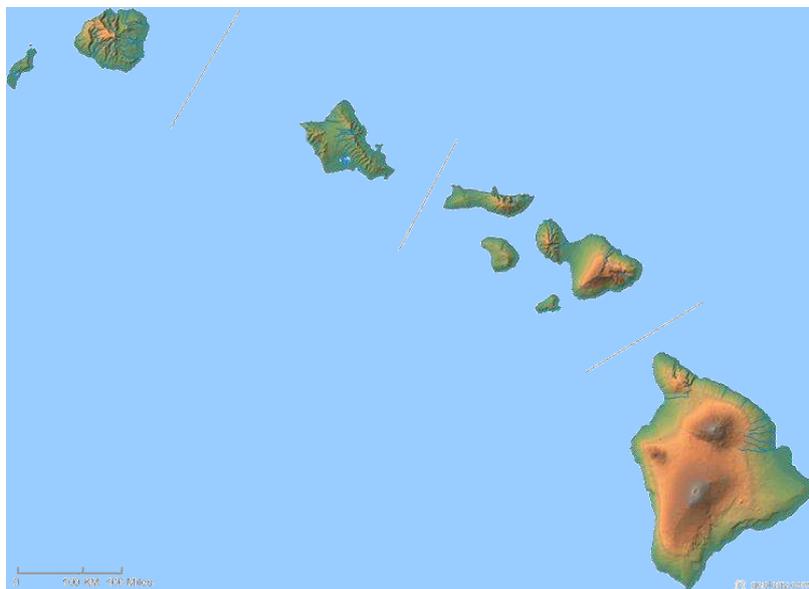

Source: Loope 1998

Hawaii's agreeable climate derives from its location mainly within the tropics (Giambelluca and Schroeder 1998). The annual variation in mean monthly temperatures is only about 5°C, and the length of the daylight period between the shortest and longest days of the year varies only by about 2.5 hours. Only two seasons generally are recognized in the state, the warm season (summer), extending from

about May through September, and a cooler and wetter season (winter), from October to April. Average annual rainfall ranges from 250 millimeters (mm) to 11,300 mm; the summit of Mt. Waialeale on the island of Kauai is one of the wettest places on Earth. Although generally equable, climate exhibits substantial spatial variability due to the influence of the islands' mountainous topography. Rainfall, solar radiation, temperature, humidity, and wind all may show spectacular differences over short distances (Giambelluca and Schroeder 1998). Changes in climate are particularly evident along elevation gradients where temperatures may dip below freezing on the highest mountain peaks. The varied topography and climate have been major influences on the high rates of speciation and resulting diversity within the Hawaiian biota (Peck et al. 1999; Price 2004).

As of 2006, the State of Hawaii (16,635 km² in land area; [USCB 2006]) had a population of 1,285,498 (HDBEDT 2007). This equates to an average density of 77 persons per km². Figure A-4 shows the State of Hawaii with counties demarcated, from upper left to lower right: Kauai County (comprising the islands of Kauai and Niihau), City and County of Honolulu (Oahu and the northwestern Hawaiian Islands excluding Midway), Maui County (Maui, Molokai, Lanai, and Kahoolawe), and Hawaii County (Hawaii Island) (HDBEDT 2007). The majority of residents (75% or more) lives on the island of Oahu (Schmitt 1998), at an average density of about 585 persons per km². In general, Hawaii residents exhibit educational levels, family incomes, and employment rates above the national average, while experiencing exceptionally high costs of living (Schmitt 1998).

Figure A-4: The Eight Main Islands of the State of Hawaii

Source: Modified from: <http://geology.com/state-map/hawaii.shtml>

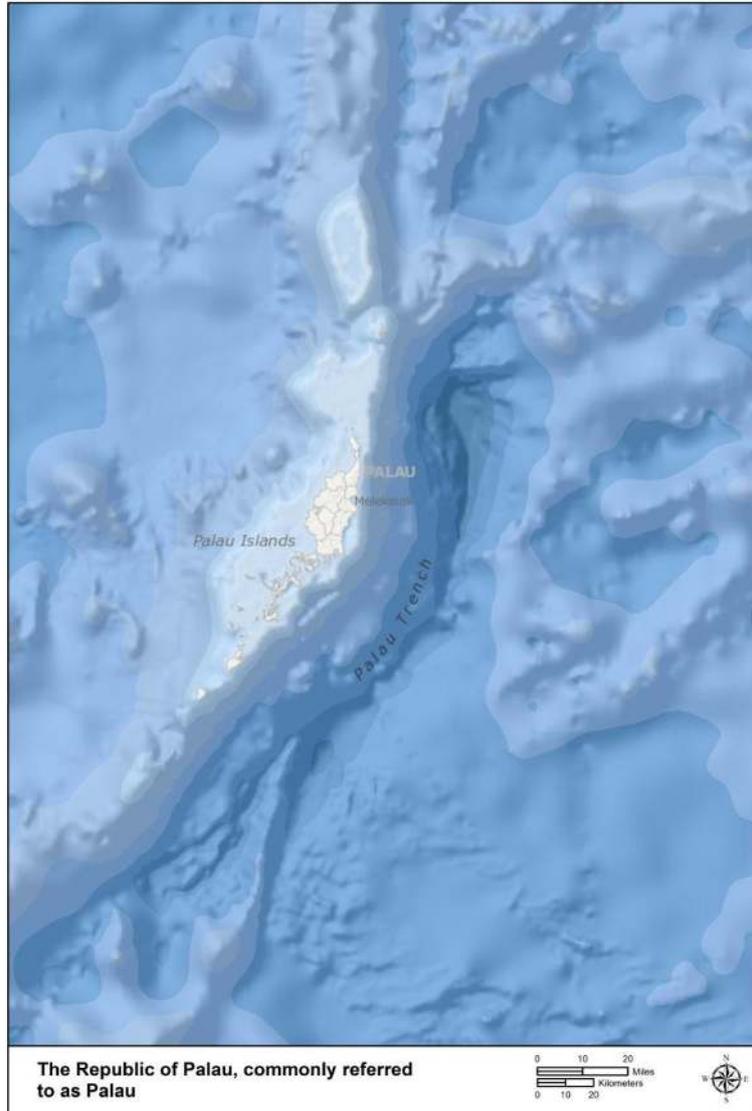

Gross state product in 2005 was \$53.7 billion (HDBEDT 2007). The top three contributors are federal government expenditures (\$12.2 billion in 2004, of which defense spending contributed \$4.8 billion), tourism (\$11.9 billion in 2005), and agriculture (\$516.1 million in 2004).

During the first half of the twentieth century, agriculture dominated the economy in Hawaii, and was itself dominated by sugarcane and pineapple production; however, with the closing of several plantations in recent years, diversified agriculture has gained in importance (Kelly 1998a). The state's agriculture can be divided into three sectors: traditional plantation crops (pineapple and sugarcane) produced for export; commodities, such as vegetables, eggs, and milk, produced for local consumption; and newer export crops, such as macadamia nuts, flowers, and nursery stock. Although more than two-thirds of the food supply is imported, Hawaii is self- or near-self-sufficient in the production of certain commodities (Kelly 1998a). All of the papaya and most of the pineapple consumed in the state is grown locally, as are most of the head cabbage, Chinese cabbage, green onions, and watermelons. Fewer than half of the bananas, tomatoes, pork and other meats, onions, lettuce, and carrots consumed are produced in Hawaii.

Republic of Palau

The islands of Palau are within the western portion of the Caroline Islands (Figure A-5). Much of the information summarized below is taken from van der Brug (1984c), Scott (1993), Crombie and Pregill (1999), and Hein et al. (2005). The islands of Palau range in size from very small islets to quite large islands, with a total land area of only about 494 km² (Scott 1993; Crombie and Pregill 1999). Of the islands in the chain, only 12 are greater than 1 km² in land area (Steadman 2006). Babeldaob, with an area of about 396 km², approximately 80% of Palau's total land area, is the largest island in Palau and one of the largest in the entire western Pacific. A few of the other larger islands of Palau, all dwarfed by Babeldaob, include Koror (9.3 km²), Arakabesang (2.3 km²), and Malakal (0.8 km²). The island of Koror and its major town (also known as Koror) contains the largest proportion of inhabitants and is the commercial center of the republic. The highest point is Mount Ngerchelchuus on the northern part of Babeldaob Island, cited as ranging anywhere from about 242 m to 287 m (794 ft. to 941 ft.) in elevation (Crombie and Pregill 1999; Hein et al. 2005). The Palau Islands are physiographically diverse, with various areas categorized as volcanic, high limestone, low platform, reef, or atoll. Some islands (e.g., Koror, Peleliu, and Angaur) contain multiple physiographic areas. The northern group of larger islands form a dissected volcanic plateau characterized by rolling uplands, sharp ridges and cliffs, flat alluvial areas, and extensive coastal mangroves. Most of the Palau Islands are coralline limestone ridges covered by dense tropical vegetation. The climate within the archipelago is warm and humid; mean annual temperature is about 27.6°C (81.7°F) and average annual rainfall is about 376 cm (148 inches) per year (van der Brug 1984c). The wettest months are from July to October and the driest months are from December to April when northeast trade winds prevail. Although Palau lies outside the main paths of severe typhoons, the islands occasionally receive strong tropical storms. Most visitors to Palau are from Southeast Asia.

Figure A-5: The Republic of Palau

Summary details of the Republic of Palau:

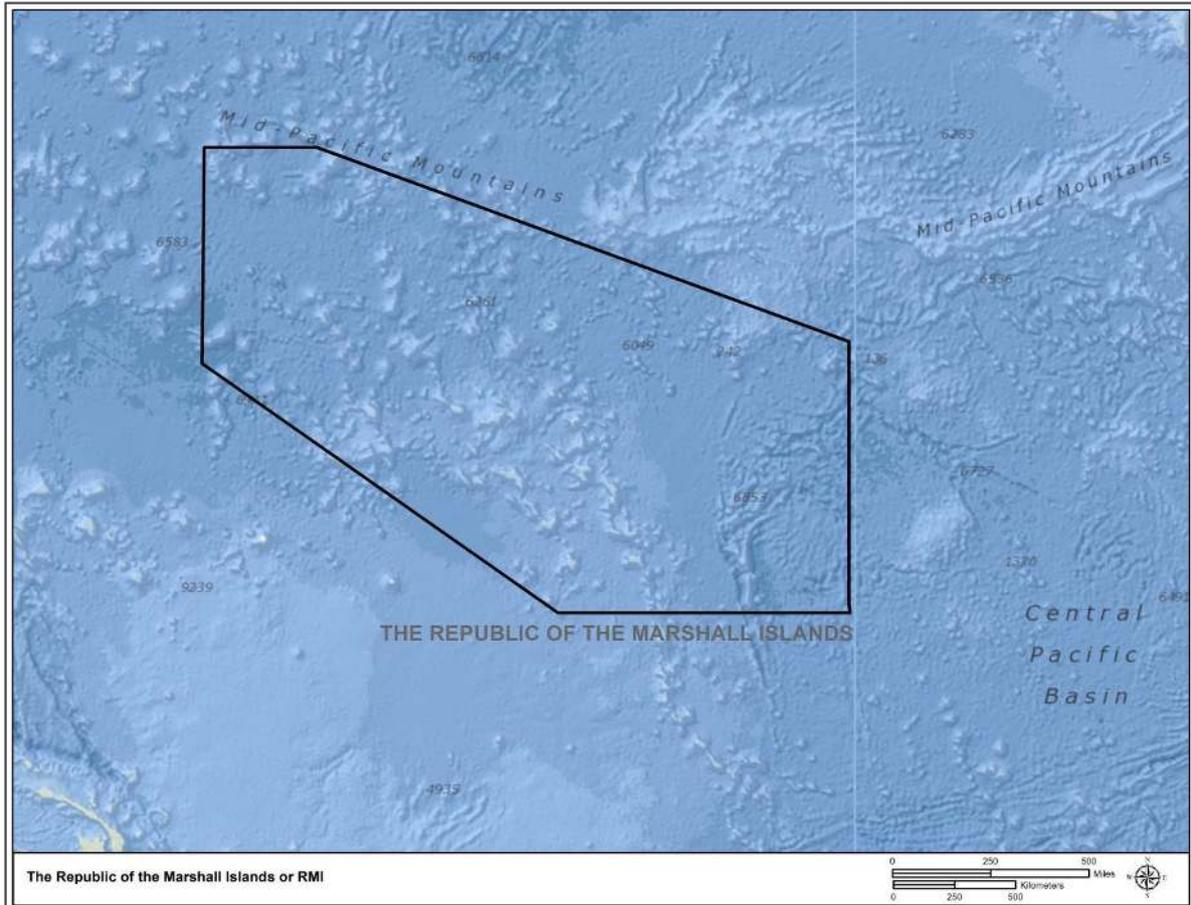

1. Location: The Republic of Palau extends across nearly 240 km (150 mi) in western Micronesia between latitude 6°53' to 8°12'N and longitude 134°07' to 134°44'E. It is located about 770 km (480 mi) north of New Guinea, 800 km (500 mi) east of the Philippines, and 1,135 km (700 mi) southwest of Guam.
2. Number of islands: 250+ (approximately 200 of these are the uninhabited rock islands)

- a. Koror
 - b. Barbeldaob
 - c. Angaur
 - d. Peleliu
 - e. Kayangel
 - f. Rock Islands
 - g. Southwest Islands
3. Size: 458 km²
 4. Population: approximately 21,000 spread across 16 states with more than half of the population living in the state of Koror
 5. Main economic drivers: Tourism, agriculture, and fisheries
 6. Examples of native species that are imperiled: Hawksbill Sea Turtle, Dugong (*Dugong dugon*), Micronesian Megapode, Saltwater Crocodile (*Crocodylus porosus*), Rock Island Palm (*Gulubia palauensis*), Palau Palm (*Ponapea palauensis*) (IUCN listed species)
 7. Examples of established IAS of concern: Long-tailed macaque monkey (*Macaca fascicularis*), Tilapia (*Oreochromis mossambicus*), Mikania (*Mikania micrantha*), Cogon grass (*Imperata cylindrica*), Philippine Fruit Fly (*Bactrocera philippinensis*), Praxelis (*Praxelis clematidea*), Water Hyacinth (*Eichornia crassipes*), Singapore ant (*Monomorium destructor*), Giant reed (*Arundo donax*), Cycad scale (*Aulacaspis yasumatsui*), Rats – (*Rattus spp.* 3 species) (PNISC 2013)
 8. Examples of IAS of significant concern of establishing: Brown Treesnake, Little Fire Ant, Coqui Frog (*Eleutherodactylus coqui*), Red Imported Fire Ant (*Solenopsis invicta*), Other tilapia species, and hybrids, Other frogs, Ivy Gourd (*Coccinia grandis*) (PNISC 2013)
 9. Import examples: electronic parts, cars and beverages (Japan, Philippines, China, South Korea, Australia) and Milkfish (*Chanos chanos*) fry (Arthur et al. 2012) imported from Taiwan POC
 10. Export examples: Marine products (93%) to Japan (94%)
 11. Ports
 - a. Air
 1. Palau International Airport on the island of Barbeldaob has international flights to and from various counties including: Guam (USA), Yap (FSM), Manila (Philippines), Seoul (South Korea), Taipei, and Narita (Japan). DoD also utilizes this airport.
 - b. Sea
 1. Malakal Harbor, Malakal Islands is the main seaport

Republic of the Marshall Islands

The Republic of the Marshall Islands is composed of a large number of islands on the western side of Micronesia (Figure A-6). The Marshall Islands are bordered to the east by the Federated States of Micronesia, to the north by Wake Island, and to the south Kiribati and Nauru.

Figure A-6: The Republic of the Marshall Islands

Summary details of the Republic of the Marshall Islands:

1. Number of islands: 1156 islands spread out within 29 coral atolls and 5 isolated islands
 - a. Majuro
 - b. Ebeye
 - c. Arno
 - d. Kwajalein

- e. Other islands
- 2. Size: 181 km²
- 3. Population: 68,000 (2009 UN estimate)
- 4. Main economic drivers: Service, fisheries, and agriculture
- 5. Examples of native species that are imperiled: Hawksbill Sea Turtle, Leatherback Sea Turtle, Green Sea Turtle, Loggerhead Sea Turtle, Pacific Ridley Sea Turtle (*Lepidochelys olivacea*), Ratak Micronesian Pigeon (*Ducula oceanica ratakensis*), various cetaceans (IUCN listed species, CITES and/or RMI listed species)
- 6. Examples of established IAS of concern: Siam Weed (*Chromolaena odorata*), Merremia (*Merremia peltata*), Mile-a-minute Vine (*Mikania micrantha*), Ivy Gourd (*Coccinia grandis*), Rats (*Rattus* spp.), Feral Pigeon (*Columba livia*), Red-vented Bulbul (*Pycnonotus cafer*)
- 7. Examples of IAS of significant concern of establishing: Coconut Rhinoceros Beetle, Brown Treesnake
- 8. Import examples
 - a. Giant Clam (for export to the US) imported from the FSM (Arthur et al. 2012)
 - b. Coral (for export to the US) imported from the FSM (Arthur et al. 2012)
- 9. Export examples: Copra oil, Copra, Frozen fish
 - 1. Aquarium fish (US, Taiwan POC, China, Japan, Korea) (Arthur et al. 2012)
 - 2. Coral (US)
 - 3. Giant clams (US)
- 10. Ports
 - a. Air (official ports of entry are listed, other minor airstrips exist)
 - 1. Amata Kabua International Airport, Majuro: The airport is capable of handling all propeller driven aircrafts, turbo props, business jets and small to medium size jet aircraft (e.g. Boeing 737, Boeing 727) and Boeing 767s. In 2003 the Republic of the Marshall Islands port authority took over the management of the airport from the Marshall Islands Airport Authority. Three airlines utilize this airport: United Airlines, Air Marshall Islands, and Our Airline. Japan Airlines also occasionally runs charter flights to Majuro direct from Tokyo. Air Marshall Islands provides links to the following islands: Airok, Aur, South Tarawa, Ebon, Enejit, Jaluit, Jen, Kaben, Kili, Kwajalein, Majkin, Maloelap, Mejit, Mili, Namdrik, Utirik, and Wotje. It is not clear how often flights take place nor what types of materials may be moving around the Marshall Islands via these linkages, but there is definite potential that IAS could be transported and internal mechanisms should be considered to reduce this potential. With the opening of Our Airline, Micronesia now (again) has direct air linkages with several South Pacific locations via flights from Majuro. Destinations with Our Airline from Majuro include: Fiji, Brisbane, Nauru, and Tarawa. Both passengers and air cargo are moved between Majuro and these destinations via multiple flights per week. United Airlines connects Majuro directly to both Hawaii and Kwajalein and indirectly to other destinations beyond these 2 locations. There are daily United Airline flights which transport both passengers and air cargo.
 - 2. The Bucholz Army Airfield: This U.S. Army airfield is located on Kwajalein Island. The airport is available to civilians through Air Marshall Islands and United Airlines. All civilian and military flights into Kwajalein require prior 24 hour approval. Kwajalein Island is the southernmost and largest island in Kwajalein Atoll. The Kwajalein airfield is 267 miles (430 kilometers) west of Majuro. The atoll lies in the

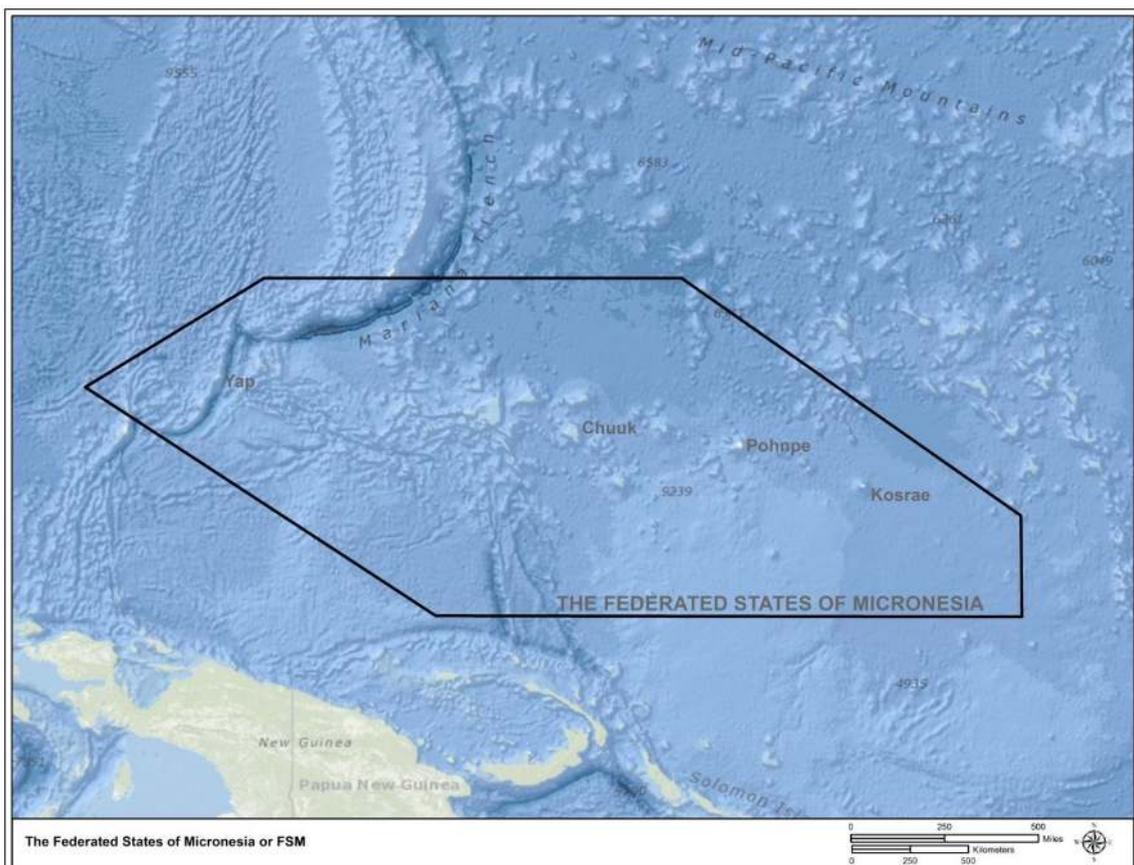

Ralik Chain and is 2,100 nautical miles (3900 kilometers) south west of Honolulu, Hawaii.

- b. Sea (official ports of entry are listed, other anchorages also exist)
 - 1. Port of Majuro
 - 2. Port of Kwajalein

Federated States of Micronesia

The FSM comprises a vast region of over 600 islands spanning a distance of about 2,700 km (1,678 mi). It is located within that part of Micronesia and the western Pacific known as the Caroline Islands, just north of the equator and north-northwest of New Guinea (Figure A-7). The FSM is an independent island nation that includes four states, three located in the eastern part of the Caroline Islands (Chuuk, Pohnpei and Kosrae) and one (Yap) in the western part of the Caroline Islands. Most visitors to FSM are from the United States (43%), Japan (16%), and Europe (13%). IAS of concern already established in the FSM include: Mile-a-Minute (*Mikania micrantha*), Cane Toad (*Rhinella marina*), various rat species (*Ratus* spp.), feral pigs (*Sus scrofa*) and feral cats (*Felis catus*) (FSM NBSAP 2002). Main imports are: food and beverages (topping the list were rice, poultry meat, canned fish and beer) (30% of total imports in 2005). Main exports are: offshore fish (91% total exports in 2005), reef fish, and betelnut. Japan and Guam are the two main recipients of exports. On a smaller scale, the FSM also exports coral, aquarium fish, *Tridacna* spp. (to Europe), and sponges (to New Zealand) (Arthur et al. 2012). Imports include: *Tridacna* spp. from Palau and the RMI.

Figure A-7: The Federated States of Micronesia

Summary details of the four states of the FSM:

a. Chuuk State (Figure A-8)

Mean annual air temperature in Chuuk State is about 27°C (81°F) and varies little throughout the year. Annual rainfall averages about 356 cm (140 inches) per year, ranging from about 254-457 cm (100-180 inches) per year for the Chuuk Island group. Droughts are common; rainfall from January through March is about half that of the remainder of the year (Hamlin and Takasaki 1996).

1. Location: The islands of Chuuk State are located between latitude 4° to 10°N and longitude 148° to 154°E.
2. Number of islands: 19 high volcanic islands and about 65 smaller coralline islands divided into five major island groups: Chuuk, Western, Namonweito, Hall, and Mortlock (Hamlin and Takasaki 1996).
3. Size: 91 km² (van der Brug 1983a). The volcanic islands comprise about 97% of the total land area (van der Brug 1983a).
4. Population: 48,651
5. Ports
 - a. Air (official ports of entry are listed, other minor airstrips may also exist)
 1. Chuuk International Airport
 2. Satowan Airstrip
 3. Ta Airstrip
 - b. Sea (official ports of entry are listed, other anchorages also exist)
 1. Weno Anchorage: This is the main seaport for the state of Chuuk.
 2. Satowan Anchorage
 - c. Post office
 1. Weno

b. Kosrae State (Figure A-9)

The summit of Mount Finkol (Mt. Crozer), elevation 629 m (2,065 ft.), is the highest point of the Kosrae island, and one of the highest peaks in the western Pacific (van der Brug 1984a). Mean annual air temperature near the coast is about 27°C (81°F) and fluctuates relatively little throughout the year. Annual rainfall is about 508 cm (200 inches) per year near the coast and as high as 571 cm (225 inches) inland, although the latter value was an estimate based on drainage runoff calculations rather than actual rainfall stations (van der Brug 1984a).

1. Location: Kosrae is the easternmost of the Caroline Islands, situated near the equator between latitude 5°16' to 5°23'N and longitude 162°55' to 163°03'E
2. Number of islands: 1
3. Size: 110 km²
4. Population: 6616 (2010)
5. Main trade partners: USA, Japan
6. Main imports: food, building material and equipment, fuel
7. Main exports: marine products, Kosrae lime
8. Ports
 - a. Air
 1. Kosrae International Airport
 - b. Sea
 1. Lelu harbor

- 2. Okat harbor
- c. Post office
 - 1. Tofol
- c. Pohnpei State (Figure A-10)

Pohnpei Island is the third largest island in Micronesia and contains the highest peaks which include Mt. Nahna Laud, at about 782 m (2,565 ft.) in elevation and Nghnjeni Peak, at about 768 m (2,519 ft.) in elevation (van der Brug 1984b). Pohnpei Island is circular in shape, and the deeply dissected mountainous interior is dome shaped, with valleys and steep ridges extending radially to the coasts. Monthly air temperatures on Pohnpei Island are similar to those on Kosrae and also vary relatively little throughout the year. Pohnpei receives extensive rainfall that varies considerably with topography; mean annual rainfall in coastal areas and at the town of Kolonia is about 305-482 cm (120-190 inches). The greatest mean annual rainfall occurs in the interior highland rainforest with about 762-864 cm (300-340 inches) (van der Brug 1984b; Landers and Khosrowpanah 2004).

 - 1. Location: between latitude 6°47' to 7°01'N and longitude 158°06' to 158°22'E.
 - 2. Number of islands: Pohnpei State consists of the volcanic, high island of Pohnpei and six smaller atolls.
 - 3. Size: 344 km² (Pohnpei island makes up most of the state's territory at 334 km²)
 - 4. Population: 35,981 (2010 census)
 - 5. Ports
 - a. Air (official ports of entry are listed, other minor airstrips may also exist)
 - 1. Pohnpei International Airport
 - 2. Kapingamarangi airstrip
 - 3. Sapwuahfik airstrip
 - b. Sea (official ports of entry are listed, other anchorages also exist)
 - 1. Mesenieng Harbor
 - 2. Temwem Harbor
 - 3. Kapingamarangi anchorage
 - c. Post offices
 - 1. Kolonia
 - 2. Palikir
- d. Yap State (Figure A-11)

Maximum elevation is about 183 m (600 ft.) on Yap Island and about 76 m (250 ft.) on the other islands. Mean annual air temperatures are about 27°C (81°F), with a maximum difference between monthly extremes of about 2.6°C (7.1°F) (van der Brug 1983b). Annual rainfall totals about 310 cm (122 inches) per year and on the islands of Yap and Tomil-Gagil about half of the yearly rainfall drains directly to the ocean.

 - 1. Location: between latitude 9°27' to 9°38'N and longitude 138°03' to 138°12'E.
 - 2. Number of islands: Yap proper is composed of four major islands which include Yap, Tomil-Gagil, Map, and Rumung. In addition there are 14 outer atolls reaching to the east and south for about 800 km.
 - 3. Size: 100 km² (Yap proper encompasses approximately 98 km²)
 - 4. Population: 6300 (2003)
 - 5. Ports
 - a. Air (official ports of entry are listed, other minor airstrips also exist)
 - 1. Yap International Airport

- 2. Ulithi airstrip
- 3. Woleai airstrip
- b. Sea (official ports of entry are listed, other anchorages also exist)
 - 1. Tomil Harbor
 - 2. Ulithi anchorage
 - 3. Woleai anchorage
- c. Post office
 - 1. Colonia

Figure A-9: Kosrae State

Figure A-10: Pohnpei State

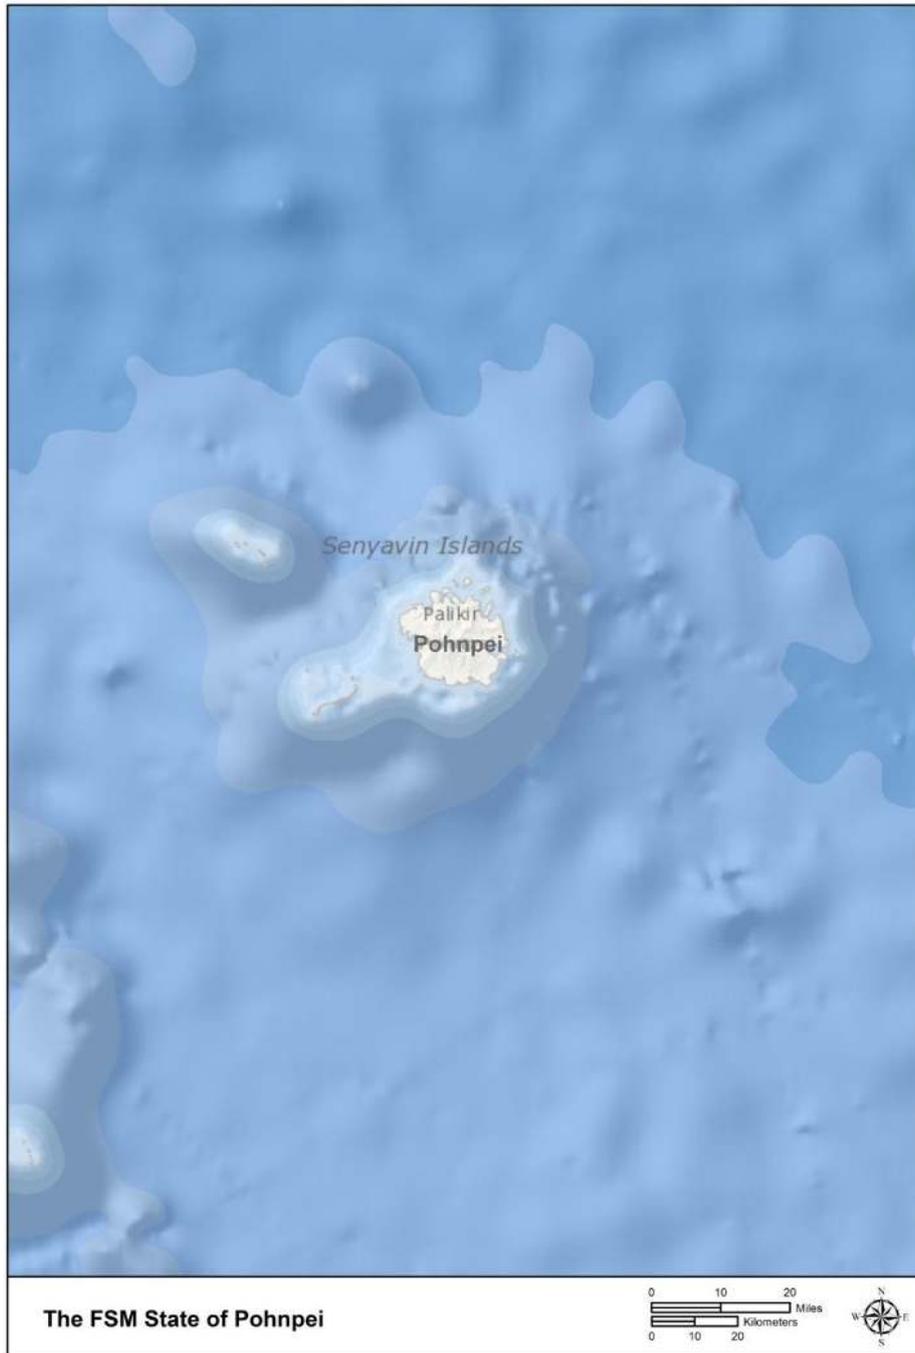

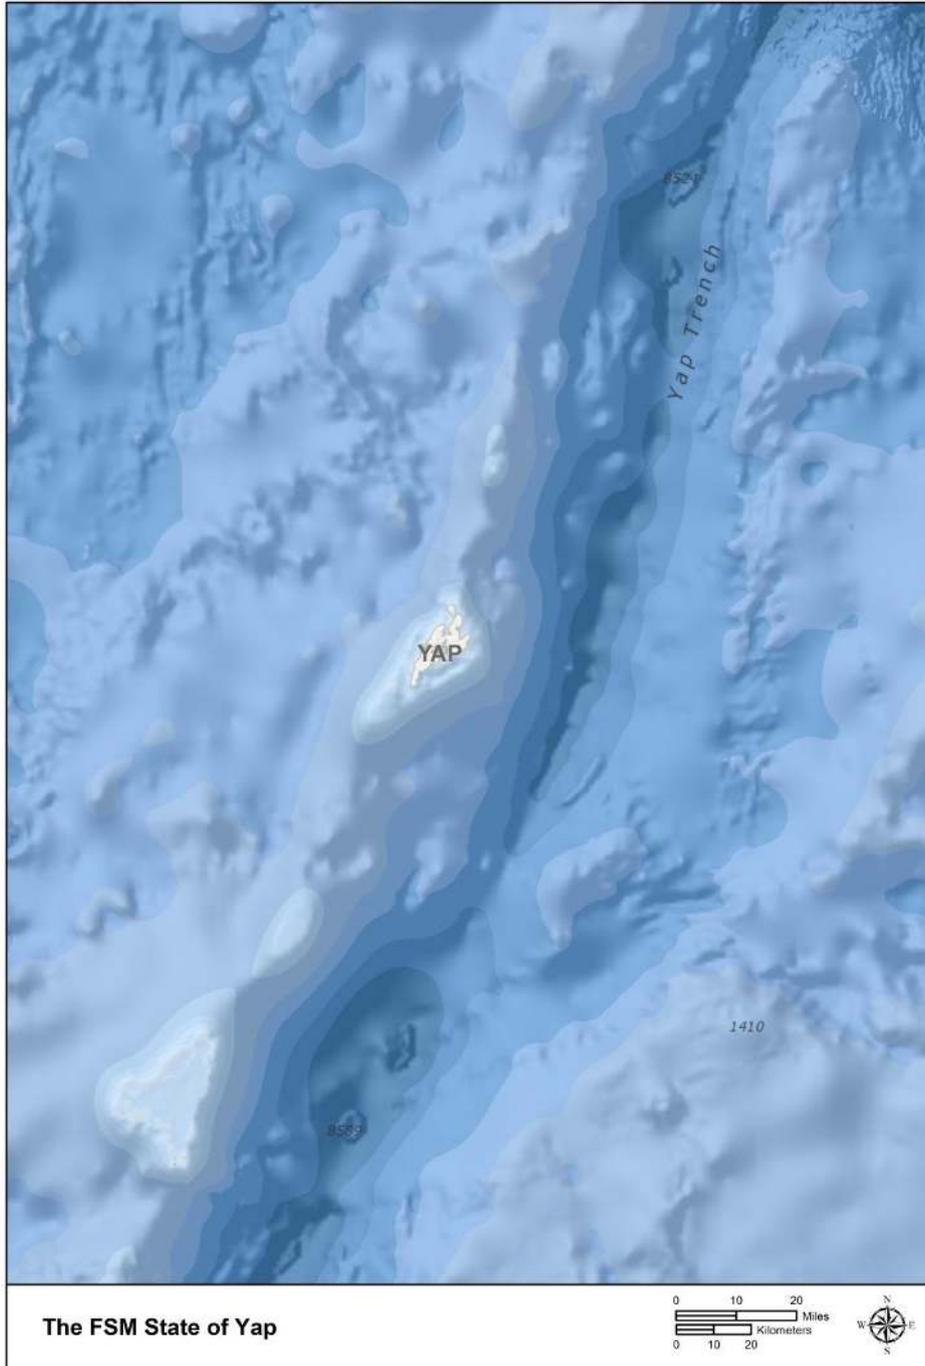

Figure A-11: Yap State

Attachment B: Existing Pertinent Rules and Regulations

The independent nations of the FSM, RMI and Palau have each entered a compact of Free Association with the United States. They are therefore not bound by the U.S. Constitution, but are subject to the National Environmental Policy Act, which was enacted prior to declarations of independence. National invasive species action plans have been formed by each of these countries (Pacific Invasives Initiative 2010).

A. Global Biosecurity Directives, Statutes and Regulations

The global concern about biological invasions is reflected by a diverse number of international agreements and strategies to minimize risks associated with invasions. These global agreements and strategies include, but are likely not limited to the following:

- The International Plant Protection Convention (1951, revision 1987; 1997 FAO Conference)
- The United Nations Convention of the Law of the Sea (1982, Article 196(1))
- The European Inland Fisheries Advisory Commission (EIFAC) Codes of Practice and Manual of Procedures for Consideration of Introductions and Transfers of Marine and Freshwater Organisms (1988)
- The Convention on Biological Diversity (1992, Article 8; see also Global Biodiversity Outlook 3 2010, www.cbd.int/GBO3)
- The World Trade Organization (Agreement on the Application of Sanitary and Phytosanitary Measures, 1995)
- The International Maritime Organization (IMO) (International Convention for the Control and Management of Ships' Ballast Water and Sediment, 2004)
- The International Council for the Exploration of the Sea (ICES) Code of Practice on the Introductions and Transfers of Marine Organisms (2004)
- The Convention on Biological Diversity's "Consideration for implementing international standards and codes of conduct in national invasive species strategies and plans" (2011): <http://www.cbd.int/invasive/doc/cbd-invasive-species-strategies-en.pdf>
- The International World Organization for Animal Health (Fifth Strategic Plan, 2011-2015)
- The United Nations Food and Agriculture Organization (FAO) Code of Conduct for Responsible Fisheries
- The FAO Code of Conduct for the Import and Release of Exotic Biological Control Agents

- The FAO/Network of Aquaculture Centers in Asia-Pacific (NACA) Asia Regional Guidelines on Fish Health
- The Convention on the International Trade of Endangered Species of Wild Fauna and Flora (CITES)
- The Global Convention on Migratory Species
- The Ramsar Convention on Wetlands, resolution VII.14: Invasive Species and Wetlands.
http://www.ramsar.org/cda/en/ramsar-documents-resol-resolution-vii-14/main/ramsar/1-31-107%5E20830_4000_0

As an example of how these international agreements work, trade in certain live organisms is regulated at the international level by CITES, to which the US and Palau are signatories, and whose conventions are followed in the FSM and the RMI. With the goal of protecting endangered or threatened species, CITES restricts the trade of organisms appearing in its three appendices. Of relevance to the region, giant clams (those in the Family Tridacnidae) and many coral species are CITES species, and are thus subject to specific restrictions. By working to protect CITES listed species, it is possible to address numerous invasive species concerns.

It is important to note that currently there are no international conventions specifically prohibiting trade of organisms considered to be non-native, invasive, or potentially invasive species. Trade in live marine organisms and plants/plant products are both known major vectors for the transfer of non-native species around the globe. Trade in other organisms such as reptiles is also likely an important contributor of both direct and indirect movement of non-native species.

B. United States Biosecurity Directives, Statutes, Regulations, and Guidance

A patchwork of U.S. Federal laws and regulations address invasive species. There is no one agency or office with sole leadership on, or authority for, invasive species within the United States. While many invasive plant issues fall under the purview of the U.S. Department of Agriculture, IAPS are also covered by agencies with additional oversight of aquatic invasive species. U.S. federal and local government mandates and regulations include guidance promulgated by USDA-APHIS, EPA, USFWS, and DoD. The U.S. does not have a specific biosecurity department or agency.

- Lacey Act of 1900: the Lacey act combats trafficking in “illegal” wildlife, fish, and plants.
- Animal Damage and Control Act: 7 U.S.C. §§ 426-426c, 2 March 1931, as amended in 1987 and 1991. This Act gives the Secretary of Agriculture broad authority to investigate and control certain predatory or wild animals and nuisance mammal and bird species.
- National Environmental Policy Act (NEPA) of 1969 [as amended 42 U.S.C. 4321 et seq.]:
<http://www.nepa.gov/jm/>

- Endangered Species Act (ESA) of 1973 [as amended 16 U.S.C. 1531 et. seq.] requires U.S. federal agencies to not jeopardize the continued existence of any listed threatened or endangered species or adversely affect critical habitat for such species. The purpose of the ESA is to protect and recover imperiled species and the ecosystems upon which they depend. It is administered by USFWS and the National Marine Fisheries Service.
- Federal Noxious Weed Act of 1974 (7 U.S.C. 2814) although the Plant Protection Act (PPA) superseded and repealed most of the Federal Noxious Weed Act of 1974 (FNWA), it left intact section 15, "management of undesirable plants on federal lands" (7 U.S.C. 2814). Section 15 of the FNWA requires U.S. federal land management agencies to develop and establish a management program for control of undesirable plants that are classified under state or federal law as undesirable, noxious, harmful, injurious, or poisonous, on federal lands under the agency's jurisdiction (7 U.S.C. 2814(a)). Based on authorities established in the PPA, USDA-APHIS is the primary agency responsible for preventing introductions of invasive species into the U.S. and its territories. The APHIS plant protection and quarantine (PPQ) program is responsible for safeguarding agricultural and natural resources by implementing plant importation regulations and permitting, and operating the pest detection and the federal noxious weed programs.
- Executive Order (EO) 12114 – Environmental effects abroad of major Federal actions (January 4, 1979): the purpose of this EO is to enable responsible officials of federal agencies having ultimate responsibility for authorizing and approving actions encompassed by this EO to be informed of pertinent environmental considerations and to take such considerations into account, with other pertinent considerations of national policy, in making decisions regarding such actions.
- Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990, revised and renamed the National Invasive Species Act in 1996 (as amended, p.l. 106–580, 29 December 2000) addresses unintentional introductions of aquatic invasive species. The act established the aquatic nuisance species task force under the leadership of the USFWS and NOAA. The act also promoted the development and implementation of state plans for managing aquatic species as well as regional panels (Guam and Hawaii are part of the western regional panel).
- Alien Species Prevention Enforcement Act of 1992: section 631 of the Treasury, Postal Service and General Government appropriations for fiscal year 1993, Public Law 102-393, 6 October 1992, requires the Secretary of Agriculture to operate a program to protect the state of Hawaii from the introduction of prohibited plants, plant pests, and injurious animals that may be contained in the mail.
- Wild Bird Conservation Act (WBCA) of 1992: importation of exotic birds into the U.S. must comply with APHIS and USFWS requirements. Certain exotic birds are protected by CITES and the WBCA.

- Executive Order 13112 (3 February 1999) created the National Invasive Species Council (NISC) and directed U.S. federal agencies to: prevent the introduction of invasive species; detect and respond rapidly to and control invasive species in a cost-effective and environmentally sound manner; restore native species and habitat conditions in ecosystems that have been invaded; promote public education on invasive species and the means to address them; and to not authorize, fund, or carry out actions that are likely to cause or promote the introduction or spread of invasive species in the United States or elsewhere unless, pursuant to prescribed guidelines, the benefits of such actions clearly outweigh the potential harm caused by invasive species and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions.
- Plant Protection Act (PPA) of 2000 consolidates the authorities formerly based within the Plant Quarantine Act, Federal Plant Pest Act (7 U.S.C. 150a et seq.), Federal Noxious Weed Act of 1974 (7 U.S.C. 2801 et seq.), and others (7 U.S.C. §7701 et seq.). The PPA allows the U.S. Secretary of Agriculture to restrict or prohibit the importation, entry, exportation or movement in interstate commerce, including Hawaii, Guam and the CNMI, of any plant, plant product, or noxious weeds. Plant products include all flowers, fruits, vegetables, roots, bulbs, seeds, or other plant parts. Noxious weeds are defined broadly to include any plant that may cause harm to “crops (including nursery stock or plant products), livestock, poultry, or other interests of agriculture, irrigation, navigation, the natural resources of the U.S., the public health, or the environment” (7 U.S.C. 7702). Civil and criminal penalties for violations of the PPA serve as a deterrent to individuals and businesses interested in cultivating or transporting invasive plant species and other invasive organisms.
- Animal Health Protection Act (AHPA) of 2002: the AHPA is purposed to prevent, detect, control, and eradicate diseases and pests of animals in efforts to protect animal health, the health and welfare of the people of the United States, the economic interest of the livestock and related industries of the U.S., the environment of the U.S., and the interstate and foreign commerce of the U.S. in animals and other articles (7 U.S.C. § 8301 et seq.).
- Animal Welfare Act (AWA): a modification to AWA, the Animal Fighting Enforcement Act of 2007, made interstate commerce of a bird for the purpose of participation in a fighting venture illegal, regardless of the law in the destination state, including Guam.
- Implementing recommendations of the 9/11 commission act of 2007: the implementing recommendations of the 9/11 commission act of 2007 (public law 110-53) implements some of the recommendations of the 9/11 commission including mandating 100% inspection of all air and sea cargo entering the U.S., and a new method of redistributing antiterrorism funding.
- National Defense Authorization Act of 2008, public law 110-181, section 314: requires prohibiting the transport and spread of Brown Treesnake via aircraft.

- USCG Regulations 33 CFR Part 151 and 46 CFR Part 162 will enter into force on 21 June 2012 and apply to all new ships constructed on or after December 2013 as well as to existing ships from 2014 onwards at certain time intervals. The USCG is amending its ballast water management regulations by establishing a standard for the allowable concentration of living organisms in ships' ballast water discharged in U.S. waters. The USCG is also amending its engineering equipment regulations by establishing an approval process for ballast water management systems. Ships calling at U.S. ports and intending to discharge ballast water must either carry out exchange or treatment, in addition to fouling and sediment management (there are some exceptions to this). The exchange of ballast water will only be allowed until the implementation deadlines for treatment systems. A third option is to use potable water (from the U.S. public water system) and in such case the ballast tanks need to be cleaned and sediments removed beforehand.
- USDA-APHIS plant health regulations (title 7 code of federal regulations): 7 cfr §§ 318.13-9; 318.60; 319; 330.111; 330.400-403.
- USDA-APHIS animal health regulations (title 9 code of federal regulations): 9 cfr §§ 71-89, 92, 93, 93.201, 209, 94.5, 94.6, 95, 166.
- USDA animal product manual: guidelines for regulating the importation of specific animal products and by-products. The manual can be downloaded at: http://www.aphis.usda.gov/import_export/plants/manuals/ports/apm.shtml
- USDA combined animal and plant health risk ratings for countries: USDA-APHIS analysis of relative risks presented from other countries as a result of animal and plant diseases found inside their borders (CPHST, VS-center for epidemiology and animal health, October 2010).
- USDA fruits and vegetables import requirements (FAVIR) online reference: www.aphis.usda.gov/favir/
- USDA-APHIS manual for agricultural clearance: the APHIS manual of agricultural clearance (MAC) provides comprehensive guidance for practices required for safeguarding imported products and articles. Safeguarding is a preventive action for handling, maintaining, or disposing of prohibited or restricted products and articles to maintain cargo control and eliminate the risk of plant and animal pest and disease dissemination. The manual can be downloaded at: http://www.aphis.usda.gov/import_export/plants/manuals/ports/downloads/mac.pdf
- USDA-APHIS PPQ manuals: guidelines for regulating the importation of specific plants, plant products, and international regulated garbage.

In the U.S., some non-native species are specifically listed and prohibited from importation by the Lacey Act 1900 (for animals) and the Plant Protection Act 2000 (for plants and plant pests). Organisms listed as "injurious wildlife" are prohibited for importation or interstate movement of live

organisms without a federal permit. Organisms listed as “noxious weeds” under the Plant Protection Act are also prohibited for importation into the U.S. or transportation across state boundaries without federal permit. The importation of live organisms into the U.S. for any purpose, including food, pets, bait, and aquaculture is regulated through the USFWS and the USDA for animals and plants (and plant pests), respectively. Importers and exporters are required to have a license to do business, to file a declaration at an official port of entry, and to receive clearance from Customs before these goods can be released. In most cases, they also need to present health certifications from the importing country. In addition to U.S. federal regulations, many states and territories, including Hawaii, Guam and CNMI, have their own regulations regarding live organism imports. In general Hawaii, Guam and the CNMI, as U.S. jurisdictions, must abide by U.S. Federal regulations and requirements.

Enforcement of U.S. live import regulations is carried out by state and federal quarantine inspectors at airports and seaports. On Guam and CNMI, imports of wildlife arriving by air or sea cargo are monitored by USFWS (Guam), U.S. Customs and Border Patrol, Department of Fish and Wildlife (CNMI) and DAWR, with some assistance from NOAA (Guam) when illegal imports of marine life are suspected. Under federal law, U.S. mail cannot be inspected unless there is a reason to suspect that it contains an illegal substance or import, so routine inspections are not carried out on mail arriving into Hawaii, Guam, or CNMI.

All commercial airline baggage is screened by Transportation Security Administration (TSA) agents/airline employees upon departure using X-ray machines on Guam, Saipan, and Hawaii. Inspectors are looking for weapons and other prohibited items, but could potentially find and confiscate live organisms.

Regulatory drivers are in place to prevent the transport of vertebrate species within the U.S., but these regulations are only realized under well-funded, comprehensive enforcement.

Two pertinent regulatory drivers are the National Defense Authorization Act (NDAA), Public Law 110-181, Section 314 that requires prohibiting the transport and spread of Brown Treesnake via aircraft, and the Non-indigenous Aquatic Nuisance Prevention and Control Act of 1990 that authorizes a cooperative program to control Brown Treesnake outside its historic range. These two regulations if fully implemented could result in the mandatory 100% inspection of vessels and cargo departing Guam.

Enforcement of existing biosecurity regulations may differ across sectors. For example, the military is exempt from biosecurity inspections if such inspections jeopardize national security (e.g., when craft is actively engaged in warfare, cargo is classified, or mission is an emergency situation). Also, within the United States, regulatory drivers have the tendency to differ in level of enforcement by state. This is seen in the implementation of biocontrol where policies can differ vastly in stringency by state, leading to disjointed implementation of the regulation (Messing and Wright 2006). Therefore, monitoring and surveillance of enforcement such as detailed reports, summaries of prosecution of regulation breaches, and corresponding trends of introduction incidences are all

necessary checks and balances to evaluate the efficacy of the upholding of regulations regarding invasive species through enforcement.

Biological Opinions (BOs), resulting from Endangered Species Act consultations, are critical regulatory drivers for the management of species including some IAS such as Brown Treesnake.

C. United States Department of Defense Biosecurity Guidance and Instructions

- Air Force Instruction (AFI) 32-1053 integrated pest management program
- AFI 32-7064 integrated natural resources management
- Air Force Joint Instruction (AFJI) 48-104, quarantine regulations of the armed forces: incorporates regulations to mitigate the risk for introduction and dissemination of arthropod vectors by movement of vessels, aircraft, and other transport of the armed forces arriving at or leaving U.S. and foreign ports, installations, or other facilities. The quarantine regulations of the armed forces (QRAF), AFJI 48-104, states that cargo is subject to inspection by a representative of the USDA to prevent the introduction or spread of animal and plant diseases or pests (DoD 1992). For the purposes of these regulations, Guam is considered part of the U.S. DoD maintains customs and border clearance policies and procedures for wildlife, agricultural and animal products, pets, plants and plant products.
- Air Force Policy Directive (AFPD) 32-10 installations and facilities
- Armed Forces Pest Management Board (AFPMB) Technical Guide No. 31 (2004): delineation of responsibilities for the military with meeting USDA APHIS requirements for internal and external inspections for terrestrial vertebrate species, insects, and plant species. This guide covers retrograde wash-downs—cleaning and inspection procedures.
- Andersen Air Force Base Integrated Pest Management Plan
- Army Regulation 40-12 quarantine regulation of the armed forces
- COMNAVMAR Instruction 5090.10a: Brown Treesnake control and interdiction plan. This instruction outlines specific responsibilities and establishes policy for coordination and procedures governing the control and interdiction of Brown Treesnake on Navy installations on Guam and during military training within the Commander, U.S. Naval Forces Marianas (COMNAVMAR) Area of Responsibility (AOR).
- DoD Instruction 4150.07 DoD pest management program
- DoD Foreign Clearance Manual 25 January 2012 issued under authority of DoD Directive 4500.54e

- DoD Instruction 4500.9-r defense transportation regulations: (<http://www.transcom.mil/dtr/part-i>)
- DoD Instruction 4715.03 natural resource conservation program
- DoD Directive 5158.04 U.S. Transportation Command (USATRANSCOM)
- DoD memorandum: DoD memorandum outlines Navy personnel with authority to inspect and issue ship sanitation certificates (ship sanitation control exemption certificate and ship sanitation control certificate) for Navy, Army, military sealift command, Coast Guard, and National Oceanic and Atmospheric Administration vessels to provide standard procedures and policy-IAW article 39 of the WHO 2005–certificate (good for 6 months) with section for observed rodent infestations.
- Defense electronic foreign clearance guide (<https://www.fcg.pentagon.mil/fcg/fcg.cfm>)
- DoD SDDC PPCIG 2010 personal property consignment: the DoD personal property consignment instruction guide online system, which provides guidance to military and DoD civilian personnel being assigned to foreign duty stations, states that there are “no restrictions identified” for plant movement into Guam.
- Guam and the CNMI military relocation EIS/OEIS: the Guam and the CNMI military relocation EIS/OEIS provides a description of military relocation plans, schedules, impacts and mitigations.
- MIL-STD-904b: provides guidance on the detection, identification, and prevention of pest infestations.
- Naval supplemental publication number 486, volume 1: Naval policy parallels APHIS requirements for foreign garbage.
- NAVFAC Pacific 2010: master planning process, Navy sustainability summary report
- NAVMED P-5010-8, the Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology (U.S. Navy BMS 2004) outlines preventive measures for rodent control on ships, including proper sanitation, pier side inspections, rat guards, illumination and movement restrictions, glue boards, snap traps, and limitations on vessel access points.
- NAVMED p-5052-26: U.S. Navy shipboard pest control manual provides guidance on inspection and de-ratting procedures for ships.
- Naval Base Guam Integrated Pest Management Plan
- OPNAVINST 5090.1D Environmental Readiness Program

- OPNAVINST 6210.2: quarantine regulations of the Navy. This instruction is intended to prevent the introduction and dissemination, domestically or internationally originated, of diseases affecting humans, plants, and animals; prohibited or illegally taken wildlife; arthropod vectors; and pests of health and agricultural importance. USDA APHIS PPQ personnel may inspect cargo to prevent the introduction of plant and animal pests or diseases.
- OPNAVINST 6250.4b pest management program
- SECNAVINST 6210.2a afr 161-4, DoD, 1992, section 9: rat guards are used at ports with known rodent infestations
- Senior officer present afloat Pearl Harbor instruction 5000.1g
- Subsistence manual COMDTINST m4061.3c: waste disposal requirements
- USAF 36 WG INSTRUCTION 32-7004 (2006) Brown Tree Snake Management
- USAF 611 CES Wake Island biosecurity plan

D. Territory of Guam Biosecurity Directives, Statutes, and Regulations

- Guam Administrative Rules and Regulations (GARR) Titles 8, 9, and 10: Title 8, division 2-plant industry, chapter 10 provides regulations for food and agriculture and importation of plants and plant products. Title 9, division 1, chapter 1 of the GARR provides regulations regarding the importation of live animals. Section 2 of § 1103 (GARR) states that under no circumstances shall any animal be turned loose at the port, and that hogs and sheep may be confined in temporary pens or crates, cattle and horses may be tied, and dogs and cats shall be confined in crates. GDOA: Title 8 GARR chapter 10; Title 9 GARR 1 §§ 1100-1113, 2101 and 2102, division 1, chapter 1. Title 9 GARR, division 1, chapter 1, § 1109 requires that all cats and dogs originating from Africa, Asia, or islands of the Pacific Ocean (except Australia, Hawaii and New Zealand) must have a certificate from the national chief livestock sanitary officer stating that the animals originated in a state, country, or other political subdivision officially declared free of Surra, animal African Trypanosomiasis, and Leishmaniasis. Title 9 GARR 1 § 1110 of Guam territorial regulations require all imported birds and hatching eggs to be accompanied by an entry permit and a health certificate approved by the chief livestock sanitary officer, or a state or federal veterinarian. Subchapters §§ 2101 and 2102 provide regulations for the importation of pet birds (all birds except poultry).
- Title 5 Guam Code Annotated (GCA) §60108: the importation of pets to Guam is regulated by the Guam Department of Agriculture (GDOA). Title 10 GCA chapter 34 article 3 states that animals imported are to complete a maximum of 120-day confinement in a commercial quarantine facility.

- Guam public law 31-43 establishes the Guam invasive species council (GISC) and states that GISC will develop a Guam invasive species management plan (GISMP). This law also authorizes the Guam Department of Agriculture to establish a Guam Invasive Species Inspection fee. This fee is to support an invasive species coordinator position for Guam and to fund a biosecurity division within the Guam Department of Agriculture. This law and the GISC are to support and update the Guam interagency biosecurity task force work plan originally established 10 November 2009. The Guam invasive species council (GISC) was established in 2005 by executive order no. 2005-13 and enacted into law in 2011 by bill no. 111-31 (COR). The purpose of the GISC is for “providing policy direction, coordination, and planning among government of Guam departments and federal government agencies; to provide local initiatives for the control and eradication of harmful invasive species throughout the island of Guam; and to assist in preventing the introduction of other invasive species that may be potentially harmful to Guam”. The GISC is co-chaired by the director of the GDOA, and the president of UOG. Other members include the directors of GCQA, Department of Administration, Bureau of Statistics and Plans; the Homeland Security advisor; the administrator of the Guam EPA; the executive manager of the Guam International Airport Authority, the general manager of the Port Authority of Guam, and the Guam Visitors Bureau. The GISC will develop an invasive species management plan which shall “detail and recommend performance-oriented goals and objectives and specific measures of success for Government of Guam agency efforts concerning invasive species”. The plan will be updated biennially. Bill no. 111-31 also establishes the Guam invasive species inspection fee and fund which imposes a one dollar per ton fee on all freight brought into Guam. The fees collected will be used to “support efforts to provide inspection, quarantine, and eradication of invasive species contained in freight brought to Guam; support efforts to eradicate invasive species present on Guam by means of a rapid response team; and develop the Guam invasive species management plan and its updates.” Finally, the bill authorizes the Department of Agriculture to “create a biosecurity division to function as its first responders in efforts to address invasive species coming to, and present on, Guam.” **Bill No. 111-31 (Cor) "An Act to Add a New Chapter 70 to Division 6 of Title 5, Guam Code Annotated, Relative to Establishing the Guam Invasive Species Council; to Establishing the Guam Invasive Species Inspection Fee and Fund; and to Authorizing the Department Of Agriculture To Establish A Biosecurity Division"**
- Agricultural inspections and quarantine of cargo in Guam are performed by APHIS PPQ as well as GDOA. The authority to “inspect cargo, stores, quarters, baggage and any other thing” is granted to GDOA according to Title 5 GCA § 61103. Regulations exist for the importation of nursery stock, herbs, rhizomes, seed, leaf, root, fruit, or any other plant-growth or plant-product to Guam (Title 9 GARR 1-§4201). Importation and sale of aquatic plants is limited to a white list, however, this list is not codified in rule or statute. Commercial shipments of aquatic plants are held by GCQA until DAWR can inspect the contents and confirm plants are on the white list. Guam’s Department of Aquatic and Wildlife Resources (DAWR) maintains an informal “white list” of marine and aquatic organisms that can be imported live, including aquarium species and

food species, such as New England lobster (*Homarus americanus*) and Pacific oysters (*Crassostrea gigas*). The white list mainly includes species already present on Guam (native or already established non-natives) and those that have a long history of importation into Guam with no known negative impacts. A few organisms are allowed for import only for Underwater World, Guam's main public aquarium, as the biosecurity and sanitation procedures at the aquarium presumably meet high standards. Permits must be obtained to bring in species on the white list, even small numbers of individuals for personal use. Importers can submit requests for permits to import organisms not on the list; these are reviewed and approved on a case-by-case basis, with the onus on the importer to prove an organism is not harmful. Importers must have a certificate of health from the point of origin for organisms being brought to Guam.

- As a territory of the United States, Guam is subject to Federal regulations that restrict the importation of certain live aquatic animals intended for aquaculture food production. For example, under the injurious wildlife provisions of the Lacey Act (P.L. 97-79 as amended), the USFWS prohibits the importation and interstate transport of certain injurious terrestrial and aquatic animals, including various species of mammals, birds, fish, amphibians, reptiles, mollusks, and crustaceans.
- Any animal found clinically affected or recently exposed to any infectious, contagious, or communicable disease or infested with ectoparasites must be returned to the point of origin or destroyed (GARR 2004).

E. State of Hawaii Biosecurity Directives, Statutes, and Regulations

Hawaii has the most extensive and active IAS policies in the Region. Large amounts of cargo move through Hawaii before passing on to other locations including Guam. Materials from foreign countries or U.S. territories are inspected by U.S. Customs, USDA PPQ, or U.S. Fish and Wildlife Service Law Enforcement Division (USFWS - LE). USDA APHIS and PPQ conduct pre-departure agricultural inspections of baggage and cargo leaving Hawaii and heading to the U.S. Mainland or Guam. No agricultural/quarantine inspections are made on cargo leaving the region except in Hawaii.

- Hawaii Department of Agriculture (HDOA) is the sole state agency with responsibility to prevent introductions from the U.S. to ports in Hawaii. The HDOA plant quarantine program is responsible for inspecting domestic cargo and passengers incoming to Hawaii air and sea ports (HRS 150a) (Ikuma et al. 2002). Imported plants are either regulated (require permits, treatments and /or require quarantine, or may be prohibited), restricted (noxious weed list), or allowed entry subject to inspection and clearance (Shluker 2003).
- Hawaii's Department of Agriculture maintains a list of organisms that cannot be brought into the state, including many marine fishes and some species of crabs, octopus, and jellyfish (scyphozoans), as well as a list of conditionally approved and restricted organisms, both of which contain numbers of marine species. An importer must have a permit to import anything on the

list of conditionally approved organisms. Businesses wishing to import organisms on the restricted list must, as a condition of obtaining a permit, undergo a site inspection. Although terrestrial plants, microorganisms, and pathogens appear on the various lists, we could find no lists for macroalgae. The state's rules and lists are available on the state Department of Agriculture's website: <http://hdoa.hawaii.gov/>.

- The Hawaii Division of Aquatic Resources (HDAR) in the Hawaii Department of Land and Natural Resources (HDLNR) is responsible for management of Hawaii's aquatic resources (HRS 187a-2.1). Release of non-native fish or other aquatic life into state waters is prohibited (except for permitted fish stocking) and HDLNR staff may seize, confiscate, or destroy any prohibited or restricted organisms (HRS 187a-6.5). Violation of this statute may result in a petty misdemeanor charge and a fine from \$250 to \$1000 (HRS 187a-13).
- The Hawaii Invasive Species Council (HISC), established in 2003 by HRS 194-2, is co-chaired by the HDLNR and the HDOA. The HISC has five working groups that make recommendations to the council; the prevention working group is chaired by the HDOA and recognizes the need to understand and minimize all pathways for both terrestrial and aquatic species into Hawaii and between Hawaiian islands. Designation of noxious weeds follows criteria set by the HDOA (HRS 152-2). The list of invasive species recognized by the HISC (HAR 4-68) is nearly 20 years old and includes just three freshwater aquatic plants: Buddha Pea (*Aeschynomene indica*), Giant Sensitive Tree (*Mimosa pigra*), and Torpedo Grass (*Panicum repens*) (HAR 4-68). The import or sale of Giant Salvinia (*Salvinia molesta*), Common Salvinia (*Salvinia minima*) and Water Cabbage (*Pistia stratiotes*) plants and propagative material is prohibited by statute (HRS §150a-6.1). The authority to control recognized invasive species, including noxious weeds, on private property is granted through HRS 194-5 to any department that is a member of the HISC.
- The HISC provides policy recommendations, coordination and planning between agencies and initiatives for the control or eradication of potentially harmful invasive species (HRS 194-2). HISC developed the Hawaii invasive species strategy 2008-2013. County-level invasive species committees (ISCs) exist on the Big Island (Hawaii), Kauai, Maui, Molokai and Oahu. County ISCs focus on localized needs for early detection, rapid response and outreach to the general public.
- The Hawaiian Ecosystems at Risk (HEAR) project (<http://www.hear.org/>) provides "technology, methods, and information to; and to facilitate communication among: decision-makers, resource managers, and the general public to help support effective science-based management of harmful non-native species in Hawaii and the Pacific". HEAR provides general information regarding the threat of invasive species, as well as a species-specific bibliography and other information. Information on weed risk assessments (WRA) are available on the HEAR website, including the Hawaii/Pacific weed risk assessment protocol (HPWRA). HPWRA was developed based on the Australian and New Zealand WRA (Daehler and Carino 2000; Daehler et al. 2004). The HPWRA is designed to identify species with high and low risk for invasion. Working in

tandem with HPWRA, the Hawaii exotic plant evaluation protocol (HEPEP) gathers field observations of plants in order to evaluate ecosystem impacts.

F. Commonwealth of the Northern Mariana Islands Biosecurity Directives, Statutes, and Regulations

Offices in the CNMI that play a role in biosecurity include: CNMI Department of Lands and Natural Resources including the Division of Fish and Wildlife and the Division of Agriculture and the CNMI Department of Finance, Division of Customs. The CNMI Division of Agriculture in the Department of Land and Natural Resources (DLNR) is responsible for inspection of imported and exported commercial and passenger cargo and implements quarantine programs in order to protect natural resources from invasive species. DLNR agricultural inspectors are, similar to operations by GCQA in Guam, guided by Federal regulations and work under the guidance of APHIS PPQ (D. Berringer, APHIS-PPQ, pers. comm.).

Imports to CNMI are regulated by USFWS and the Commonwealth's Department of Fish and Wildlife (DFW) and the Department of Agriculture. The DFW website (<http://www.dfw.gov.mp/Enforcement/Fishing%20Regulations.html>) lists species that are allowed for importation; these include several species of birds and mammals. No amphibians or reptiles are permitted. For invertebrates, including marine invertebrates, only those that can be demonstrated to be "not harmful" are permitted. Marine invertebrate importations tend not to be closely regulated. Giant clam spat (young clams) have been provided to the CNMI from Palau on several occasions over the past 25 years. The only requirements were health certificates from Palau that stated that the clams were not harmful for human consumption. No fish or algae are listed on the DFW website, although enforcement officers are using an unofficial "white list" of freshwater fish species from Australia to make determinations for import permits to CNMI. These rules apply regardless of the number of individuals or purpose of the importation.

Aircraft from foreign countries arriving in the CNMI are cleared by CNMI Quarantine. Fourteen quarantine officers are assigned to the Saipan Airport. Intensive blooms/blossoms and cut flowers examinations are undertaken to check for import violations, and orchid shipments are limited to a total of 12 individuals per shipment. Plants imported into CNMI arrive via Guam from California or Hawaii. Propagative plant shipments and cut flowers are inspected for plant pests and diseases and for import permit violations. Every large bag or box brought into CNMI by a foreign passenger is inspected visually. The CNMI is part of the alien snake rapid response team and has federal and commonwealth staff on the ground to inspect incoming cargo and planes from Guam for Brown Treesnakes. Current Brown Treesnake inspection capacity includes visual searches, detector dogs, and sentinel traps as well as specific quarantine facilities at the sea ports in Saipan and Tinian.

- Council on environmental quality (CEQ): environmental impact statement; 40 CFR §§ 1502.09 and 1502.20

- CNMI regulations part 5 sections 10 and 20 cover importation and introduction of animals to the CNMI. Section 10 includes a list of permitted species (and also indicates some prohibited species or groups of species). These regulations are enforced by the CNMI DLNR.

G. Republic of the Marshall Islands Biosecurity Directives, Statutes and Regulations

Offices in the RMI which play a role with biosecurity include: the Ministry of Resources and Development, Department of Quarantine and the Environmental Protection Authority; Ministry of Finance, Division of Customs, Treasury, Revenue, and Taxation. Within the RMI, inspections of aircraft and vessel cargo, baggage and ships stores are permitted by agricultural quarantine inspectors who have authority to seize and destroy any materials subject to plant and animal quarantines and regulations (MIRC Title 8 §102 et seq.). The Division of Agriculture in the RMI Ministry of Resources and Development processes plant quarantine permits for all plants, plant parts, and seeds, but it is unclear what specific plants are currently prohibited from import, export, or transit within RMI. The Marshall Islands Invasive Species Taskforce (MIIST) has drafted the Marshall Islands Invasive Species Taskforce Strategic Action Plan 2007-2010 that addresses threats to marine habitats, including ballast water introductions, and four targeted organisms (fire ants and three terrestrial species) (Pacific Invasives Initiative 2010). The Ministry of Resources and Development enacted its Animal and Plant Inspection Act in 2004. The act is responsible for the protection of endangered areas and the designation, maintenance, and surveillance of pest-free areas and areas of low pest prevalence. It is also responsible for the inspection of consignments of plants and plant products moving in international traffic and, where appropriate, the inspection of other regulated articles, particularly with the object of preventing the introduction and/or spread of pests. The RMI has trained inspectors who are part of the regional alien snake rapid response team and they have an ERP for alien snakes.

The RMI does not maintain a list of either prohibited or allowed marine species. Requests for importation permits are decided on a case-by-case basis by Marine Resources and Agricultural Quarantine. For a permit to be approved, an importer must make the case that a proposed species does not pose an environmental threat. A health certificate from an independent veterinarian must accompany live imports. The RMI is in the process of reviewing its quarantine regulations. A draft biosecurity bill is also now being reviewed and if enacted may revise import and export regulations and practices. In this bill, discharge of ballast or bilge water is prohibited “at sea” in the Marshall Islands rather than specifically in port and the maximum fine for such discharge is \$100,000 (no specific fine is listed in the Palauan bill). This is the only specific reference to marine species and their vectors.

Aquatic organisms imported into the RMI (and not for direct export to other countries) require the following: quarantine for 1-2 weeks, sterilization of quarantine media using UV light before release from the holding tanks, and visual inspection for signs of stress/disease (Arthur et al. 2012).

Evaluation of the risk associated with the import of live aquatic organisms is conducted by an interagency committee (including members from the Coastal Management Advisory Council & the Marshall Islands Invasive Species Taskforce). At the moment, this is done in an ad-hoc style, because the Biosecurity Bill is still pending with the legislature (Arthur et al. 2012).

Agencies and/or departments responsible for aquatic animal health at the national level: FSM Quarantine Office and FSM R&D Office

Agencies and/or departments responsible for aquatic animal health for Pohnpei State: Pohnpei State Office of Fisheries and Aquaculture (OFA), Environmental Protection Agency Office, Pohnpei State and Conservation Society of Pohnpei (CSP) Office

Offices in the FSM which play a role in biosecurity include: Resources and Development Agriculture Unit, Yap Department of Resources and Development; Kosrae Department of Economic Affairs; Department of Finance, FSM Division of Customs, departments of Agriculture for each of the 4 states. Within the FSM (Chuuk, Kosrae, Pohnpei, and Yap) quarantine inspectors may inspect all aircraft and vessels, or their cargoes, for animals and plants or their parts and refuse their entry (FSMC Title 22 §410). Customs inspections, agricultural inspections and quarantines may be performed on all vessels or aircraft entering or departing from any ports of entry (FSMC Title 18 §206). Noxious weeds have not been designated by FSM, but the Plant and Animal Quarantine Regulations (2000) includes two lists that specify plants prohibited for import from outside FSM (Schedule 1), and plants prohibited from transport between states of FSM (Schedule 2); neither schedule includes aquatic plants. Plants or plant material produced within the FSM may be issued a phytosanitary certificate by inspectors following pre-export inspections according to the FSM Plant and Animal Quarantine Regulations of 2000.

FSM Resources & Development, Agriculture Unit, enacted the FSM Plant and Animal Quarantine Regulations in 1991, revised them in 2000, and began to enforce the FSM Biotechnology and Biosafety Act in 2007. The FSM Resources & Development, Agriculture Unit, is responsible for the protection of endangered areas and the designation, maintenance, and surveillance of pest-free areas and areas of low pest prevalence as well as for the inspection of consignments of plants and plant products moving in international traffic and, where appropriate, the inspection of other regulated articles, particularly with the object of preventing the introduction and/or spread of pests.

The FSM national government and/or the individual states have a variety of draft plans for responding to invasive organisms. These include a national government draft contingency plan for Avian Influenza, draft Coconut Rhinoceros Beetle ERP, and draft Alien Snake ERPs for each of the states. Several FSM quarantine staff members have received advanced training in alien snake early detection and rapid response.

The FSM National Biodiversity Strategy and Action Plan (FSM-NBSAP 2002) recognizes the top ten invasive weed species (all are terrestrial) within FSM. The plan acknowledges that a comprehensive lists of aquatic invasive organisms (e.g. African land snail and cane toad) is not available (FSM-NBSAP 2002).

By federal law, Federated States of Micronesia prohibits the importation of exotic plants or animals, except under permit by the Director of Resources and Development (FSM Code, Title 23, Resource Conservation, Section 315). The code also states that no CITES species can be imported (FSM Code, Title 23, Section 8). All import permits must be approved by federal quarantine and undergo a pest risk analysis before a permit is approved. Under Kosrae State Code, if a plant or animal is not already found in the state, an importer must apply to the Department of Agriculture, Land and Fisheries for permission (KSC Title 14 Section 14.204), but it appears that review of permit applications happens at the federal level. Importers must have a certificate of health from the point of origin. Elsewhere in FSM, there do not appear to be any additional regulations at the state level regarding the importation of live marine species. A biosecurity bill is being considered for the FSM, which if enacted, may change some of the existing biosecurity regulations.

The Invasive Species Taskforce of Pohnpei (ISTOP) surveys and manages invasive species for the state. The ISTOP Strategic Action Plan 2010-2013 targets ten invasive plant and animal species; outlines goals, objectives, and activities; and identifies partners and funding sources.

Chuuk State's Invasive Species Taskforce has developed a draft strategic action plan (Chuuk Invasive Species Task Force Strategic Action Plan, draft version November 2010). The plan focuses on programmatic development, including finding funding and resources, building capacity, increasing coordination between agencies, and generating public awareness. However, it also (a) includes eradication/control measures for two terrestrial plants on the island of Weno, (b) identifies one marine species – the crown-of-thorns sea star (*Acanthaster planci*), a native species which can severely impact coral reefs -- for control measures in Chuuk Lagoon as well as some of the outer islands and (c) calls for 10 surveys in the Chuuk Lagoon and six on outer islands to identify other invasive marine species. No measures for preventing non-native species transfers are addressed.

Kosrae's Invasive Species Action Plan is modeled on the SPREP plan, based on that plan's three major theme areas and nine sub-themes (Section 6.1.3). The Kosrae plan lists specific objectives to achieve the more general objectives suggested by SPREP, however the proposed activities do not appear to meet objectives in many instances. For example, the general Objective 2 in Table B1.2 is "Monitoring invasive species movement on island, and between countries and territories." The matching proposed specific objective is to "review existing port and border surveillance and rapid response arrangements" and the proposed activity is "quarterly visits to Quarantine for bio-security updates." It is not evident how this would result in species-level monitoring information. Although marine species are mentioned in the Kosrae plan, no specific vectors are addressed nor are any actions proposed to deal with marine species.

I. Republic of Palau Biosecurity Directives, Statutes and Regulations

The Palau Ministry of Natural Resources, Environment, and Tourism houses several bureaus involved with national biosecurity, including the Bureau of Marine Resources, the Bureau of Agriculture, and the Bureau of Protected Areas Network. The Republic of Palau Bureau of Agriculture established its Plant and Animal Quarantine regulations in 1999 and revised them in 2008 and is responsible for the inspection of consignments of plants and plant products moving in international traffic and, where appropriate, the inspection of other regulated articles, particularly with the object of preventing the introduction and/or spread of pests. Palau's Plant and Animal Quarantines and Regulations (1999) contain schedules of prohibited plants and animals. These schedules were updated in 2002 to include any species or hybrid of tilapia (*Oreochromis* spp.), which is currently the only listed marine or aquatic species; however, the government is currently considering removing tilapia from the prohibited list to promote its use in agriculture. In 2006, the regulations were again amended, giving the Palau National Invasive Species Council (Palau NISC) the responsibility of reviewing applications for the importation of any species not already present within Palau. The Palau NISC has 30 days to carry out its review, but may request longer if further study (at the importer's expense) is required. This amendment also gives the Palau NISC the responsibility of advising the Palau Department of Agriculture on species that should be added or removed from the prohibited species schedules.

At ports of entry, including the post office, inspectors from the Palau Bureau of Agriculture are charged with carrying out inspections of cargo, mail, baggage, passengers, ships and airplanes. All live imports must have a permit issued by the Palau Bureau of Agriculture and live organisms must have received a certificate of health from their country of origin. Imported organisms can be placed in quarantine for further observation and treatment at the importer's cost if necessary.

In Palau, species intended for aquaculture must be approved by the Bureau of Aquaculture, and are to be held in quarantine for seven days for observation by the Bureau of Marine Resources. Nonetheless, there appears to be little capacity to do more than qualitative, visual screening to make a judgment about whether organisms "look healthy" and to sort out obvious non-target species accidentally included in shipments before release. Quarantine officials have the legal authority to inspect an importer's facilities after organisms have passed through quarantine and can order organisms back into quarantine and/or destroy them after release, but it is not clear how frequently, if ever, this has been done.

The national government of Palau is tasked by the National Environmental Protection Council (NEPC) to "provide and enforce an appropriate legislative framework, including quarantine and environmental legislation, necessary to prevent the introduction or reduce the impact of invasive species and prevent them from spreading" according to the Palau National Invasive Species Strategy originally developed in 2004.

The Bureau of Agriculture has the authority to inspect plants and animals intended for export, but it is unclear how frequently this occurs.

- Bureau of Agriculture: in Palau, quarantine laws are enforced by the Bureau of Agriculture (Title 25 PNC § 2003). Quarantine inspectors may inspect “all aircraft and vessels or their cargoes, including baggage, ship's stores, and ballast, entering or moving” within Palau for “all animals and plants or parts thereof, including seeds, fruits, vegetables and cuttings” (Title 25 PNC § 2005). Plants and plant material require a permit to enter Palau and, if in transit through the country, material requires a permit to transit and must follow certain safeguarding measures.
- Executive Order 219, issued in November 2003 by the President of the Republic of Palau, instructed the National Environmental Protection Council (NEPC) to create the Palau National Invasive Species Committee (PNISC).
- Palau National Invasive Species Strategy drafted by PNISC lays out the roles and responsibilities of landowners, land users, communities, industry, traditional leaders, and the state and national governments. According to the Palau National Invasive Species Strategy, the national government of Palau is tasked to “provide and enforce an appropriate legislative framework, including quarantine and environmental legislation, necessary to prevent the introduction or reduce the impact of invasive species and prevent them from spreading”.
- The invasive weeds committee (also known as weedbusters) of the Palau Natural Resource Council (PNRC) has worked on invasive plant issues, but according to Space et al. 2009, this group has been inactive recently.

Palau’s National Invasive Species Strategy (2004) includes consideration of marine species and outlines a number of action items:

- 1) Periodic review of the country’s legal and regulatory framework with regards to invasive species, and the revision and adoption of updates to these as needed;
- 2) Preparation of a National Invasive Species Strategy (below), which was drafted nearly simultaneously with the National Invasive Species Policy;
- 3) Surveys in terrestrial and marine environments to identify and quantify invasive species;
- 4) Identification of priority species for management actions, and the identification of areas at greatest risk for entry and establishment of invasive species;
- 5) Prevention of new invasions, detection through regular monitoring, and management/eradication of established species;
- 6) Restoration and re-establishment of native species to be included as part of management activities; and
- 7) Cooperation between various local, regional and international agencies working on invasive species.

Many of these items have since moved forward.

Palau's National Invasive Species Strategy (2004), or NISS, acknowledges explicitly the potential importance of marine invasions in a country that depends heavily on a healthy marine environment. The NISS was written by the country's National Invasive Species Committee, after a review of relevant documents from Australia, SPREP, the Global Invasive Species Programme, the Convention on Biological Diversity, and the Bahamas National Invasive Species Strategy. The NISS lays out a series of objectives to meet four major goals:

- 1) The provision of a national framework for dealing with invasive species;
- 2) The prevention of new invasions;
- 3) Management of invasive species already in Palau; and
- 4) Coordination with other regional and international organizations dealing with invasive species.

Additionally, the document details the roles and responsibilities for dealing with invasive species for the national and state governments, traditional leaders and community members.

The NISS was formed after a SPREP-led workshop in 2003, and recommendations from this workshop appear as an appendix to the strategy document. Two specific recommendations for dealing with aquatic/marine species in Palau came out of this workshop: 1) immediate action to eradicate tilapia and 2) working with dive operators to involve recreational divers in hull inspections of yachts and commercial vessels. In addition, the appendices include voluntary codes of conduct for many sectors (vectors), including aquaculture. It was agreed that use of non-native species for aquaculture ought to be discouraged generally, and, wherever used, the species should be contained in secure facilities.

In 2006, the PNISC reviewed the NISS. The committee modified language for clarity and to make several of the major goals and objectives more comprehensive. The NISS added a fifth major goal, that of increasing public awareness and support for invasive species prevention and management.

Following its review of the NISS, PNISC developed an Action Plan (Palau National Invasive Species Committee 2007). The PNISC Action Plan follows the structure of the NISS closely, laying out specific actions to be taken to achieve the goals and objectives of the NISS as well as time frames for these.

Palau has taken initial steps to gather baseline data on invasive marine species within its borders. With help from Australian scientists, the PNISC and other agencies carried out a training workshop and a baseline survey of its major port in 2007. Several new non-native species were found as a result of this survey and a manual removal of some of these was attempted. In addition, a public

awareness campaign was carried out by Koror state on an invasive anemone in Jellyfish Lake (Palau National Invasive Species Committee 2007).

Palau also launched major campaigns to eradicate tilapia that involved the assistance and support of many agencies and community members. Tilapia was also added to the list of species prohibited for import into Palau, although the government is now reconsidering this.

Palau is considering the adoption of a biosecurity bill. The bill would create a Division of Biosecurity, increasing the ability of biosecurity agents to inspect incoming vessels and goods and to act to control or eradicate pest or disease outbreaks. The bill would specifically prohibit the release of bilge or ballast water in Palauan ports (draft version February 2010), but otherwise would not address ship-mediated invasions. Many of its provisions, such as requiring an incoming vessel to submit voyage records prior to arrival, and granting biosecurity agents the power to sample vessels or parts of vessels, would create an initial framework to reduce ship-mediated invasions associated with ballast water and hull biofouling.

Palau has trained alien snake rapid response team members and Palau has developed an ERP for alien snakes. Palau also has ERPs for fruit flies and tramp ants. There is also an established emergency response standard operating procedure for Avian Influenza.

Palau Code Title 25 Chapter 20 Plant and Animal Control: This Chapter regulates certain aspects of the international trade in plants and animals in order to protect Palau against the introduction and further dissemination of injurious insects, pests, and diseases into and within the Republic. With the prior approval of the President, the Chief of the Division of Agriculture shall issue plant and animal quarantines and regulations relating to the administration and enforcement of the controls established by this Chapter. Letters and memoranda may be issued from time to time by the Chief of the Division of Agriculture and the President relating to the administration and enforcement of such quarantines and regulations. The Chief of the Division of Agriculture shall administer the provisions of the plant and animal quarantines and regulations. Agricultural quarantine inspectors may be appointed by the President, and shall, under the direction of the Chief of the Division of Agriculture, enforce the provisions of the plant and animal quarantines and Regulations.

Live aquatic organisms for import require 3-7 days holding quarantine to examine the stock for any contamination by alien species and the presence of diseased or sick fry as well as a health certificate issued by a veterinarian certifying that the stock being imported is free from Finfish disease, Mollusk disease, Crustacean disease, and the bacterium *Vibrio anguillarum*.

Requests to introduce new species must be reviewed by the National Invasive Species Committee before the Director of Agriculture may issue an import permit.

Attachment C: Chuuk State Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Chuuk section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	Chuuk Invasive Species Taskforce	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	FSM RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Chuuk RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including distributing a written report to the region and beyond.	continuous, yearly	State RISC Representatives and ISC	Biosecurity cost recovery system	High
Establish a jurisdictional invasive species coordination office that is tasked with supporting statewide IAS efforts across agencies and offices as well as working nationally and regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the invasive species coordination position.	2015	CIST and Governor's office	Biosecurity cost recovery system	High
	Once established this office should support and assist in coordinating efforts with invasive species within the state. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that state governance is regularly updated regarding both state and regional invasive species developments.	2015	CIST	Biosecurity cost recovery system	High
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of R&D	Biosecurity cost recovery system	High
	Add GMO and LMO coverage to the draft bill.	Complete by August 2014	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	2014	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	2014	CIST	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	Chuuk RISC representatives and the Governor's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support state efforts with engaging external resources to support state invasive species efforts.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support capacity building, training, and advice.	As soon as the office can be established	Chuuk RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Assistance with protocol and methods development.	As soon as the office can be established	Chuuk RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Support with establishing ER &RR capacity.	As soon as the office can be established	Chuuk RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Support the development of guidelines and regulations.	As soon as the office can be established	Chuuk RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Seek and coordinate regional funding.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Support management, response, and eradication efforts.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts within the state.	As soon as the office can be established	Chuuk RISC representatives and the Chuuk ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve state level communication and coordination	Develop a state invasive species task force (CIST) or council and includes NGOs, state and national government stakeholders.	2015	Governor's Office	Biosecurity cost recovery system	High
	Ensure the task force meets regularly (quarterly).	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Develop a state invasive species action plan and update regularly (every 3-5 years).	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Report annually on the status of elements of the state invasive species action plan.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Develop State biosecurity act.	2016	Chuuk ISC or Task force	Biosecurity cost recovery system	High
Improve capacity to identify biosecurity intercepts and organisms detected post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity such as SPC) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	Chuuk Invasive Species Coordinator	Biosecurity cost recovery system	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Chuuk Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	College of Micronesia	external donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of Micronesia	external donor	Low
	Support the development of an algal risk assessment for the region.	2016	College of Micronesia	external donor	Medium
	Support the development of an arthropod risk assessment for the region.	2016	College of Micronesia	external donor	Medium
	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	Office of the Governor	SPC	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.)	2015 and on-going	Chuuk ISC	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Chuuk ISC	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region.	2016	College of Micronesia	external donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Chuuk RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Chuuk RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	Chuuk RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Chuuk RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Chuuk RISC representatives	NA	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Chuuk RISC representatives	external donor	Medium
Prevention					
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 support national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	Biosecurity cost recovery system	High
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve border biosecurity	Support national government efforts to acquire X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Support national government efforts to ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Support national government efforts to ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority	
Improve border biosecurity (continued)	Support 100% x-ray of all arriving passenger baggage.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High	
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High	
	Support the development of a canine pest detection program for items such as snakes, fruits, and vegetables. Consider the potential to combine this program with similar programs for detection of illicit materials such as drugs.	2016 hold national consultation on the need for a biosecurity canine program; 2017 establish program if deemed appropriate		Ministry of Resources and Development	Initial support might have to be sought in the form of external donor funding; once the program is established, it should be supportable under an appropriately managed cost recovery system for biosecurity	Low
	Develop specific regulations and enforcement SOPs for imported seeds. All imported and viable seeds should require completed risk assessments and permitting.	2015		Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support biosecurity cross training of staffs from agencies which are involved in border inspection processes.	implement in 2015		Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Develop appropriate inspection facilities including a biosecure inspection facility at the seaport large enough for sea containers and wash-down areas with appropriate retention and treatment facilities for waste water produced.	2015 Develop planning; 2016 fund and move forward with developing infrastructure; 2017 operational		Ministry of Resources and Development	External donor support may be needed for infrastructure; once completed, cost recovery funds should be able to support up keep	Medium
	Establish a centralized facility for quarantine offices, including quarantine areas (plant and animal and aquatic organisms), treatment areas, laboratory space, offices, and equipment storage.	2017		Ministry of Resources and Development	External donor support may be needed for infrastructure; once completed, cost recovery funds should be able to support up keep	Medium
	Ensure that quarantine freezer facilities are restricted used (only quarantine should have access to these) and that they are functional back up power supplies.	2015		Ministry of Resources and Development		Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border biosecurity (continued)	Ensure that inspectors have access to freezers and incinerators at both air and sea ports for destroying pests and other materials as needed.	2015	Ministry of Resources and Development	Equipment may best come from external donors; Space and maintenance of equipment will need to be under agreements with local port authorities	High
	Support improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection. Mail should be inspected via x-ray and visual inspections (as well as by canine teams if possible) and should be standardized, not only by request from Customs (which is the current procedure).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, etc.).	on-going	Ministry of Resources and Development	SPC	Medium
	Support development of quarantine exchange programs with New Zealand, Australia, and/or U.S. biosecurity agencies as a mechanism for improving inspector capacity and further development of the nation's biosecurity program.	2016	Ministry of Resources and Development	External donor	High
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Support efforts to ensure that FSM quarantine is appropriate funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts in all 4 states).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border biosecurity (continued)	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Address IAS concerns as they relate to smuggled goods by developing appropriate SOPs, enhancing inspections, instituting fines and other actions such as confiscation and destruction of smuggled goods. Efforts should be both border and pre-border and will need the support of both national and state offices to ensure the best level of protection possible.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should include materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support development of legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	SPC, Regional ISC Office	Medium
	Support national efforts to address the lack of marine biosecurity oversight by FSM quarantine. Need to build legislation to support FSM quarantine having marine biosecurity capacity.	should be added to current draft legislation 2014	Ministry of Resources and Development	External donor	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2016	Ministry of Resources and Development	SPC, Regional ISC Office	Low
	support the establishment of national standards for the importation and use of GMO and LMO.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High	
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	CIST	external donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of WPM (continued)	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering Chuuk should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve ability to better enforce pre-departure sanitation	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	SPC	Medium
	Develop and institute standards which would increase pre-departure inspections. Visual inspections are conducted pre-departure which focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture. All jurisdictions should add quarantine inspections to the SOP of departing materials.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
Improve overall post border biosecurity	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2017	Chuuk ISC	External donor	Low
	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	2016 develop strategy; 2017 begin implementation	Chuuk ISC	External donor	Low
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	Chuuk ISC	External donor	Medium
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the state.	2015	Chuuk ISC	Biosecurity cost recovery system	Medium
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct onsite capacity training in ant id and inspection in the near future.	2015	Chuuk Agriculture	SPC and/or UH	Medium
	Establish watch list of high risk non-native species that can or may pose significant ecological, economic, social or cultural impacts.	2015	Chuuk ISC	Biosecurity cost recovery system	Medium
	Develop surveillance programs for high risk species not yet established such as fruit flies, coconut rhinoceros beetle, tramp ants, and alien snakes.	2015	Chuuk ISC	Biosecurity cost recovery system	Medium
Improve biosecurity for intra-state and inter-state away from the main air and seaports	Develop biosecurity standards for ports throughout the state.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve biosecurity for intra-state and inter-state away from the main air and seaports (continued)	Coordinate National Government field trip ship and Quarantine inspections at each port.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement and enforce biosecurity standards at ports throughout the state.	2017	lead will be determined during consultation and planning phases	Biosecurity cost recovery system	Medium
	Conduct an state wide consultation regarding intrastate biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	Chuuk Agriculture and Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct risk assessments for outer islands for terrestrial and aquatic concerns.	commence planning in 2015; risk assessments should be completed by 2018	Chuuk Agriculture and Marine Resources	External donor	Low
	Helicopters and private planes (or small scale commercial ventures) can be used to move passengers and cargo and where they exist or where there are plans for their use, they should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Establish internal biosecurity to prevent spread of established non-natives from one island to another e.g. tramp ants.	2017	Chuuk Agriculture and Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Implement and follow up recommendation to improvement of internal biosecurity.	2017	Chuuk Agriculture and Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Use Pohnpei (Nukuoro Island) as model for quarantine protocols and biosecurity standards.	2016	Chuuk Agriculture and Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve biosecurity for intra-state and inter-state away from the main air and seaports (continued)	Develop state biosecurity regulations to support intra-state efforts.	2017	Chuuk Agriculture and Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns	Develop a state endorsed white list of species permitted for import.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update white list.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop a state endorsed black list of prohibited species.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	update black list.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national level efforts to ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts to the state. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list. The state does this now for plant species proposed for import.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Support national government with developing and updating public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via existing FSM government website and linked to state websites.	Implement in 2015; update annually once implemented	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade.	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery biosecurity system	High
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	FSM Office of the Attorney General	Biosecurity cost recovery system	High
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	Office of Environmental Planning and Policy Coordination	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Department of Agriculture	Biosecurity cost recovery system	Medium
	Improve capacity and infrastructure regarding animal health. There should be a national veterinarian with support staff (para-vets?) in each state.	2016	Department of Agriculture	Animal health cost recovery system	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop biosecurity standards for small scale, private citizen aquaculture set-ups and enforce these standards.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support national government efforts to establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct an national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Develop plan for containment and control measures in regards to exotic farmed and traded species.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Improve screening and reporting system for lawful export of live organisms.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	Chuuk Invasive Species Coordinator	external donor	Low
Increase export potential	Support national efforts to establish produce export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national efforts to establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Improve capacity to export crops, which will involve finding/establishing markets with trade partners.	2016	Chuuk Agriculture	Biosecurity cost recovery system	High
	train and certify state agricultural staff to support local farmers with enhancing the potential for export crops.	2016	Chuuk Agriculture	SPC	Medium
	Support local farms with capacity development to increase potential to export crops.	2016	Chuuk Agriculture	SPC	Medium
	Ensure that fumigation for export crops is available and appropriate used.	2016	Chuuk Agriculture	SPC	Medium
	State officials should work with proposed external trade partners to ensure that export crops of interest are permitted for importation.	2015	Chuuk Agriculture	SPC	High
	Improve ability to meet import standards imposed by trade partners in regards to agricultural produces and processed foods.	2015	Chuuk Agriculture	SPC/USDA	High
	Increase protection of export crops from invasive pests by better management of established species and improved border security to reduce the introduction of new pests to the state.	on-going	Chuuk Agriculture	SPC	High
	Ensure that all proposed agricultural exports go through an establish protocol to ensure cleanliness before entering the shipping lines to reduce the potential for transport of unwanted pests.	2016	Chuuk Agriculture	SPC	High
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	USCG	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	USCG	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Develop capacity to deal with grounded and/or abandoned vessels (continued)	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
Support the national government with establishing and enforcing biofouling standards	Support establishment of standards and regulations regarding biofouling, including inspection and certification for all vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support establishment of additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support establishment of additional regulations for impounded vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support development of capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	Ministry of Resources and Development	External donor	High
	Support establishment of regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support the establishment of criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government with establishing and enforcing biofouling standards (continued)	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support establishment of the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	External donor	High
	Review and revise (as needed) legal authority to implement a biofouling management program.	2014: this should be included in the current draft biosecurity legislation; May need to update and expand in 2016-17 as elements come on line	FSM Office of the Attorney General	Biosecurity cost recovery system	High
	Support ensuring that regulations include the ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Support the national government with establishing and enforcing ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national level participation and enforcement of globally ballast water requirements including discharge 200nm from shore and inspection of ship logs for compliance.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support of establishment of ballast water management and reporting requirements for all vessels utilizing ballast water.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government with establishing and enforcing ballast water standards (continued)	Support development of capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support national level adoption of proposed USCG regulations to move to in hull sanitation of ballast water.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Increase marine system protection from invasive species	Support the establishment of biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for fishing vessels that operate in jurisdictional waters to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	external donor	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015	Ministry of Health	external donor	Low
Address climate change linkages to invasive pests		Framework should be in place by 2016	Chuuk ISC	US AID	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address food security for the state in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of Micronesia	FAO	Low
Early detection and rapid response					
Improve early detection and rapid response capacity	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	Chuuk ISC or Task force	Regional ISC office	High
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	Chuuk ISC or Task force	External donor	Medium
	Develop taxa specific ERPs as needed.	On-going	Chuuk ISC or Task force	Regional ISC office	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	Chuuk ISC or Task force	External donor	Medium
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2016	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2016	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2016	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Develop protocols for responding to non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Hold consultations to determine what agency(s), office(s) and/or groups will be responsible for surveillance programs.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Increase support for BTS Early Detection/Rapid Response.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	Medium
	Develop and institute surveillance programs for non-established species consider high risk of arrival such as CRB, alien snakes, fruit flies, tramp ants, etc.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	High
	Work with police to develop MOU to assist with enforcing internal quarantine if needed during a response action.	2015	Chuuk ISC or Task force	Biosecurity cost recovery system	Low
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	start in 2015	Chuuk ISC or Task force	Biosecurity cost recovery system	Low
Management and eradication					
Increase management and control of established invasive species	Determine which established invasive species are actionable and proceed with developing management strategies.	conduct consultations 2015; develop strategies 2016	Chuuk ISC	External donor	Medium
	Create GIS layers regarding the distribution of established IAS and use to support biosecurity and IAS management efforts.	2015	College of Micronesia	External donor	Low
	Key staff need to receive GIS training both in regards to field data collection and the utilization of GIS databases and computer systems.	2015	College of Micronesia	SPC	Low
	Key offices need resources to support electronic mapping efforts (GIS), including computers, software, and GPS units.	2015	CIST	External donor	Low
	Train natural resource staffs at the local level in regards to IAS management support.	2015	Chuuk ISC	Regional ISC office	Low
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	2015	Chuuk ISC	Regional ISC office	Low
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2015	Chuuk Agriculture	External donor	Low
	Develop standardized SOPs for IAS monitoring and surveys.	2015	Chuuk ISC	External donor	Low
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distribution is current.	2015	Chuuk Agriculture	External donor	Low
	Identify frog found on Satowan Island.	2014	CIST	External donor	High
	Investigate spiders encountered on Polowat.	2014	CIST	External donor	High
Coordinate management of monitor lizards on Houk Island.	2015	Chuuk Agriculture	External donor	Low	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase management and control of established invasive species (continued)	Survey islands within the state to determine baseline information regarding both native species and established non-natives such as tramp ants.	Develop strategy 2015; start survey work in 2016	Chuuk Agriculture	External donor	Low
	Train natural resource staffs at the local level in regards to IAS management support.	2015 this should be implemented	Chuuk ISC	SPC, Regional ISC Office	Low
	Document the differences between established non-native species such as ant faunas amongst various islands.	2015 develop strategy; 2016 begin implementation	Chuuk Agriculture	External donor	Low
Increase efforts to eradicate targeted species	Conduct surveys and hold stakeholder consultations to determine what established species are viable candidates for eradication efforts.	2015 consultations; 2016 develop strategy; 2017 implement	Chuuk ISC	External donor	Low
	Develop strategies to conduct eradication campaigns including securing funding streams to support these efforts.	2016	Chuuk ISC	External donor	Low
	Develop resources to respond to new pest incursions beyond ED & RR, including conducting delimiting surveys and potential eradication efforts.	2016	Chuuk ISC	Biosecurity cost recovery system	Medium
	Eradicate small and feasible invasive species incursions promptly, while it is most feasible, least expensive, and before extensive damage has occurred.	Develop capacity by 2017; process should be on-going from that point	Chuuk ISC	External donor	Medium
	Determine feasibility of fruit fly eradication on Chuuk in relation to current biosecurity levels.	2016	Chuuk Agriculture	USDA	Low
	Consider ant species with limited distribution for eradication.	2016	Chuuk Agriculture	SPC	Low
Awareness					
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and state wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	CIST	External donor	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the state from unwanted pests.	2015	CIST	External donor	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	CIST	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	CIST	External donor	High
	Coordinate existing outreach efforts.	2015	CIST	External donor	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2015	Chuuk ISC	Regional ISC office	Medium
	Support adding invasive species education as a standard part of school curriculums region wide.	2017	CIST/Ministry of Education	External donor	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2016	CIST/Ministry of Education	External donor	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	on-going	CIST	External donor	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	On-going	CIST	External donor	Medium
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	CIST	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	C ISC	Regional ISC office	Medium
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop a wildlife reference collection (i.e., taxidermy mounts, computer photo files, etc.) to aid identification of incoming species. Adequate resources (taxonomic keys, microscopes, etc.) should be available for assistance in taxonomic identifications.	2016	Chuuk Agriculture	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	Chuuk RISC representatives	External donor	Medium
	Provide reports and newsletters to educators, journalists, lawmakers, and business and community leaders.	2016	CIST	External donor	Medium
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials in Chuuk , including the potential loss of business if invasive species are permitted to establish.	2015	CIST	Biosecurity cost recovery system	High
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of Micronesia	External donor	Low
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2016	College of Micronesia	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment D: Kosrae State Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Kosrae section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	KIST	Biosecurity Cost Recovery System	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	Kosrae RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Kosrae RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including distributing a written report to the region and beyond.	continuous, yearly	State RISC Representatives and ISC	Biosecurity Cost Recovery System	High
Establish a jurisdictional invasive species coordination office that is tasked with supporting statewide IAS efforts across agencies and offices as well as working nationally and regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Conduct a state wide consultation to determine the most appropriate way forward with establishing a single office which can support state wide IAS efforts.	2015	Governor's Office	External donor	High
	Following consultations, develop planning and implement strategy, including staffing the office.	2015	Governor's Office	External donor	High
	Once established this office should support and assist in coordinating efforts with invasive species within the state. Part of this effort will	on-going	Governor's Office	Biosecurity Cost Recovery System	High
	Once established this office should serve as the main linkage between the state and the region on invasive species issues, communicating state activities to the region as well as engaging the region and beyond when feasible to support and assist with invasive species efforts within the state.	On-going	Governor's Office	Biosecurity Cost Recovery System	High
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward (continued)	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	2014	KIST	Biosecurity Cost Recovery System	High
Update and regularly maintain the state invasive species action plan and annually report on progress	Update current plan.	2014	KIST	External donor	High
	Establish protocol to revisit and update every 3 to 5 years.	On-going	KIST	External donor	High
	Include annual reporting on progress of the state ISAP at the MCES and development a short annual 1-2 pagers to share progress regionally and beyond (combine with similar activities for the RBP).	On-going annually	State RISC Representatives and State ISC	External donor	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office	ideally this office would be up and running before the end of 2015	Kosrae RISC representatives and the Governor's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information	As soon as the office can be established	Kosrae RISC representatives and the Kosrae ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support state efforts with engaging external resources to support state invasive species efforts	As soon as the office can be established	Kosrae RISC representatives and the Kosrae ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued)</p>	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Assistance with protocol and methods development</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Support with establishing ER &RR capacity</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Kosrae ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued)</p>	<p>Support the development of guidelines and regulations</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Seek and coordinate regional funding</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Kosrae ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Support management, response, and eradication efforts</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Kosrae ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information</p>	<p>As soon as the office can be established</p>	<p>Kosrae RISC representatives and the Kosrae ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued)	Engage the regional invasive species coordination office to support outreach and education efforts within the state	As soon as the office can be established	Kosrae RISC representatives and the Kosrae ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve capacity to identify biosecurity intercepts and organisms detected post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	Kosrae Invasive Species Coordinator	Biosecurity Cost Recovery System	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Kosrae Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	College of Micronesia	External donor	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of Micronesia	External donor	Low
	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	Office of the Governor	SPC	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	Kosrae ISC	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Kosrae ISC	Regional ISC office	Low
	Support the development of a algal risk assessment for the region.	2016	College of Micronesia	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of a arthropod risk assessment for the region.	2016	College of Micronesia	External donor	Medium
	Support the development of a weeds risk assessment for the region.	2016	College of Micronesia	External donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Kosrae RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Kosrae RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	Kosrae RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Kosrae RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Kosrae RISC representatives	NA	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Kosrae RISC representatives	External donor	Medium
Ensure that the Kosrae Invasive Species Taskforce (KIST) is functional and meeting regularly	KIST should ensure that it is endorsed and supported by the governance and state agencies and has appropriate bi-laws in place	2014	Governor's Office	Biosecurity Cost Recovery System	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Ensure that the Kosrae Invasive Species Taskforce (KIST) is functional and meeting regularly (continued)	KIST should elect officers (minimally a chairperson, treasurer and secretary)	annually	Governor's Office	Biosecurity Cost Recovery System	High
Prevention					
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations.	2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Improve communication and information sharing in regards to IAS and biosecurity	SOPs should be developed at the state level to facilitate communication and information sharing between offices and agencies within the state in regards to invasive species.	2015	Kosrae ISC	External donor	High
	Support the development of SOPs at the national level to facilitate communication and information sharing between offices and agencies in regards to invasive species and biosecurity.	2015	Kosrae ISC and FSM ISC	External donor	High
	Support the improvement of communication, information sharing, and active support between agencies and offices at the national and state levels.	2015	Kosrae ISC and FSM ISC	External donor	High
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 support national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	Biosecurity Cost Recovery System	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve pre-border sanitation efforts (continued)	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA, APHIS materials	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Improve border security	Support national government efforts to acquire X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Establish a quarantine buoy, develop standards for its use, and enforce these standards.	2016	Ministry of Resources and Development	External donor	High
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support national government efforts to ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support national government efforts to ensure appropriate long term maintenance for X-ray machines used for biosecurity	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, etc.).	on-going	Ministry of Resources and Development	SPC	Medium
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	Biosecurity Cost Recovery System	Low
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Support development of legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2016	Ministry of Resources and Development	SPC, Regional ISC Office	Low
	Support efforts to ensure that FSM quarantine is appropriate funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts in all 4 states).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	SPC, Regional ISC Office	Medium
	Support national efforts to address the lack of marine biosecurity oversight by FSM quarantine. Need to build legislation to support FSM quarantine having marine biosecurity capacity.	should be added to current draft legislation 2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	support the establishment of national standards for the importation and use of GMOs and LMOs.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Improve overall post border biosecurity	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2016	KIST	External donor	Low
	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	2016 develop strategy; 2017 implement	KIST	External donor	Low
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the state.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	Ministry of Resources and Development	External donor	Medium
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species.	2015	KIST	Biosecurity Cost Recovery System	Medium
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	Ministry of Resources and Development	External donor	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering Kosrae should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of WPM (continued)	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
Improve ability to better enforce pre-departure sanitation	Develop a secure departure area for both personnel and baggage which reduces the potential for invasive species to hitchhike on air passengers and cargo. Currently this area is open air and therefore there is little potential in stopping the movement of potential pest species from Kosrae to other locations such as Pohnpei, Kwajalein, and Majuro.	2016	Port Authority and Ministry of Resources and Development	External donor	Medium
	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	SPC	Medium
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Mandate and enforce regulations for handling palletized cargo. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	External donor	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015	Ministry of Health	External donor	Low
Increase export potential	Support national efforts to establish produce export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Support national efforts to establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Develop capacity to export citrus and other produce. For citrus, there is currently a experimental effort to reduce citrus canker which should be supported and if found viable, instituted state wide.	2016	Kosrae Agriculture	External donor	Medium
	Ensure that fumigation for export crops is available and appropriate used.	2016	Kosrae Agriculture	Biosecurity Cost Recovery System	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase export potential (continued)	Improve ability to meet import standards imposed by trade partners in regards to agricultural produces and processed foods.	2015	Kosrae Agriculture	SPC/USDA	High
	Ensure that all proposed agricultural exports go through an establish protocol to ensure cleanliness before entering the shipping lines to reduce the potential for transport of unwanted pests.	2016	Kosrae Agriculture	SPC	High
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery/biosecurity	High
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or traded in Kosrae.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms within Kosrae.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Improve capacity and infrastructure regarding animal health. There should be a national veterinarian with support staff (para-vets?) in each state.	2016	Kosrae Department of Agriculture	Animal health cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Establish explicit aquaculture biosecurity practices for Kosrae (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Support national government efforts to establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct a national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Develop biosecurity standards for small scale, private citizen aquaculture set-ups and enforce these standards.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	Low
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	Kosrae Invasive Species Coordinator	External donor	Low
	Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns	Develop a state endorsed white list of species permitted for import.	2014	Ministry of Resources and Development	Biosecurity Cost Recovery System
Update white list.		annually	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
Develop a state endorsed black list of prohibited species.		2014	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Update black list.		annually	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
Support national government with developing and updating public dissemination of white and black lists as well as details on the risk assessment process for proposed species imports. This could likely be done via existing FSM government website and linked to state websites.		Implement in 2015; update annually once implemented	Ministry of Resources and Development	Biosecurity Cost Recovery System	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns (continued)	Support national level efforts to ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts to the state. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
Better develop infrastructure to support port biosecurity efforts	Support national government efforts to provide adequate offices, inspection space, laboratory for pest identification, quarantine areas, treatment areas, etc. proximal to the ports for quarantine staff and activities.	2017	Ministry of Resources and Development	External donor	Medium
	Support national government efforts to ensure that quarantine staff has appropriate day to day resources such as computers, phones, internet access, vehicles, fuel, microscopes, etc. and that equipment can be both utilized and maintained.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Support the national government with establishing and enforcing biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government with establishing and enforcing ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Support national level participation and enforcement of globally ballast water requirements including discharge 200nm from shore and inspection of ship logs for compliance.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Support national level adoption of proposed USCG regulations to move to in hull sanitation of ballast water.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	USCG	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
Increase marine system protection from invasive species	Support the establishment of biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
	Establish biosecurity practices and requirements for fishing vessels that operate in jurisdictional waters to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase marine system protection from invasive species (continued)	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity Cost Recovery System	Medium
Address climate change linkages to invasive pests		Framework should be in place by 2016	Kosrae ISC	US AID	Medium
Address food security for the state in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of Micronesia	FAO	Low
Early detection and rapid response					
Improve early detection and rapid response capacity	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	KIST	Regional ISC office	High
	Establish a watch list of high-risk non-native species that are known or thought to pose significant ecological, economic, social, or cultural impacts to Kosrae.	2015	KIST	External donor	Medium
	Develop a detection program and response plan for new incursions by a few focal non-native species on the watch list of high-risk non-native species for Kosrae, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	KIST	Biosecurity Cost Recovery System	Medium
	Develop taxa specific ERPs as needed.	On-going	KIST	Regional ISC office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	KIST	External donor	Medium
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2016	KIST	Biosecurity Cost Recovery System	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2016	KIST	Biosecurity Cost Recovery System	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2016	KIST	Biosecurity Cost Recovery System	High
	Develop protocols for responding to non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response.	2015	KIST	Biosecurity Cost Recovery System	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	KIST	Regional ISC Office	High
	Work with police to develop MOU to assist with enforcing internal quarantine if needed during a response action.	2015	KIST	Biosecurity Cost Recovery System	Low
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	KIST	Regional ISC Office	Low
Management and eradication					
Increase management and control of established invasive species	Determine which established invasive species are actionable and proceed with developing management strategies (this should be part of the state ISAP).	2015	KIST	External donor	Medium
	Create GIS layers that delineate management zones, land tenure, and current distribution of established IAS and use to support biosecurity and IAS management efforts.	2015	KIST	External donor	Low
	Advance efforts to address the Giant African Snail infestation.	on-going	KIST	External donor	High
	Train natural resource staffs at the local level in regards to IAS management support.	2015	KIST	Regional ISC office	Medium
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	2015	KIST	Regional ISC office	Low
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2015	Kosrae Agriculture	Biosecurity Cost Recovery System	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase management and control of established invasive species (continued)	Advance efforts to address the white fly outbreak. There is work already being done in regards to the white fly, it is not clear if sufficient resources are available or have been brought to bear to ensure appropriate levels of management. Stakeholders and experts should convene to discuss the topic and agree on a plan of action which should include appropriate identification of the pest, surveys to determine extent of the spread and surveys outside of Kosrae to determine if it has been transported to other locations outside of the state. Effectiveness of released biocontrol agents needs to be determined as well as if more biocontrol need to be raised and released and if so how many and by whom should this be done. Field crews and funding will also need to be established to deal with the management of this pest.	on-going	KIST	External donor	High
	Advance efforts to address the coconut termite infestation. A response plan should be developed with clear, concise actions and who or what agencies/groups will be response for these actions. Extent of the spread of this pest on the island, when it arrived, where it came from and if it has spread from Kosrae to other locations all need to be determined (if feasible). Ground crews and funding to support the response and/or management plan for this pest need to be established.	on-going	KIST	External donor	High
	Develop standardized SOPs for IAS monitoring and surveys.	2015	KIST	External donor	Medium
	Develop a management plan for the established non-native oyster.	2016	KIST	External donor	Medium
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distribution is current.	2016	KIST	External donor	Low
Increase efforts to eradicate targeted species	Conduct surveys and hold stakeholder consultations to determine what established species are viable candidates for eradication efforts.	2015	KIST	External donor	Medium
	Develop strategies to conduct eradication campaigns including securing funding streams to support these efforts.	2015	KIST	External donor	Medium
	Develop resources to respond to new pest incursions beyond ED & RR, including conducting delimiting surveys and potential eradication efforts.	2015	KIST	External donor	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase efforts to eradicate targeted species (continued)	Eradicate small and feasible invasive species incursions promptly, while it is most feasible, least expensive, and before extensive damage has occurred.	on-going	KIST	External donor	High
Improve usage and better regulation of pesticides used for both agricultural purposes and to treat specific pest infestations (termites, etc.)	Pesticide training courses should be held to provide farmers and others with basic skills in pesticide use. Use of restricted pesticides should be done by licensed applicators only.	2015	KIRMA	External donor	Low
	Educational materials regarding pesticides are needed for distribution to assist farmers and others with appropriate use of chemicals, but also to better inform the public regarding pesticide use. UH extension has already developed posters for chemical education which could be used once verbiage in local language(s) is add to these posters.	2015	KIRMA	University of Hawaii	Low
Awareness					
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and state wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	KIST	External donor	High
	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the state from unwanted pests.	2015	KIST	External donor	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	KIST	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	KIST	External donor	High
	Coordinate existing outreach efforts.	2015	KIST	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Support adding invasive species education as a standard part of school curriculums region wide.	2017	KIST/Ministry of Education	External donor	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2016	KIST/Ministry of Education	External donor	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	on-going	KIST	External donor	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	On-going	KIST	External donor	Medium
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	KIST	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	Kosrae ISC	Regional ISC office	Medium
	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	Kosrae RISC representatives	RISC	Medium
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2015	Kosrae ISC	Regional ISC office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials in Kosrae, including the potential loss of business if invasive species are permitted to establish.	2015	Ministry of Resources and Development	Biosecurity Cost Recovery System	High
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of Micronesia	External donor	Low
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2015	College of Micronesia	External donor	Low
Restoration					
Increase restoration efforts of native systems where IAS management and/or eradication efforts are underway or have been successful.		on-going	KIST	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment E: Pohnpei State Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Pohnpei section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	iSTOP	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	Pohnpei RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Pohnpei RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report distributed to the region and beyond.	continuous, yearly	State RISC Representatives and ISC	Biosecurity cost recovery system	High
Establish a jurisdictional invasive species coordination office that is tasked with supporting statewide IAS efforts across agencies and offices as well as working nationally and regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the invasive species coordination position. The concept of this position is established in the state ISAP but until funding can be ensure the position remains unfilled.	2015	Governor's Office	Biosecurity cost recovery system	High
	Once established this office should support and assist in coordinating efforts with invasive species within the state. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that state governance is regularly updated regarding both state and regional invasive species developments.	2015	Governor's Office	Biosecurity cost recovery system	High
	Once established this office should serve as the main linkage between the state and the region on invasive species issues, communicating state activities to the region as well as engaging the region and beyond when feasible to support and assist with invasive species efforts within the state.	2015	Governor's Office	Biosecurity cost recovery system	High
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of R&D	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward (continued)	Add GMO and LMO coverage to the draft bill.	Complete by August 2014	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	2014	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	2014	iSTOP	Biosecurity cost recovery system	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	Pohnpei RISC representatives and the Governor's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	Pohnpei RISC representatives and iSTOP	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support state efforts with engaging external resources to support state invasive species efforts.	As soon as the office can be established	Pohnpei RISC representatives and iSTOP	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Assistance with protocol and methods development.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. 	<p>Support with establishing ER &RR capacity.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and ISTOP</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Support the development of guidelines and regulations.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Seek and coordinate regional funding.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and ISTOP</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Support management, response, and eradication efforts.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and ISTOP</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.</p>	<p>As soon as the office can be established</p>	<p>Pohnpei RISC representatives and ISTOP</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to support outreach and education efforts within the state.	As soon as the office can be established	Pohnpei RISC representatives and iSTOP	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve capacity to identify biosecurity intercepts and organisms detected post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity such as SPC) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	Pohnpei Invasive Species Coordinator	Biosecurity cost recovery system	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Pohnpei Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	College of Micronesia	External donor	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of Micronesia	External donor	Low
	Support the development of an algal risk assessment for the region.	2016	College of Micronesia	External donor	Medium
	Support the development of an arthropod risk assessment for the region.	2016	College of Micronesia	External donor	Medium
	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	Office of the Governor	SPC	High
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Pohnpei Invasive Species Coordinator	Regional ISC office	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	Pohnpei Invasive Species Coordinator	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region.	2016	College of Micronesia	External donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Pohnpei RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Pohnpei RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	Pohnpei RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Pohnpei RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Pohnpei RISC representatives	NA	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Pohnpei RISC representatives	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Prevention</i>					
Improve pre-border sanitation efforts	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 support national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve border security	Support national government efforts to acquire X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and	External donor	High
	Establish a quarantine buoy, develop standards for it use, and enforce these standards.	2016	EPA/Port Authority	External donor	Medium
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support national government efforts to ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Support national government efforts to ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, etc.).	on-going	Ministry of Resources and Development	SPC	Medium
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	External donor	Low
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support efforts to ensure that FSM quarantine is appropriate funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts in all 4 states).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Review and update ship clearance procedures.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support development of legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2016	Ministry of Resources and Development	SPC, Regional ISC Office	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	SPC, Regional ISC Office	Medium
	Support national efforts to address the lack of marine biosecurity oversight by FSM quarantine. Need to build legislation to support FSM quarantine having marine biosecurity capacity.	should be added to current draft legislation 2014	Ministry of Resources and Development	External donor	High
	Support the establishment of national standards for the importation and use of GMO and LMO. GMOs and LMOs should be labelled as such.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Support review of the draft FSM biosafety act in regards to its coverage of GMOs and LMOs.	June 2014	Pohnpei Economic Affairs	Biosecurity cost recovery system	Low
	Support national review of GMOs and LMOs and if and how they may be covered by intellectual property rights.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Develop MOU's between FSM Quarantine and other agencies involved in border inspections so that these offices/agencies can support FSM Quarantine with biosecurity aspects.	2015	Ministry of Resources and Development	NA	Low
	Support review of official ports of entry for the nation to better determine if and how FSM Quarantine's biosecurity role needs to be expanded to include additional ports.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support review of field ship ports of call and development of biosecurity standards for field ships and other intra and inter state conveyances.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Support development of regulations regarding biosecurity and visiting cruise ships. These ships, if visiting multiple jurisdictions should fund having a biosecurity office on board during their time within the FSM, provide for inspection services at all ports of call, cover all travel expenses for the biosecurity office, and coordinate with FSM Quarantine to ensure that the inspector's home port does not experience a drop in quarantine services during their absence (this may including paying for overtime).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Develop SOPs regarding specifics of how other agencies and offices can support the role of FSM Quarantine during border inspection process.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Support biosecurity cross training of staffs from agencies which are involved in border inspection processes such as the office of health and social affairs, Pohnpei EPA, Port Authority, and Customs.	implement in 2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	NA	High
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	Ministry of Resources and Development	External donor	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering Palau should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	SPC	Medium
	Mandate and enforce regulations for handling palletized cargo. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
Improve overall post border biosecurity	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2016	iSTOP	External donor	Low
	Develop a local depository for pest information.	Implement in 2015	College of Micronesia	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve overall post border biosecurity (continued)	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	2016 develop strategy; 2017 begin implementation	iSTOP	External donor	Low
	Develop best management practices for public utilities and contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	iSTOP	External donor	High
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the state.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support development of a regional depository for pest information.	2015	Pohnpei Invasive Species Coordinator	Regional ISC office	Low
	Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other businesses as appropriate to promote the sale and use of locally sourced plants, preferably native plants. If non-natives are going to be used for landscaping, ensure that they are non-invasive species. If plants will be brought into an area from outside for landscaping, ensure that they are pest free. This code of conduct should encourage businesses: to make their staff knowledgeable about invasive plants, to inform their customers about invasive plants, to report immediately any likely exotic pest organisms found on their premises, and to use native or non-invasive plants locally sourced.	2015	iSTOP	External donor	Low
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species.	2015	iSTOP	Biosecurity cost recovery system	Medium
Improve capacity for intra-state biosecurity	Develop MOUs between the State Economic Affairs Office, iSTOP, and FSM Quarantine. Pohnpei State Control Plan Indicates that the State Department of Economic Affairs is responsible for all IAS issues within the state but iSTOP and the national quarantine office would have the best capacity.	2015	Economic Affairs	NA	High
	As the agency responsible for IAS within the state, the Office of Economic Affairs should be updated on a regular basis regarding IAS issues and a primary partner in any ERP documents.	2015	iSTOP	NA	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve capacity for intra-state biosecurity (continued)	Develop biosecurity standards for all ports.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement and enforce biosecurity at all ports.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct an state wide consultation regarding intrastate biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	iSTOP	External donor	Medium
	Conduct risk assessments for outer islands for terrestrial and aquatic concerns.	commence planning in 2015; risk assessments should be completed by 2018	iSTOP	External donor	Low
	Consider example of Nukuoro Island (which does have its own biosecurity standards which FSM Quarantine supports) when considering how to develop intra-state biosecurity.	2016	iSTOP and Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Helicopters, private planes and small boats (or other small scale commercial ventures) can be used to move passengers and cargo and where they exist or where there are plans for their use, they should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns	Develop a state endorsed white list of species permitted for import.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update white list, working with and informing local partners.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop a state endorsed black list of prohibited species.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	update black list, working with and informing local partners.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns (continued)	Support national level efforts to ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts to the state. Organisms which are deemed potentially harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Support national government with developing and updating public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via existing FSM government website and linked to state websites.	Implement in 2015; update annually once implemented	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Better develop infrastructure to support port biosecurity efforts	Support national government efforts to provide adequate offices, inspection space, laboratory for pest identification (have lab but lacking equipment), quarantine areas, treatment areas, etc. proximal to the ports for quarantine staff and activities.	2016	Ministry of Resources and Development	External donor	Medium
	Support national government efforts to ensure that quarantine staff has appropriate day to day resources such as computers, phones, internet access, vehicles, fuel, microscopes, etc. and that equipment can be both utilized and maintained.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Seaport inspection site needs to be developed and should include an indoor biosecure inspection site large enough to enclose an entire container.	2016	Ministry of Resources and Development	External donor	High
	Develop an appropriate wash down area at the seaport (USDA has guidelines which should be considered).	2016	Ministry of Resources and Development	External donor	High
	Airport inspection area should be enclosed.	2016	Ministry of Resources and Development	External donor	High
	Develop partnership with health care facilities in regards to sharing incinerator facilities at the land fill (proximal to Kolonia air and sea ports).	2015	FSM Quarantine	Biosecurity cost recovery system	Medium
Increase export potential	Support national efforts to establish produce export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase export potential (continued)	Support national efforts to establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Improve ability to sanitize produce prior to shipping. Consider forced hot air and/or fumigation treatments.	2016	Pohnpei Agriculture	SPC	Medium
	Improve ability to meet import standards imposed by trade partners in regards to agricultural produces and processed foods.	2015	Pohnpei Agriculture	SPC/USDA	Medium
	Ensure that all proposed exports go through an establish protocol to ensure cleanliness before entering the shipping lines to reduce the potential for transport of unwanted pests. Should be clean and free of pest and disease.	2016	Pohnpei Agriculture	SPC	Medium
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	External donor	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015	Ministry of Health	External donor	Low
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a state/national biosecurity advisory committee to review proposals for the importation of exotic species. There is currently a national risk assessment process but no specific protocol in place.	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery biosecurity system	High
Reduce risk associated with live traded species (continued)	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	Pohnpei office of Economic Affairs	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Improve capacity and infrastructure regarding animal health. There should be a national veterinarian with support staff (paravets?) in each state.	2016	Pohnpei Department of Agriculture	Animal health cost recovery system	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Support national government efforts to establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct a national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop biosecurity standards for small scale, private citizen aquaculture set-ups and enforce these standards.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Finalize state draft plan for containment and control measures in regards to exotic farmed and traded species.	2014	iSTOP	NA	Medium	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	Pohnpei Invasive Species Coordinator	External donor	Low
Support the national government with establishing and enforcing ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national level participation and enforcement of globally ballast water requirements including discharge 200nm from shore and inspection of ship logs for compliance.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national level adoption of proposed USCG regulations to move to in hull sanitation of ballast water.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Support the national government with establishing and enforcing biofouling standards	Support the establishment of criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	External donor	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	USCG

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Develop capacity to deal with grounded and/or abandoned vessels (continued)	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel	2017	Ministry of Resources and Development	USCG	Medium
Increase marine system protection from invasive species	Support the establishment of biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for fishing vessels that operate in jurisdictional waters to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Address climate change linkages to invasive pests		Framework should be in place by 2016	iSTOP	US AID	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address food security for the state in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of Micronesia	FAO	Low
Early detection and rapid response					
Improve early detection and rapid response capacity	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and the government. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	iSTOP	Development of a generic ERP is mentioned in the 2013 state ISAP	High
	Consider linking invasive species ED & RR capacity with the State disaster management office.	2014	iSTOP	NA	Medium
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species on the watch list (established in the 2013 state ISAP) of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	iSTOP	External donor	Medium
	Develop taxa specific ERPs as needed.	On-going	iSTOP	ERPs exist for fruit flies, alien snakes; Ministry of RAD is currently developing a tampa nt ERP, and planning is underway to develop a CRB ERP	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	iSTOP	Bisoecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable). Currently have 8 advertised office numbers plus port numbers which are available 24/7. But no dedicated pest hotline and no protocols in place for reacting to calls coming in on currently advertised lines.	2015	iSTOP	Biosecurity cost recovery system	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2015	iSTOP	Biosecurity cost recovery system	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2015	iSTOP	Biosecurity cost recovery system	High
	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	iSTOP	Biosecurity cost recovery system	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	iSTOP	Regional ISC Office	High
	Work with police to develop MOU to assist with enforcing internal quarantine if needed during a response action.	2015	iSTOP	Biosecurity cost recovery system	Low
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	iSTOP	Regional ISC Office	Low
Management and eradication					
Improve post border invasive species control and management capacity	Develop a coordinated mosquito monitoring program	2015	State offices of EPA, Health, and Agriculture	External donor	Medium
	Develop a coordinated mosquito control program	2015	State offices of EPA, Health, and Agriculture	External donor	Medium
Improve usage and better regulation of pesticides used for both agricultural purposes and to treat specific pest infestations (termites, etc.)	Pesticide training courses should be held to provide farmers and others with basis skills in pesticide use. Use of restricted pesticides should be done by licensed applicators only.	2015	Pohnpei EPA	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve usage and better regulation of pesticides used for both agricultural purposes and to treat specific pest infestations (termites, etc.) (continued)	Support development of a regional standard in pesticide labelling (US pesticides are already labelled, but those coming from Asia typically are not). US Mainland standards may not be appropriate for the region and therefore while they should be consider, they should not necessarily be the final determination.	2015	Pohnpei EPA	FAO may in fact be developing something similar and they should be consulted and worked with in this regard	Medium
	Educational materials regarding pesticides are needed for distribution to assist farmers and others with appropriate use of chemicals, but also to better inform the public regarding pesticide use. UH extension has already developed posters for chemical education which could be used once verbiage in local language(s) is add to these posters.	2015	Pohnpei EPA	University of Hawaii	Medium
Improve the management of established invasive species	Conduct surveys to determine the extent of the Tilapia and catfish invasions.	2015	iSTOP	External donor	Medium
	Determine what species/hybrids of Tilapia and catfish are present and extent of the range of each if more than one.	2015	iSTOP	External donor	Medium
	Develop and implement a Tilapia management/eradication plan.	2016	iSTOP	External donor	Medium
	Develop and implement a catfish management/eradication plan.	2016	iSTOP	External donor	Medium
	Train natural resource staffs at the local level in regards to IAS management support.	2015	iSTOP	External donor	Low
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distribution is current. SPC did some of this 2012. Existing survey information needs to be compiled, made available to managers, and updated as needed.	2016	iSTOP	See state ISAP	Low
Awareness					
Increase outreach and education on biosecurity and invasive species	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	iSTOP	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	iSTOP	External donor	High
	Coordinate existing outreach efforts.	2015	iSTOP	External donor	Medium
	Support adding invasive species education as a standard part of school curriculums region wide.	2017	iSTOP/Ministry of Education	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and analysis to assess the role of citizens and visitors in regards to protecting the state from unwanted pests.	2015	iSTOP	External donor	High
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2016	iSTOP/Ministry of Education	External donor	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	on-going	iSTOP	External donor	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	On-going	iSTOP	External donor	Medium
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	iSTOP	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	Pohnpei Invasive Species Coordinator	Regional ISC office	Medium
	Support the development of a regional video to be shown on air flights prior to arrival and at baggage claim areas which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	Pohnpei RISC representatives	RISC	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2015	iSTOP	Regional ISC office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of Micronesia	External donor	Low
Identify knowledge gaps for existing IAS concerns	Expand research capabilities and projects in regards to IAS	2015	College of Micronesia	External donor	Low
	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2015	College of Micronesia	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment F: Yap State Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Yap section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	YIST	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	Yap RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Yap RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including distributing a written report to the region and beyond.	continuous, yearly	State RISC Representatives and ISC	Biosecurity cost recovery system	High
Improve support and functionality of the state invasive species coordination office/position.	This office supports and assists in coordinating efforts with invasive species within the state. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that state governance is regularly updated regarding both state and regional invasive species developments.	on-going	Governor's Office	Biosecurity cost recovery system	High
	This office should serve as the main linkage between the state and the region on invasive species issues, communicating state activities to the region as well as engaging the region and beyond when feasible to support and assist with invasive species efforts within the state.	On-going	Governor's Office	Biosecurity cost recovery system	High
Coordinate with stakeholders both at the national level and with other states to support a united effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	41883	Ministry of R&D	Biosecurity cost recovery system	High
	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	41974	YIST	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Update and regularly maintain the state invasive species action plan and annually report on progress	Update current plan.	2014	YIST	Biosecurity cost recovery system	High
	Establish protocol to revisit and update every 3 to 5 years.	On-going	YIST	Biosecurity cost recovery system	Medium
	Include annual reporting on progress of the state ISAP at the MCES and development a short annual 1-2 pagers to share progress regionally and beyond (combine with similar activities for the RBP).	On-going annually	State RISC Representatives and State ISC	Biosecurity cost recovery system	High
Improve communications and ability to address biosecurity concerns between US DoD and civilian government agencies	Establish an MOU between the state and DoD regarding biosecurity within Yap in regards to DoD activities.	2015	Governor's Office	External donor	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	Yap RISC representatives and the Governor's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	Yap RISC representatives and the Yap ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support state efforts with engaging external resources to support state invasive species efforts.	As soon as the office can be established	Yap RISC representatives and the Yap ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Assistance with protocol and methods development.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Support with establishing ER &RR capacity.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Yap ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Support the development of guidelines and regulations.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Seek and coordinate regional funding.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Yap ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Support management, response, and eradication efforts.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Yap ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.</p>	<p>As soon as the office can be established</p>	<p>Yap RISC representatives and the Yap ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to support outreach and education efforts within the state.	As soon as the office can be established	Yap RISC representatives and the Yap ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve capacity to identify biosecurity intercepts and organisms detected post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity such as SPC) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	Yap Invasive Species Coordinator	Biosecurity cost recovery system	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Yap Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	College of Micronesia	External donor	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of Micronesia	External donor	Low
	Support the development of an algal risk assessment for the region.	2014	Office of the Governor	SPC	High
	Support the development of an arthropod risk assessment for the region.	2015 and on-going	YIST	Regional ISC office	Low
	Request that SPC develop a biosecurity position specifically for supporting the region.	2015 and on-going	YIST	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2016	Yap Invasive Species Coordinator	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2016	Yap Invasive Species Coordinator	External donor	Medium
	Support the development of a weeds risk assessment for the region.	2016	College of Micronesia	External donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Yap RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Yap RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	Yap RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Yap RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Yap RISC representatives	NA	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Yap RISC representatives	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Prevention</i>					
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 support national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	Biosecurity cost recovery system	High
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve border security	Support national government efforts to acquire X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Support national government efforts to ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	Support national government efforts to ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support 100% x-ray of all arriving passenger baggage.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support the development of a canine pest detection program for items such as snakes, fruits, and vegetables. Consider the potential to combine this program with similar programs for detection of illicit materials such as drugs.	2016 hold national consultation on the need for a biosecurity canine program; 2017 establish program if deemed appropriate	Ministry of Resources and Development	Initial support might have to be sought in the form of external donor funding; once the program is established, it should be supportable under an appropriately managed cost recovery system for biosecurity	Low
	Develop specific regulations and enforcement SOPs for imported seeds. All imported and viable seeds should require completed risk assessments and permitting.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support biosecurity cross training of staffs from agencies which are involved in border inspection processes.	implement in 2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Develop appropriate inspection facilities including a biosecure inspection facility at the seaport large enough for sea containers and wash-down areas with appropriate retention and treatment facilities for waste water produced.	2017	Ministry of Resources and Development	External donor	Medium
	Establish a centralized facility for quarantine offices, including quarantine areas (plant and animal and aquatic organisms), treatment areas, laboratory space, offices, and equipment storage.	2017	Ministry of Resources and Development	External donor	Medium
	Ensure that quarantine freezer facilities are restricted used (only quarantine should have access to these) and that they are functional back up power supplies.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that inspectors have access to freezers and incinerators at both air and sea ports for destroying pests and other materials as needed.	2015	Ministry of Resources and Development	Equipment may best come from external donors; Space and maintenance of equipment will need to be under agreements with local port authorities	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection. Mail should be inspected via x-ray and visual inspections (as well as by canine teams if possible) and should be standardized, not only by request from Customs (which is the current procedure).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, etc.).	on-going	Ministry of Resources and Development	SPC	Medium
	Support development of quarantine exchange programs with New Zealand, Australia, and/or U.S. biosecurity agencies as a mechanism for improving inspector capacity and further development of the nation's biosecurity program.	2016	Ministry of Resources and Development	External donor	High
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Develop a lab for quarantine and ensure that appropriate support linkages are in place with USDA, SPC, and others to support pest intercept identification.	2017	Ministry of Resources and Development	External donor	Medium
	Support efforts to ensure that FSM quarantine is appropriate funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts in all 4 states).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Address IAS concerns as they relate to smuggled goods by developing appropriate SOPs, enhancing inspections, instituting fines and other actions such as confiscation and destruction of smuggled goods. Efforts should be both border and pre-border and will need the support of both national and state offices to ensure the best level of protection possible.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Support development of legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2016	Ministry of Resources and Development	SPC, Regional ISC Office	Low
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	SPC, Regional ISC Office	Medium
	Support national efforts to address the lack of marine biosecurity oversight by FSM quarantine. Need to build legislation to support FSM quarantine having marine biosecurity capacity.	should be added to current draft legislation 2014	Ministry of Resources and Development	External donor	High
	support the establishment of national standards for the importation and use of GMO and LMO.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve overall post border biosecurity	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2017	YIST	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve overall post border biosecurity (continued)	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	2017	YIST	External donor	Low
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2016	YIST	External donor	Medium
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the state.	2015	YIST	Biosecurity cost recovery system	Medium
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species	2015	Ministry of Resources and Development	External donor	Medium
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replace of WPM with recycled plastics.	on-going	Ministry of Resources and Development	External donor	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering Yap should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	SPC	Medium
	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Develop and institute standards which would increase pre-departure inspections. Visual inspections are conducted pre-departure which focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture. All jurisdictions should add quarantine inspections to the SOP of departing materials.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Improve biosecurity for intra-state and inter-state away from the main air and seaports	Develop biosecurity standards for ports throughout the state, potentially including having FSM quarantine staff in Woleai, Ulithi, and Satwal.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve biosecurity for intra-state and inter-state away from the main air and seaports (continued)	Implement and enforce biosecurity standards at ports throughout the state.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct an state wide consultation regarding intrastate biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	YIST	Biosecurity cost recovery system	Medium
	Conduct risk assessments for outer islands for terrestrial and aquatic concerns.	commence planning in 2015; risk assessments should be completed by 2018	Yap Agriculture and State Marine Resources office	External donor	Low
	Helicopters and private planes (or small scale commercial ventures) can be used to move passengers and cargo and where they exist or where there are plans for their use, they should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	External donor	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015	Ministry of Health	External donor	Low
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns	Develop a state endorsed white list of species permitted for import.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update white list.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop a state endorsed black list of prohibited species.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update black list.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve national capacity to regulate the importation of live organisms, including ensuring that national capacity supports state concerns (continued)	Support national level efforts to ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts to the state. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list. The state does this now for plant species proposed for import.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Support national government with developing and updating public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via existing FSM government website and linked to state websites.	Implement in 2015; update annually once implemented	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a state/national biosecurity advisory committee to review proposals for the importation of exotic species. There is currently a national risk assessment process but no specific protocol in place.	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery biosecurity system	High
	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	FSM Office of the Attorney General	Biosecurity cost recovery system	High
	Improve capacity and infrastructure regarding animal health. There should be a national veterinarian with support staff (para-vets?) in each state.	2016	Ministry of Resources and Development	Animal health cost recovery system	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop biosecurity standards for small scale, private citizen aquaculture set-ups and enforce these standards.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national government efforts to establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct a national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Develop plan for containment and control measures in regards to exotic farmed and traded species.	2015	YIST	Biosecurity cost recovery system	Medium
	Improve screening and reporting system for lawful export of live organisms.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	Yap Invasive Species Coordinator	External donor	Low
Support the national government efforts with establishing and enforcing biofouling standards	Support establishment of standards and regulations regarding biofouling, including inspection and certification for all vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government efforts with establishing and enforcing biofouling standards (continued)	Support establishment of additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support establishment of additional regulations for impounded vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support development of capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	Ministry of Resources and Development	External donor	High
	Support establishment of regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	Ministry of Resources and Development	External donor	Medium
	Support the establishment of criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support establishment of the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	External donor	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government with establishing and enforcing biofouling standards (continued)	Review and revise (as needed) legal authority to implement a biofouling management program.	2014: this should be included in the current draft biosecurity legislation; May need to update and expand in 2016-17 as elements come online	FSM Office of the Attorney General	Biosecurity cost recovery system	High
	Support ensuring that regulations include the ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	Ministry of Resources and Development		Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	USCG	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
Support the national government with establishing and enforcing ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national level participation and enforcement of globally ballast water requirements including discharge 200nm from shore and inspection of ship logs for compliance.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the national government with establishing and enforcing ballast water standards (continued)	Support of establishment of ballast water management and reporting requirements for all vessels utilizing ballast water.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support development of capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2017	Ministry of Resources and Development	External donor	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support national level adoption of proposed USCG regulations to move to in hull sanitation of ballast water.	2016	Ministry of Resources and Development	USCG	Medium
Increase marine system protection from invasive species	Support the establishment of biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Increase marine system protection from invasive species (continued)	Establish biosecurity practices and requirements for fishing vessels that operate in jurisdictional waters to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Address climate change linkages to invasive pests		Framework should be in place by 2016	YIST	US AID	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address food security for the state in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of Micronesia	FAO	Low
Early detection and rapid response					
Improve early detection and rapid response capacity	Consider linking invasive species ED & RR capacity with the State disaster management office.	2014	YIST	NA	Medium
	State agriculture office should be an active part of the disaster management team.	2014	Yap Agriculture	NA	Medium
	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	YIST	External donor	High
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	YIST	External donor	Medium
	Develop taxa specific ERPs as needed.	On-going	YIST	External donor	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	YIST	Biosecurity cost recovery system	High
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2015	YIST	Biosecurity cost recovery system	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2015	YIST	Biosecurity cost recovery system	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2015	YIST	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	YIST	Regional ISC Office	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	YIST	Regional ISC Office	High
	Hold consultations to determine what agency(s), office(s) and/or groups will be responsible for surveillance programs.	2015	YIST	Biosecurity cost recovery system	Medium
	Develop and institute surveillance programs for non-established species consider high risk of arrival such as CRB, alien snakes, fruit flies, tramp ants, etc.	2015	YIST	Biosecurity cost recovery system	High
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	YIST	Regional ISC Office	Low
	Work with police to develop MOU to assist with enforcing internal quarantine if needed during a response action.	2015	YIST	Biosecurity cost recovery system	Low
Management and eradication					
Increase management and control of established invasive species	Determine which established invasive species are actionable and proceed with developing management strategies.	conduct consultations 2015; develop strategies 2016	YIST	External donor	Medium
	Create GIS layers regarding the distribution of established IAS and use to support biosecurity and IAS management efforts.	2015	College of Micronesia	External donor	Low
	Key staff need to receive GIS training both in regards to field data collection and the utilization of GIS databases and computer systems.	2015	College of Micronesia	External donor	Low
	Key offices need resources to support electronic mapping efforts (GIS), including computers, software, and GPS units.	2015	Yap Agriculture	External donor	Low
	Train natural resource staffs at the local level in regards to IAS management support.	2015	YIST	Regional ISC Office	Low
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	2015	YIST	Regional ISC Office	Low
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2015	Yap Agriculture	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase management and control of established invasive species (continued)	Develop standardized SOPs for IAS monitoring and surveys.	2015	YIST	External donor	Low
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distribution is current.	2015	Yap Agriculture	External donor	Low
	Conduct surveys to determine the extent of the Tilapia invasion.	2015	YIST	External donor	High
	Determine what species/hybrids of Tilapia are present and extent of the range of each if more than one.	2015	YIST	External donor	High
	Re-engage rodent control efforts throughout the state.	2016	Yap Health Office	External donor	Medium
	Develop and implement a Tilapia management/eradication plan (increased awareness in local communities will need to be a significant part of this program).	2016	YIST	External donor	High
	Develop control plan for mile a minute vine (<i>Mikania micrantha</i>).	2015	YIST	External donor	High
	Implement action against mile a minute vine.	2016	YIST	External donor	High
Increase efforts to eradicate targeted species	Conduct surveys and hold stakeholder consultations to determine what established species are viable candidates for eradication efforts.	2015 consultations; 2016 develop strategy; 2017 implement	YIST	External donor	Low
	Develop strategies to conduct eradication campaigns including securing funding streams to support these efforts.	2016	YIST	External donor	Low
	Develop resources to respond to new pest incursions beyond ED & RR, including conducting delimiting surveys and potential eradication efforts.	2016	YIST	External donor	Medium
	Eradicate small and feasible invasive species incursions promptly, while it is most feasible, least expensive, and before extensive damage has occurred.	Develop capacity by 2017; process should be on-going from that point	YIST	External donor	Medium
Increase export potential	Support national efforts to establish produce export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support national efforts to establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Improve capacity to export crops, including betelnut, which will involve finding/establishing markets with trade partners.	2016	Yap Agriculture	SPC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase export potential (continued)	train and certify state agricultural staff to support local farmers with enhancing the potential for export crops.	2016	Yap Agriculture	SPC	Medium
	Support local farms with capacity development to increase potential to export crops.	2016	Yap Agriculture	SPC	Medium
	Ensure that fumigation for export crops is available and appropriate used.	2016	Yap Agriculture	SPC	Medium
	State officials should work with proposed external trade partners to ensure that export crops of interest are permitted for importation (example: betelnut).	2015	Yap Agriculture	SPC	High
	Improve ability to meet import standards imposed by trade partners in regards to agricultural produces and processed foods.	2015	Yap Agriculture	SPC/USDA	High
	Increase protection of export crops from invasive pests by better management of established species and improved border security to reduce the introduction of new pests to the state.	on-going	Yap Agriculture	SPC	High
	Ensure that all proposed agricultural exports go through an establish protocol to ensure cleanliness before entering the shipping lines to reduce the potential for transport of unwanted pests.	2016	Yap Agriculture	SPC	High
Improve usage and better regulation of pesticides used for both agricultural purposes and to treat specific pest infestations (termites, etc.)	Pesticide training courses should be held to provide farmers and others with basis skills in pesticide use. Use of restricted pesticides should be done by licensed applicators only.	2015	Yap Agriculture	External donor	Medium
	Support development of a regional standard in pesticide labelling (US pesticides are already labelled, but those coming from Asia typically are not). US Mainland standards may not be appropriate for the region and therefore while they should be consider, they should not necessarily be the final determination.	2016	Yap Invasive Species Coordinator	FAO may in fact being developing something similar and they should be consulted and worked with in this regard	Medium
	Educational materials regarding pesticides are needed for distribution to assist farmers and others with appropriate use of chemicals, but also to better inform the public regarding pesticide use. UH extension has already developed posters for chemical education which could be used once verbiage in local language(s) is add to these posters.	2016	Yap Agriculture	University of Hawaii	Low
Increase alien snake detection capacity	FSM quarantine officers and state counterparts should be trained in alien snake inspection SOPs, detection and response.	2015	Ministry of Resources and Development	Regional ISC Office	High
	Install a snake proof fence at main seaport.	2016	Port Authority	External donor	Low
	Institute snake sentinel trapping at main ports.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Awareness</i>					
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and state wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	YIST	External donor	High
	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the state from unwanted pests.	2015	YIST	External donor	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	YIST	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	YIST	External donor	High
	Coordinate existing outreach efforts.	2015	YIST	External donor	Medium
	Support adding invasive species education as a standard part of school curriculums region wide.	2017	YIST/Ministry of Education	External donor	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2016	YIST/Ministry of Education	External donor	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	on-going	YIST	External donor	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	On-going	YIST	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	Yap Invasive Species Coordinator	Regional ISC office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	YIST	External donor	Medium
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	Yap RISC representatives	RISC	Medium
	Develop a wildlife reference collection (i.e., taxidermy mounts, computer photo files, etc.) to aid identification of incoming species. Adequate resources (taxonomic keys, microscopes, etc.) should be available for assistance in taxonomic identifications.	2016	Yap Agriculture	External donor	Low
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials in Yap, including the potential loss of business if invasive species are permitted to establish.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2015	YIST	Regional ISC office	Medium
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of Micronesia	External donor	Low
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2015	College of Micronesia	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Restoration</i>					
Increase restoration efforts of native systems where IAS management and/or eradication efforts are underway or have been successful.	Implement investigations into firefly and dragonfly declines (may be associated with IAS).	2015	Yap Agriculture	External donor	Low
	Improve documentation of native species declines.	2015	Yap Agriculture	External donor	Low
	Investigate primary causes of mangrove die offs which reported have been extended by wind damage.	2015	Yap Agriculture	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment G: Federated States of Micronesia National Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the FSM section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	FSM RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	FSM RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report shared with the region and beyond.	continuous, yearly	RISC Representatives and National ISC	Biosecurity cost recovery system	Medium
Establish a national invasive species coordination office that is tasked with supporting nation wide IAS efforts across agencies and offices as well as working regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the national invasive species coordination position.	2015	Ministry of Resources and Development	This should be part of the cost recovery biosecurity system	Medium
	Once established this office should support and assist in coordinating efforts with invasive species within the nation. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that the heads of government are regularly updated regarding both national and regional invasive species developments.	2015	Ministry of Resources and Development	This should be part of the cost recovery biosecurity system	Medium
	Once established this office should serve as the main linkage between the nation and the region on invasive species issues, communicating national activities to the region as well as engaging the region and beyond when feasible to support and assist with invasive species efforts within the nation.	2015	Ministry of Resources and Development	This should be part of the cost recovery biosecurity system	Medium
Coordinate with stakeholders both national and state levels to support a united effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of R&D	NA	High
	Add GMO and LMO coverage to the draft bill.	Complete by August 2014	Ministry of R&D	NA	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	Complete by September 2014	Ministry of R&D	NA	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Coordinate with stakeholders both national and state levels to support a united effort towards moving draft biosecurity legislation forward (continued)	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	Complete by December 2014	FSM ISC	NA	High
Improve communication and information sharing in regards to IAS and biosecurity	Develop SOPs at the national level to facilitate communication and information sharing between offices and agencies at both national and state levels in regards to invasive species and biosecurity.	2015	FSM ISC	Biosecurity cost recovery system	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	FSM RISC representatives and President's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	FSM RISC representatives and the FSM ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.	As soon as the office can be established	FSM RISC representatives and the FSM ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support capacity building, training, and advice.	As soon as the office can be established	FSM RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office with supporting protocol and methods development.</p>	<p>As soon as the office can be established</p>	<p>FSM RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting establishing ER & RR capacity.</p>	<p>As soon as the office can be established</p>	<p>FSM RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>FSM RISC representatives and the FSM ISC</p>	<p>initial support might come from the US and the region. 	<p>Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.</p>	<p>As soon as the office can be established</p>	<p>FSM RISC representatives and the Ministry of Resources and Development</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.</p>	<p>As soon as the office can be established</p>	<p>FSM RISC representatives and the FSM ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued)	Engage the regional invasive species coordination office to support management, response, and eradication efforts.	As soon as the office can be established	FSM RISC representatives and the FSM ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	As soon as the office can be established	FSM RISC representatives and the FSM ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts.	As soon as the office can be established	FSM RISC representatives and the FSM ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve capacity to identify biosecurity intercepts and organisms detected post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity such as SPC) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	FSM Invasive Species Coordinator	Biosecurity cost recovery system	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	FSM Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going, finalize by 2018	College of Micronesia	External donor	Low
	Support the development of an algal risk assessment for the region.	2016	College of Micronesia	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of Micronesia	External donor	Low
	Support the development of an arthropod risk assessment for the region.	2016	College of Micronesia	External donor	Medium
	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	FSM Office of Foreign Affairs	SPC	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	FSM ISC	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going		Regional ISC office	Low
	Support the development of a weeds risk assessment for the region.	2016	College of Micronesia	External donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	FSM RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	FSM RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	FSM RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	FSM RISC representatives	RISC	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve the functionality of RISC	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	FSM RISC representatives	NA	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	FSM RISC representatives	External donor	Medium
Prevention					
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 Hold national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	External donor	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	Biosecurity cost recovery system	High
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security	Acquire and install X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	Ministry of Resources and Development	External donor	High
	ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Institute 100% x-raying of all arriving passenger baggage.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Consider developing SOPs for incoming baggage and cargo inspections which are based on successful models (such as New Zealand); would require hiring and training additional personnel, installing appropriate equipment (X-ray, etc.), training additional canine teams for detection of specific high risk IAS (reptiles, fruits, meats, etc.); insuring appropriate data collection and development and maintaining of databases to track efforts and interceptions.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that inspections process while targeting high risk goods also ensure random sampling of all imports, travelers, and baggage in order to better detect hitchhiker pests.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	An area not well covered by biosecurity currently is the use of the internet for trade. Regulated and prohibited goods arrive in the region via the mail pathway with bogus labelling from people buying on the internet. A plan will be needed to address this pathway. Of significant concern in this regard is the potential for shipping of pets such as reptiles and plant material via the mail system with little ability to detect and intercept these organisms by current biosecurity systems within the region. Trained detector dogs, visual inspections and X-ray machines could all be utilized to reduce the potential for illicit mail trade, but appropriate regulations need to be established which would permit the potential inspection of most if not all arriving mail.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Ensure that restrictions on soil importation are backed up with regulations supported by legislation.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Establish a canine pest detection program for items such as snakes, fruits, and vegetables. Consider the potential to combine this program with similar programs for detection of illicit materials such as drugs.	2016 hold national consultation on the need for a biosecurity canine program; 2017 establish program if deemed appropriate	Ministry of Resources and Development	Initial support might have to be sought in the form of external donor funding; once the program is established, it should be supportable under an appropriately managed cost recovery system for biosecurity	Low
	All imported animal products, including food items should be check for compliance with international standards (or national standards if they exist). Standards should be enforced equally and items found to be non-compliant should be either turn away or destroyed.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Implement advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, identification of livestock, wildlife and poultry diseases and pests, etc.).	on-going	Ministry of Resources and Development	SPC	Medium
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Ensure that restrictions on soil importation are applied to all soils, including bags of soil and other similar items which can also harbor live organisms. If pre-bagged soil and soil like materials are going to be imported, then they should be pre-treated to insure that they are sterile on arrival.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	External donor	Low
	ensure that the national quarantine office is appropriate funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts nation wide).	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Hire and train additional quarantine staff as needed. Should be based on needs assessment. An inspections database should be able to document existing needs.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Develop legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Protocols need to be established regarding quarantine inspection of arriving vessels: manifest should be check, cargo, ships stores, galleys, garbage, and cabins should all be inspected. Distinct SOPs are most likely needed for a variety of vessel types including aircraft, fishing vessels, support ships, cargo ships, tankers, yachts, barges. Non-compliance with regulations should be noted and appropriate follow-up actions should be taken including fines, confiscations, and turning away cargo and possibly entire vessels if needed. Inspection data should be collected and recorded into a system wide database.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Establish an electronic database for quarantine inspection data that can be searched and data extracted for analysis. Such a database would support better targeting of vectors and pathways, permit tracking of known violators, provide documentation regarding interceptions, fee and penalty payments, demonstrate appropriate use of resources, quantify gaps and needs in current system, assist in determining pathways associated with post border detections, tracking of live imported species and number of individuals, tracking changes in vector arrivals and embarkation locations, etc.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Training quarantine staff in data collection, entry, management and analysis, develop appropriate field inspection forms, conduct quality control of data systems, ensure that field data is entered into system in a scheduled manner to prevent backlogging, ensure that the data system is appropriately and regularly backed up to prevent systematic losses.	2015	Ministry of Resources and Development	SPC	High
	Protocols should be established by quarantine for documenting interceptions and final disposition of materials. These reports should be entered into a database and information should be shareable to assist all locations within the FSM to better protect borders but also with other jurisdictions of the region to better protect the region. Protocols should be established regarding how and when (how often) this type of	2015	Ministry of Resources and Development	should be covered by the cost recovery system	High
	Institute quarterly reporting on quarantine inspections based on database information and ensure that reports are appropriate shared.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop regulations regarding garbage as it pertains to arriving vessels. Regulations need to be enforce and systems need to be developed and in place to deal with regulated garbage. Protocols for regulated garbage should include specifics on handling, where it will be take, how it will be transported, and how it will be handled once it has arrived at final location (burned?, buried? Or treated?). Regulated garbage because of its potential of harboring IAS needs to be kept separate from other trash and needs to be sterilized in some fashion.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Develop and institute quarantine exchange programs with New Zealand, Australia, and/or U.S. biosecurity agencies as a mechanism for improving inspector capacity and further development of the nation's biosecurity program.	2016	Ministry of Resources and Development	External donor	High
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	SPC, Regional ISC Office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Address the lack of marine biosecurity oversight. Need to build legislation to support national quarantine having marine biosecurity capacity.	should be added to current draft legislation 2014	Ministry of Resources and Development	External donor	High
	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations. Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2016	Ministry of Resources and Development	SPC, Regional ISC Office	Low
	Establish national standards for the importation and use of GMO and LMO. GMOs and LMOs should be labelled as such.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Low
	Conduct a national review of GMOs and LMOs regarding if and how they may be covered by intellectual property rights.	2014	Ministry of Resources and Development	External donor	Low
	Develop MOU's between the national quarantine office and other agencies involved in border inspections (such as customs) so that these offices/agencies can support the quarantine office with biosecurity aspects.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop SOPs regarding specifics of how other agencies and offices can support the role of the national quarantine office during border inspection process.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Institute biosecurity cross training of staffs from agencies which are involved in border inspection processes.	2015	Ministry of Resources and Development	Regional ISC office	Low
	Review official ports of entry for the nation to better determine if and how biosecurity aspects can be expanded to include additional ports.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Review field ship ports of call and develop biosecurity standards for field ships and other conveyances that operate within the nation or internationally.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Develop regulations regarding biosecurity and visiting cruise ships. These ships, if visiting multiple sites within the nation should fund having a biosecurity office on board during the period that they within national waters, provide for inspection services at all ports of call, cover all travel expenses for the biosecurity officer, and coordinate with the national quarantine office to ensure that the inspector's home port does not experience a drop in quarantine services during their absence (this may include paying for overtime).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	Ministry of Resources and Development	External donor	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering the FSM should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
Improve ability to better enforce pre-departure sanitation	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	SPC	Medium
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Ministry of Resources and Development	should be covered by the cost recovery system	Medium
	Develop and institute standards which would increase pre-departure inspections. Visual inspections are conducted pre-departure which focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture. All jurisdictions should add quarantine inspections to the SOP of departing materials.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Low
Address the fact that humans can serve as vectors of invasive species	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address the fact that humans can serve as vectors of invasive species (continued)	National health authorities should work with CDC to determine what, if any, role DoD can support in the advent of a human pathogen outbreak. For example, could CDC direct DoD to transport sick patients to appropriate support facilities either within or outside of the national in the case of a human pathogenic outbreak?	2015	Ministry of Health	External donor	Low
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015: Develop agreements with shippers for medical services (consider working with airlines and/or DoD)	Ministry of Health	External donor	Medium
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update white list on a regular basis.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop a government endorsed black list of prohibited species.	2014	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Update black list on a regular basis.	annually	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	Implement in 2015; update annually once implemented	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a national biosecurity advisory committee to review proposals for the importation of exotic species.	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery biosecurity system	High
	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	FSM Office of the Attorney General	External donor	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Ministry of Resources and Development	External donor	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Improve capacity and infrastructure regarding animal health. There should be a national veterinarian with support staff (para-vets?) in each state.	2016	Ministry of Resources and Development	Develop a cost recovery system that supports national animal health services	Medium
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct an national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	FSM ISC	External donor	Low
Increase export potential	Establish produce export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Establish and enforce biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish standards and regulations regarding biofouling, including inspection and certification for all vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establish additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish additional regulations for impounded vessels.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	Ministry of Resources and Development	External donor	High
	Establish regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	External donor	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	External donor	High
	Ensure that regulations include ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a biofouling management program	2014: this should be included in the current draft biosecurity legislation; May need to update and expand in 2016-17 as elements come on line	FSM Office of the Attorney General	Biosecurity cost recovery system	High
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase marine system protection from invasive species	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for fishing vessels that operate in Micronesia to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
Establish and enforce ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Adopt and enforce international ballast water regulations (discharge at least 200nm off shore). Inspection of ship logs for compliance.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Establish ballast water management and reporting requirements for all vessels utilizing ballast water.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2017	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support national level adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	Ministry of Resources and Development	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	NA	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	USCG	Medium
Address climate change linkages to invasive pests		Framework should be in place by 2016	FSM ISC	US AID	Medium
Address food security for the nation in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of Micronesia	FAO	Low
Awareness					
Increase outreach and education on biosecurity and invasive species	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the nation from unwanted pests.	2015	FSM ISC	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	FSM ISC	External donor	High
	Coordinate existing outreach efforts.	2015	FSM ISC	External donor	Medium
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	FSM ISC	External donor	High
	Add invasive species education as a standard part of school curriculums.	2016	FSM ISC/Ministry of Education	External donor	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2015	FSM ISC/Ministry of Education	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Develop an educational strategy that is long term, extensive and nation wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	FSM ISC	External donor	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	2016	FSM ISC	External donor	Low
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts	on-going	FSM ISC	External donor	Low
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	FSM ISC	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	FSM ISC	Regional ISC office	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2014	FSM ISC	External donor	Medium
	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	FSM ISC	RISC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish.	Start in 2014	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
<i>Research</i>					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of Micronesia	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment H: Republic of the Marshall Islands Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the RMI section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	MIIST	Biosecurity cost recovery program should fund this activity	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	MIIST	Regional ISC office	Medium
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	MIIST	Regional ISC office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCEES, including a written report shared with the region and beyond.	continuous, yearly	RISC Representatives and National ISC	NA	High
Establish a jurisdictional invasive species coordination office that is tasked with supporting nation wide IAS efforts across agencies and offices as well as working regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the invasive species coordination position.	2015	MIIST	This should be a long term position with funding and other resources coming from the port biosecurity cost recovery program	High
	Once established this office should support and assist in coordinating efforts with invasive species within the nation. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that the heads of government are regularly updated regarding both national and regional invasive species developments.	continuous	RMI Invasive Species Coordinator	This should be a long term position with funding and other resources coming from the port biosecurity cost recovery program	High
	Once established this office should serve as the main linkage between the nation and the region on invasive species issues, communicating national activities to the region as well as engaging the region and beyond when feasible to support and assist with invasive species efforts within the nation.	continuous	RMI Invasive Species Coordinator	This should be a long term position with funding and other resources coming from the port biosecurity cost recovery program	High
Coordinate with stakeholders to provide a united and active effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by August 2014	Ministry of Resources and Development	NA	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Coordinate with stakeholders to provide a united and active effort towards moving draft biosecurity legislation forward (continued)	Add GMO and LMO coverage to the draft bill.	Complete by August 2014	Ministry of Resources and Development	NA	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	2014	Ministry of Resources and Development	NA	High
	Ensure that supporters of the bill are advocating for it with the legislature and president's office on a regular basis with the expectation that it will be passed before the end of the calendar year.	2014	MIIST	NA	High
Update and regularly maintain the national invasive species action plan (ISAP) and annually report on progress	Update current plan.	in progress completed July 2013	Office of Environmental Planning and Policy Coordination	External donor	High
	Establish protocol to revisit and update every 3 to 5 years.	On-going	MIIST	NA	High
	Include annual reporting on progress of the national ISAP at the MCES and development a short annual 1-2 pagers to share progress regionally and beyond (combine with similar activities for the RBP).	On-going annually	RISC Representatives and RMI ISC	NA	High
Improve communications and ability to address biosecurity concerns between US DoD and the RMI civilian government agencies	Establish an MOU between the RMI and DoD regarding biosecurity within the RMI in regards to DoD activities and facilities.	2015	Ministry of Foreign Affairs	NA	High
Improve communication and information sharing in regards to IAS and biosecurity	Develop SOPs at the national level to facilitate communication and information sharing between offices and agencies in regards to invasive species and biosecurity.	2015	MIIST	RMI Biosecurity Cost Recovery system	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	RMI RISC representatives and President's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	RMI RISC representatives and the RMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.	As soon as the office can be established	RMI RISC representatives and MIIST	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support capacity building, training, and advice.	As soon as the office can be established	RMI RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office with supporting protocol and methods development.	As soon as the office can be established	RMI RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office with supporting establishing ER & RR capacity.	As soon as the office can be established	RMI RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.	As soon as the office can be established	RMI RISC representatives and the RMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.	As soon as the office can be established	RMI RISC representatives and the Ministry of Resources and Development	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.	As soon as the office can be established	RMI RISC representatives and the RMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support management, response, and eradication efforts.	As soon as the office can be established	RMI RISC representatives and the RMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	As soon as the office can be established	RMI RISC representatives and the RMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts.	As soon as the office can be established	RMI RISC representatives and MIIST	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve capacity to identify biosecurity intercepts and organisms detection post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity such as SPC) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	RMI Invasive Species Coordinator	Biosecurity cost recovery system	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	RMI Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going	College of the Marshall Islands	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of the Marshall Islands	External donor	Low
	Support the development of an algal risk assessment for the region.	2016	College of the Marshall Islands	External donor	Medium
	Support the development of an arthropod risk assessment for the region.	2016	College of the Marshall Islands	External donor	Medium
	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	Office of Environmental Planning and Policy Coordination	SPC	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	Office of Environmental Planning and Policy Coordination	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Office of Environmental Planning and Policy Coordination	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region.	2016	College of the Marshall Islands	External donor	Medium
Improve the functionality of RISC	RISC members should work with national governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	RMI RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the invasive species community and governance.	Reviews should correspond with turn over in Government	RMI RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	RMI RISC representatives	RISC	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve the functionality of RISC (continued)	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	RMI RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	on-going	RMI RISC representatives	NA	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	RMI RISC representatives	External donor	Medium
Prevention					
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 Hold national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve pre-border sanitation efforts (continued)	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
Improve border security	Acquire and install X-ray machines for biosecurity at all ports of entry.	2015	Ministry of Resources and Development	External donor	Medium
	ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2015	Ministry of Resources and Development	External donor	Medium
	ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2015	Ministry of Resources and Development	External donor	Medium
	Institute 100% x-raying of all arriving passenger baggage.	2015	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	Medium
	Consider developing SOPs for incoming baggage and cargo inspections which are based on successful models (such as New Zealand); would require hiring and training additional personnel, installing appropriate equipment (X-ray, etc.), training additional canine teams for detection of specific high risk IAS (reptiles, fruits, meats, etc.); insuring appropriate data collection and development and maintaining of databases to track efforts and interceptions.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	Medium
	Ensure that inspections process while targeting high risk goods also ensure random sampling of all imports, travelers, and baggage in order to better detect hitchhiker pests.	2015	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	Medium
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	Medium
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Ministry of Resources and Development	External donor	Low
	Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	An area not well covered by biosecurity currently is the use of the internet for trade. Regulated and prohibited goods arrive in the region via the mail pathway with bogus labelling from people buying on the internet. A plan will be needed to address this pathway. Of significant concern in this regard is the potential for shipping of pets such as reptiles and plant material via the mail system with little ability to detect and intercept these organisms by current biosecurity systems within the region. Trained detector dogs, visual inspections and X-ray machines could all be utilized to reduce the potential for illicit mail trade, but appropriate regulations need to be established which would permit the potential inspection of most if not all arriving mail.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	Medium
	All imported animal products, including food items should be check for compliance with international standards (or national standards if they exist). Standards should be enforced equally and items found to be non-compliant should be either turn away or destroyed.	2015	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	Medium
	Implement advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, identification of livestock, wildlife and poultry diseases and pests, etc.).	on-going	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	Medium
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	Review relevant APHIS guidelines 2014; Develop and implement RMI guidelines 2015	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity; technical support from the Regional ISC Office and SPC	Medium
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should including materials previously treated or cleaned (due to the potential for recontamination after treatment).	Immediate	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2015	Ministry of Resources and Development	External donor	Medium
	ensure that the national quarantine office is appropriately funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts nation wide).	Conduct a national review in 2015; move forward with planning and development of cost recovery system in 2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	High
	Hire and train additional quarantine staff as needed. Should be based on needs assessment. An inspections database should be able to document existing needs.	Conduct needs assessment 2014; Hire and train additional staff in 2015 as indicated by the needs assessment	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	High
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	on-going	Ministry of Resources and Development	External donor	Low
	Protocols need to be established regarding quarantine inspection of arriving vessels: manifest should be checked, cargo, ships stores, galleys, garbage, and cabins should all be inspected. Distinct SOPs are most likely needed for a variety of vessel types including aircraft, fishing vessels, support ships, cargo ships, tankers, yachts, barges. Non-compliance with regulations should be noted and appropriate follow-up actions should be taken including fines, confiscations, and turning away cargo and possibly entire vessels if needed. Inspection data should be collected and recorded into a system wide database.	Draft protocols 2014; review and finalize before end of 2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Establish an electronic database for quarantine inspection data that can be searched and data extracted for analysis. Such a database would support better targeting of vectors and pathways, permit tracking of known violators, provide documentation regarding interceptions, fee and penalty payments, demonstrate appropriate use of resources, quantify gaps and needs in current system, assist in determining pathways associated with post border detections, tracking of live imported species and number of individuals, tracking changes in vector arrivals and embarkation locations, etc.	Consultation on this topic should occur no later than early 2015; design and development should begin before the end of 2015; Database should be in place and staff trained in its use and up keep before the end of 2016	Ministry of Resources and Development	External donor	High
	Training quarantine staff in data collection, entry, management and analysis, develop appropriate field inspection forms, conduct quality control of data systems, ensure that field data is entered into system in a scheduled manner to prevent backlogging, ensure that the data system is appropriately and regularly backed up to prevent systematic losses.	Should be developed in tandem with the biosecurity database	Ministry of Resources and Development	External donor	High
	Protocols should be established by quarantine for documenting interceptions and final disposition of materials. These reports should be entered into a database and information should be shareable to assist all locations within the RMI to better protect borders but also with other jurisdictions of the region to better protect the region. Protocols should be established regarding how and when (how often) this type of information is shared. Information collected and stored should include date of incident, inspector in charge, what was intercepted, what IAS were found, numbers of pests found, origin of the material in question, disposition of the material(s) and specimen(s), what remedial actions (if any) were taken against the shipper, and if fines were instituted, were they collected.	Should be developed in tandem with the biosecurity database	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	High
	Establish of national standards for the importation and use of GMO and LMO. GMOs and LMOs should be labelled as such.	2015	Ministry of Resources and Development	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Institute quarterly reporting on quarantine inspections based on database information and ensure that reports are appropriately shared.	Reports should be forthcoming before the end of 2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.	Review USDA user fee structure 2014; On passage of the RMI biosecurity legislation (2014), specific regulations regarding fees should follow	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	High
	Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.	Consult with the region 2014; Develop and implement fee 2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Develop regulations regarding garbage as it pertains to arriving vessels. Regulations need to be enforce and systems need to be developed and in place to deal with regulated garbage. Protocols for regulated garbage should include specifics on handling, where it will be take, how it will be transported, and how it will be handled once it has arrived at final location (burned?, buried? Or treated?). Regulated garbage because of its potential of harboring IAS needs to be kept separate from other trash and needs to be sterilized in some fashion.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system would ideally cover the costs of these needs. Until this system is functional, other funding sources may be required to fill the funding gap	Medium
	Develop and institute quarantine exchange programs with New Zealand, Australia, and/or U.S. biosecurity agencies as a mechanism for improving inspector capacity and further development of the nation's biosecurity program.	2015	Ministry of Resources and Development	External donor	Low
	Institute biosecurity cross training of staffs from agencies which are involved in border inspection processes.	2015	Ministry of Resources and Development	SPC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Address the lack of marine biosecurity oversight. Need to build legislation to support national quarantine having marine biosecurity capacity.	2014 should be added to the current draft biosecurity legislation under consideration	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Security protocols for ports should be established, enforced and applied equally to all. For example having a badge system with gated entry to all ports should be established and appropriately utilized.	2014	Port Authorities	RMI Biosecurity Cost Recovery system	High
	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations. Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2014	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Conduct a national review of GMOs and LMOs regarding if and how they may be covered by intellectual property rights.	2014	Ministry of Resources and Development	External donor	Medium
	Develop MOU's between the national quarantine office and other agencies involved in border inspections (such as customs) so that these offices/agencies can support the quarantine office with biosecurity aspects.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop SOPs regarding specifics of how other agencies and offices can support the role of the national quarantine office during border inspection process.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Establish a centralized joint facility for customs and quarantine offices, including quarantine areas, treatment areas, laboratory space, offices, and equipment storage.	Further develop planning and coordination for this effort in 2015; develop facilities in 2016-17	Ministry of Resources and Development	External donor	Medium
	Enforce biosecurity regulations, including the collection of fines and fees.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	High
	Develop a mechanism so that fines, fees and other monies are placed into a revolving fund that is used specifically to support biosecurity activities.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Establish a taskforce amongst RMI offices involved in border protection. This taskforce could coordinate activities and develop options for improving overall border protection including determining where offices can assist each other with joint tasks. Currently, all RMI border offices seem to have similar problems (lack of funding, staff, capacity, and resources). A joint taskforce could establish more clearly what needs to be done to improve the situation across the board, how the RMI could best address these issues and then find funding to support efforts to move forward with development, training, and implementation. Generally RMI offices need improved resource availability, increased staffing, and increased training.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop a system in which arriving sea vessels submit pre-clearance biosecurity information and wait to receive approval prior to entering lagoons or be turned away. Such information	2016	Ministry of Resources and Development	External donor	Medium
	Review official ports of entry for the nation to better determine if and how biosecurity aspects can be expanded to include additional ports.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop national biosecurity standards. For example, quarantine inspectors must be present to clear arriving containers.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	High
	Review field ship ports of call and develop biosecurity standards for field ships and other conveyances that operate within the nation or internationally.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2014	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop regulations regarding biosecurity and visiting cruise ships. These ships, if visiting multiple sites within the nation should fund having a biosecurity office on board during the period that they within national waters, provide for inspection services at all ports of call, cover all travel expenses for the biosecurity officer, and coordinate with the national quarantine office to ensure that the inspector's home port does not experience a drop in quarantine services during their absence (this may including paying for overtime).	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
Improve overall post border biosecurity	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	on-going	MIIST	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve overall post border biosecurity (continued)	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2016	Office of Environmental Planning and Policy Coordination	External donor	Medium
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	Office of Environmental Planning and Policy Coordination	External donor	Medium
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the nation: develop guidelines and implement policy including inspections and follow-up as required.	2014	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop a local depository for pest information including an intercept reference collection.	Set up depository by 2016; continuously update once established	College of the Marshall Islands	External donor	Low
	Support development of a regional depository for pest information.	2017	RMI Invasive Species Coordinator	External donor	Low
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	MIIST	External donor	Medium
	Require treatment of all WPM according to ISPM No. 15. All WPM entering the RMI or moving between islands within the RMI should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of wood packaging material (WPM) (continued)	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
Improve ability to better enforce pre-departure sanitation	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Ministry of Resources and Development	SPC	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop and institute standards which would increase pre-departure inspections. Visual inspections are conducted pre-departure which focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture. All jurisdictions should add quarantine inspections to the SOP of departing materials.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
Improve capacity for internal biosecurity	Develop biosecurity standards for ports other than those at Majuro Atoll and Kwajalein Atoll.	2016	Ministry of Resources and Development	External donor	Medium
	Implement and enforce biosecurity at ports other than those at Majuro and Kwajalein Atolls.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Conduct a nation wide consultation regarding internal biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	Ministry of Resources and Development	External donor	High
	Conduct risk assessments for outer islands for terrestrial and aquatic concerns.	this should be an on-going process	Office of Environmental Planning and Policy Coordination	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve capacity for internal biosecurity (continued)	Helicopters and private planes (or small scale commercial ventures) can be used to move passengers and cargo and where they exist or where there are plans for their use, they should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import.	2014	MIIST	Biosecurity cost recovery system	High
	Update white list.	annually	MIIST	Biosecurity cost recovery system	Medium
	Develop a government endorsed black list of prohibited species.	2014	MIIST	Biosecurity cost recovery system	High
	Update black list.	annually	MIIST	Biosecurity cost recovery system	Medium
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	Ministry of Resources and Development oversees risk assessment process and determines if it is sufficient and rules on outcome	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	Implement in 2015; update annually once implemented	MIIST	Biosecurity cost recovery system	Low
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a national biosecurity advisory committee to review proposals for the importation of exotic species.	2015	Ministry of Resources and Development	This should be supported by user fees as part of the cost recovery biosecurity system	High
	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Ministry of Resources and Development	External donor	Medium
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	RMI Office of the Attorney General	External donor	High
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	Office of Environmental Planning and Policy Coordination	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Office of Environmental Planning and Policy Coordination	External donor	Medium
	Improve capacity and infrastructure regarding animal health, including development of quarantine/holding facilities and hiring of a national veterinarian.	2016	Ministry of Resources and Development	External donor	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Establish a certification system for the movement (domestic and international) of live organisms.	2015 conduct a national consultation; 2016 develop draft system; 2017 implement system nation wide	Ministry of Resources and Development	Biosecurity cost recovery system	Medium
	Develop biosecurity standards for small scale, private citizen aquaculture set-ups and enforce these standards.	2015		Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Ministry of Resources and Development	Biosecurity cost recovery system	High
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	RMI Invasive Species Coordinator	External donor	Low
Establish and enforce biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Ministry of Resources and Development	External donor	Medium
	Establish standards and regulations regarding biofouling, including inspection and certification for all vessels.	2017	Ministry of Resources and Development	External donor	High
	Establish additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	Ministry of Resources and Development	External donor	Medium
	Establish additional regulations for impounded vessels.	2017	Ministry of Resources and Development	External donor	Medium
	Develop capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Establish regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	Ministry of Resources and Development	External donor	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Ministry of Resources and Development	External donor	Medium
	Establish the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Establishment biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	External donor	Medium
	Review and revise (as needed) legal authority to implement a biofouling management program	2014: this should be included in the current draft biosecurity legislation; May need to update and expand in 2016-17 as elements come on line	RMI Office of the Attorney General	External donor	High
	Ensure that regulations include ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	Ministry of Resources and Development	External donor	Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	External donor	Medium
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Ministry of Resources and Development	Technical support: USCG	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Ministry of Resources and Development	Technical support: USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	Technical support: USCG	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Develop capacity to deal with grounded and/or abandoned vessels (continued)	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Ministry of Resources and Development	Technical support: USCG	Medium
Establish and enforce ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Ministry of Resources and Development	External donor	Medium
	Adopt and enforce international ballast water regulations (discharge at least 200nm off shore). Inspection of ship logs for compliance.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Establish ballast water management and reporting requirements for all vessels utilizing ballast water.	2015	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	High
	Support national level adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	Ministry of Resources and Development	External donor	Medium
Increase marine system protection from invasive species	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase marine system protection from invasive species (continued)	Establish biosecurity practices and requirements for fishing vessels that operate in Micronesia to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2017	Ministry of Resources and Development	RMI Biosecurity Cost Recovery system	Medium
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	External donor	Medium
	National health authorities should work with CDC to determine what, if any, role DoD can support in the advent of a human pathogen outbreak. For example, could CDC direct DoD to transport sick patients to appropriate support facilities either within or outside of the national in the case of a human pathogenic outbreak?	2015	Ministry of Health	NA	Low
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved (i.e. donors need to be have dependable and rapid shipping available for medical supplies, etc. if such a situation was to arise).	2015: Develop agreements with shippers for medical services (consider working with airlines and/or DoD)	Ministry of Health	Emergency response	Medium
Address climate change linkages to invasive pests		2015 develop framework	Office of Environmental Planning and Policy Coordination	US AID	Medium
Address food security for the nation in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	College of the Marshall Islands	FAO	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Early detection and rapid response</i>					
Improve early detection and rapid response capacity	Establish a watch list of high-risk non-native species that are known or thought to pose significant ecological, economic, social, or cultural impacts	2015	MIIST	External donor	Medium
	Develop a detection program and response plan for new incursions by a few focal non-native species on the watch list of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	MIIST	External donor	Medium
	Develop taxa specific ERPs as needed.	on-going	MIIST	RMI Biosecurity Cost Recovery system	High
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	MIIST	RMI Biosecurity Cost Recovery system	High
	Develop a generic national emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	MIIST	External donor	High
	Establish a watch list of high-risk non-native species that are known or thought to pose significant ecological, economic, social, or cultural impacts.	2015	MIIST	External donor	Medium
	Develop a detection program and response plan for new incursions by a few focal non-native species on the watch list of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	MIIST	External donor	Medium
	Develop taxa specific ERPs as needed.	on-going	MIIST	RMI Biosecurity Cost Recovery system	High
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	MIIST	RMI Biosecurity Cost Recovery system	High
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2015	MIIST	RMI Biosecurity Cost Recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Ensure that the public reporting system is fully functional including supported by trained staff.	2015	MIIST	RMI Biosecurity Cost Recovery system	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	this should be an on-going process	MIIST	RMI Biosecurity Cost Recovery system	High
	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	MIIST	RMI Biosecurity Cost Recovery system	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	MIIST	Regional ISC office	High
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	this should be an on-going process	MIIST	External donor	Low
Management and eradication					
Increase management and control of established invasive species	Create GIS layers that delineate management zones, land tenure, and current distribution of established IAS and use to support biosecurity and IAS management efforts.	2015	College of the Marshall Islands	External donor	Low
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	on-going, start in 2015	RMI Invasive Species Coordinator	SPC, regional ISC office	Low
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2016	College of the Marshall Islands	SPC	Low
	Develop standardized SOPs for IAS monitoring and surveys.	2015	MIIST	External donor	Medium
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distributions are current.	on-going	MIIST	External donor	Medium
	Determine if the explosive algal growth seen on the ocean side of some areas of Majuro Atoll is due to an invasive species or a native species experiencing release. Once the species and its context is known, develop a control/management program to get it under control or possibly eradicate if it is in fact invasive.	2014	College of the Marshall Islands	External donor	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase management and control of established invasive species (continued)	Work with stakeholders and experts on a long term rodent management and control program for the country. Consider contracting outside experts (if needed) to assist with both the program development and implementation of specific aspects of the program as warranted. Specific components of the rodent control program should include: enforcement of the use of rat excluders on all mooring lines when vessels are docked, developing monitoring strategies, implement trapping strategies to reduce current rodent densities, and to ensure that port areas are clean and waste free.	Hold national consultancy (consider including outside experts) 2015; Develop planning 2016; implement program 2017	Ministry of Health/MIIST	External donor	Medium
	Determine which established invasive species are actionable and proceed with developing management strategies	Hold national consultancy 2016; Select actionable elements and develop management strategies 2017; implement 2018	MIIST	External donor	Medium
	Train natural resource staffs at the local level in regards to IAS management support.	on-going, start in 2015	Office of Environmental Planning and Policy Coordination	SPC, regional ISC office	Low
Increase efforts to eradicate targeted species	Conduct surveys and hold stakeholder consultations to determine what established species are viable candidates for eradication efforts.	2016	Office of Environmental Planning and Policy Coordination	External donor	Medium
	Develop strategies to conduct eradication campaigns including securing funding streams to support these efforts.	2016	Office of Environmental Planning and Policy Coordination	External donor	Medium
	Develop resources to respond to new pest incursions beyond ED & RR, including conducting delimiting surveys and potential eradication efforts.	2016	Office of Environmental Planning and Policy Coordination	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase efforts to eradicate targeted species (continued)	Develop and implement an eradication effort for the Majuro non-native caterpillar.	2014	MIIST	External donor	High
	Develop and implement an eradication effort for the Red-vented Bulbul.	2015	MIIST	External donor	High
	Eradicate small and feasible invasive species incursions promptly, while it is most feasible, least expensive, and before extensive damage has occurred.	should be an ongoing effort	Office of Environmental Planning and Policy Coordination	External donor	Medium
Awareness					
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and nation wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	MIIST/College of the Marshall Islands	External donor	High
	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the nation from unwanted pests.	2015	MIIST/College of the Marshall Islands	External donor	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	MIIST/College of the Marshall Islands	External donor	High
	Establish long term funding to support core outreach and educational efforts.	2016	MIIST/College of the Marshall Islands	NA	High
	Coordinate existing outreach efforts.	2015	MIIST/College of the Marshall Islands	NA	Medium
	Add invasive species education as a standard part of school curriculums.	2016	Ministry of Education/College of the Marshall Islands	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2015	Ministry of Education/ College of the Marshall Islands	External donor	Medium
	Develop posters, brochures and other print media to support invasive species awareness campaigns. Insure that these types of items are tied into the larger outreach strategy for the nation.	2016	MIIST/College of the Marshall Islands	External donor	Low
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	on-going	MIIST/College of the Marshall Islands	External donor	Low
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2015	MIIST/College of the Marshall Islands	External donor	Medium
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2014	Ministry of Resources and Development	Biosecurity cost recovery program should fund this activity	High
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	RMI Invasive Species Coordinator	RISC	High
	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations.	2015	RISC representatives	RISC	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2014	RMI Invasive Species Coordinator	Regional ISC office	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish.	Start in 2014	RMI Invasive Species Coordinator	External donor	Medium
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2015	College of the Marshall Islands	External donor	Low
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the nation that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts.	2016	College of the Marshall Islands	External donor	Low
Policy					
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations.	2014	Ministry of Resources and Development	NA	High
	Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2014	Ministry of Resources and Development	External donor	High
Restoration					
Increase restoration efforts of native systems where IAS management and/or eradication efforts are underway or have been successful.		on-going	Office of Environmental Planning and Policy Coordination	External donor	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment I: Republic of Palau Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Palau section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	Palau NISC	Biosecurity cost recovery program	Medium
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	Palau RISC representatives	Regional ISC Office	Medium
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Palau RISC representatives	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report shared with the region and beyond.	continuous, yearly	RISC Representatives and Palau NISC	NA	Medium
Improve support and functionality of the national invasive species coordination office/position.	This position should work country wide with appropriate offices, agencies, and NGOs involved in biosecurity efforts as well as internationally within the region and broader scope as needed.	on-going	President's Office	Funding should be in part from the biosecurity cost recovery system, in part from natural resources funding, and in part from donor grants	Medium
	This position/office should be adequately funded and supported technically and politically to ensure that Palau's needs in regards to IAS are being appropriate addressed and that the support for regional concerns is maximized.	on-going	President's Office	Funding should be in part from the biosecurity cost recovery system, in part from natural resources funding, and in part from donor grants	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve support and functionality of the national invasive species coordination office/position (continued).	Palau has a National Invasive Species Coordinator position, but not a separate office – the Coordinator reports to the Director of the Bureau of Agriculture at the present time. Consideration should be given to whether or not this is the best organizational structure. When the Coordinator position was first created, it sat in the Office of Environmental Response and Coordination with the President’s Office. The Palau National Invasive Species Committee (PNISC) recommended this location so that the Coordinator could work with all Ministries without being part of one Ministry or another.	2015	President's Office	Funding should be in part from the biosecurity cost recovery system, in part from natural resources funding, and in part from donor grants	Low
	Ensure that the Palau National Invasive Species Coordination position is a long term endeavor.	2014	President's Office	Funding should be in part from the biosecurity cost recovery system, in part from natural resources funding, and in part from donor grants	High
Coordinate with stakeholders to provide a united and active effort towards moving draft biosecurity legislation forward	Ensure that the current draft legislation is adequate specifically in regards to aquatic concerns.	Complete by April 2014	Palau NISC	NA	High
	Ensure that final draft legislation, including any updating, is available for appropriate authorities, including the national legislature to review and consider.	Complete by April 2014	Palau NISC	NA	High
	Ensure that supporters of the bill are advocating for it with the legislature and president’s office on a regular basis with the expectation that it will be passed before the end of the calendar year.	Complete by April 2014	Palau NISC	NA	High
Improve communications and ability to address biosecurity concerns between US DoD and civilian government agencies	Establish an MOU between Palau and DoD regarding biosecurity responsibilities and actions within the nation pertaining to mitigation of DoD activities and facilities.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	NA	Medium
	Establish SOPs on aspects of how DoD and Palau’s civilian agencies work together regarding biosecurity inspection process, etc. Turn over at DoD facilities in Palau is frequent and having established SOPs would assist with keeping processes in place.	2015	BOA	Biosecurity cost recovery program	High
Improve communication and information sharing in regards to IAS and biosecurity	Develop SOPs at the national level to facilitate communication and information sharing between offices and agencies at both national and state levels in regards to invasive species and biosecurity.	2015	Palau NISC	NA	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.</p>	<p>Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.</p>	<p>2014 - 2015</p>	<p>Palau RISC representatives and President's office</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and Palau NISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and BOA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office with supporting protocol and methods development.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and BOA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office with supporting establishing ER &RR capacity.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and BOA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and BOA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>
	<p>Engage the regional invasive species coordination office to support management, response, and eradication efforts.</p>	<p>As soon as the office can be established</p>	<p>Palau RISC representatives and BOA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>Medium</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	As soon as the office can be established	Palau RISC representatives and BOA	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	Medium
	Engage the regional invasive species coordination office to support outreach and education efforts.	As soon as the office can be established	Palau RISC representatives and Palau NISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	Medium
Improve capacity to identify biosecurity intercepts and organisms detection post border, including micro organisms and viruses	Develop linkages with Hawaii (or other proximal locations with established capacity) for rapid shipment of specimens for testing and identification. SOPs should be developed once agreements with testing and identification facilities have been established.	2015	Palau Invasive Species Coordinator	Biosecurity cost recovery program	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2015	Ministry of Resources and Development	This should be covered as part of the biosecurity cost recovery system	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Palau Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going, establish by 2018	Palau Community College	external donor support	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	Palau Community College	external donor support	Low
	Support the development of an algal risk assessment for the region.	2016	Palau Community College	external donor support	Medium
	Support the development of an arthropod risk assessment for the region.	2016	Palau Community College	external donor support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Request that SPC develop a biosecurity position specifically for supporting the region.	2014	Palau Office of Foreign Affairs	SPC	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	Palau ISC	external donor support	Medium
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Palau ISC	Regional ISC office	Medium
	Support the development of a weeds risk assessment for the region.	2016	Palau Community College	external donor support	Low
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bi-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Palau RISC representatives	RISC	Medium
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Palau RISC representatives	RISC	Medium
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance).	Within 1 month of the December MCES on an annual basis	Palau RISC representatives	RISC	Medium
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Palau RISC representatives	RISC	Medium
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Palau RISC representatives	NA	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Palau RISC representatives	external donor support	Low
Prevention					
Improve pre-border sanitation efforts	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 Hold national consultation including review of pertinent models (New Zealand); 2016 Develop draft national standards; 2017 implement standards	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP. This concept was utilized already in Palau when gravel was brought in for the compact road and should be used as an example of what should be done across the board to better protect the nation from IAS. As an example, all imported plywood should meet minimal sanitation levels.	Should track with the preceding action item	BOA	Biosecurity cost recovery program	Medium
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo through cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	BOA	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security	Acquire and install X-ray machines for biosecurity at all ports of entry.	2016	BOA	external donor support	High
	ensure appropriate capacity for the use of X-ray machines for biosecurity at all ports of entry.	2016	BOA	external donor support	High
	ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	BOA	external donor support	High
	Institute 100% x-raying of all arriving passenger baggage.	2016	BOA	Biosecurity cost recovery program	High
	Consider developing SOPs for incoming baggage and cargo inspections which are based on successful models (such as New Zealand); would require hiring and training additional personnel, installing appropriate equipment (X-ray, etc.), training additional canine teams for detection of specific high risk IAS (reptiles, fruits, meats, etc.); insuring appropriate data collection and development and maintaining of databases to track efforts and interceptions.	2016	BOA	Biosecurity cost recovery program	High
	Re-establish fumigation capacity specifically for re-conditioning items like cut flowers on arrival if they are found to harbor pests.	2016	BOA	TBD	High
	Develop a canine pest detection program for items such as snakes, fruits, and vegetables. Consider the potential to combine this program with similar programs for detection of illicit materials such as drugs.	2017	BOA	external donor support	Medium
	Develop a wildlife reference collection (i.e., taxidermy mounts, computer photo files, etc.) to aid identification of incoming species. Adequate resources (taxonomic keys, microscopes, etc.) should be available for assistance in taxonomic identifications.	2016	BOA	external donor support	Medium
	Ensure that quarantine has access to freezers and incinerators at ports. Freezers need to have back up power supplies to ensure functionality. Freezers need to be restricted access for quarantine only.	2015	BOA	Biosecurity cost recovery program	High
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Bins should be placed so as to support use (not directly in front of quarantine stations). Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	BOA	Biosecurity cost recovery program	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Ensure that port authorities are working with quarantine in regards to use and placement of amnesty bins. Standard trash bins should also be located in appropriate areas and well signed so that passengers don't use amnesty bins for regular trash.	2015	BOA	Biosecurity cost recovery program	High
	Develop appropriate inspection facilities including a biosecure inspection facility at the seaport large enough for sea containers and wash-down areas with appropriate retention and treatment facilities for waste water produced.	2017	BOA	external donor support	Medium
	Ensure that inspections process while targeting high risk goods also ensure random sampling of all imports, travelers, and baggage in order to better detect hitchhiker pests.	2015	BOA	Biosecurity cost recovery program	High
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2015	BOA	Biosecurity cost recovery program	High
	Develop and institute quarantine exchange programs with New Zealand, Australia, and/or U.S. biosecurity agencies as a mechanism for improving inspector capacity and further development of the nation's biosecurity program.	2016	BOA	external donor support	Medium
	An area not well covered by biosecurity currently is the use of the internet for trade. Regulated and prohibited goods arrive in the region via the mail pathway with bogus labelling from people buying on the internet. A plan will be needed to address this pathway. Of significant concern in this regard is the potential for shipping of pets such as reptiles and plant material via the mail system with little ability to detect and intercept these organisms by current biosecurity systems within the region. Trained detector dogs, visual inspections and X-ray machines could all be utilized to reduce the potential for illicit mail trade, but appropriate regulations need to be established which would permit the potential inspection of most if not all arriving mail.	2015	BOA	Biosecurity cost recovery program	Medium
	Ensure ability to implement fines and collect fees to recover costs of re-conditioning when this option is utilized.	2015	BOA	Biosecurity cost recovery program	High
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	BOA	external donor support	Medium
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	BOA	Biosecurity cost recovery program	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Implement advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, identification of livestock, wildlife and poultry diseases and pests, etc.).	on-going	BOA	SPC, regional ISC Office, UH, others	High
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	BOA	Biosecurity cost recovery program	High
	Ensure that quarantine officers have adequate day to day resources such as computers, phones, vehicles, etc.	2015	BOA	Biosecurity cost recovery program	High
	Ensure that the national quarantine office is appropriately funded and that all biosecurity elements have adequate funding and day to day operational resources. Support the establishment of a cost recovery system for biosecurity so that any efforts beyond standard inspections have costs covered by the party or parties involved in the importation/shipping and that these costs as paid go directly to support the national biosecurity system (revolving fund that is used to support biosecurity efforts nation wide).	2015	BOA	Biosecurity cost recovery program	Medium
	Improved biosecurity standards in regards to mail services, including inspection of mail at port of arrival rather than at postal facilities which are post border. All mail should pass through biosecurity inspection.	2016	BOA	Biosecurity cost recovery program	High
	Hire and train additional quarantine staff as needed. Should be based on needs assessment. An inspections database should be able to document existing needs. Hired staff should need to meet minimal qualifications set by the oversight office (Bureau of Agriculture) and come through appropriate channels.	2016	BOA	Biosecurity cost recovery program	Medium
	Institute quarterly reporting on quarantine inspections based on database information and ensure that reports are appropriate shared.	2016	BOA	Biosecurity cost recovery program	Medium
	Review (and update if necessary) penalty assessment structure for noncompliance with biosecurity regulations.	2015	BOA	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	<p>Protocols need to be established regarding quarantine inspection of arriving vessels: manifest should be check, cargo, ships stores, galleys, garbage, and cabins should all be inspected. Distinct SOPs are most likely needed for a variety of vessel types including aircraft, fishing vessels, support ships, cargo ships, tankers, yachts, barges. Non-compliance with regulations should be noted and appropriate follow-up actions should be taken including fines, confiscations, and turning away cargo and possibly entire vessels if needed. Inspection data should be collected and recorded into a system wide database.</p>	2015	BOA	Biosecurity cost recovery program	Medium
	<p>Establish an electronic database for quarantine inspection data that can be searched and data extracted for analysis. Such a database would support better targeting of vectors and pathways, permit tracking of known violators, provide documentation regarding interceptions, fee and penalty payments, demonstrate appropriate use of resources, quantify gaps and needs in current system, assist in determining pathways associated with post border detections, tracking of live imported species and number of individuals, tracking changes in vector arrivals and embarkation locations, etc.</p>	2016	BOA	Cost recovery biosecurity system	Medium
	<p>Training quarantine staff in data collection, entry, management and analysis, develop appropriate field inspection forms, conduct quality control of data systems, ensure that field data is entered into system in a scheduled manner to prevent backlogging, ensure that the data system is appropriately and regularly backed up to prevent systematic losses.</p>	2016	BOA	Biosecurity cost recovery program	High
	<p>Develop legislation to create a user fee structure similar to that employed by USDA to support biosecurity efforts.</p>	2015	BOA	Biosecurity cost recovery program	Medium
	<p>Consider implementation of a visitor's fee to support biosecurity efforts. A standardized fee employed throughout the region would be ideal.</p>	2015	BOA	Biosecurity cost recovery program	Low
	<p>Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.</p>	2015	BOA	Biosecurity cost recovery program	High
	<p>Address the lack of marine biosecurity oversight. Need to build legislation to support national quarantine having marine biosecurity capacity.</p>	2015	BOA	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	<p>Protocols should be established by quarantine for documenting interceptions and final disposition of materials. These reports should be entered into a database and information should be shareable to assist all locations within the Palau to better protect borders but also with other jurisdictions of the region to better protect the region. Protocols should be established regarding how and when (how often) this type of information is shared. Information collected and stored should include date of incident, inspector in charge, what was intercepted, what IAS were found, numbers of pests found, origin of the material in question, disposition of the material(s) and specimen(s), what remedial actions (if any) were taken against the shipper, and if fines were instituted, were they collected.</p>	2016	BOA	Biosecurity cost recovery program	Medium
	<p>Consider developing a national tax on imports to support biosecurity development in Palau. A tax similar to the Green Fee but levied on certain imports (high risk items?) is desirable. This would basically be a user fee. Funds collected in this manner should be held separate and made available to support enhance biosecurity capacity.</p>	2015	BOA	Biosecurity cost recovery program	Low
	<p>Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.</p>	2015	BOA	Biosecurity cost recovery program	High
	<p>Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations. Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.</p>	2015	BOA	Biosecurity cost recovery program	Medium
	<p>Develop MOU's between the national quarantine office and other agencies involved in border inspections (such as customs) so that these offices/agencies can support the quarantine office with biosecurity aspects.</p>	2015	BOA	Biosecurity cost recovery program	High
	<p>Support the development and implementation of regional standards for biosecurity inspections and data collection and management.</p>	2015	BOA	SPC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Develop SOPs regarding specifics of how other agencies and offices can support the role of the national quarantine office during border inspection process.	2015	BOA	Biosecurity cost recovery program	Medium
	Institute biosecurity cross training of staffs from agencies which are involved in border inspection processes.	2015	BOA	SPC	Medium
	Establish a centralized facility for quarantine offices, including quarantine areas (plant and animal and aquatic organisms), treatment areas, laboratory space, offices, and equipment storage.	2017	BOA	external donor support	High
	Develop regulations regarding biosecurity and visiting cruise ships. These ships, if visiting multiple sites within the nation should fund having a biosecurity office on board during the period that they within national waters, provide for inspection services at all ports of call, cover all travel expenses for the biosecurity officer, and coordinate with the national quarantine office to ensure that the inspector's home port does not experience a drop in quarantine services during their absence (this may including paying for overtime).	2015	BOA	Biosecurity cost recovery program	Medium
	Develop specific regulations and enforcement SOPs for imported seeds. All imported and viable seeds should require completed risk assessments and permitting.	2015	BOA	Biosecurity cost recovery program	Medium
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2015	BOA	Biosecurity cost recovery program	High
	Undertake to implement more comprehensive data collection and better data management on IAS vectors and pathways, including detailed inspection processes, intercept records, preservation and compiling of voucher specimens, detailed records on where shipments, etc. are arriving from and specifically what is known to have harbored IAS and where it come from and how it arrived. Ensure that records are entered into a useable database and that data is analyzed and shared with partners as warranted. The tracking of live organisms would be better enabled with a data collection systems which tracked not only shipments but species and number of individuals as well.	2017	BOA	Biosecurity cost recovery program	Medium
Improve overall post border biosecurity	Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2017	Palau NISC	external donor support	Medium
	Conduct localized risk assessments of terrestrial, freshwater, and marine systems as feasible.	2017	Palau NISC	external donor support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve overall post border biosecurity (continued)	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	Palau NISC	external donor support	Medium
	Ensure proper cleaning of all large equipment and construction materials prior to moving between sites within the state.	2015	BOA	Biosecurity cost recovery program	Medium
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry in regards to invasive species.	2015	BOA	Biosecurity cost recovery program	Medium
	Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other businesses as appropriate to promote the sale and use of locally sourced plants, preferably native plants. If non-natives are going to be used for landscaping, insure that they are non-invasive species. If plants will be brought into an area from outside for landscaping, insure that they are pest free. This code of conduct should encourage businesses: to make their staff knowledgeable about invasive plants, to inform their customers about invasive plants, to report immediately any likely exotic pest organisms found on their premises, and to use native or non-invasive plants locally sourced.	2015	Palau NISC	external donor support	Medium
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replace of WPM with recycled plastics.	on-going	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering Palau should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	BOA	Biosecurity cost recovery program	Medium
	Do not permit the unloading of noncompliant WPM.	2015	BOA	Biosecurity cost recovery program	High
	Treat or destroy any noncompliant WPM that is offloaded.	2015	BOA	Biosecurity cost recovery program	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of wood packaging material (WPM) (continued)	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	BOA	Biosecurity cost recovery program	High
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	BOA	Biosecurity cost recovery program	High
Improve ability to better enforce pre-departure sanitation	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	BOA	Biosecurity cost recovery program	Medium
	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping. Currently rented containers are inspected for internal cleanliness before departure. This should be expanded to include all containers and both internal and external surfaces.	2015	BOA	SPC	Medium
	Develop and institute standards which would increase pre-departure inspections. Visual inspections are conducted pre-departure which focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture. All jurisdictions should add quarantine inspections to the SOP of departing materials.	2016		Biosecurity cost recovery program	Medium
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	BOA	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2015	BOA	Biosecurity cost recovery program	Medium
Improve intra-state biosecurity and foreign arrivals at ports other than the main air and sea ports	Develop biosecurity standards for ports other than the main air and sea ports.	2016	BOA	Biosecurity cost recovery program	Medium
	Implement and enforce biosecurity at ports other than the main air and sea ports.	2016	BOA	Biosecurity cost recovery program	Medium
	Conduct a nation wide consultation regarding intrastate biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	BOA	Biosecurity cost recovery program	Medium
	Conduct risk assessments for outer islands for terrestrial and aquatic concerns.	2017	Palau NISC	external donor support	Medium
	States should develop biosecurity (kayangel is doing this now) others states should consider following suite, especially the outlying states.	2016	Individual States	NA	Medium
	Helicopters and private planes (or small scale commercial ventures) can be used to move passengers and cargo and where they exist or where there are plans for their use, they should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	BOA	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Ministry of Health	external donor support	Low
	National health authorities should work with CDC to determine what, if any, role DoD can support in the advent of a human pathogen outbreak. For example, could CDC direct DoD to transport sick patients to appropriate support facilities either within or outside of the national in the case of a human pathogenic outbreak?	2015	Ministry of Health	external donor support	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015: Develop agreements with shippers for medical services (consider working with airlines and/or DoD)	Ministry of Health	external donor support	Medium
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import.	Dec-14	BOA	Biosecurity cost recovery program	Medium
	Update white list on a regular basis.	annually	BOA	Biosecurity cost recovery program	Medium
	Develop a government endorsed black list of prohibited species.	Dec-14	BOA	Biosecurity cost recovery program	High
	Update black list on a regular basis.	annually	BOA	Biosecurity cost recovery program	Medium
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	BOA	Importer pays for all aspects of the risk assessment (regardless of outcome)	Medium
	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	2015	BOA	utilize student support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a national biosecurity advisory committee to review proposals for the importation of exotic species.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Funding: should be part of the biosecurity cost recovery system; technical support SPC/FAO	High
	Palau is currently considering importing shrimp from the CNMI and should be aware of what potential diseases, etc. may be associated with the CNMI stock and which if any of these are not yet established within the state and therefore should be kept out.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Funding: should be part of the biosecurity cost recovery system; technical support SPC/FAO	High
	Improve reporting and screening systems for import of live organisms, such that all live organisms to be imported need to be fully vetted with written documentation on species, numbers, origin, anticipated final disposition, pre-arrival sanitation inspection and health check, arrival inspection and health check are all clearly documented. Additionally live imports should receive prior approve for importation and any new species will need to go through a risk assessment process to be paid for by the user.	2015	BOA	Funding: should be part of the biosecurity cost recovery system; technical support SPC/FAO	Medium
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	BOA	external donor support	High
	Develop plan for containment and control measures in regards to exotic farmed and traded species.	2015	BOA	Biosecurity cost recovery program	Medium
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	BOA	Biosecurity cost recovery program	Medium
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2014, should be included in the current draft biosecurity legislation	Palau Office of the Attorney General	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	High
	Develop specific guidelines for unwanted pets. PAWS has something that should be review and further expanded as needed.	2015	BOA	NA	Medium
	Improve capacity and infrastructure regarding animal health. Koror State does have a veterinarian and perhaps this office should be engaged to support national efforts.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Develop biosecurity standards for household aquaculture set ups and enforce these standards. Small scale crab farming is currently developing.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Get support from FAO	Medium
	Develop guidelines for cages.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish a certification system for the movement (domestic and international) of live organisms. Might be difficult to do for the entire nation but may be feasible for outlying islands.	2015 conduct an national consultation; 2016 develop draft system; 2017 implement system nation wide	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	BOA	NA	High
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	Palau Invasive Species Coordinator	external donor support	Medium
Increase export potential	Establish produce and live organism export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	BOA	FAO	Low
	Establish processed foods export standards. Appropriate sanitation and consistency over time will be essential to insuring long term external market engagement.	2016	BOA	FAO	Low
	Improve capacity to export crops, which will involve finding/establishing markets with trade partners.	2016	BOA	FAO/SPC	Medium
	Train and certify agricultural staff to support local farmers with enhancing the potential for export crops.	2015	BOA	SPC	Medium
	Support local farms with capacity development to increase potential to export crops.	2016	BOA	SPC	Medium
	Ensure that fumigation for export crops is available and appropriate used.	2015	BOA	SPC	Medium
	Work with proposed external trade partners to ensure that export crops of interest are permitted for importation (example: betelnut).	2016	BOA	FAO	Medium
	Improve ability to meet import standards imposed by trade partners in regards to agricultural produces and processed foods.	2016	BOA	SPC/USDA	Medium
	Increase protection of export crops from invasive pests by better management of established species and improved border security to reduce the introduction of new pests to the state.	2015	BOA	external donor support	Medium
	Support appropriate development of slaughter house for pork product production. If appropriate established and sanitation guidelines are develop and established then it might be feasible to consider exportation in regards to this on-going development.	2015	BOA	FAO	Medium
Ensure that all proposed agricultural exports go through an establish protocol to ensure cleanliness before entering the shipping lines to reduce the potential for transport of unwanted pests.	2015	BOA	SPC	Medium	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish standards and regulations regarding biofouling, including inspection and certification for all vessels. Inspections can be trained to inspect hulls from top side with mirrors. If further inspection is warranted, then the craft pays for divers to inspect and make a report. If determined to be dirty, then the craft must either be cleaned or leave port and jurisdictional waters. Self clean outside of jurisdictional waters could be an option. Hull needs to be clean of all organisms, as the ability to identify all marine organisms is not available.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish additional regulations for impounded vessels.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium
	Develop capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Ensure that regulations include ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Review and revise (as needed) legal authority to implement a biofouling management program.	2014. This should be included in the current draft biosecurity legislation; May need to update	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Develop capacity to deal with grounded and/or abandoned vessels	Determine what agency has the legal authority for removal of grounded and/or abandoned vessels.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	USCG	Medium
	Develop a response plan for grounded and abandoned vessels that includes assessment and removal of non-native species in a timely manner to reduce the potential of incursions.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	USCG	Medium
	Establish a core team of responders (likely from a variety of agencies) with established SOPs for use in the advent of a grounded or abandoned vessel.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	USCG	High
	Ensure that funding is in place and can be utilized without delay in the case of a grounded or abandoned vessel.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	USCG	High
Increase marine system protection from invasive species	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium
	Biosecurity inspection of vessels (including the hull) before entering the rock islands should be added to the current permitting process. Permits already required, so why not ensure vessels are clean before departing for this protected area. Koror State could run this program. They have divers already and could do the inspections themselves.	2015	Koror State	Funding should come from entry fees	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase marine system protection from invasive species (continued)	Establish biosecurity practices and requirements for fishing vessels that operate in Micronesia to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
Establish and enforce ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	external donor support	Medium
	Adopt and enforce international ballast water regulations (discharge at least 200nm off shore). Inspection of ship logs for compliance.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Establish ballast water management and reporting requirements for all vessels utilizing ballast water.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2017	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
	Support national level adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium
Address climate change linkages to invasive pests		2016	Palau NISC	US AID	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address food security for the nation in regards to invasive pests.	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2016	Palau Community College	FAO	Medium
Early detection and rapid response					
Improve early detection and rapid response capacity	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	Palau NISC	external donor support	High
	The Palau national emergency framework includes IAS and has a process for mobilizing funding. Consider utilizing this framework as the basis for the IAS ED and RR efforts. Stakeholders need to be fully engaged in this framework if it is to be utilized as such.	2015	Palau NISC	NA	Medium
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	Palau NISC	external donor support	Medium
	Develop taxa specific ERPs as needed.	On-going	Palau NISC	Biosecurity cost recovery program	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	Palau NISC	Biosecurity cost recovery program	Medium
	Ensure that the public reporting system is fully functional including supported by trained staff.	2015	Palau NISC	Biosecurity cost recovery program	Medium
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2015	Palau NISC	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
improve early detection and rapid response capacity (continued)	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2015	Palau NISC	Biosecurity cost recovery program	Medium
	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	Palau NISC	Biosecurity cost recovery program	Medium
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2015	Palau NISC	Regional ISC office	Medium
	Hold consultations to determine what agency(s), office(s) and/or groups will be responsible for surveillance programs.	2015	Palau NISC	external donor support	Medium
	Develop and institute surveillance programs for non-established species consider high risk of arrival such as alien snakes, fruit flies, tramp ants, etc.	2015	Palau NISC	external donor support	Medium
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	Palau NISC	Regional ISC office	Medium
Management and eradication					
Increase management and control of established invasive species	Determine which established invasive species are actionable and proceed with developing management strategies. Covered in part by national ISAP.	2015	Palau NISC	ISSAP	Medium
	Create GIS layers regarding the distribution of established IAS and use to support biosecurity and IAS management efforts.	2015	Palau Community College	external donor support	Medium
	Train natural resource staffs (including protected areas staffs) at the local level in regards to IAS management support.	2015	Palau NISC	Regional ISC office	Medium
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	2015	Palau NISC	Regional ISC office	Medium
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2015	Palau NISC	external donor support	Low
	Develop standardized SOPs for IAS monitoring and surveys.	2015	Palau NISC	external donor support	Medium
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distribution is current.	2015	BOA	external donor support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase management and control of established invasive species (continued)	Create community funding sources for local (village level) programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2016	Palau NISC	external donor support	Medium
	Conduct terrestrial and aquatic risk assessments for all protected areas.	2016	Palau Conservation Society	Palau Green Fund or external funding sources	Medium
Increase efforts to eradicate targeted species	Conduct surveys and hold stakeholder consultations to determine what established species are viable candidates for eradication efforts.	2016	Palau NISC	external donor support	Medium
	Develop strategies to conduct eradication campaigns including securing funding streams to support these efforts.	2016	Palau NISC	external donor support	Medium
	Develop resources to respond to new pest incursions beyond ED & RR, including conducting delimiting surveys and potential eradication efforts.	2016	Palau NISC	external donor support	Medium
	Continue with Tilapia eradication efforts and document. Report to the region on outcome. Continue to monitor for Tilapia.	2014	Palau NISC	external donor support	High
	Continue with management efforts with invasive primates established in specific areas within the country.	2014	Palau NISC	external donor support	Medium
	Develop and conduct surveys for primates in areas where primates have been reported but currently are not known to exist.	2015	Palau NI	external donor support	Medium
	Eradicate small and feasible invasive species incursions promptly, while it is most feasible, least expensive, and before extensive damage has occurred. Covered in part by national ISAP.	2016	Palau NISC	external donor support	Medium
Awareness					
Increase outreach and education on biosecurity and invasive species	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	Palau NISC	external donor support	Medium
	Conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the nation from unwanted pests.	2015	Palau NISC	external donor support	Medium
	Establish long term funding to support core outreach and educational efforts.	2016	Palau NISC	external donor support	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species(continued)	Develop an educational strategy that is long term, extensive and nation wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	Palau NISC	external donor support	Medium
	Coordinate existing outreach efforts.	2015	Palau NISC	external donor support	Medium
	Add invasive species education as a standard part of school curriculums.	2016	Palau NISC/Palau Ministry of Education	external donor support	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2015	Palau NISC/Palau Ministry of Education	external donor support	Medium
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	2016	Palau NISC	external donor support	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	on-going	Palau NISC	external donor support	Medium
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2016	Palau NISC	external donor support	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2015	Palau ISC	Regional ISC office	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2015	Palau ISC	RISC	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges. Create awareness of the potential legal consequences of violating biosecurity regulations. Palau could develop their section of the video or their own entire video with the support of the PVA.	Start in 2014	Palau ISC	external donor support	High
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish.	2015	Palau NISC	external donor support	Medium
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Conduct baseline surveys.	2016	Palau Community College	external donor support	Medium
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2015	Palau Community College	external donor support	Low
Policy					
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations.	2015	Palau NISC	Biosecurity cost recovery program	Medium
	Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2015	Palau Ministry of Natural Resources, Environment, and Tourism	Biosecurity cost recovery program	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance (continued)	Current system of fines and penalties needs to be improved to better support biosecurity efforts.	2015	BOA	Biosecurity cost recovery program	High
<i>Restoration</i>					
Increase restoration efforts of native systems where IAS management and/or eradication efforts are underway or have been successful.		2016	Palau Conservation Society	external donor support	Medium

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment J: Commonwealth of the Northern Mariana Islands Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Support</i>					
Increase funding for biosecurity	Ensure adequate long-term funding is available for biosecurity equipment and infrastructure.	2016	Quarantine	External donor	High
	Ensure sufficient funding for agriculture and wildlife disease and pest exclusion activities by developing legislation to create a user fee structure similar to that employed by the DHS and USDA.	2016	Quarantine	Biosecurity cost recovery system	High
	Consider developing and institution user fees for passengers and baggage inspections.	2016	Quarantine	Biosecurity cost recovery system	High
	Visitors to the CNMI should be able to support biosecurity efforts via user fees. Any fees which are collected should go to the appropriate biosecurity agency for each jurisdiction and should be held in a revolving fund and utilized as needed to support biosecurity work. It would be ideal if a Micronesia wide fee schedule was established.	2016	Quarantine	Biosecurity cost recovery system	High
	Identify and establish dedicated, long-term and short-term funding to implement the various biosecurity recommendations. In addition to advancing individual objectives, there is a critical need to sustain biosecurity as a long-term and vital activity, just as customs and border security (for goods and people) is an ongoing activity. To sustain biosecurity and provide long-term continuity requires some core level of activities, personnel, and coordination, which will require dedicated funding.	2017	Quarantine	TBD	Medium
	Ensure sufficient funding to conduct routine surveillance, implement response plans, and provide outreach and education, in addition to port of entry exclusion activities and training for inspectors.	2016	Quarantine	Biosecurity cost recovery system	High
	Increased funding for regional biosecurity so necessary efforts to prevent, control, and eradicate animal and plant pests and diseases throughout the region are effective.	2017	CNMI RISC representatives	TBD	Low
	Identify funding and mechanisms to assess and respond to biosecurity threats across a broad geographic range in the CNMI. Efforts should include resources to also support efforts in Tinian, Rota, Aguigan, Pagan and even the Monument Islands of Uracas, Maug and Asuncion.	2017	TBD	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the CNMI section of the RBP on a regular basis and share regionally.	continuous, at least every 5 years	CNMI Invasive Species Task Force	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Develop a region wide communication plan for biosecurity and IAS. Examine the potential of using existing models for the plan development including that which was produced for Oahu recently (maybe 4 years ago). The Oahu plan was ultimately not utilized but it potentially could serve as a model for networking regionally.	2015	CNMI RISC representatives	Regional ISC Office	High
	Establish communication and coordination system for information derived from outreach programs, port inspections, pest identifications, and reports from the public of sightings or encounters with suspected invasive species or illegal movements of foods, plants, animals, insects, etc.	2016	CNMI Invasive Species Task Force	External donor	High
	Implement more comprehensive data collection and better data management on IAS vectors and pathways, including detailed inspection processes, intercept records, preservation and compiling of voucher specimens, detailed records on where shipments, etc. are arriving from and specifically what is known to have harbored IAS and where it come from and how it arrived. Ensure that records are entered into a useable database and that data is analyzed and shared with partners as warranted.	2016	CNMI Quarantine	Biosecurity cost recovery system	High
	Develop a region wide net of experts to support IAS efforts throughout the region. The general concept would be for each jurisdiction to have an IAS coordinator who could work extensively with RISC. Additionally a regional IAS coordinator should be developed to support and assist as well as coordinate efforts both within and between jurisdictions. Agreements with key thematic experts could then be developed and utilized as needed to support regional and jurisdictional activities.	2016	CNMI RISC representatives	Regional ISC Office	Medium
Improve communications and ability to address biosecurity concerns between US DoD and civilian government agencies	Establish an MOU detailing responsibilities, actions and cooperative agreements between the CNMI and DoD to work jointly on biosecurity issues related to DoD activities and mitigation within the CNMI.	2015	DNLR	DoD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish a jurisdictional invasive species coordination office that is tasked with supporting commonwealth wide IAS efforts across agencies and offices as well as working nationally and regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the invasive species coordination position(s), possibly having a coordination position for each island (Rota, Tinian, and Saipan).	2015	Governor's Office	Biosecurity cost recovery system	High
	Once established this office should support and assist in coordinating efforts with invasive species within the CNMI. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that governance is regularly updated regarding both commonwealth and regional invasive species developments.	2015	Governor's Office	Biosecurity cost recovery system	High
Improve communication and information sharing in regards to IAS and biosecurity	Although areas outside Micronesia and Hawaii are understandably not included in the RBP, information sharing outside the area should be better developed in regards to biosecurity and IAS. In particular, communication and info sharing from Micronesian governments and biosecurity authorities/organizations to other entities outside the region (with respect to notification about species that will or might be problematic and which could originate from within the region) should be developed. Establishing a regional IAS office would facilitate these efforts.	2016	CNMI Invasive Species Task Force	External donor	Low
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	CNMI RISC representatives and the Governor's office	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.</p>	<p>As soon as the office can be established</p>	<p>CNMI RISC representatives and the CNMI ISC</p>	<p>initial support might come from the US and the region. 	<p>Engage the regional invasive species coordination office with supporting establishing ER &RR capacity.</p>	<p>As soon as the office can be established</p>	<p>CNMI RISC representatives and the CNMI ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support management, response, and eradication efforts.	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts	As soon as the office can be established	CNMI RISC representatives and the CNMI ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	CNMI Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	College of the Northern Mariana Islands	External donor	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	College of the Northern Mariana Islands	External donor	Low
	Support the development of an algal risk assessment for the region.	2016	College of the Northern Mariana Islands	External donor	Medium
	Support the development of an arthropod risk assessment for the region.	2016	College of the Northern Mariana Islands	External donor	Medium
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	CNMI Invasive Species Coordinator	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	CNMI Invasive Species Coordinator	Regional ISC office	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of a weeds risk assessment for the region.	2016	College of the Northern Mariana Islands	External donor	Medium
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	CNMI RISC representatives	External donor	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC bills and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	CNMI RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	CNMI RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance)	Within 1 month of the December MCES on an annual basis	CNMI RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	CNMI RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	CNMI RISC representatives	NA	High
Improve regional coordination regarding biosecurity and IAS	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2015	CNMI RISC representatives	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Prevention</i>					
Improve pre-border biosecurity	Emphasis should be directed towards audited off-shore hygiene systems such as those utilized very successfully in Australia and New Zealand. This is ultimately the best way to prevent IAS incursions.	2015 Hold jurisdictional consultation including review of pertinent models (New Zealand); 2016 Develop draft standards; 2017 implement standards	Quarantine	Biosecurity cost recovery system	High
	Large, used machines such as tanks and bulldozers intended for importation should be cleaned and inspected for IAS at points of origin immediately prior to shipping.	2015	Quarantine	Biosecurity cost recovery system	High
	Insure proper cleaning of all large equipment such as construction and military items according to APHIS guidelines prior to entry.	2015: consider establishing guidelines based on existing USDA-APHIS materials	Quarantine	Biosecurity cost recovery system	High
Improve border security	Develop SOPs for border inspections.	2015	Quarantine	Biosecurity cost recovery system	High
	Improve capacity for IAS detection and interception at/within the transport pathways as well as ports of entry.	2016	Quarantine	Biosecurity cost recovery system	Medium
	Create and institute a mixed model biosecurity approach based on both vector sanitation and focusing on key high risk species for terrestrial, freshwater, and marine habitats.	2015	Quarantine	Biosecurity cost recovery system	High
	Consider developing SOPs for incoming baggage and cargo inspections which are based on successful models (such as New Zealand); would require hiring and training additional personnel, installing appropriate equipment (X-ray, etc.), training additional canine teams for detection of specific high risk IAS (reptiles, fruits, meats, etc.); insuring appropriate data collection and development and maintaining of databases to track efforts and interceptions.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Institute 100% x-raying of all arriving passenger baggage.	2016	Quarantine	Biosecurity cost recovery system	Medium
	Follow up consideration should be given to current agricultural imports and importer locations to adjust the risk assessment results to the current situation. The same is true for exports.	2016	DLNR	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Provide essential equipment to inspection services, including x-ray machines, computer, communication devices, etc. and support for both the use and maintenance of this equipment.	2015	Quarantine	External donor	High
	Develop appropriate vector management with feedback and monitoring mechanisms.	2016	Quarantine	Biosecurity cost recovery system	High
	Establish decontamination sites for cleaning both military and civilian equipment.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Improve capacity to inspect and track permitted imports. Consider enhancing quarantine requirements for specific species or taxon groups when imported (need to develop facilities for this in most cases) which would help with disease detection and control.	2015	Quarantine	Biosecurity cost recovery system	High
	Insure proper cleaning of all large equipment such as construction and military items according to APHIS guidelines prior to moving between sites (islands or locations on specific islands).	2015	DLNR	Biosecurity cost recovery system	High
	Establish a protocol which will permit the inspection of US, and all other types of mail, including private courier items.	2016	Quarantine	Biosecurity cost recovery system	Medium
	Provide quarantine agents with the necessary legal authority, training, and support to enforce requirements at border entry and post-border locations (e.g. aquaculture facilities and sales outlets).	2015	Quarantine	Biosecurity cost recovery system	High
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	Quarantine	External donor	Low
	Develop a plan to address the IAS introduction pathway of mail. Of significant concern in this regard is the potential for shipping of pets such as reptiles via the mail system with little ability to detect and intercept these organisms by current biosecurity systems within the region. Trained detector dogs, visual inspections and X-ray machines could all be utilized to reduce the potential for illicit mail trade, but appropriate regulations need to be established which would permit the potential inspection of most if not all arriving mail.	2016	Quarantine	Biosecurity cost recovery system	Medium
	Develop/enhance the tracking system for all cargo with unique identifiers for cargo shipments. Include an electronic system for tracking, identifying, and collecting data from manifests for containerized commercial cargo arrivals to the CNMI to streamline the import process while maintaining biosecurity.	2017	Quarantine	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Develop a wildlife reference collection (i.e., taxidermy mounts or computer photo files with APHIS-WS) to aid identification of incoming species. Adequate resources (taxonomic keys, microscopes, etc.) should be available for assistance in taxonomic identifications.	on-going	DLNR	External donor	Low
	Programs could be established that would allow passengers of airlines or ships to be able to surrender any potentially invasive animals with assurances that there would be no prosecution (excluding illegally smuggled animals protected by law, such as species listed under CITES). Similar to "honor bins" placed in some airports that allow passengers to anonymously dispose of contraband, such as fruit or other plant products, mechanisms could be established that would allow travelers to surrender nonindigenous species that have been transported in luggage. Such an option could be disseminated by means of mass media outlets as part of public outreach.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Conduct sanitary inspections of all incoming construction materials including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	Quarantine	Biosecurity cost recovery system	High
	Conduct annual invasive species awareness and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect, capture, or detain the invasive species upon discovery at the port, and point of contact to report an incident.	2015	DLNR	Biosecurity cost recovery system	Low
	Conduct biosecurity inspection for all arriving conveyances, military and non-military, for plant pests and animal contamination. Inspection must include a thorough search of the exterior and the interior of the conveyance for plant and animal pests and wildlife of concern. CNMI quarantine officers must be allowed to inspect military vessels as USDA-APHIS cooperators.	2015	Quarantine	Biosecurity cost recovery system	High
	Helicopters and private planes (or small scale commercial ventures) should be considered as possible IAS vectors and therefore a biosecurity threat that needs to be appropriate monitored and inspected.	2015	Quarantine	Biosecurity cost recovery system	Low
	Ensure that the biosecurity system is tracking changes in aircraft arrivals, especially as new linkages are established and/or additional carriers are added.	2015	Quarantine	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests. Follow all APHIS policies and guidelines as applicable (or establish similar guidelines). Evaluate the effectiveness of current cleaning methods, and improve as appropriate.	2015	Quarantine	Biosecurity cost recovery system	High
	Improve detection methods for rodents and other wildlife on vessels and in cargo. Rodents and other wildlife have been implicated in the transmission of zoonotic diseases. Methods may include trapping, monitoring for signs, etc. Rodent detection methods are not well developed and other wildlife detection methods have not been well documented.	2016	DLNR	External donor	Low
	Vessels need to have SOPs for safe keeping of garbage and basic standards in regards to garbage need to be enforced. Port inspectors should include insuring garbage is in an enclosed bin and secured. In proper garbage management should be addressed ASAP and fines levied to better insure future compliance.	On-going	Quarantine	Biosecurity cost recovery system	High
Improve regulation and compliance of wood packaging material (WPM)	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign, military and non-military WPM entering the Micronesia Region should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	on-going	Quarantine	Biosecurity cost recovery system	Medium
	Do not permit the unloading of noncompliant WPM.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Conduct phytosanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign, military and non-military WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Support a regional approach to switch from WPM to other options such as recycled plastics; interim solution is the enforce certification of WPM and to inspect regularly.	2014	Quarantine	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2016	Quarantine	Biosecurity cost recovery system	Low
	Mandate and enforce regulations for handling palletized cargo. Contamination can occur during the packing, handling, and staging processes prior to arrival as imported cargo or after arrival when staged for loading for inland transport. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for labeling, packing, and transport prior to arrival and for eventual staging and loading for inland transport after arrival. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places, especially for BTS detection by canine inspection teams.	2016	Quarantine	Biosecurity cost recovery system	Medium
	Establish and utilize container racks at all locations where containers are stored for preloading, etc. and establish SOPs with shippers for pre-departure cleanliness in regards to containers.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2016	Quarantine	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve ability to better enforce pre-departure sanitation (continued)	Adopt standards which would increase pre-departure inspections. In the CNMI, commercial airline baggage is screened by Transportation Security Administration (TSA) agents/airline employees immediately prior to departure using X-ray machines. These pre-departure inspections focus on searching for weapons and other prohibited items, but during these inspections, inspectors could potentially find and confiscate live organisms. These inspectors should receive training in IAS detection and capture.	2018	Quarantine	Biosecurity cost recovery system	Medium
Improve overall post border biosecurity	Provide training and support to DFW to conduct post border inspections and follow-up activities.	2016	DFW	Biosecurity cost recovery system	Medium
	Develop and/or improve capacity to carry out investigations and effective enforcement beyond ports of entry.	2016	DFW	Biosecurity cost recovery system	Medium
	Develop jurisdictional capacity in regards to post-border IAS concerns. Train natural resource staffs at the local level in regards to IAS management support. Train interested citizens to support IAS management efforts.	2016	DLNR	External donor	Medium
	Conduct periodic surveys of ethnic markets, pet stores, and grocery stores to identify and intercept prohibited animals and animal and plant products following the model of the USDA-APHIS-PPQ Smuggling, Interdiction, and Trade Compliance program.	On-going	Quarantine	Biosecurity cost recovery system	Low
	Establish and develop relationships with key industrials such as landscaping and pet stores to help develop their ability to institute internal standards to support IAS prevention.	2016	DLNR	TBD	Medium
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	DLNR	TBD	Medium
	Improve capacity to identify biosecurity intercepts and organisms detection post border, including micro organisms and viruses.	2016	DLNR	External donor	Medium
	Ensure that funding mechanisms are established and that funding is available as needed to support IAS specimen sampling, testing, and identification.	2016	DLNR	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve overall post border biosecurity (continued)	Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other businesses as appropriate to promote the sale and use of locally sourced plants, preferably native plants. If non-natives are going to be used for landscaping, insure that they are non-invasive species. If plants will be brought into an area from outside for landscaping, insure that they are pest free. This code of conduct should encourage businesses: to make their staff knowledgeable about invasive plants, to inform their customers about invasive plants, to report immediately any likely exotic pest organisms found on their premises, and to use native or non-invasive plants locally sourced.	2015	Quarantine and Forestry	TBD	Low
Increase agricultural biosecurity/food security	Conduct background surveys as soon as possible to establish baselines for plant pests and livestock and wildlife populations and diseases.	2017	DLNR	External donor	Medium
	Implement initial surveillance and monitoring strategy to prevent introduction of livestock, poultry, and wildlife diseases and to determine whether measures perform adequately. These measures then should adjust to improve biosecurity.	2017	DLNR	External donor	Medium
	The collection and analysis of baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained. In a similar fashion collecting and analyzing data regarding both existing pests and pests at high risk of invasion should be a continuous effort. Information gathered should be shared on a regular basis within the region and beyond. There are existing models at least for some components of this process that should be considered and utilized where appropriate.	2017	DLNR	External donor	Medium
Improve internal biosecurity	Conduct a jurisdictional review and consultation period to determine: A. need for internal biosecurity, B. if needed, how it could best be implemented, and C. Follow up with recommendations which come from this process.	2016	DLNR	Biosecurity cost recovery system	High
	Determine best methods for protecting currently uninhabited islands such as Pagan from additional IAS incursions and consider options for IAS management on these islands in regards to already established species.	2017	DLNR	Biosecurity cost recovery system	High
Increase alien snake detection capacity	Develop a BTS quarantine facility for the island of Rota as well as develop resources to enhance the BTS detection capacity for the island.	2017	DLNR	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Department of Health	External donor	Medium
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import.	2014	Quarantine	Biosecurity cost recovery system	High
	Update white list on a regular basis.	annually	Quarantine	Biosecurity cost recovery system	Medium
	Develop a government endorsed black list of prohibited species.	2014	Quarantine	Biosecurity cost recovery system	High
	Update black list on a regular basis.	annually	Quarantine	Biosecurity cost recovery system	Medium
	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	2015	Quarantine	utilize student support	Low
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	Quarantine	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Improve reporting and screening systems for import of live organisms.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Improve tracking of live plant and animals imports. Importers should list the types and numbers of each species in each shipment, and such information should be recorded by border agents, retained in an electronic database, and shared as appropriate.	2016	DLNR	Biosecurity cost recovery system	Medium
Reduce risk associated with live traded species	Establish a formal risk analysis process/guidelines for all organisms used or proposed for live trade.	2015	DLNR	This should be supported by user fees as part of the cost recovery biosecurity system	High
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	DLNR	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	Development of strict contingency plans/emergency preparedness programs regarding possible escapees of exotic organisms being farmed or traded.	2015	DLNR	Biosecurity cost recovery system	High
	Ensure that specific quarantine facilities are available (will need to build) and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species). Facilities need to include quarantine facilities for terrestrial and aquatic species, examination and inspection areas. Facilities are best located proximal or within port areas to reduce on island transit prior to reach quarantine.	2016	Quarantine	External donor	Medium
	Improve disease diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	DLNR	Biosecurity cost recovery system	Medium
	Ensure that all aquaculture facilities are secure including from natural disasters.	2015	DLNR	Biosecurity cost recovery system	High
	Support regional and international cooperation on the responsible use and control of exotic species.	continuous	CNMI Invasive Species Coordinator	External donor	Medium
	Develop standards for backyard aquaculture set ups and enforce as feasible.	2015	DLNR	Biosecurity cost recovery system	Low
	Develop specific guidelines for the adequate disposal of unwanted pets.	2015	DLNR	External donor	Low
Increase existing biosecurity capacity by providing adequate day to day resources	Provide training to increase inspection and identification expertise. Safeguarding inspectors (both civilian and military) should receive regular adequate training in proper techniques for detecting, collecting, recognizing, and identifying pests. A communication network for continuous sharing of new information is recommended.	2015	Quarantine	Biosecurity cost recovery system	High
	Increase capacity and training of both current and new quarantine inspectors to better enable them to handle current and future inspection levels, identify key IAS of concern, collect and enter data, and insure that all regulations are being equally applied to all (there should be no exceptions in regards to border security regardless of person or position).	2015	Quarantine	Biosecurity cost recovery system	High
	Train inspectors specifically in livestock, wildlife, and poultry diseases and pests.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Hire and train biosecurity staff in order to meet current inflow levels and any anticipated near term increases. This applies across the board: inspections, management and control operations, and early detection and rapid response.	2015	Quarantine	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase biosecurity surveillance measures at both military and commercial airports and harbors including all entry points and screening check points.	Keep a well-documented process of pest and disease prioritization, surveillance, data collection, and record keeping. Specific surveillance methodology should be appropriate for target species (i.e. modifying sampling programs to account for behavioral differences in diurnal and nocturnal lifestyles).	2016	Quarantine	Biosecurity cost recovery system	High
	Communicate survey results among all island mitigation programs.	2017	Quarantine	Biosecurity cost recovery system	High
	Utilize systematic surveillance for plant pests following the model of the Cooperative Agriculture Pest Surveys (CAPS), and include both military and civilian properties as appropriate.	2017	Quarantine	Biosecurity cost recovery system	High
	Biosecurity surveillance system should include routine surveillance for wildlife, livestock, and poultry diseases and vectors as well as plant pests.	2017	Quarantine	Biosecurity cost recovery system	Medium
Establish and enforce biofouling standards	Establish biosecurity criteria (requirements) for acceptable levels of hull biofouling for all commercial vessels (including cargo ships, cruise ships, passenger ships, barges, dredges, fishing vessels, and other vessel types).	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish reporting requirements on hull husbandry practices and operational characteristics for commercial vessels (including cargo ships, cruise ships, passenger ships, barges, dredges, fishing vessels, and other vessel types).	2017	DNLR	Biosecurity cost recovery system	Medium
	Establish requirements for routine inspection and certification of biofouling levels for any commercial vessel with a long port residence time or lay-up.	2017	DLNR	Biosecurity cost recovery system	Medium
	Review and establish criteria for in-water cleaning methods for commercial vessels that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	DLNR	Biosecurity cost recovery system	Medium
	Develop the capacity to (a) assess the extent to which commercial vessels achieve acceptable levels of biofouling, and (b) respond to high-risk commercial vessels (i.e., those with high biofouling) that arrive to a port.	2017	DLNR	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement biofouling management program for commercial ships.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of biofouling management requirements for commercial ships.	2017	DLNR	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Implement inspections of any impounded vessel (a) assess level of hull biofouling and (b) treat vessels (if needed) to reduce biofouling to acceptable level.	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat (if necessary) recreational vessels to reduce associated biofouling to an acceptable level.	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for recreational vessels to reduce the transfer of biofouling organisms.	2017	DLNR	Biosecurity cost recovery system	Medium
	Review and establish criteria for in-water cleaning methods for hull fouling that do not post a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement targeted outreach and administrative tools to increase compliance with biofouling requirements for military and civilian vessels.	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within the CNMI.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the fishing industry, ports, and resource management agencies of biofouling management requirements for fishing vessels.	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within the CNMI to reduce associated biofouling to an acceptable level.	2017	DLNR	Biosecurity cost recovery system	Medium
Establish and enforce ballast water standards	Plan for in-hull treatment of ballast water with support from the USCG in regards to developing biosecurity for marine organisms. USCG has proposed to change regulations from ballast water exchange to in hull treatment. Matson's new ship builds already have treatment inline for ballast water.	2017	DLNR	USCG	Medium
	Implement a system for U.S. Navy ships to report ballast water discharge, modeled after that used by USCG, such that the data are compiled electronically at a centralized database.	2017	DLNR	DoD	Medium
	Establish ballast water management and reporting requirements for all commercial vessels (including cargo ships, cruise ships, passenger ships, barges, and any other vessel that can carry ballast water).	2017	DLNR	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce ballast water standards (continued)	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance by commercial vessels.	2017	DLNR	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement ballast water management program for commercial ships.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for commercial ships.	2017	DLNR	Biosecurity cost recovery system	Medium
Increase marine system protection from invasive species	Ensure the marine biosecurity regulations, inspections, quarantine, and outreach efforts are appropriate.	2017	DLNR	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within the CNMI.	2017	DLNR	Biosecurity cost recovery system	Medium
	Ensure capacity building training to inspectors regarding aquatic biosecurity and develop SOPs for inspections regarding both marine and freshwater biosecurity.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program for DoD and civilian populations with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within the CNMI.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program for DoD and civilian populations with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within the CNMI.	2017	DLNR	Biosecurity cost recovery system	Medium
	Implement a long-term monitoring program for key harbor and marina areas including other high use mooring and anchorage areas like those below the preposition ships.	2017	TBD	Biosecurity cost recovery system	Medium
Address climate change linkages to invasive pests		2017	DLNR	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Early detection and rapid response</i>					
Improve early detection and rapid response capacity	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	CNMI Invasive Species Task Force	External donor	High
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	DLNR	Biosecurity cost recovery system	High
	Develop taxa specific ERPs as needed (Little Fire Ant, Coconut Rhinoceros Beetle, etc.).	On-going	DLNR	External donor	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	CNMI Invasive Species Task Force	TBD	High
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable). This would be similar to 28-SNAKE but would be developed for all organisms, not just snakes.	2016	DLNR	Biosecurity cost recovery system	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2016	DLNR	Biosecurity cost recovery system	High
	Develop and institute surveillance programs for non-established species consider high risk of arrival such as CRB, alien snakes, fruit flies, tramp ants, etc.	2015	DFW, Forestry, and Quarantine	Biosecurity cost recovery system	High
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	DFW, Forestry, and Quarantine	Biosecurity cost recovery system	Low
Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2016	DLNR	Biosecurity cost recovery system	High	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve early detection and rapid response capacity (continued)	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2016	DLNR	Biosecurity cost recovery system	High
	Training and maintain a core group of ED & RR staff from local agencies/stakeholder groups.	2016	DLNR	Biosecurity cost recovery system	High
	Hold consultations to determine what agency(s), office(s) and/or groups will be responsible for surveillance programs.	2015	DLNR	External donor	Medium
Management and eradication					
Increase management and control of established IAS	Eradicate small and feasible IAS incursions promptly.	on-going	DFW, Quarantine, and Forestry	External donor	High
	Create GIS layers that delineate management zones, land tenure, and current distribution of established IAS.	2015	College of the Northern Mariana Islands	External donor	Low
	Develop and implement more control and management programs to deal with existing IAS and to reduce the potential of spreading them to non-infected locations both within and outside of the CNMI.	on-going	DLNR	External donor	Medium
	Improve surveillance and monitoring of existing invasive species.	2015	DLNR	External donor	Medium
Awareness					
Evaluate social, cultural, economic, and ecological values that may be impacted negatively by non-native species.	Establish a watch list of high-risk non-native species that are known or thought to pose significant ecological, economic, social, or cultural impacts.	2015	DLNR	External donor	Medium
	Raising awareness about the potential negative ecological, cultural, economic, and human health effects of invasive species is an important component of both prevention and early detection. The following measures could heighten public awareness among the military and the public: surveys of the current level of understanding of IAS and their impacts as well as more specific surveys on the procurement and use of plants, animals, and their products by local communities, transient workers, and visitors are all needed.	2016	DLNR	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and nation wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	CNMI Invasive Species Task Force	External donor	High
	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the nation from unwanted pests.	2015	CNMI Invasive Species Task Force	External donor	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	CNMI Invasive Species Task Force	External donor	Medium
	Establish long term funding to support core outreach and educational efforts.	2016	CNMI Invasive Species Task Force	External donor	High
	Coordinate existing outreach efforts.	2015	CNMI Invasive Species Task Force	External donor	High
	Add invasive species education as a standard part of school curriculums.	2017	CNMI Invasive Species Task Force/Department of Education	External donor	Medium
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2017	CNMI Invasive Species Task Force/Department of Education	External donor	Medium
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	2016	CNMI Invasive Species Task Force	External donor	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	2016	CNMI Invasive Species Task Force	External donor	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2016	CNMI Invasive Species Task Force	External donor	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2016	CNMI Invasive Species Task Force	External donor	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2016	CNMI Invasive Species Task Force	External donor	High
Research					
Prioritize IAS research for the CNMI	Develop standardized SOP's for IAS monitoring and implement surveys.	2016	DLNR	External donor	High
	More specific localized risk assessments should be conducted for all habitat types.	2018	DLNR	External donor	Low
	Identify experts in IAS taxonomy and proactively develop agreements with them for processing and identifying samples. Details should include preservation requirements and turnaround times.	2017	DLNR	External donor	Low
Policy					
Improve ability to address invasive species and biosecurity	Establish an IAS council, committee, or taskforce that is endorsed by and works with the governance.	2015	Governor's Office	Biosecurity cost recovery system	High
	Develop a comprehensive IAS SAP for the CNMI, including priority species, current capacity, and recommendations to address existing gaps.	2015	CNMI Invasive Species Task Force	Biosecurity cost recovery system	High
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance.	Conduct a review of existing laws and regulations governing biosecurity in the CNMI, particularly as they pertain to import from foreign countries and export to other areas of Micronesia and Hawaii.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Review relevant biosecurity related guidelines and SOPs to insure they are clear, complete, detailed, and in compliance with appropriate laws and regulations. Update existing guidelines and SOPs as needed. Develop guidelines or SOPs for specific activities if they are lacking.	2015	Quarantine	Biosecurity cost recovery system	Medium
	Expand existing or create new regulations (as needed) and SOP to encompass all potential IAS including terrestrial (agricultural and non-agricultural), freshwater, and marine concerns. Current systems are mainly based on agriculture and a handful of high risk species such as the Brown Treesnake.	2016	Quarantine	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Ensure that appropriate biosecurity regulations are in place and enforced. Regulations should support the issuance of penalties and fines to enforce compliance (continued).	Review (an update if necessary) penalty assessment structure for noncompliance with regulations covering animal and plant health as a source of additional funding.	2015	Quarantine	Biosecurity cost recovery system	Medium

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment K: State of Hawaii Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Hawaii section of the RBP regularly and share regionally.	continuous, at least every 5 years	HISC	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	HISC	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	HISC	Regional ISC Office	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report shared with the region and beyond.	continuous, yearly	HISC	Biosecurity cost recovery system	High
Improve Statewide biosecurity and coordination	Develop statewide IAS SAP with input from stakeholders of the state (may be possible to utilize HISC strategic plan and HDOA biosecurity plan).	2014-15	HISC, HDOA	HISC, HDOA	High
	Update risk assessment for terrestrial IAS using current HDOA data.	2015	HDOA	TBD	Medium
	Rebuild biosecurity capacity at HDOA to at least 2009 levels (Fill vacated position, provide training to get staff up to speed).	2016	HDOA	Biosecurity cost recovery system	High
	Need to move forward with hiring and training staff members to meet current and future expected needs within HDOA quarantine.	2016	HDOA	Biosecurity cost recovery system	High
	HDOA should consider creating and filling a position that will be focused on IAS issues. This position may serve as the ISC for HDOA. Could be similar to the DOFAW IS coordinator and might serve as the primary point of contact for IS issues with the HDOA.	2016	HDOA	Biosecurity cost recovery system	Medium
	Document and analyze numbers and types of interceptions from all pathways and made available to appropriate agencies and staffs.	2015	HDOA	Biosecurity cost recovery system	Medium
	Hire and allocate additional staff and resources to support intra-island biosecurity efforts.	2017	HDOA	Biosecurity cost recovery system	High
	Create and institute a mixed model biosecurity approach based on both vector sanitation and focusing on key high risk species for all habitats.	2015	HDOA	Biosecurity cost recovery system	High
	Develop appropriate vector management with feedback and monitoring mechanisms. If INVICTA becomes fully operational it could serve as the feedback mechanism.	2015	HDOA, DOT, DOH	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve Statewide biosecurity and coordination (continued)	Implement a more comprehensive data collection and better data management on IAS vectors and pathways, including detailed inspection processes, intercept records, preservation and compiling of voucher specimens, detailed records on where shipments, etc. are arriving from and specifically what is known to have harbored IAS and where it come from and how it arrived.	2015	HDOA	Biosecurity cost recovery system	Medium
	Enter records into database, analysis and share results with partners as warranted.	2015	HDOA	Biosecurity cost recovery system	High
	Consider helicopters and private planes (or small scale commercial ventures) as possible IAS vectors and therefore a biosecurity threat that needs to be appropriately monitored and inspected.	2015	HDOA, DOT	Biosecurity cost recovery system	Low
	Identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of cargo staging facilities.	2016	HDOA	Biosecurity cost recovery system	Low
	Review relevant biosecurity related guidelines and SOPs to insure they are clear, complete, detailed, and in compliance with appropriate laws and regulations.	2015	HDOA, HISC	Biosecurity cost recovery system	Medium
	Update existing guidelines and SOPs as needed.	2015	HDOA	Biosecurity cost recovery system	Medium
	Improve communication between different levels of government, agencies, and others involved in biosecurity work.	2015	HISC, HDOA		Medium
	Document the cost of IAS control and management compared to prevention is needed.	on-going	HISC, HDOA	USFWS/USDA/DoD	Medium
	Hawaii state should implement an electronic inspection system.	2015	HDOA	TBD	High
	Better direct use of limited resources based on interception records.	2015	HDOA	Biosecurity cost recovery system	High
	Provide sufficient funds to conduct routine surveillance, implement response plans, and provide outreach and education, in addition to port of entry exclusion activities and training for inspectors.	2016	HDOA, HISC	Biosecurity cost recovery system	High
	Identify and establish dedicated, long-term and short term funding to implement the various biosecurity recommendations.	2016	HDOA, HISC	Biosecurity cost recovery system	High
	Identify a core level of activities, personnel, and coordination to sustain biosecurity and provide long-term continuity.	2016	HDOA, HISC	Biosecurity cost recovery system	High
	Support increased funding for regional biosecurity so that necessary efforts to prevent, control, and eradicate animal and plant pests and diseases throughout the region are effective.	2015	HISC	External donor	Medium
	Implement user fees attached to military related passengers and baggage inspections (as needed).	2015	HDOA, HISC	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve Statewide biosecurity and coordination (continued)	Conduct Hawaii port and hot spot risk assessments and tie into the RBP once completed.	2015	USDA, HDOA	TBD	Medium
	Conduct an aquatic plant risk assessment that includes potential impacts from Micronesia as this aspect is not well covered in the RBP risk assessments.	2016	DLNR, HDOA, HISC	USFWS/USDA/DoD	Medium
	HDOA and federal agencies should continue to work together on redevelopment of the HDOA detector dog program for port inspections.	on-going	HDOA, USDA	USFWS	High
	Ensure that the State of Hawaii continues to work with DoD to ensure that biosecurity needs are appropriately addressed regarding the potential movement of DoD components from Okinawa to Hawaii and any other DoD activities.	2015	HDOA	DoD	High
	Finalize process of merging State and Federal IAS risk lists and establish MOAs so that federal agents can react to and enforce state concerns.	2015	HDOA, CGAPS, HISC, USDA	USDA	High
	Ensure adequate long-term funding is available for equipment and infrastructure.	2016	HDOA	Biosecurity cost recovery system	High
Improve communications and ability to address biosecurity concerns between US DoD and civilian government agencies	Establish an MOU between Hawaii and DoD regarding biosecurity actions, responsibilities and mitigation in regards to DoD activities and facilities. In 2013 a MOU was developed between DoD and HDOA which is a good start but needs to be expanded.	2015	HDOA/DoD	DoD	Medium
	Establish SOPs on aspects of how DoD and Hawaii's civilian agencies work together regarding biosecurity inspection process, response actions and other activities as needed in response to increased DoD activities.	2015	DoD	DoD	Medium
Improve regional coordination regarding biosecurity and IAS	Establish a central repository for plant pathogens information for the region.	2017	University of Hawaii	TBD	Low
	Join RISC directly or minimally participate in RISC activities as an outside Micronesia stakeholder.	2014	HISC	RISC	High
	Develop pre-entry requirements for certain commodity imports from high-risk areas to reduce the likelihood of pest and invasive species introductions for a Regional monitoring and surveillance program.	2015	USDA, HDOA	Biosecurity cost recovery system	High
	Establish a biosecurity surveillance system to serve as an early detection program for plant, animal, and zoonotic pests and pathogens emerging in Pacific Rim countries.	2016	HDOA	Biosecurity cost recovery system	Low
	Support development of standardized SOPs for IAS monitoring and implement surveys throughout the region.	2016	USDOI, RISC	External donor	Low
	Strengthen regional and international cooperation on the responsible use and control of exotic species.	2016	RISC	External donor	Medium
	Develop eradication programs for extremely harmful species already present in Hawaii.	2016	DLNR, HDOA, HISC	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.</p>	<p>Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office</p>	<p>ideally this office would be up and running before the end of 2015</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office with supporting protocol and methods development</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. 	<p>Engage the regional invasive species coordination office with supporting establishing ER &RR capacity</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting the development of guidelines and regulations</p>	<p>As soon as the office can be established</p>	<p>Hawaii RISC representative(s) and HISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office with both seeking for and coordinating regional funding	As soon as the office can be established	Hawaii RISC representative(s) and HISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support management, response, and eradication efforts	As soon as the office can be established	Hawaii RISC representative(s) and HISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information	As soon as the office can be established	Hawaii RISC representative(s) and HISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts	As soon as the office can be established	Hawaii RISC representative(s) and HISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	HISC	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going; finalized by 2018	University of Hawaii	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	University of Hawaii	TBD	Low
	Support the development of an algal risk assessment for the region.	2016	University of Hawaii	TBD	Medium
	Support the development of an arthropod risk assessment for the region.	2016	University of Hawaii	TBD	Medium
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	University of Hawaii	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	University of Hawaii	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region (Hawaii already has one, which could be used possibly as a model).	2016	University of Hawaii	TBD	Medium
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Hawaii RISC representative(s)	TBD	Medium
Prevention					
Improve pre-border biosecurity	Improve pre-departure cleanliness of items shipped to Hawaii. Orchids from Thailand were on item which was pointed out as needing improved pre-arrival sanitation.	2016	HDOA	Biosecurity cost recovery system	High
	Implement the use of pre-border sanitation compliance agreements with shippers and contractors. Consider using HACCP as a model.	Should track with the preceding action item	HDOA, USDA	Biosecurity cost recovery system	High
	All large, used machines (bulldozers, etc.) which are to be imported should be required to undergo thorough cleaning and inspection for invasive species immediately prior to shipping.	2015: consider establishing guidelines based on existing USDA-APHIS materials	HDOA	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve pre-border biosecurity (continued)	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized in Australia and New Zealand. Preventing the arrival of potential IAS is ultimately the most cost effective way to ensure appropriate biosecurity levels are in place and they offer the best protection from the potential hazards which IAS could cause.	2015 Hold state consultation including review of pertinent models (New Zealand); 2016 Develop draft standards; 2017 implement standards	HDOA	TBD	High
	Develop stronger pre-border regulations regarding the movement of non-native species.	2016	HDOA	Biosecurity cost recovery system	Medium
Improve WPM capacity	Require treatment of all domestic and foreign, military and non-military WPM entering Hawaii according to ISPM No. 15.	2015	HDOA	Biosecurity cost recovery system	Medium
	Conduct phytosanitary inspection of WPM.	2015	HDOA	Biosecurity cost recovery system	Medium
	Inspect thoroughly an adequate percentage of all domestic and foreign, military and non-military WPM accompanying agricultural and nonagricultural cargo for pests.	2015	HDOA	Biosecurity cost recovery system	Medium
	Require consistent inspection methods within SOPs.	2015	HDOA	Biosecurity cost recovery system	Medium
	Document all inspections and interceptions.	2015	HDOA	Biosecurity cost recovery system	Medium
	Record pest interceptions in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2016	HDOA	Biosecurity cost recovery system	Medium
	Prohibit the unloading of noncompliant WPM.	2015	HDOA	Biosecurity cost recovery system	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	HDOA	Biosecurity cost recovery system	Medium
	Treat or destroy infested WPM.	2015	HDOA	Biosecurity cost recovery system	High
	Treat Infested WPM as regulated garbage and incinerated or sterilized.	2015	HDOA	Biosecurity cost recovery system	High
	Support a regional approach to switch from WPM to other options such as recycled plastics.	2017	HDOA	External donor	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve agriculture biosecurity and food security	Collect, analyze, establish and maintain baseline data regarding key crops and animal stocks for internal consumption as well as for export	2016	HDOA	USDA	Low
	Collect and analyze data regarding both existing pests and pests at high risk of invasion.	2015	HDOA	Biosecurity cost recovery system	Low
	Share information on a regular basis within the region and beyond.	2015	HISC	TBD	Medium
	Conduct periodic surveys of ethnic markets, pet stores, and grocery stores to identify and intercept prohibited animals and animal and plant products following the model of the USDA-APHIS-PPQ Smuggling, Interdiction and Trade Compliance program.	2015	HDOA	Biosecurity cost recovery system	Low
Improve intra-state biosecurity and foreign arrivals at ports other than the main air and sea ports	Develop biosecurity standards for ports other than the main air and sea ports.	2017	HDOA, DOT, DOH	Biosecurity cost recovery system	High
	Implement and enforce biosecurity at ports other than the main air and sea ports	2017	HDOA, DOT, DOH	Biosecurity cost recovery system	High
	Conduct a state wide consultation regarding intrastate biosecurity before attempting to develop capacity and regulations to determine what is actually needed and what the citizenry will support.	2015	HDOA, DOT, DOH	Biosecurity cost recovery system	High
	Develop a comprehensive reporting system for intra-state biosecurity efforts.	2016	HDOA, DOT, DOH	Biosecurity cost recovery system	High
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a state biosecurity advisory committee to review proposals for the importation of exotic species.	2015	State agencies with support from feds	Biosecurity cost recovery system	High
	Improve reporting and screening systems for import of live organisms. Currently done for most marine organisms and should be expanded to all live organisms.	2015	State agencies with support from feds	Biosecurity cost recovery system	High
	Ensure that specific quarantine facilities are available and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species).	2016	State agencies with support from feds	TBD	High
	Develop plan for containment and control measures in regards to exotic farmed and traded species.	2015	State agencies with support from feds	Biosecurity cost recovery system	Medium
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	State agencies with support from feds	Biosecurity cost recovery system	High
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2015	HDOA/DLNR	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	HDOA, UH	Biosecurity cost recovery system	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	HDOA, DAR	Biosecurity cost recovery system	High
Develop biosecurity standards for household aquaculture set ups and enforce these standards.	2015	HDOA	Biosecurity cost recovery system	Medium	

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Reduce risk associated with live traded species (continued)	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	State agencies with support from feds	Biosecurity cost recovery system	Medium
	Develop specific guidelines for unwanted pets.	2015	State agencies	TBD	Low
	Establishment lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	USFWS, HDOA, DLNR	Biosecurity cost recovery system	Low
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	USDA	TBD	Low
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import.	2014	HDOA	Biosecurity cost recovery system	High
	Update white list on a regular basis.	annually	HDOA	Biosecurity cost recovery system	Medium
	Develop a government endorsed black list of prohibited species.	2014	HDOA	Biosecurity cost recovery system	High
	Update black list on a regular basis.	annually	HDOA	Biosecurity cost recovery system	Medium
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	HDOA	Importer pays for all aspects of the risk assessment (regardless of outcome)	High
	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	2015	HDOA	utilize student support	Low
Increase biosecurity surveillance measures and interception at both military and commercial airports and harbors including all entry points and screening check points	Address regulations to permit HDOA PQ to inspect containers as needed.	2015	HDOA	Biosecurity cost recovery system	High
	Find working solution to improve overall inspection levels of goods arriving to Hawaii from domestic ports.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Find working solution to improve inspection levels of housing goods arriving to Hawaii from Guam (both directly and indirectly).	2015	HDOA	DoD	High
	Train personnel in identifying high-risk cargo and handling to reduce contamination.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Track changes in aircraft arrivals, especially as new linkages are established and/or additional carriers are added.	2015	HDOA, USDA	Biosecurity cost recovery system	High
	Develop staging areas for safeguarding high and low risk cargo.	2015	HDOA, USDA	TBD	Medium
	Inspect shipping containers and other vessels holding goods as vectors for hitch-hiker IAS.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Provide training in proper techniques for detecting, collecting, recognizing, and identifying pests to increase inspection and identification expertise.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Increase biosecurity surveillance measures and interception at both military and commercial airports and harbors including all entry points and screening check points (continued).	X-ray all incoming passengers baggage.	2016	HDOA, USDA	Biosecurity cost recovery system	Medium
	Train inspectors specifically on livestock, wildlife, and poultry diseases and pests.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Training TSA inspectors in IAS detection and capture.	2015	HDOA/TSA	Biosecurity cost recovery system	Medium
	Develop a biosecurity surveillance system for improved data collecting, reporting, and information sharing.	2016	HDOA	(may already have with INVICTA)	Medium
	Follow a well-documented process of pest and disease prioritization, surveillance, data collection, and record keeping.	2016	HDOA	Biosecurity cost recovery system	Medium
	Include routine surveillance for wildlife, livestock, and poultry diseases and vectors as well as plant pests in biosecurity system.	2016	HDOA	Biosecurity cost recovery system	High
	Modify surveillance methodology as appropriate for targeted species, (i.e. modifying sampling programs to account for behavioral differences in diurnal and nocturnal lifestyles).	2016	HDOA	Biosecurity cost recovery system	Medium
	Utilize systematic surveillance for plant pests following the model of the Cooperative Agriculture Pest Survey (CAPS), and include both military and civilian properties as appropriate.	2015	State Government	Biosecurity cost recovery system	Medium
Improve mail biosecurity	Find a working solution which will permit the inspection of US mail (and all other mail types).	2016	HISC, USDA, Postal Service	Biosecurity cost recovery system	High
Improve biosecurity for the movement of vehicles and equipment	Develop functional cleaning facilities (wash racks, etc.) at all DoD installations where warranted and provide appropriate training for military personnel to utilize these facilities.	2015	HDOA, DoD	DoD	High
	Utilize APHIS training courses or manuals to support wash down efforts.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Clean containers and conveyances that arrive contaminated with soil and/or exotic plant pests	2015	HDOA, USDA	Biosecurity cost recovery system	High
	Evaluate the effectiveness of current cleaning methods, and improve as appropriate.	2015	HDOA, USDA	Biosecurity cost recovery system	High
	Conduct inspections of all incoming construction materials including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Clean and inspect large, used machines such as tanks and bulldozers intended for importation for IAS at points of origin immediately prior to shipping.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve biosecurity for the movement of vehicles and equipment (continued)	Insure proper cleaning of all large equipment such as construction and military items according to APHIS guidelines prior to entry.	2015	HDOA, USDA	Biosecurity cost recovery system	Medium
	Insure proper cleaning of all large equipment such as construction and military items according to APHIS guidelines prior to moving between sites.	2015	HDOA, USDA	Biosecurity cost recovery system	High
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests.	2015	HDOA, USDA	TBD	Medium
	Implement "clean" practices at construction sites, including the minimization of land disturbance which may contribute to the spreads plant pests.	2015	HDOA	TBD	Medium
Establish and enforce biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish additional regulations for impounded vessels.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish standards and regulations regarding biofouling, including inspection and certification for all vessels. Inspections can be trained to inspect hulls from top side with mirrors. If further inspection is warranted, then the craft pays for divers to inspect and make a report. If determined to be dirty, then the craft must either be cleaned or leave port and jurisdictional waters. Self clean outside of jurisdictional waters could be an option. Hull needs to be clean of all organisms, as the ability to identify all marine organisms is not available.	2017	DLNR DAR	Biosecurity cost recovery system	High
	Develop capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2017	DLNR DAR	TBD	High
	Establish regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	DLNR DAR	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Establish the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2017	DLNR DAR	TBD	High
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Ensure that regulations include ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2017	DLNR DAR	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a biofouling management program	2014: this should be included in the current draft biosecurity legislation; May need to update and expand in 2016-17 as elements come online	DLNR DAR	Biosecurity cost recovery system	High
Increase marine system protection from invasive species	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	DLNR DAR	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Establish and enforce ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	DLNR DAR	Biosecurity cost recovery system	High
	Establish ballast water management and reporting requirements for all vessels utilizing ballast water.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	DLNR DAR	Biosecurity cost recovery system	High
	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to support a ballast water management program.	2016	DLNR DAR	Biosecurity cost recovery system	High
	Support adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	DLNR DAR	Biosecurity cost recovery system	Medium
Address climate change linkages to invasive pests		2017	University of Hawaii, PICCC, HISC	TBD	Low
Early detection and rapid response					
Improve early detection and rapid response capacity	Increase BTS inspection of goods and conveyances arriving from Guam both directly and indirectly.	2015	HDOA	OIA	High
	Increase ability to respond effectively to alien snake encounter reports, through improved communication and cooperation with agencies on the ground as well as external supporters, by increasing the numbers of trained responders available on all vulnerable islands, by insure that trained responders received appropriate update training, and by insuring that there are sufficient support staff to assist primary trained responders.	2016	HDOA	OIA	High
	Re-instate mosquito vector monitoring for infectious diseases throughout the state.	2016	DOH, HISC	USFWS	Low
	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	HISC	USFWS/USDA/DoD	High
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2015	ISCS	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve early detection and rapid response capacity (continued)	Develop taxa specific ERPs as needed.	On-going	HISC	TBD	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	HISC	TBD	High
	Develop and institute surveillance programs for non-establish species consider high risk of arrival such as CRB, alien snakes, fruit flies, tramp ants, etc.	2016	HISC, ISCs	USFWS	Medium
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities.	2015	ISCs	TBD	Low
Management and eradication					
Increase management and control of established invasive species	Determine which established invasive species are actionable and proceed with developing management strategies. Covered in part by national ISAP.	2015	HISC	ISAP	Medium
	Train natural resource staffs (including protected areas staffs) at the local level in regards to IAS management support.	2015	HISC	TBD	Medium
	Train interested citizens to support IAS management efforts (volunteer citizen scientists).	2015	HISC	TBD	Low
	Conduct surveys on the procurement and use of plants, animals, and their products by local communities.	2015	HDOA	Biosecurity cost recovery system	Low
	Develop standardized SOPs for IAS monitoring and surveys.	2015	DLNR	USFWS	Medium
	Conduct regular background field surveys to ensure that knowledge of established invasive species and their distributions are current.	on-going	DLNR	USFWS	Medium
	Create community funding sources for local (village level) programs to promote environmental awareness and stewardship through local training, education, and eradication efforts.	2016	HISC	TBD	Low
	Support Little fire ant management and eradication efforts with funding and resources.	on-going	HISC, HDOA, DLNR, UH	TBD	High
	Conduct delimiting surveys for CRB, followed immediately by a well-developed management strategy and possibly eradication efforts.	2014	HDOA	TBD	High
	Provide funding and other resources immediately for the best possible chance at CRB eradication success.	2014	HDOA, USDA	TBD	High
	Address rats, especially their parasites, such as <i>Agrostrongylus patenetus</i> which is a major concern for public health.	2015	DLNR, USFWS	TBD	Medium
	Improve detection methods for rodents and other wildlife on vessels and in cargo.	2017		TBD	Low
	Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other businesses as appropriate to promote the sale and use of locally sourced plants, preferably native plants.	2015	CGAPS and HDOA	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Increase management and control of established invasive species (continued)	Encourage businesses to make their staff knowledgeable about invasive plants, to inform their customers about invasive plants, to report immediately any likely exotic pest organisms found on their premises, and to use native or non-invasive plants locally sourced.	2015	TBD	TBD	Low
	Establish and develop relationships with key industrials such as landscaping and pet stores to help develop their ability to institute internal standards to support IAS prevention.	2015	DLNR	TBD	Low
	Improve capacity to carry out investigations and effective enforcement beyond ports of entry.	2016	HDOA	Biosecurity cost recovery system	Medium
Awareness					
Increase outreach and education on biosecurity and invasive species	Develop an educational strategy that is long term, extensive and nation wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	HISC	TBD	High
	conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the nation from unwanted pests.	2015	CGAPS	TBD	High
	Conduct follow-up surveys and tweak system accordingly to insure long term viability and usefulness of the educational strategy	Every 3-5 years	CGAPS	TBD	High
	Provide information to local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	CGAPS	TBD	High
	Establish long term funding to support core outreach and educational efforts.	2016	HISC	TBD	High
	Increase coordinate existing outreach efforts.	2015	HISC, PCSU	TBD	High
	Add invasive species education as a standard part of school curriculums.	2016	CGAPS/Department of Education	TBD	High
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2016	CGAPS/Department of Education	TBD	High
Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2016	HISC	Regional ISC Office	Medium	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2016	CGAPS	TBD	High
	Advertise amnesty/honor bin option by means of mass media outlets as part of public outreach.	2015	CGAPS	TBD	Medium
	Create awareness of the potential legal consequences of violations.	2016	CGAPS	TBD	Medium
	Distribute multi-lingual biosecurity poster free to pet shops, grade schools, universities, sporting goods stores, gardening stores, naturalist clubs, parks and natural areas, military facilities, air and sea ports, community centers and perhaps even seafood stores, farmers' markets and restaurants.	2016	CGAPS	TBD	Medium
	Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers to inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers.	2016	CGAPS	TBD	Medium
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials,	2016	CGAPS	TBD	Medium
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted by invasions by non-native species.	Conduct baseline surveys.	2015	University of Hawaii	TBD	High
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the state that can be shared with universities and others. Such a list could be a positive influence in engaging research groups to support management efforts within the state.	2015	University of Hawaii	TBD	Low
Policy					
Improve laws and regulations	Conduct a review of both state and federal biosecurity regulations as they apply to Hawaii.	2015	CGAPS, HISC	Biosecurity cost recovery system	Medium
	Agriculturally driven regulations should be reviewed and revised to better address invasive pests whether they are agriculturally related or not.	2015	HDOA/USDA	Biosecurity cost recovery system	High
	Expand existing or create new regulations (as needed) and SOPs to encompass all potential IAS include terrestrial (agricultural and non-agricultural), freshwater, and marine concerns.	2016	HDOA, CGAPS	Biosecurity cost recovery system	High
	Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law.	2016	CGAPS, HDOA, DLNR	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/ Resources	Priority
Improve laws and regulations (continued)	Ensure that appropriate biosecurity regulations are in place and enforced.	2016	HDOA, USDA	Biosecurity cost recovery system	High
	Issue penalties and fines to enforce compliance.	2015	HDOA, DLNR	Biosecurity cost recovery system	High
<i>Restoration</i>					
Improve efforts to restore native ecosystems and species	Increase restoration efforts of native systems where IAS management and/or eradication efforts have been successful.	should be an on-going process	DLNR and UH	USFWS/DoD	Low
	Localized risk assessments should be conducted for all habitat types.	start process in 2016 as needed	DLNR and UH	TBD	Low

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment L: Territory of Guam Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the Guam section of the RBP regularly and share regionally.	continuous, at least every 3 years	GISAC	Biosecurity cost recovery system	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	Guam RISC representatives	Regional ISC Office	High
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2015	Guam RISC representatives	Regional ISC Office	Medium
	Work with managers and advisory councils of the Pacific Marine National Monuments (including the Mariana Trench Marine National Monument) to collaboratively address marine biosecurity threats.	2015	NOAA / USFWS	TBD	Medium
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report shared with the region and beyond.	Yearly	Guam RISC representatives	TBD	High
Establish a jurisdictional invasive species coordination office that is tasked with supporting territory wide IAS efforts across agencies and offices as well as working nationally and regionally with IAS stakeholders to ensure appropriate levels of communication and support.	Develop funding to support the invasive species coordination position.	2015	Governor's Office	Biosecurity cost recovery system	High
	Hire and establish jurisdictional coordination office. Consider housing this office at the Governor's complex under direct supervision of the Governor's Office to insure its ability to work across offices and agencies on Guam.	2015	Governor's Office	Biosecurity cost recovery system	High
	Once established this office should support and assist in coordinating efforts with invasive species within the territory. Part of this effort will be ensure that information regarding emerging issues is appropriate disseminated and that governance is regularly updated regarding both territorial and regional invasive species developments.	2015	Governor's Office	Biosecurity cost recovery system	High
Improve communications and ability to address biosecurity concerns between US DoD and civilian government agencies	Establish an MOU between Guam and DoD regarding biosecurity within the territory in regards to DoD activities and facilities.	2015	GDOA	DoD	High
	Establish SOPs on aspects of how DoD and Guam's civilian agencies work together regarding biosecurity inspection process, etc.	2015	GDOA	DoD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.</p>	<p>Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.</p>	<p>2015</p>	<p>Guam RISC representatives and the Governor's office</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office with supporting protocol and methods development.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting establishing ER &RR capacity.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. 	<p>Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.</p>	<p>2015</p>	<p>Guam RISC representatives and the Guam ISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.	2015	Guam RISC representatives and the Guam ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support management, response, and eradication efforts.	2015	Guam RISC representatives and the Guam ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	2015	Guam RISC representatives and the Guam ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts.	2015	Guam RISC representatives and the Guam ISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	Guam Invasive Species Coordinator	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	University of Guam	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	University of Guam	TBD	Low
	Support the development of an algal risk assessment for the region.	2016	University of Guam	TBD	Medium
	Support the development of an arthropod risk assessment for the region.	2016	University of Guam	TBD	Medium
	Documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	Guam Invasive Species Coordinator	Regional ISC office	Low
	Documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	Guam Invasive Species Coordinator	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region	2016	University of Guam	TBD	Medium
Improve the functionality of RISC	RISC members should work with state governance to review the RISC by-laws and re-establish or enhance ties between appointed RISC members and jurisdictional leadership in order to facilitate communication between council members and leadership ensuring closer working relations.	2014	Guam RISC representatives	RISC	High
	Ensure that RISC membership is regularly reviewed and that council members are known to the state invasive species community and governance.	Reviews should correspond with turn over in Government	Guam RISC representatives	RISC	High
	RISC members should provide an annual overview of MCES activities regarding biosecurity to state stakeholders (both thematic and governance)	Within 1 month of the December MCES on an annual basis	Guam RISC representatives	RISC	High
	Support development of a clearly defined role for RISC to improve the council's ability to support biosecurity and invasive species efforts. RISC as a council established by and for the chief executives of Micronesia can and should play a major role in biosecurity of the region. RISC's ability to facilitate regional biosecurity and IAS initiatives needs to be improved.	2014	Guam RISC representatives	RISC	High
	Support participation of Hawaii in the RISC.	By the end of 2014 Hawaii should be part of RISC	Guam RISC representatives	NA	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve territorial IAS/biosecurity coordination	Share information between biosecurity offices at different levels of government between agencies as well as with DoD in regards to pathways, vectors, inspections, interceptions, and enforcement actions taken. Consider utilizing a joint agency work group to facilitate communication and sharing.	2014	GDOA, GCQA, UOG	Current funding	High
	Improve communication and coordination between GCQA and GDOA through establishment and utilization of Guam Biosecurity Division as dictated by Guam Public Law 31-43.	2014	GDOA, GCQA	Biosecurity Fee	High
	Develop list of recommended plants for landscaping	2015	GDOA - Division of Forestry	TBD	Medium
	Enhance collaboration between USFWS and GCQA through quarterly meetings and training.	2014	GCQA	USFWS	High
	Increase effectiveness of interdiction capabilities and inspections for wildlife and their products at the ports of entry to prevent the introduction of animal and zoonotic diseases by increasing rate of inspections and coordinating efforts of GCQA and other agencies with port-of-entry inspection responsibilities with USFWS.	2014	GCQA, Port Authority of Guam	USFWS	High
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	Guam RISC representatives	TBD	Medium
Support increased Federal assistance with biosecurity	Re-evaluate the operation and staffing needs of the Guam Plant Inspection Station.	2014	GDOA	USDA - APHIS	High
	Relocate the Guam Plant Inspection Station within the airport fence in order to limit the extent to which uninspected items need to be transported prior to inspection.	2015	GDOA	USDA - APHIS	Medium
	Train TSA inspectors in IAS detection and capture. An initial training for existing staff with yearly joint follow-up training with other agencies (GCQA, GDOA) would be appropriate. Train new cohorts as they are coming on board. Such training could be facilitated by SPC and/or UOG and/or USDA.	2015	GDOA, GCQA, UOG	TSA	Medium
	Ensure that the Guam Plant Inspection Station has adequate resources on hand for necessary day to day activities and the full range of inspections which may be required.	2015	GDOA	Biosecurity Fee	Medium
	The USDA-APHIS office on Guam needs to increase inspection and oversight of inspection processes.	2015	GDOA, GCQA	USDA - APHIS	Medium
	Increase USDA-WS pre-departure inspections of for brown treesnakes to enable WS to inspect 100% of all departing cargo and vessels as well as establishing enforcement standards and penalties for non-compliance.	2014	GCQA	USDA - WS, DOI	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support increased Federal assistance with biosecurity (continued)	Hire an additional federal wildlife inspector to increase the percentage of shipments which USFWS can inspect with goal of 100% inspection.	2015	GDOA - Biosecurity Division	USFWS	Medium
	Require that imported organisms be held in quarantine for a brief period to provide time to examine each shipment.	2015	GDOA - Biosecurity Division	USFWS	Medium
	Coordinate USDA-APHIS agreements with commercial air cargo shipping agencies to prevent invasive species transportation.	2015	GDOA - Biosecurity Division	USDA - APHIS	Medium
	Continue to improve partnering with the military (in each location where DoD has facilities) in regards to biosecurity, including when necessary working on DoD lands. The military should have their own staff at each DoD facility working in conjunction with local authorities to monitor for pests, to conduct biosecurity inspections, to respond to incursions, and to implement management efforts as needed. Where staff are in place, as they are at most facilities, improvements to existing systems, communication, and partnering with local civilian agencies should continue to be advanced.	2015	GDOA, GCQA	TBD	High
	Coordinate with agencies responsible for the Pacific Marine Monuments to address marine IAS prevention efforts.				Medium
Support efforts to increase marine and aquatic biosecurity efforts in the region	Raise awareness of potential threats from marine and aquatic IAS. With particular attention on inreach to local and federal decision makers and resource managers.	2015 and on-going	TBD	TBD	Medium
	Support capacity building to establish marine and aquatic IAS programs in the region.	2015 and on-going	TBD	TBD	Medium
	Establish and support monitoring efforts for marine and aquatic IAS.	2015 and on-going	TBD	TBD	Medium
	Increase collaboration between local and federal agencies working on marine and aquatic invasive species.	2015 and on-going	TBD	TBD	Medium
	Seek funding support for marine and aquatic IAS prevention and response.	2015 and on-going	TBD	TBD	Medium
Prevention					
Improve pre-border biosecurity	Utilize trapping, monitoring for signs, etc. to improve detection methods for rodents, insects and other wildlife on vessels and in cargo.	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	Develop risk assessments for Guam by identifying where guest workers, construction materials, and food stuffs will be coming from and then investigating both general and specific IAS concerns for these areas.	2015	GDOA, GCQA	TBD	Medium
	Develop risk assessments for Guam by identifying where guest workers, construction materials, and food stuffs will be coming from and then investigating both general and specific IAS concerns for these areas.	2015	GDOA, GCQA	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve pre-border biosecurity (continued)	Develop audited off-shore hygiene systems such as those utilized very successfully in Australia and New Zealand.	2015 Hold jurisdictional consultation including	GDOA - Biosecurity Division	Biosecurity Fee	High
	Develop the capacity to pre-screen vessels arriving at the seaport	2014	GDOA - Biosecurity Division, Port Authority of Guam	Biosecurity Fee	High
	Ensure inspection of gravel and other construction materials and equipment to be imported into Guam prior to shipping.	2015	GDOA - Biosecurity Division, Port Authority of Guam	USDA - APHIS	Medium
	Contracting efforts and language should establish minimal sanitation standards for all construction equipment and materials to be shipped to Guam and provide entry level training for guest workers in terms of how to assist in assuring that they are not bringing in invasive species.	2015	GDOA - Biosecurity Division, Port Authority of Guam	Biosecurity Fee	High
	Ensure that only companies which can ensure levels of biosecurity similar to HACCP guidelines should be considered for those who will need to bring in guest workers and materials from foreign ports. Check with Federal Acquisitions Regulation and legal to see if this type of restriction already exists.	2015	GDOA, GCQA	TBD	Medium
	Develop standardized SOPs as per HACCP guidelines to improve IAS surveillance and monitoring.	2014	GDOA, GCQA, UOG	Current funding	High
Improve border security	Develop an SOP that allows PPQ, GCQ, GDOA, and other authorities responsible for inspection and identification to react to changing risks based on countries of origin of arriving travelers and cargo.	2015	PPQ, GCQA, GDOA	Current funding	Medium
	Establish a communication and coordination system for information derived from outreach programs, port inspections, pest identifications, and reports from the public of sightings or encounters with suspected invasive species or illegal movements of foods, plants, animals, insects, etc.	2014	GCQA, GDOA, UOG, GISAC	Current funding	High
	Acquire and install X-ray machines for biosecurity at all ports of entry.	2016	Biosecurity Division	Biosecurity cost recovery system	Medium
	Ensure staff is appropriate trained for use of X-ray machines at all ports of entry.	2016	Biosecurity Division	Biosecurity cost recovery system	Medium
	Ensure appropriate long term maintenance for X-ray machines used for biosecurity.	2016	Biosecurity Division	Biosecurity cost recovery system	Medium
	Ensure that port authorities are working with quarantine in regards to use and placement of amnesty bins. Standard trash bins should also be located in appropriate areas and well signed so that passengers don't use amnesty bins for regular trash.	2015	Biosecurity Division	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Develop SOPs for incoming baggage and cargo inspections which are based on successful models (such as New Zealand); would require hiring and training additional personnel, installing appropriate equipment (X-ray, etc.), training additional canine teams for detection of specific high risk IAS (reptiles, fruits, meats, etc.); ensuring appropriate data collection and development and maintaining of databases to track efforts and interceptions.	2016	Biosecurity Division	Biosecurity cost recovery system	Medium
	Support the development of a canine pest detection program for items such as fruits, and vegetables. Consider the potential to combine this program with similar programs for detection of illicit materials.	2018	Biosecurity Division	Biosecurity cost recovery system	Medium
	Ensure that amnesty bins are available at ports and that they are well signed (identified) and are cleaned immediately after each arrival. Bins should be placed so as to support use (not directly in front of quarantine stations). Items deposited in amnesty bins should be treated as restricted garbage and destroyed promptly and on site to reduce the potential of spread of pests associated with anything within the bins.	2015	Biosecurity Division	Biosecurity cost recovery system	High
	Develop appropriate inspection facilities including a biosecure inspection facility at the seaport large enough for sea containers and wash-down areas with appropriate retention and treatment facilities for waste water produced.	2017	Biosecurity Division	Biosecurity cost recovery system	High
	Ensure that inspections process while targeting high risk goods also ensure random sampling of all imports, travelers, and baggage in order to better detect hitchhiker pests.	2015	Biosecurity Division	Biosecurity cost recovery system	High
	Improve compliance, enforcement and fee and penalty issuance and collection in regards to biosecurity measures.	2016	GDOA	Biosecurity cost recovery system	High
	Implement advanced on-site capacity training of quarantine officers such as specific taxon identification, data collection and entry, improved inspection methods, and new method/criteria based on updated regulations (such as training for tramp ant identification, inspection of aquatic conveyances, reporting on ballast water documentation, identification of livestock, wildlife and poultry diseases and pests, etc.)	on-going	GDOA	Biosecurity cost recovery system	Medium
	Clean containers and conveyances that arrive with soil and/or exotic plant pests. Establish guidelines similar to those used by APHIS in the US. Evaluate the effectiveness of current cleaning methods, and improve as appropriate. Importers/shippers should be required to pay for costs (cost recovery system).	2015	Biosecurity Division	Biosecurity cost recovery system	Medium
	Inspect all incoming construction materials and equipment as high risk for transporting pest species. Inspections should including materials previously treated or cleaned (due to the potential for recontamination after treatment).	2015	Biosecurity Division	Biosecurity cost recovery system	Medium
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	GDOA	TBD	Low
	Hire and train additional quarantine staff as needed. Should be based on needs assessment. An inspections database should be able to demonstrate needs.	2015	GCQA	Biosecurity cost recovery system	High
	Institute fines for soil packages if they continue to arrive harboring non-native species.	2015	GCQA/DOA	Biosecurity cost recovery system	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Establish an electronic database for quarantine inspection data that can be searched and data extracted for analysis. Such a database would support better targeting of vectors and pathways, permit tracking of known violators, provide documentation regarding interceptions, fee and penalty payments, demonstrate appropriate use of resources, quantify gaps and needs in current system, assist in determining pathways associated with post border detections, tracking of live imported species and number of individuals, tracking changes in vector arrivals and embarkation locations, etc.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Enforce the Guam law prohibiting the importation of soils for all soil and similar materials, specifically the bags of soil and soil like products soil in hardware stores. Either these items should not be imported or should need to be sterilized prior to import.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Train quarantine staff in data collection, entry, management and analysis, develop appropriate field inspection forms, conduct quality control of data systems, ensure that field data is entered into system in a scheduled manner to prevent backlogging, ensure that the data system is appropriately and regularly backed up to prevent systematic losses.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Institute quarterly reporting on quarantine inspections based on database information and ensure that reports are shared.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Protocols should be established by GCQA for documenting interceptions and final disposition of materials. These reports should be entered into a database and information should be shareable to assist Guam offices and agencies with improving border protection but also with other jurisdictions of the region to better protect the region. Protocols should be established regarding how and when (how often) this type of information is shared. Information collected and stored should include date of incident, inspector in charge, what was intercepted, what IAS were found, numbers of pests found, origin of the material in question, disposition of the material(s) and specimen(s), what remedial actions (if any) were taken against the shipper, and if fines were instituted, were they collected.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Support the development and implementation of regional standards for biosecurity inspections and data collection and management.	2017	Biosecurity Division	SPC	Low
	Conduct annual invasive species awareness, first detector training and outreach training sessions for port-of-entry workers. Training sessions should include basic biology of target pest species, point of origin and host materials associated with the invasive species. Provide participants with general means to collect capture or detain the invasive species upon discovery at the port, and point of contact to report an incident.	2015	UOG, GDOA, GISAC	USDA, SPC	Medium
	Develop MOU's between GCQA and other agencies involved in border inspections so that these offices/agencies can support the quarantine office with biosecurity aspects.	2016	GCQA	existing funding	Low
	Develop SOPs regarding specifics of how other agencies and offices can support the role of quarantine office during border inspection process.	2016	GCQA	existing funding	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Institute biosecurity cross training of staffs from agencies which are involved in border inspection processes.	2016	GCQA	existing funding	Low
	Treat all materials in amnesty bins as restricted garbage and appropriate destroyed.	2015	GCQA/DOA	existing funding	High
	Establish programs that would allow passengers of airlines or ships to be able to surrender any potentially invasive animals with assurances that there would be no prosecution (excluding illegally smuggled animals protected by law, such as species listed under CITES).	2016	Biosecurity Division	Biosecurity cost recovery system	Low
	Ensure that biosecurity regulations are applied to all equally (there should be no exceptions for diplomatic status or otherwise).	2015	Biosecurity Division	Biosecurity cost recovery system	Medium
	Develop multi-agency MOU to train USDA/APHIS and military personnel and authorize them to conduct border inspections for Guam.	2016	Biosecurity Division	Biosecurity cost recovery system	Medium
	Build physically secure facilities at the Guam Commercial Seaport with ample warehouse space and equipment and resources required to unload cargo and conduct agricultural inspections in order to centralize inspection of maritime cargo.	2017	Port Authority of Guam, GCQA	Biosecurity cost recovery system	Medium
	Conduct biosecurity inspection for all arriving conveyances, military and non-military, for plant pests and animal contamination.	2015	GCQA	Biosecurity cost recovery system	Medium
	Allow GCQA officers to inspect military vessels as USDA-APHIS cooperators.	2015	GCQA	Biosecurity cost recovery system	Medium
	Maintain secure areas for storage of vehicles and cargo at the air and sea facilities to prevent the dissemination of plant pests and reduce risks of cross contamination of other cargo items.	2015	GCQA	Biosecurity cost recovery system	Medium
	Establish decontamination sites for cleaning both military and civilian equipment.	2015	GCQA	Biosecurity cost recovery system	Medium
	Update the Port Authority of Guam Master Port Plan to address equipment and other resources needed to handle regulated international garbage properly.	2015	GCQA	Biosecurity cost recovery system	Medium
	Standardize methods similar to those of the APHIS-PPQ Agriculture Quarantine Inspection Monitoring program for random container searches.	2015	GCQA	Biosecurity cost recovery system	Medium
	Allocate funding to increase the number of containerized and crated air cargo shipments to be inspected.	2015	GCQA	Biosecurity cost recovery system	Medium
	Automate paperwork for air cargo shipments arriving in crates and containers for more rapid selection of containers to be screened.	2015	GCQA	Biosecurity cost recovery system	Medium
	Develop SOPs regarding container hygiene to support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping.	2015	GCQA	Biosecurity cost recovery system	Medium
	Provide essential equipment to inspection services, including computers, communication devices, etc. and support for both the use and maintenance of this equipment.	2015	GCQA/DOA	Biosecurity cost recovery system	High
	Standardize inspection practices between Guam and U.S. mainland.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve border security (continued)	Treat cargo shipments (import and export) as foreign in regards to inspection practices.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Biosecurity surveillance system should include routine surveillance for wildlife, livestock, and poultry diseases and vectors as well as insect and plant pests.	2015	GDOA - Biosecurity Division	Biosecurity cost recovery system	Medium
	Specify surveillance methodology to be appropriate for targeted species , (i.e. modifying sampling programs to account for behavioral differences in diurnal and nocturnal lifestyles).	2015	GDOA - Biosecurity Division	Biosecurity cost recovery system	Medium
	Utilize systematic surveillance for plant pests following the model of the Cooperative Agriculture Pest Survey (CAPS), and include both military and civilian properties as appropriate.	2015	GCQA	Biosecurity cost recovery system	Medium
	Standardize the use of reconditioning practices for both inter-state and international commodities arriving on Guam.	2015	GDOA	Biosecurity cost recovery system	Medium
	Create and institute a mixed model biosecurity approach based on both vector sanitation and focusing on key high risk species for terrestrial, freshwater and marine habitats.	2015	Biosecurity Division	Biosecurity cost recovery system	High
	Develop appropriate vector management with feedback and monitoring mechanisms.	2015	Biosecurity Division	Biosecurity cost recovery system	High
Improve post border biosecurity	Develop an IAS action plan for Guam and update regularly (every 3 to 5 years). This plan should be inclusive of all environments and taxa and be developed by all stakeholders (not only active GISAC members).	2014	GISAC	Current funding	High
	Develop and implement new IAS control and management programs to supplement current work and reduce the potential of spreading them to non-infected locations.	2014	GDOA, GCQA, UOG, GISAC	Biosecurity Fee	High
	Develop jurisdictional capacity where gaps exist through training or added resources.	2015	GDOA, GCQA, UOG, GISAC	Biosecurity Fee	Medium
	Eradicate small (new) IAS incursions promptly that are feasible and can be accomplished through current program limitations and funding.	2015	GDOA, GCQA, UOG, GISAC	Biosecurity Fee	Medium
	Eradicate population of Java Sparrows.	2015	GDOA	TBD	High
	Develop and enforce best management practices for contractors and construction sites. To include, the minimization of land disturbance and ensuring the proper cleaning of all construction items according to APHIS guidelines.	2014	GDOA, GCQA, UOG, GISAC	Current funding	High
	Ensure proper cleaning of all large equipment is treated prior to moving between sites on Guam or preparation for departure from Guam.	2014	GCQA, Port Authority of Guam, A.B. Wood Pat	TBD	High
	Consider helicopters and private planes (or small scale commercial ventures) as possible IAS vectors and therefore a biosecurity threat that needs to be monitored and inspected as per USDA/APHIS guidelines.	2015	GCQA, A.B. Wood Pat International Airport Authority	Biosecurity Fee	Medium
	Consider small boats and yachts (including small scale commercial ventures) as possible IAS vectors and determine if monitoring and inspection may be necessary to prevent IAS introduction or spread.	2015	TBD	TBD	
	Determine the extent of the little fire ant infestation and then to manage and/or eradicate this species.	2014	UOG, GDOA, GISAC	USFWS	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve post border biosecurity (continued)	Improve enforcement and enforcement capacity regarding smuggled animals.	2014	GCQA, GDOA, GISAC	USFWS	High
	Create GIS layers that delineate the distribution of established IAS and integrate them with other GIS layers such as land ownership, management areas, etc. to improve capacity to manage and control existing established invasive species.	2015	UOG, GDOA, GISAC	BSP, UOG	Medium
	Continue with Coconut Rhinoceros Beetle rearch and management efforts.	2014	CRB Eradication Team/ Task Force	Current funding	High
	Establish and develop relationships with key industrials such as landscaping, pet stores and fish hatcheries to develop their ability to institute internal standards to prevent IAS and curtail smuggling and create safe avenues for import (i.e. no imports or sales of prohibited animals or plant pests).	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	Train landscaping company staff to be knowledgeable about invasive plants, to inform their customers about invasive plants, to ensure only pest free plants are used, to report immediately any likely exotic pest organisms found on their premises, and to use native or non-invasive plants locally sourced. This could be a yearly training event run by a local agencies or with support from an external group such as SPC.	2014	GDOA - Division of Forestry	TBD	High
	Conduct periodic surveys of fish hatcheries, ethnic markets, pet stores, and grocery stores to identify and intercept prohibited animals and animal and plant products following the model of the USDA-APHIS-PPQ Smuggling, Interdiction and Trade Compliance program.	2015	GDOA - Biosecurity Division	USDA - APHIS, PPQ	Medium
	Develop and/or improve capacity through the addition of resources such as staff, training, equipment etc. to carry out investigations and effective enforcement beyond ports of entry.	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	Create an Island-wide green waste management program to reduce the amount of green waste breeding sites for CRB.	2014	CRB Eradication Team/ Task Force	Current funding	High
	Formalize the local production of bio-control options (GMF and virus) for the management of CRB on Guam.	2014	CRB Eradication Team/ Task Force	TBD	Medium
	Incorporate new/improved tools as they become available in regards to Brown Treesnake control and management activities.	2014	GDOA	OIA, USFWS, USDA	High
Improve biosecurity in regards to wood packaging material (WPM)	Require and enforce treatment of all WPM according to ISPM No. 15.	on-going	GQCA	Biosecurity cost recovery system	Medium
	Inspect an adequate percentage of all domestic and foreign, military and non-military WPM accompanying agricultural and nonagricultural cargo for pests. 100% inspection would be ideal but many not be feasible given capacity limitations and time constraints.	2015	GQCA	Biosecurity cost recovery system	Medium
	Prohibit the unloading of noncompliant WPM.	2015	GQCA	Biosecurity cost recovery system	Medium
	Incinerate or sterilize any noncompliant or infested WPM that is offloaded; it should be treated as regulated garbage .	2014	GQCA	Biosecurity cost recovery system	Medium
	Support a regional approach to switch from WPM to other options such as recycled plastics; interim solution is the enforce certification of WPM and to inspect regularly.	2014	GQCA	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase agricultural biosecurity/food security	Update terrestrial biosecurity risk assessment in regards to agricultural commodities.	2016	GDOA - Biosecurity Division	Biosecurity Fee	Low
	Update list of commodities and importer countries.	2016	GDOA - Biosecurity Division	Biosecurity Fee	Low
	Conduct background surveys for plant pests and livestock and wildlife populations and diseases.	2015	GDOA, UOG	TBD	Medium
	Implement initial surveillance and monitoring for the prevention of livestock, poultry, and wildlife diseases and determine whether measures perform adequately. Adjust efforts as needed to improve and ensure that potential gaps are addressed.	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	Collect and analyze baseline data regarding key crops and animal stocks for internal consumption as well as for export need to be established and maintained.	2015	GDOA, UOG	TBD	Medium
	Analyze biosecurity intercept data.	On-going	GDOA, UOG, GCQA	Current funding	Medium
	Share information gathered quarterly within the region and beyond via a working group. Create region communication network to facilitate information sharing.	On-going	GDOA, UOG, GCQA, RISC representative(s)	Current funding	High
Address the fact that humans can serve as vectors of invasive species.	Screening of humans either during the arrival or departure process needs to be considered. Even with screening in place the potential for missed detections is high and therefore dependence on rapid response to initial localized outbreaks of human disease vectors is essential and must be appropriately planned for and supported.	2015	Department of Health	TBD	Medium
	National health authorities should work with US DoD to determine what, if any, role DoD can support in the advent of a human pathogen outbreak. For example, could DoD transport sick patients to appropriate support facilities either within or outside of the national in the case of a human pathogenic outbreak?	2015	Department of Health	TBD	Medium
	Shipping conditions of medical items needs to support potential invasive pathogenic outbreaks must be improved.	2015	Department of Health	TBD	Medium
Improve capacity to regulate the importation of live organisms	Develop a government endorsed white list of species permitted for import.	2014	GQCA/DOA	existing funding	High
	Update white list on a regular basis.	annually	GQCA/DOA	existing funding	Medium
	Develop a government endorsed black list of prohibited species.	2014	GQCA/DOA	existing funding	High
	Update black list on a regular basis.	annually	GQCA/DOA	existing funding	Medium
	Ensure that all species proposed for import that are neither black or white listed undergo appropriate risk assessment to determine potential impacts. Organisms which are deemed potential harmful should be added to the black list. Organisms which are deemed non-harmful should be added to the white list.	Continuous	GDOA	Importer pays for all aspects of the risk assessment (regardless of outcome)	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve capacity to regulate the importation of live organisms (continued)	Develop and update regularly public dissemination of white and black lists as well as a details on the risk assessment process for proposed species imports. This could likely be done via an existing government website.	2015	GQCA/DOA	utilize student support	Low
Reduce risk associated with live traded species	Establish formal risk analysis process/guidelines for all organisms used or proposed for live trade. Institute a territorial biosecurity advisory committee to review proposals for the importation of exotic species.	2015	GDOA	Biosecurity cost recovery system	High
	Standardize reporting and screening systems for the importation of live organisms.	2015	GDOA	Biosecurity cost recovery system	High
	Regulations regarding the importation of pets and other animal species need to be standardized, applied to all equally, and enforced.	2015	GDOA	Biosecurity cost recovery system	Medium
	Develop plan for containment and control measures in regards to exotic farmed and traded species.	2015	GDOA	Biosecurity cost recovery system	Medium
	Develop emergency preparedness procedures regarding possible escape of exotic organisms being farmed or trade.	2015	GDOA	Biosecurity cost recovery system	High
	Ensure that specific quarantine facilities are available and establish specific quarantine SOPs for the movement of live organisms (plant and animal, including aquatic species).	2016	GDOA	Biosecurity cost recovery system	High
	Establish legal instruments/framework regarding the responsible use and control of exotic species.	2015	GDOA	Biosecurity cost recovery system	High
	Improve diseases diagnosis and monitoring, as well as epidemiological surveillance implementation for farmed organisms.	2015	GDOA	Biosecurity cost recovery system	Medium
	Ensure that all aquaculture, mariculture, and other captive breeding facilities of non-native species are secure including from natural disasters.	2015	GDOA	Biosecurity cost recovery system	High
	Develop biosecurity standards for household aquaculture set ups and enforce these standards.	2015	GDOA	Biosecurity cost recovery system	Low
	Establish explicit aquaculture biosecurity practices (e.g. control of stocking densities, use of all-male populations, use of triploids, etc.).	2015	GDOA	Biosecurity cost recovery system	Medium
	Require all health certificates and necessary permits accompany imported livestock, poultry, and other animals.	2014	GDOA	Biosecurity cost recovery system	Medium
	Ensure that all imported animals are subject to health inspection by the territorial veterinarian and appropriately quarantined as required.	2014	GDOA	Biosecurity cost recovery system	Medium
	Improve the regulation of the importation of exotic animals for zoos and aquaria.	2015	GDOA	Biosecurity cost recovery system	Low
	Develop specific guidelines for unwanted pets.	2015	GDOA	Biosecurity cost recovery system	Low
	Require all aquaculture shipments entering Guam must have an import permit, certificate of origin, and health certificate, and undergo physical inspection for amphibians and their eggs.	2014	GDOA	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Reduce risk associated with live traded species (continued)	enhancing quarantine requirements for specific species or taxon groups when imported (need to develop facilities for this in most cases) which would help with disease detection and control.	2016	GDOA	Biosecurity cost recovery system	Medium
	Establish lists of countries and competent authorities in regards to introduction and trade of exotic species.	2015	GDOA	Biosecurity cost recovery system	Low
	Support regional and international cooperation on the responsible use and control of live exotic species.	continuous	GDOA	Biosecurity cost recovery system	Medium
Increase export biosecurity	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pest from entering or being stuck to the outside of containers prior to shipping. Currently rented containers are inspected for internal cleanliness before departure. This should be expanded to include all containers and both internal and external surfaces.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Preferentially load conveyances in a way that minimizes pest entry whenever possible, for example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times. Develop SOPs to support this practice and train workers accordingly.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Enforce the use of container racks for all loading and unloading areas to ensure that containers are kept dirt free when loading and to facilitate inspections during unloading.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Institute pre-departure biosecurity inspections for more than just BTS.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Develop staging areas to safeguard high and low risk cargo.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
	Identify the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of staging facilities.	2015	Biosecurity Division	Biosecurity cost recovery system	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase export biosecurity (continued)	Coordinate agreements and procedures with air cargo shipping agencies for handling cargo, including packing, over-land transport, cargo-staging, palletizing, canine inspection, and final loading.	2015	Biosecurity Division	Biosecurity cost recovery system	Low
Increase quarantine capabilities	Implement the Biosecurity fee at the port and hire biosecurity officer positions to staff the Biosecurity Division of DOA.	2014	GDOA, GCQA, Guam Legislature	Biosecurity cost recovery system	High
	Ensure that the Biosecurity Division is appropriately staffed and funded and that it has adequate resources to conduct day to day operations.	2014	GDOA, GCQA, Guam Legislature	Biosecurity Fee	High
	Define clear roles for proposed biosecurity division which dovetail with GCQA and GDOA's roles.	2014	GDOA, GCQA, Guam Legislature	Biosecurity Fee	High
	Provide preliminary training for biosecurity staff and then insure that advanced trainings are provided to improve capacity over time.	2014	GCQA	Current funding	High
	Increase coordination to address marine and aquatic IAS including GDOA, GEPA, UOGML, NOAA, USFWS and others.	2014	UOG	NOAA	
Improve biosecurity for the movement of vehicles/equipment	Inspect, clean, and treat, if needed, vehicles, construction materials and equipment, and other commercial equipment at the port of entry.	2014	Port Authority of Guam, GCQA	Biosecurity cost recovery system	High
	Ensure that vehicles are cleaned prior to shipping.	2014	Port Authority of Guam, GCQA	USDA - APHIS	High
	Clean containers and conveyances that arrive with soil and/or exotic plant pests according to APHIS guidelines.	2014	Port Authority of Guam, GCQA	USDA - APHIS	High
	Evaluate the effectiveness of current cleaning methods, and improve as appropriate.	2015	GDOA - Biosecurity Division	Biosecurity Fee	High
	Ensure that used machines such as wood chippers and bulldozers are cleaned and inspected at point of departure immediately prior to shipping.	2014	GCQA, Port Authority of Guam	Biosecurity Fee	High
	Ensure that all vessels and equipment, including barges, dry docks, and dredging equipment, are free of fouling organisms before introduction to Guam's waters.	2015	TBD	TBD	
Improve importation protocols	Develop/enhance the system for tracking cargo in order to streamline the importation process and improve biosecurity.	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	For the shipment of live organisms, require importers to list the types and numbers of each species in each shipment. This information should be recorded by border agents, retained in an electronic database, and shared as appropriate.	2015	GDOA - Biosecurity Division	Biosecurity Fee	Medium
	Importation of house plants should be restricted and controlled or prohibited as per USDA regulations (especially on plants coming from the Caribbean and Florida).	2015	GDOA - Biosecurity Division	USDA	Medium
	Improve capacity to monitor, inspect, treat or restrict and track permitted imports including all plants and propagative material. Require and enforce the use of USDA or GDOA VS import permits for restricted animal products.	2014	GDOA - Biosecurity Division	Biosecurity Fee, USDA, USFWS	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve biosecurity elements at the Guam International Airport	Reconsider the layout of the arrival area, including replacing the temporary barriers erected to segregate arriving passengers from departing passengers in accordance with Homeland Security regulations with a more permanent solution.	2015	GCQA, A.B. Won Pat International Airport Authority	Biosecurity Fee	Medium
	Ensure primary inspection facilities for arriving air passengers and goods are located within the secure zone internal to the perimeter fence to reduce the potential for the spread of IAS during transit from entry points to inspection facilities.	2015	GCQA, A.B. Won Pat International Airport Authority	Biosecurity Fee	Medium
	GCQA personnel should be stationed with DHS, Transportation Security Administration (TSA) personnel in order to better develop expertise in screening transiting passengers for restricted or prohibited materials or all transiting passengers should be routed through GCQA inspection before they move to the departure area.	2015	GCQA, Guam Homeland Security/Office of Civil Defense	DHS, TSA	Medium
	Provide sufficient inspection facilities for express courier operations at the airport.	2015	GCQA, A.B. Won Pat International Airport Authority	Biosecurity Fee	Medium
	Consider all garbage within the passenger sterile area for incoming and transiting passengers at the A.B. Won Pat International Airport to be regulated garbage.	2014	GCQA, A.B. Won Pat International Airport Authority	Biosecurity Fee	High
	Ensure that the biosecurity system is tracking changes in aircraft arrivals, especially as new linkages are established and/or additional carriers are added.	2015	GDOA - Biosecurity Division, A.B. Won Pat International Airport Authority	Biosecurity Fee	Medium
	Institute 100% x-raying of all incoming passengers baggage to reduce illegal importations.	2014	GDOA - Biosecurity Division, A.B. Won Pat International Airport Authority	TSA, Biosecurity Fee	High
Improve mail inspections	Develop a plan to address the IAS introduction pathway of mail. Of significant concern in this regard is the potential for shipping of pets such as reptiles via the mail system with little ability to detect and intercept these organisms by current biosecurity systems within the region.	2014	GDOA - Biosecurity Division	USPS	High
	Find and implement a working solution which will permit and increase the inspection of US mail (and all other mail types including private courier services) including mail arriving at both civilian and military facilities. Appropriate regulations should be established which would permit the potential inspection of most if not all arriving.	2014	GDOA - Biosecurity Division	USPS	High
	Use current x-ray technology for all foreign-origin mail. Ensure that it is in working order and operable.	2015	GDOA - Biosecurity Division	USPS	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve mail inspections (continued)	Utilize trained detector dogs, visual inspections and X-ray machines to reduce the potential for illicit mail trade.	2015	GDOA - Biosecurity Division	USPS	Medium
Establish and enforce biofouling standards	Establish criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish standards and regulations regarding biofouling, including inspection and certification for all vessels. Inspections can be trained to inspect hulls from top side with mirrors. If further inspection is warranted, then the craft pays for divers to inspect and make a report. If determined to be dirty, then the craft must either be cleaned or leave port and jurisdictional waters. Self clean outside of jurisdictional waters could be an option. Hull needs to be clean of all organisms, as the ability to identify all marine organisms is not available.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish additional regulations for impounded vessels.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Develop capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a biofouling management program.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Establish and enforce biofouling standards (continued)	Ensure that regulations include ability to levy and collect fines and/or require vessels to depart national waters for repeat offenders and for non-compliance with treatment requirements.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Ensure that any required in-depth inspections or treatments are funding in full by the owner/operator. Consider developing a cost recovery system.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Implement targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
Increase marine ecosystem protection from invasive species	Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Implement a targeted outreach program with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Inspection of boats travelling inter-island from the CNMI especially during fishing derby.	2015	GDOA - DAWR	Guam Fisherman's Coop, GOSA	Medium
	Establish biosecurity practices and requirements for fishing vessels that operate in Micronesia to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
Establish and enforce ballast water standards	Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Establish ballast water management and reporting requirements for all vessels utilizing ballast water.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Review and revise (as needed) legal authority to implement a ballast water management program.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Ensure that regulations include ability to levy and collect fines for non-compliance.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
	Support national level adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	GCQA/DOA	Biosecurity cost recovery system	Medium
Address climate change linkages to invasive pests		2018	Governor's Office	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Early detection and rapid response</i>					
Improve early detection and rapid response capacity	Develop an SOP for communication between agencies within various levels of government in regards to risk detection and response.	2015	GDOA	existing funding	High
	Design and implement a public reporting system for new or suspected non-native species incursions (a 24 hour pest hotline is advisable).	2015	GDOA	existing funding	High
	Develop a generic state emergency response plan (ERP) that is funded and approved by key agencies and governance. The generic ERP should be readily modifiable to utilize for terrestrial, freshwater, and marine incursions. The ERP should list necessary actions in sequence, authorities, partners and available resources, including funding sources which can be brought to bear immediately for a response action. Ensure that all appropriate authorities are involved in the development and planning process including public health authorities for diseases with serious animal and/or human health and zoonotic potential.	2015	GDOA	existing funding	High
	Develop a detection(surveillance) program and response plan for new incursions by a few focal non-native species of high-risk non-native species, ensuring that these specific plans cover freshwater, marine, and terrestrial systems.	2016	GDOA	TBD	Medium
	Develop taxa specific ERPs as needed.	On-going	GDOA	TBD	Medium
	Update all ERPs (both generic and species specific) to ensure that they current and functional.	annually	GDOA	existing funding	High
	Ensure that the public reporting system is fully functional including supported by trained staff.	2015	GDOA	existing funding	High
	Ensure that the public reporting system is appropriately advertised and that the citizenry and visitors are aware of its existence, its purpose and how to utilize it.	2015	GDOA	existing funding	High
	Develop protocols for responding the non-native species reports in a timely manner including interview policies, interview formats, timelines, ground truthing, and field action response time.	2015	GDOA	existing funding	High
	Train and maintain a core group of early detection & rapid response staff from local agencies/stakeholder groups, including aquatic and marine IAS detection and response.	2015	GDOA	existing funding	High
	Hold consultations to determine what agency(s), office(s) and/or groups will be responsible for surveillance programs.	2015	GDOA	existing funding	High
	Develop and institute surveillance programs for non-established species consider as high risk for arrival.	2015	Guam DOA	TBD	Medium
	Provide training to interested citizens with regards to supporting ED & RR efforts. Frequency of training events would depend on interest levels but minimally there should be one such course per year that can be used to train and refresh volunteers from local communities. Such trainings could be developed and run with the assistance of the regional invasive species coordination office.	2015	GISAC	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Awareness					
Increase outreach and education on biosecurity and invasive species	Conduct a pre-education survey of residents, visitors, transient workers and other stakeholders to gauge their understanding of invasive species, their potential impacts, biosecurity regulations, and the role of citizens and visitors in regards to protecting the territory from unwanted pests.	2015	GNA/GISAC	TBD	High
	Develop an educational strategy that is long term, extensive and territory wide, reaching school students as well as all communities. Ensure that outreach efforts are extensive and engage citizenry to support and promote biosecurity and management efforts describing approaches to be used to reach the citizenry, organizations, businesses, and visitors (including visiting work forces and foreign business ventures) about potential risks from invasive species and methods to prevent, report, and control their introduction. In order to improve and expand outreach and awareness efforts, a coordinated approach must be utilized to guide activities between the various groups and agencies involved in outreach and awareness activities.	2015	Guam Nature Alliance (GNA), GISAC	TBD	High
	Improve overall coordination of existing IAS and biosecurity outreach and ensure that information is reaching local communities, businesses and visitors about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread.	2016	GNA/GISAC	TBD	High
	Establish long term funding to support core outreach and educational efforts.	2016	GNA/GISAC	TBD	High
	Work with the school systems and support efforts to provide educators with tools and services to support IAS awareness development as part of standard curriculums.	2017	GNA/GISAC/ Department of Education	TBD	High
	Develop posters, brochures and other print media to support invasive species awareness campaigns (minimally these types of outreach materials should be updated and distributed on a yearly basis both as part of systematic outreach efforts and as part of special events/circumstances).	2016	GNA/GISAC	TBD	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts.	2016	GNA/GISAC	TBD	Medium
	Develop invasive species informational videos which can be show on local TV stations. One such video could explain the potential problems which could arise from releasing pet species into the wild (especially non-native aquarium fish).	2016	GNA/GISAC	TBD	Medium
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity.	2016	Guam Invasive Species Coordinator	Regional ISC Office	Medium
	Increase engagement of donors and other support programs to develop and conduct additional outreach efforts.	2016	GNA/GISAC	TBD	High
	Advertise amnesty/honor bin option by means of mass media outlets as part of public outreach.	2015	GCQA	existing funding	Medium
Designate an agency or working group to be responsible to the Government of Guam for developing high-priority outreach messages about invasive species and their pathways and fund efforts.	2015	GCQA, GDOA, UOG, GISAC, GNA	existing funding	High	

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Increase outreach and education on biosecurity and invasive species (continued)	Support the development of a regional video to be shown on air flights prior to arrival which includes information on amnesty bins and documents the concern with invasive species asking visitors and residents to support biosecurity efforts to reduce the movement of pest species. Videos should be developed in multiple languages and could also be shown in departure and arrival lounges.	2015	Guam RISC representatives	external funding	Medium
	Create awareness of the potential legal consequences of violations.	2015	GCQA	existing funding	Medium
	Provide reports and newsletters to educators, journalists, lawmakers, and business and community leaders.	2016	GNA/GISAC	TBD	Medium
	Distribute multi-lingual biosecurity poster free to pet shops, grade schools, universities, sporting goods stores, gardening stores, naturalist clubs, parks and natural areas, military facilities, air and sea ports, community centers and perhaps even seafood stores, farmers' markets and restaurants.	2016	GNA/GISAC	TBD	Medium
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish.	2016	GNA/GISAC	TBD	Medium
	Develop IAS service learning opportunities for students to get hands on IAS experience.	2017	GDOE/GNA/GISAC	TBD	Medium
	Provide information on ways to prevent the spread of plant and animal pests and diseases to the public.	2015	DOA	TBD	Medium
Research					
Evaluate social, cultural, economic, and ecological values that may be impacted by invasions of non-native species.	Conduct baseline surveys.	2015	University of Guam	TBD	Low
Identify knowledge gaps for existing IAS concerns	Develop a priority research list for the territory that can be shared with universities and others. A list could be a positive influence in engaging research groups to support management efforts within the territory.	2015	University of Guam	TBD	Low
Policy					
Improve laws, regulations and guidelines	Coordinate laws and regulations for post-border biosecurity In order to manage IAS effectively.	2015	GQCA/DOA	existing funding	Medium
	Expand existing or create new regulations (as needed) and SOP to encompass all potential IAS include terrestrial (agricultural and non-agricultural), freshwater, and marine concerns.	2016	GQCA/DOA	existing funding	Medium
	Review relevant biosecurity related guidelines and SOPs to ensure they are clear, complete, detailed, and in compliance with appropriate laws and regulations.	2015	GQCA/DOA	existing funding	Medium
	Update existing guidelines and SOPs as needed.	2015	GQCA/DOA	existing funding	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve laws, regulations and guidelines (continued)	Ensure that biosecurity regulations are in place and enforced.	2016	GQCA/DOA	existing funding	Medium
	Include GDOA Division of Forestry into the building permitting process to review the landscaping component and ensure invasive plants are not being used.	2015	GDOA - Division of Forestry	TBD	Medium
	Issue penalties and fines to enforce compliance.	2015	GQCA/DOA	existing funding	Medium
Restoration					
Improve native ecosystems restoration efforts	Continue and move forward with restoration efforts of native systems where IAS management and/or eradication efforts have been successful.	2015	GDOA - DAWR	USFWS, State Wildlife Grant	Medium
	Specific localized risk assessments should be conducted for all habitat types.	2015	GDOA, UOG	TBD	Medium

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment M: United States Department of Defense Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Support</i>					
Ensure long term support for biosecurity efforts within the region	INRMP's (JRM, NRH, KWAJ, Wake, Palau Seabees) shall depict IAS monitoring and surveillance, detection, rapid response actions for all taxa to ensure biosecurity efforts are planned and funding is requested.	on-going	TBD	TBD	High
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the DoD section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year	DoD	TBD	High
Improve communication, facilitation, and joint biosecurity activities with civilian counterparts	Establish agreements (MOUs) between DoD and local agencies tasked with IAS control and management in specific jurisdictions where DoD operates. If not already in place, it should become SOP for DoD and specific jurisdictions to communicate and work in tandem to ensure appropriate biosecurity mechanisms are in place for all DoD activities related to individual jurisdictions. Activities covered by the MOU should include but not be limited to the facilitation of response planning, identification of command structure, and support of response actions to biosecurity threats posed by DoD activities.	End of 2015	JRM/DoD	TBD	High
	Create a Unique Defense Transportation Regulation for the Hawaiian Marine Monument, applicable to all DoD entities. Ensure the regulation mimics current civilian standards for air and marine traffic within the Hawaiian marine monument.	2016	DoD/OPNAV	TBD	Medium
	Continue to improve partnering with civilian agencies (in each location where DoD has facilities) in regards to biosecurity. The military should have at least one invasive species biologist, in addition to a supporting pest control shop or equivalent contract team at each DoD facility working in conjunction with local authorities to monitor for pests, to conduct biosecurity inspections, to respond to incursions, and to implement management efforts as needed. Improvements to existing systems, communication, and partnering with local civilian agencies should continue to be advanced.	2015	JRM	TBD	High
	Complete support capability analysis to determine and quantify the DoD's ability to afford or provide support to severe outbreak scenarios. The scenarios shall attempt to model low, medium, high risk situations, to best determine the "support gaps" or elements out of DoD ability or jurisdictional abilities.	2015	DoD (partnering with the CDC and jurisdictions)	TBD	Low
	Establish a MOU between USDA-APHIS and Pacific Military Commands to facilitate a role for APHIS as it pertains to offshore biosecurity, specific to military pre-clearance and self inspection training.	2015	PACOM/JRM	TBD	High
	Develop and update on a regular basis, the JRM and Navy Region Hawaii instructions for offshore and onshore biosecurity. Ensure that Quality Control processes are included in the instruction to ensure the efficacy is addressed.	On-going for relocation projects	TBD	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve communication, facilitation, and joint biosecurity activities with civilian counterparts (continued)	Include biosecurity requirements and provisions in contracts to reduce the risk of introduction of animal and plant pests and diseases. Provisions should include: 1) contractor-provided education for employees on import requirements and penalties associated with non-compliance; such educational materials should be developed in collaboration with regional SME's from private and government sectors; 2) contractor compliance with all import requirements [import permits, procedures at port of entry and beyond, etc.]; and 3) company-driven pre-inspection of their own materials for plant pests. Minimize pest contamination of containers and WPM by: Minimizing outdoor storage, Sealing storage site surfaces, Keeping storage sites clean, Controlling pests around storage sites, Limiting use of nighttime lighting around storage sites, and Treat storage areas with molluscicides or install barriers to prevent mollusks from infesting WPM and shipping containers. Remove weeds and other contaminants from container and WPM storage areas. Storage areas should be hard surface or gravel.	on-going	DoD, for DoD funded projects	TBD, funded by the individual project or where appropriate the Biosecurity Fee on Guam	High
Improve communication, facilitation, and joint biosecurity activities with civilian counterparts (continued)	Revise and update military guidelines and SOPs for biosecurity. In some cases, the military uses outdated guidance with inaccurate information. For example, the OPNAVINST 6210.2 lists only the States, District of Columbia, Guam, Puerto Rico, and the U.S. Virgin Islands as the U.S., notably excluding the CNMI and American Samoa (7 CFR § 330.400[a] and 9 CFR § 94.5[a]).	2016	OPNAV	TBD	High
	Live animal imports by military personnel and dependents should follow civilian regulations in each jurisdiction. Review and continue to support these regulations. All health certificates and necessary permits should accompany imported animals. Ensure that all imported animals are subject to health inspection by appropriate animal health offices and appropriate quarantine periods are enforced.	On-going	JRM	TBD	Medium
	Utilize input and market research from Government biosecurity service providers, in addition to regulatory subject matter experts when developing biosecurity instructions and guidance for active duty and civilian DoD employees, in addition to DoD contractors.	2016 develop planning strategy	TBD	TBD	High
	Finalize and utilize the Joint Region Marianas Instruction: Brown Treesnake control and interdiction.	2015	JRM	TBD	High
Support regional biosecurity and invasive species control efforts	Provide assessment of outcomes and update DOD portion of the strategic implementation plan every 3-5 years.	3-5 years	TBD	Regional ISC office	High
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.)	2015 and on-going	TBD	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	TBD	Regional ISC office	Low
	Support the development of a weeds risk assessment for military installations in Hawaii and Micronesia. Share results with cooperating territorial and state agencies.	2016	TBD	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional biosecurity and invasive species control efforts (continued)	Support the development of a regional biosecurity coordination office. Establish an IAS regional management office minimally with an invasive species coordinator who is tasked with assisting individual jurisdictions as well as the region as a whole with IAS and biosecurity concerns. This position would need to be tied in closely with the RISC and the jurisdictional IAS coordinators. This office would play a key role with insuring appropriate, long term regional communication and support and could assist both individual jurisdictions and the region with IAS issues such as funding, regulatory development guidance, capacity development, linking existing resources including subject matter experts, and facilitating the coordinate of biosecurity efforts between jurisdictions.	2015	TBD	TBD	High
	Support development of a region-wide communication plan for biosecurity and IAS. Examine the potential of using existing models for the plan development including that which was produced for Oahu recently. The Oahu plan was ultimately not utilized but it potentially could serve as a model for networking regionally.	2016	TBD	TBD	High
	All jurisdiction should develop well thought out plans for response to incursions of IAS. In areas where DoD has facilities or otherwise operates, DoD should work with local authorities to insure that DoD actions and activities are adequately covered response planning.	2016	TBD	TBD	High
	Support establishment of a centralized regional group with representatives from each country within the Micronesia Region to develop sustainable funding streams for efforts to manage interrelated risks that cross political boundaries. There should be sufficient funds to conduct routine surveillance, implement response plans, and provide outreach and education, in addition to port of entry exclusion activities and training for inspectors.	2016	TBD	TBD	High
Support improvement to biosecurity elements of partnering militaries	Risks of IAS carried by foreign military vessels and aircraft entering the region needs to be addressed. Partnering countries includes (but may not be limited to) Singapore, Philippines, Japan, and Australia. These and other countries military vessels and aircraft may enter the region to take part in training and joint exercises with the DoD. Differences in specific country practices and protocols may include actions that would not meet US biosecurity standards. Support establishing SOPs which require partner countries to comply with local/regional standards when operating within any part of the region may be appropriate. Mechanisms for driving this would likely need to be between specific jurisdictions or countries and the DoD partners which would like to train in specific jurisdictions. Monitor visiting countries and their military forces ability to abide by the JRM/NRH Biosecurity Instruction.	2015	PACOM/JRM/civilian authorities	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Prevention</i>					
Improve border security	Construction and other commercial equipment must be inspected, cleaned, and washed down at the port of entry. Tracked vehicles can be cleaned on shore only if they can be reloaded without recontamination of the treads; otherwise they should be cleaned on the ship's well-deck. They should be cleaned to USDA-APHIS standards (USDA-APHIS-PPQ Treatment Manual 2008) prior to shipment from the port of departure. Vehicles may be cleaned at the port of entry provided wastewater soil is collected and drained fully into an approved collection system.	2016	TBD	TBD	High
	Construction materials are currently inspected as part of the build-up efforts to improve biosecurity. Inspection of construction materials should be instituted as standard policy for all activities throughout the region (not only the build-up).	2016	TBD	TBD	High
	Military aircraft and other military vehicles arriving as maritime cargo should be inspected, cleaned, and washed down at a retrograde wash facility before entry. Wash down procedures for military vehicles should target soil, plants, insects, and other wildlife. Tracked vehicles can be cleaned on shore only if they can be reloaded without recontamination of the treads; otherwise they should be cleaned on the ship's well-deck. They should be cleaned to USDA-APHIS standards (USDA-APHIS-PPQ Treatment Manual 2008) prior to shipment from the port of departure. Vehicles may be cleaned at the port of entry provided wastewater soil is collected and drained fully into an approved collection system.	2016	DoD	TBD	High
	Support the development of sanitation standards, targeting methods and diagnostic and identification tools for non-visible pests.	on-going	TBD	TBD	Low
	Ensure that appropriate biosecurity policies and procedures such as HACCP are in place and enforced.	2015	TBD	TBD	High
	Establish appropriate decontamination sites for cleaning both military and civilian equipment associated with military activities	2015	TBD	TBD	High
	Inspect and clean all incoming containers, conveyances and construction materials that arrive through DoD controlled ports of entry with soil and/or exotic plant pests including materials previously treated or cleaned if recontaminated after treatment.	On-going	TBD	TBD	High
	Create a multi service invasive species database to track the impelmentation efficacy of HACCP for military exercises and construction in Hawaii and Micronesia. Information tracked by unique project in such a database shall include: detailed inspection processes, intercept records, preservation and compiling of voucher specimens, detailed records on where shipments, etc. are arriving from and specifically what is known to have harbored IAS and where it come from and how it arrived.	On-going, for relocation projects	TBD	TBD	High
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	JRM	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of wood packaging material (WPM) (continued)	Require treatment of all WPM according to ISPM No. 15 under DoD MOU with APHIS-PPQ. All domestic and foreign WPM should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	APHIS-PPQ	TBD	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in a database to be available for analysis that may contribute to safeguarding improvements and quality control.	on-going	APHIS-PPQ	TBD	Medium
	Do not permit the unloading of noncompliant WPM.	on-going	APHIS-PPQ	TBD	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	on-going	APHIS-PPQ	TBD	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	on-going	APHIS-PPQ	TBD	High
Improve biosecurity elements in regards to garbage	Ensure that appropriate garbage disposal mechanisms are in place before any DoD activities within the region.	2015	TBD	TBD	Medium
Improve pre-departure biosecurity	All departing vehicles, equipment and materials should be properly inspected, cleaned, and washed at laydown area prior to departure. Subject to wash down and canine inspection requirements, vehicles should be loaded on to transport vessels for immediate transport.	2015	TBD	TBD	High
	On Guam, if staging of vehicles is required, cleared vehicles should be placed in a BTS barrier to prevent ingress of BTS after inspection and clearance, or canine inspections performed again prior to loading for transport.	2015	TBD	TBD	High
	Capacity training on sea container hygiene and the development of SOPs regarding container hygiene would support better compliance with acceptable standards such as where to place containers and preventing pests from entering or being stuck to the outside of containers prior to shipping.	2015	TBD	TBD	Medium
	Support the establishment of a biosecurity pre-clearance program in Okinawa, Japan for materials associated with the relocation departing Okinawa for Guam, Hawaii, and the CNMI	2015	TBD	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve pre-departure biosecurity (continued)	Develop and implement specifications for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Contamination can occur during the packing, handling, and staging processes prior to export. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Develop and implement specifications for palletized cargo, including procedures for staging, labeling, packing, loading and transport. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places. Identify the appropriate agency tasked with the regulatory actions to be performed as well as the enforcement of any violations contrary to the law. In addition, staging areas need to be developed for safeguarding high and low risk cargo. Need to identify and include in the development process the appropriate office(s) that would be responsible for the planning, development, construction and maintenance of such facilities.	2015	TBD	TBD	Medium
Improve biosecurity elements on AAFB	Increase the foreign inspection area for passenger clearance in the main terminal at Andersen AFB to a sufficient size for physical inspections of passenger baggage. Ensure that it is compliant with Home Land Security and Guam CBP.	2015	DoD	DoD	Medium
	Provide space, lighting, and equipment (e.g., x-ray equipment, tables, and materials for collecting samples) sufficient to enable GCQA to complete all aspects of inspection. Amnesty bins are also need if not already in place.	2014	DoD	DoD	High
Improve specifics in regards to biosecurity and the proposed build-up in the Mariana islands	Extend outreach programs, such as the RARE project, to contract workforce involved in DoD construction to ensure private firms working on DoD projects are aware of the federal and territorial laws which are in place on Guam. Bi-lingual delivery of information is advised to ensure all labor personnel is aware of their on and off duty impacts as it pertains to invasive species.	2015	TBD	TBD	High
Improve pre-arrival biosecurity	Biosecurity emphasis should be directed towards audited off-shore hygiene systems such as those utilized very successfully in Australia and New Zealand. As an example, all large equipment such as construction and military items intended for importation should be cleaned and inspected for IAS prior to loading. Treat (clean) if necessary immediately prior to shipping.	2016 Support development	TBD	TBD	High
Improve ballast water standards and compliance	Conduct an initial comprehensive analysis of current ballast water discharge and management patterns by U.S. military vessels, including those operated under MSC and all branches of the DoD, for Micronesia and Hawaii.	2015	TBD	TBD	Medium
	Assess the extent of ballast water treatment (both in terms of percentage of vessel arrivals and discharge volumes) prior to discharge by U.S. Navy and other military vessels	2016	TBD	TBD	Medium
	Evaluate the locations and volumes of seawater operations (including both uptake and discharge) for compensating fuel tanks discharged	2016	TBD	TBD	Medium
	Establish a program that implements targeted outreach and administrative tools to increase compliance with ballast water treatment requirements for military and non-military vessels associated with the DoD.	2016	TBD	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve hull fouling standards and compliance	Evaluate the extent (including especially total abundance and species composition) of biofouling on all types of DoD and U.S. Navy vessels operating in the region, including amphibious vessels and vessels operated under MSC.	2016	TBD	TBD	Medium
	Implement (a) inspection of vessels operated under DoD with high biofouling potential, due to extended periods of lay ups or port residence times, and (b) cleaning for those that are heavily fouled prior to their movement into, out of, or within the region	2016	TBD	TBD	High
	Once developed, hull fouling regulations should be applied to all vessels operating under the various branches of the military, both military owned and civilian owned under contract.	2017	TBD	TBD	Medium
	Assess the extent to which vessels operating in the region under DoD achieve acceptable levels of biofouling, once regulations have been instituted.	2018	TBD	TBD	Medium
	Track and evaluate changes in vessel traffic patterns and operations (including vessel types, geographic regions visited, port residence times, and speed) for all types of DoD and U.S. Navy vessels operating in the region, including amphibious vessels and vessels operated under MSC.	2017	TBD	TBD	Medium
	Support USCG establishing specific biosecurity criteria (requirements) for acceptable levels of hull biofouling for all types of DoD and U.S. Navy vessels, including amphibious vessels and vessels operated under MSC.	2017	DoD, USCG	TBD	High
	Support USCG extending DoD biosecurity requirements for acceptable levels of hull biofouling to include vessels under contract to any branch of the U.S. military, such as barges, dredges, and other vessels.	2017	DoD, USCG	TBD	Medium
	Support USCG extending hull fouling requirements to all military vessels operating in Micronesia and Hawaii, including those operating under MSC and other branches of the military.	2017	DoD, USCG	TBD	Medium
	Ensure JRM/NRH Biosecurity Instruction includes guidance as it applies to hull fouling, ballast exchange, and the risks associated with the intentional and/or unintentional movement of marines IAPS.	2018	TBD	TBD	Medium
Management and eradication					
Improve facilities IAS management	Enhance training for military personnel and their dependents about phytosanitary and general sanitary regulations and the risks of sending or receiving agricultural and wildlife materials in the mail.	2016	TBD	TBD	Medium
	Develop and maintain current IAS management plans for each DoD facility within the region. A publication that reviews 12 case studies of invasive species on military bases and lays out some basic recommendations for the military was prepared for the DoD by the National Wildlife Federation (Westbrook et al. 2005). Among the recommendations is the inclusion of an invasive species management plan in a base's Integrated Natural Resource Management Plan. Recommend that DoD implements the recommendations established in Westbrook et al. (2005).	2016	JRM	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve facilities IAS management (continued)	Create GIS layers that delineate the current distribution of established IAS and utilize to improve management.	on-going	TBD	TBD	Low
	Utilize the Guam Landscaping Guidelines (June 2011). Revise facilities' landscape plans so that these dovetail with facilities' IAS management plans (this should be done throughout the region). New plantings should be locally sources, non-invasive, and preferably native species, with a minimum of 50% native species be planted for an individual project. Existing plant species, which are either known to be invasive or at least thought to have invasive potential, should be removed or managed.	on-going	TBD	TBD	Medium
	Develop best management practices for contractors and construction sites, working with the construction industry to gain support with preventing the introduction and spread of non-native plant pests. Implement "clean" practices at construction sites, including the minimization of land disturbance that may contribute to the spread of plant pests. This is part of the HACCP process already implemented on Guam. These practices should be considered for region wide implementation.	2015	TBD	TBD	High
	Ensure JRM/NVH Biosecurity Instruction addresses proper cleaning of equipment and materials prior to moving between sites within a jurisdiction (example: movement of vehicles between training sites and storage facilities within the state of Hawaii).	2014	TBD	TBD	High
	Increase efforts to eradicate targeted IAS. Improving this ability should be a long term commitment. Species targeted for eradication should be identified in each facilities IAS management plan.	2015	TBD	TBD	High
	Eradication is a biosecurity tool (removing incursion fate for a network of pathways users) and DoD should support the planning and execution of invasive species eradications on those installations where complete removal of a species is feasible or has been shown to be feasible elsewhere with similar target species.	2015	TBD	TBD	High
	Develop cleaning facilities (wash racks, etc.) at all DoD installations where warranted and provide appropriate training for military personnel to utilize these facilities.	2016	TBD	TBD	High
Awareness					
Improve awareness of biosecurity and invasive species	Develop appropriate, comprehensive education and awareness programs within DoD for biosecurity including IAS prevention. This should cover military personnel and their families as well as contracted workers and their dependents. Such programs shall be extended into DoD schools.	on-going	JRM	O&M Appropriations	High
	Support coordination of existing outreach efforts in jurisdictions where DoD has facilities. Coordination should occur between each jurisdiction and DoD.	2015; on-going on Guam	TBD	TBD	High
	Support development of posters, brochures and other print media to support invasive species awareness campaigns.	On-going	TBD	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve awareness of biosecurity and invasive species (continued)	Implement a targeted outreach program for DoD installations in Micronesia and Hawaii. Ensure program addresses active duty and civilian workforce, and includes specific guidelines on the methods known to minimize species transfers associated with small boats, jet skis, other water sports gear, and diving gear. In addition to providing guidance on marine related actions, ensure the program also addresses guidelines to follow as it applies to terrestrial items of interest, such as the movement of household goods, cars, and other pack out items.	2015	JRM	O&M Appropriations	Medium
	Utilize local media sources such as newspapers and TV and radio programs to enhance invasive species awareness efforts	On-going	TBD	TBD	Medium
	Create two forms of video guidance and education. Video 1: Guidance on the implementation of the JRM and Navy Region Hawaii instruction (in regards to biosecurity and invasive species) for DoD civilians, active duty, and contractors. Video 2: Video providing guidance for families and off base recreation focusing and on what to be aware of, and how to protect the environment from invasives when not on duty. Video 2, could be shown on public stations as well, given its applicability to a wider audience.	On-going	TBD	TBD	Low
	Support regional coordination of invasive species awareness efforts to improve overall regional biosecurity	2015	TBD	TBD	Low
	Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials, including the potential loss of business if invasive species are permitted to establish. Institute Contractor education program on installations in Hawaii and Micronesia. All DoN contracts shall, include invasive species contractor education as a task for the contractor to complete in each scope.	2015	TBD	TBD	High

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment N: United States Regional Biosecurity Recommendations*

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<i>Support</i>					
Improve funding and funding support for biosecurity within the region	Increase availability of funding specific for biosecurity activities including pre-border, border, and post-border elements.	2015	TBD	USFWS/USDA/NOAA	High
<i>Coordination and collaboration</i>					
Ensure that the RBP remains relevant by updating recommendation components on a regular basis (add new recommendations and remove completed elements)	Update the US section of the RBP implementation strategy every 3 years and share updates regionally.	continuous, every 3rd year minimally	NISC	TBD	High
Improve regional communication on invasive species and biosecurity issues and support of jurisdictional and regional efforts	Support development of a regional communication plan for invasive species issues. This plan should be based on existing and proposed IAS infrastructure such as the RISC, jurisdictional ISC, and the regional ISC office.	2015	USFWS	TBD	Medium
	Support development of a regional net of thematic experts to support efforts with invasive species. This net should include (but not be limited to) experts in human health, food security, border security, education, planning, IAS management and control, IAS eradication, IAS detection and response, and resource development (funding, etc.).	2016	USFWS	TBD	Low
	Report (to the region) on a yearly basis progress on RBP recommendations via MCES, including a written report shared with the region and beyond.	continuous, yearly	NISC	TBD	High
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region.	Assist with and support regional efforts to develop, fund, and staff a regional invasive species coordination office.	ideally this office would be up and running before the end of 2015	NISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office as the focal point for regional communication and dissemination of invasive species information.	As soon as the office can be established	NISC and USDA	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office to support efforts with engaging external resources to support invasive species efforts.</p>	<p>As soon as the office can be established</p>	<p>NISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support capacity building, training, and advice.</p>	<p>As soon as the office can be established</p>	<p>NISC and USDA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting protocol and methods development.</p>	<p>As soon as the office can be established</p>	<p>NISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting establishing ER &RR capacity.</p>	<p>As soon as the office can be established</p>	<p>NISC and USDA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
<p>Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).</p>	<p>Engage the regional invasive species coordination office to improve information sharing with trade partners outside the region in regards to biosecurity and IAS with respect to notification about species that will or might be problematic and which could originate from within the region.</p>	<p>As soon as the office can be established</p>	<p>NISC and USDA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with supporting the development of guidelines and regulations.</p>	<p>As soon as the office can be established</p>	<p>NISC and USDA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office with both seeking for and coordinating regional funding.</p>	<p>As soon as the office can be established</p>	<p>NISC</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>
	<p>Engage the regional invasive species coordination office to support management, response, and eradication efforts.</p>	<p>As soon as the office can be established</p>	<p>NISC and USDA</p>	<p>initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners</p>	<p>High</p>

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment of a regional invasive species coordination office. The regional IAS coordination office would serve as a focal point, coordinating body, communication and information center, and training resource for biosecurity activities throughout the region (continued).	Engage the regional invasive species coordination office to serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information.	As soon as the office can be established	NISC and USDA	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
	Engage the regional invasive species coordination office to support outreach and education efforts.	As soon as the office can be established	NISC	initial support might come from the US and the region. Ultimately this office might be supported in part by grants from various donor partners	High
Improve local and federal coordination of biosecurity elements	Each jurisdiction should work with federal counterparts to clarify and establish biosecurity SOPs (this should include listing out clearly what offices/agencies are responsible for each biosecurity aspect whether federal or local) and information exchange programs which are functional and followed up on a regular basis.	2015	USDA-APHIS	TBD	High
	Federal law enforcement supporting local regulations (in regards to quarantine and biosecurity) might be a workable solution for the CNMI, Guam, and Hawaii. This should be supported by MOUs between the jurisdictions and federal counterparts.	2015	USFWS-LE	TBD	High
	Local agencies should develop a standard updating mechanisms for PPQ to improve PPQs ability to assist within each jurisdiction including navigation of regulations.	2015	PPQ	Jurisdictional biosecurity cost recovery systems	Medium
	Utilize the APHIS-PPQ port manuals and training as guidance in locations with APHIS cooperators as appropriate to support jurisdictional biosecurity. The manuals contain information on port operations and commodity regulatory decision making designed to enhance biosecurity at the ports of entry.	2015	PPQ	Jurisdictional biosecurity cost recovery systems	Medium
	Improve ability to conduct broad based risk assessments that address more than agricultural concerns.	on-going	USDA-APHIS	TBD	Medium
	Implementation of an electronic manifest system could be used to assign risk levels for containerized cargo based upon the declared commodity, origin of shipment, and name and address of shipper and importer.	2016	USDA-APHIS	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve local and federal coordination of biosecurity elements (continued)	The manifest system should be used to target random inspections that will provide assessment and control of containerized cargo via water transport.	2016	USDA-APHIS	TBD	Medium
	Manifest system should be sharable amongst federal and local biosecurity offices.	2016	USDA-APHIS	TBD	High
	Agencies responsible for enforcing USDA-APHIS regulations should have access to the APHIS permits system for assistance in clearance of restricted agricultural materials. APHIS import permits may be required, in conjunction with local import permits, for various agricultural commodities imported into Guam and CNMI. All officers acting under an MOU with APHIS inspecting for agricultural commodities need access to the permits system to validate APHIS import permits presented with incoming shipments.	2016	USDA-APHIS	TBD	High
	Local authorities should be able to develop their own pest watch lists and be able to react appropriately and federal agencies should be permitted to support these efforts including having federal inspectors inspect for pest of local concern during international inspection processes. Jurisdictions should not be tied to federal APHIS agricultural lists of known federal pests.	2015	USDA-APHIS	TBD	Medium
Support regional biosecurity and invasive species control efforts	Support the regional updating of the RBP every 3 to 5 years.	3-5 years	NISC	Regional ISC office	Medium
	Support the establishment of a regional DNA barcoding library so that DNA analysis can become a more useful tool in identifying non-native organisms.	on-going with possible establishment by 2018	USGS, NOAA, USDA and USFWS	TBD	Low
	Support the development of molecular assisted alpha taxonomy surveys with standardized protocols which can and are used throughout the region (this would be most useful with cryptic marine species).	on-going process	USDA, NOAA	TBD	Low
	Support the development of an algal risk assessment for the region.	2016	NOAA	TBD	Medium
	Support the development of an arthropod risk assessment for the region.	2016	USDA-PPQ	TBD	Medium
	Support national and regional biosecurity development by documenting and sharing success stories with pest species (significant interceptions, eradications, successful management strategies, impacts prevented or reduced, etc.).	2015 and on-going	NISC	Regional ISC office	Low
	Support national and regional biosecurity development by documenting and sharing information regarding actual IAS prevention costs and comparing these costs with the costs of IAS control and management.	2015 and on-going	NISC	Regional ISC office	Low
	Support the development of a weeds risk assessment for the region.	2016	USDA	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support regional agreements to limit the movement of known harmful species	There are no international conventions prohibiting or regulating trade that focus explicitly on non-native species and the region should consider developing such regulations for the region which would be supported by all jurisdictions and prohibit the movement of specific organisms between jurisdictions and possible between islands within jurisdictions. If the region could develop such agreements it might be a step towards developing broader Pacific agreements and even global recognized conventions.	Consultation regarding regional agreement 2015; Development of regional agreement 2017	NISC	TBD	Medium
Prevention					
Improve pre-border biosecurity	APHIS should increase its work with various jurisdictions (when feasible) to certify pre-clearance facilities (internationally).	2016	USDA-APHIS	Ultimately cost for such programs should be bore by the imports/shippers as part of cost recovery programs	High
	Local authorities should work with APHIS and international trade partners to develop pre-border programs.	2016	USDA-APHIS	Ultimately cost for such programs should be bore by the imports/shippers as part of cost recovery programs	High
	In regards to large shipments of potentially high risk materials (such as construction materials related to the build-up) PPQ officers can be on the ground at international locations to ensure that items are clean prior to shipping.	2016	USDA-APHIS	Ultimately cost for such programs should be bore by the imports/shippers as part of cost recovery programs	Medium
	Extension agents (from land grant Universities) could work with international trade partner countries to improve pre-clearance sanitation. USDA should work with jurisdictions to facilitate this type of support from land grant institutions.	2016	USDA	Ultimately cost for such programs should be bore by the imports/shippers as part of cost recovery programs	Medium
Improve border biosecurity	Increase training.	2016	USDA-APHIS	TBD	High
	Increase resource availability.	2016	USDA-APHIS	TBD	High
	Increase oversight.	2016	USDA-APHIS	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve regulation and compliance of wood packaging material (WPM)	Support a regional effort to switch from WPM to recycled plastics. The technology exists, and new standards/compliance could be phased in with a multi-year approach to reach 100% replacement of WPM with recycled plastics.	on-going	USDA-APHIS	TBD	Low
	Require treatment of all WPM according to ISPM No. 15. All domestic and foreign WPM entering the region should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.	2015	USDA-APHIS	Biosecurity cost recovery systems	Medium
	Conduct sanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.	2015	USDA-APHIS	Biosecurity cost recovery systems	Medium
	Do not permit the unloading of noncompliant WPM.	2015	USDA-APHIS	Biosecurity cost recovery systems	Medium
	Treat or destroy any noncompliant WPM that is offloaded.	2015	USDA-APHIS	Biosecurity cost recovery systems	Medium
	Treat or destroy infested WPM. Infested WPM should be treated as regulated garbage and incinerated or sterilized.	2014	USDA-APHIS	Biosecurity cost recovery systems	High
Support improving biosecurity for DoD activities	Establish MOU between APHIS and DoD Pacific Command (similar MOUs already exist between APHIS and US Military in other regions of the world) to facilitate the role APHIS (and possibly APHIS's partners) can provide in supporting biosecurity for DoD related activities.	2015	USDA-APHIS	DoD	High
Improve capacity building and maintenance within biosecurity agencies	Develop jurisdiction wide (inclusive of all relevant agencies and offices both federal and local) capacity building and maintenance plans.	2016	USDA-APHIS	TBD	Medium
	There needs to be appropriate refresher training on general biosecurity procedures for front line offices of each jurisdiction so that important biosecurity issues can be reinforced.	2016	USDA-APHIS	TBD	High
	There needs to be advanced update training to support building capacity of biosecurity officers.	2016	USDA-APHIS	TBD	High
Improve biosecurity in regards to mail and private couriers	Develop secure procedures for opening international mail when warranted without customer witnesses and which are acceptable under US law.	2017	USDA-APHIS	TBD	Low
	Use canine teams to inspect mail and private courier items on arrival at each jurisdiction as feasible.	2018	USDA-APHIS	TBD	Low

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Improve biosecurity in regards to mail and private couriers (continued)	Record and analyze data on pest interceptions in mail. Analysis should improve targeting of phytosanitary and general sanitary hazards. Make information available on a regular basis to other offices that are involved in biosecurity.	2015	USDA-APHIS	TBD	High
	Mail and courier items should be inspected at arrival ports whenever feasible (rather than transported to a secondary location before inspection).	2016	USDA-APHIS	TBD	Medium
	Permit immediate detailed inspection of mail and private courier items if a canine team indicates on a specific item. This ability would assume that an indication would be sufficient probably cause to move forward with more detailed inspection.	2018	USDA-APHIS	TBD	Medium
Address climate change linkages to invasive pests		2018	TBD	TBD	Medium
Support improvements in regards to regulated garbage	Support development of jurisdictional SOPs on the handling and treatment of regulated garbage.	2016	USDA	TBD	High
	Support enforcement of regulations which apply to regulated garbage.	2016	USDA	TBD	High
	Unannounced monitoring of APHIS-regulated garbage compliance agreement holders should be conducted at least quarterly. Appropriate agency representatives must be trained to conduct enforcement visits to compliance agreement holders to monitor whether they follow required procedures.	2016	USDA	TBD	High
	Train appropriate agency representatives to conduct enforcement visits to APHIS Compliance Agreement holders handling regulated garbage. The number of personnel trained to monitor compliance agreement holders for functional equipment and appropriate procedures in handling regulated garbage is insufficient.	2016	USDA	TBD	High
	Enforce current swine health protection regulations requiring cooking of certain types of food waste (heating to an internal temperature of 212°F for 30 minutes) before feeding to pigs. The proper cooking of food waste will prevent the dissemination of foreign animal diseases of concern (9 CFR § 166).	2016	USDA	TBD	High
Support efforts to increase marine and aquatic biosecurity efforts in the region	Raise awareness of potential threats from marine and aquatic IAS.	2015 and on-going	TBD	TBD	Medium
	Support capacity building to establish marine and aquatic IAS programs in the region.	2015 and on-going	TBD	TBD	Medium
	Establish and support monitoring efforts for marine and aquatic IAS.	2015 and on-going	TBD	TBD	Medium
	Increase collaboration between local and federal agencies working on these issues.	2015 and on-going	TBD	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support efforts to increase marine and aquatic biosecurity efforts in the region (continued)	Seek funding support for marine and aquatic IAS prevention and response.	2015 and on-going	TBD	TBD	Medium
	Work with managers and advisory councils of the Pacific Marine National Monuments (including the Mariana Trench Marine National Monument) to collaboratively address marine biosecurity threats.	2015	NOAA / USFWS	TBD	Medium
Support the establishment and enforcement of biofouling standards	Address concern regarding the listing of marine species under the federal endangered species act. 66 species of coral have been proposed for listing under the US ESA. The listing of these species, may actually impede biosecurity efforts i.e. A fouled hull could potentially be protected under the ESA on entering US waters if these species were assumed to be present on the hull in question.	2016	USFWS/NOAA	TBD	High
	Support establishment of criteria for in-water cleaning methods for hull fouling that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2016	USCG/NOAA	TBD	High
	Support establishment of standards and regulations regarding biofouling, including inspection and certification for all vessels.	2016	USCG/NOAA	TBD	High
	Support establishment of additional regulations for vessels with long port residency periods. Long lay ups increase biofouling potential.	2016	USCG/NOAA	TBD	High
	Support the establishment of additional regulations for impounded vessels.	2016	USCG/NOAA	TBD	High
	Support development of capacity (personnel, training, and data management infrastructure) to conduct hull inspections (including diving as necessary). Consider establishing agreements with private industry to support hull inspection processes. For example, if a visual inspection determines that further hull examination is required, then the ship owner may need to hire local dive operators (that are government certified) to inspect the entire hull.	2016	USCG/NOAA	TBD	High
	Support establishment of regulations and facilities for hull cleaning including hull out facilities, associated waste disposal, and setting shoreline proximity limits for in-water cleaning.	2016	USCG/NOAA	TBD	High
	Support establishment of biosecurity practices and requirements for recreational vessels that operate within jurisdictional waters to reduce the transfer of biofouling organisms.	2016	USCG/NOAA	TBD	High
	Support establishment of the capacity to inspect and treat recreational vessels that operate within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	USCG/NOAA	TBD	High
	Support review and revision (as needed) of legal authority to implement a biofouling management programs throughout the region.	2016	USCG/NOAA	TBD	High

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support the establishment and enforcement of biofouling standards (continued)	Support the establishment of biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within jurisdictional waters.	2016	USCG/NOAA	TBD	High
	Support establishment of the capacity (personnel, training, and data management infrastructure) to inspect and treat (if necessary) in-water structures that are being moved into or within jurisdictional waters to reduce associated biofouling to an acceptable level.	2016	USCG/NOAA	TBD	High
	Support the development of regulations to address the need to levy and collect fines and/or require vessels to depart jurisdictional waters for repeat offenders and for non-compliance with treatment requirements.	2016	USCG/NOAA	TBD	High
	Review and establish criteria for in-water cleaning methods that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.	2016	USCG	TBD	Medium
	Address hull fouling concern with development of standards, regulations, and enforcement.	2016	USCG	TBD	High
	Support targeted outreach to inform the shipping industry, fishing industry, ports, and resource management agencies of biofouling management requirements for ships operating within jurisdictional waters.	2016	USCG/NOAA	TBD	High
Support improved ballast water standards and enforcement	Support targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements for ships operating within jurisdictional waters.	2016	USCG/NOAA	TBD	High
	Support establishment of ballast water management and reporting requirements for all vessels utilizing ballast water.	2016	USCG/NOAA	TBD	High
	Support development of the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance.	2016	USCG/NOAA	TBD	High
	Support review and revision (as needed) of legal authorities to implement ballast water management programs throughout the region.	2016	USCG/NOAA	TBD	High
	Support development of regulations to address programmatic needs, including the ability to levy and collect fines for non-compliance.	2016	USCG/NOAA	TBD	High
	Implement a system for U.S. Navy ships to report ballast water discharge per port arrival, modeled after that used by USCG, such that the data are compiled electronically at a centralized database.	2016	USCG	TBD	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Support improved ballast water standards and enforcement (continued)	propose a rule in the federal register to mandate compliance for all vessels with the 200nm ballast water exchange that is in place for civilian shipping. Attention should also be given to sea mounds and other near surface structures that may require further adjustment to the standardized 200nm limitation.	2016	UUSCG	TBD	High
	Support adoption of proposed USCG regulations to move to in hull ballast water treatment.	2016	USCG/NOAA	TBD	High
	Once developed, ballast water treatment regulations should be applied to all vessels operating under the various branches of the military, both military owned and civilian owned under contract.	2018	USCG	TBD	Medium
	Extend a ballast water reporting requirement and reporting system to all military vessels operating in Micronesia and Hawaii, including those operating under MSC and other branches of the military.	2015	USCG	TBD	Medium
	Develop standards for compensating fuel tank discharges which are equivalent to the ballast water requirements.	2016	TBD	TBD	Medium
Early detection and rapid response					
Support improved rapid response capabilities for both military and civilian lands for each jurisdiction. Improved rapid response measures could prevent the establishment of IAS. Rapid response takes place at and within the border at levels ranging from federal to local community involvement.	Review existing rapid response capacity for each jurisdiction.	2015	TBD	TBD	Medium
	Improve capacity as needed (which likely will involve better communications, increased training, improved resources, and ensuring that dedicated funding is available for field actions.	2016	TBD	TBD	Medium
Management and eradication					
Better support management and control of the Brown Treesnake (BTS) , one of the top invasive alien species (IAS) already established in the region (Guam) which threatens all other jurisdictions. The US has developed an extensive management and control program for the BTS which depends on interagency cooperation and which relies on the expired BTS control and eradication act as one of its underlying directives.	The BTS Control and Eradication Act (2004-2009) should be reauthorized to provide specific instructions and allow for additional efforts to prevent the spread of BTS from Guam. This 5-year BTS Control and Eradication Act expired in 2009. Renewal of this important regulatory driver has not yet been accomplished. Regulations pertaining to prevention, mitigation, and management of BTS that are contained in the Act are pertinent for protecting areas exposed to BTS from trade, travel, and tourism. Further, the act directs USDA and US DOI to establish rules structured to improve and expand BTS interdiction efforts. Once reauthorized, other federal agencies including the Departments of Defense, Homeland Security, and Transportation could better assist in preventing the further spread of BTS.	2015	USFWS	BTS Working Group	High
	Consideration should be given to the USDA pre-departure BTS inspections for Guam and if they are to be mandated as required and whether a fee could be associated with these inspections to cover their costs.	2015	USDA	BTS Working Group	Medium

Recommendation	Action Item	Time Line	Lead	Potential Funding/Resources	Priority
Better support management and control of the Brown Treesnake (BTS) , one of the top invasive alien species (IAS) already established in the region (Guam) which threatens all other jurisdictions. The US has developed an extensive management and control program for the BTS which depends on interagency cooperation and which relies on the expired BTS control and eradication act as one of its underlying directives (continued).	Currently USDA conducts voluntary pre-departure inspections on Guam in an attempt to intercept BTS before they are accidentally transported from the island. This effort appears to be highly successful but is based on a voluntary inspection process. Consideration should be given to whether this effort should be mandated so as to better insure 100% coverage of pre-departure inspections for BTS for the island of Guam. DoD has military instructions that mandate BTS pre-departure inspections.	2015	USDA	BTS Working Group	Medium
	Consideration should be given to the USDA pre-departure BTS inspections on Guam in regards to whether items inspected could be effectively tagged/sealed after inspection to facilitate identification of what items have passed this inspection by front line inspectors at ports of arrival else where.	2015	USDA	BTS inspection cost recovery system	Medium
	Improve awareness of BTS and BTS related issues throughout the region at all levels. Specific focus should be directed to understanding both the historic context and the current situation on Guam and how the current situation on Guam has the potential to impact other locations if interdiction efforts are not maintained.	on-going	BTS Working Group	TBD	Medium
	Improve communications and partnering with Micronesian agencies or organizations not part of the BTS Working Group to increase BTS awareness, control and management efforts.	2015	BTS Working Group	TBD	Medium
Awareness					
Develop jurisdiction specific IAS education and awareness programs that are adequately funded and otherwise supported. These programs should reach all elements of society. This should be a long term and sustained efforts. Efforts should be coordinated amongst jurisdictions in order to achieve the best possible outcomes. Regional sharing of resources and ideas and using successful programs as frameworks to establish similar programs in other locations will facilitate the growth of awareness programs throughout the region.	Conducted surveys of current awareness levels.	2015	USFWS	TBD	High
	Utilize survey results to enhance and expand existing IAS awareness programs.	2016	USFWS	TBD	High
	Integrate IAS education into school curriculums and provide teach training.	2016	USFWS	TBD	Medium
	Develop school and community volunteer programs to support appropriate IAS management actions.	2016	USFWS	TBD	Medium

*These recommendations do not create any right, obligation or legal responsibility on the part of any of the jurisdictions to fund or execute the RBP.

Attachment O: Models

RARE: Awareness via Campaigns

Overview

A. Need

With ever increasing globalization and its associated increases in vectors and pathways as trade and visitation increase throughout the region, the need for improved biosecurity systems to protect islands, environments, communities, and economies, from invasive species increases. Biosecurity efforts within each jurisdiction can only be appropriately addressed with the support of local residents and communities. To support invasive species suppression efforts, residents need to recognize the benefits of biosecurity. To garner the public support necessary to implement jurisdictional biosecurity throughout the region, educational campaigns geared towards raising local awareness regarding the benefits of biosecurity systems, changing attitudes towards biosecurity actions and promoting behaviors that reduce the potential of transporting non-native species are necessary. The following outlines the objectives and methods for creating and implementing a Jurisdictional Invasive Species Public Awareness Campaign over a three-year period based on Rare Pride Methodology (www.rare.org/rare-pride-methodology).

B. Purpose

The purpose of the Jurisdictional Invasive Species Public Awareness Campaigns is to garner the support of local residents and communities in each jurisdiction for biosecurity as expressed in the strategic recommendations of the Micronesia Biosecurity Plan.

C. Objectives

1. Collect baseline public opinion data during FY15 and FY16 to support campaign development, implementation and evaluation.
 - Develop questions for pre-campaign survey.
 - Contract marketing firm or utilize volunteers to implement pre-campaign survey and analyze results.
 - Identify action items and prepare campaign project plan.
2. Direct a focused, public awareness campaign during the latter half of FY15 and FY16 that addresses core issues identified by the systematic baseline surveys.
 - Implement campaign.
 - Develop and design appropriate media. Contract vendors when necessary.
 - Conduct presentations and public events to identified target audiences.
 - Distribute collateral materials to identified target audiences.
3. Collect post-campaign public opinion data during FY17 and FY18 to support campaign development, implementation and evaluation.

- Contract marketing firm or utilize volunteers to implement post-campaign survey and analyze results.
- Identify action items for follow-up campaign project plan.

D. Approach

For a regional campaign to be successful, objectives, target audiences, messages, methods, threats and barrier removal strategies must be localized to the specific jurisdiction. Hence, a regional manager could coordinate various jurisdictional campaigns with similar objectives or goals but possibly influence different target audiences and utilize different messages and methods. For example, to improve biosecurity efforts, it has been suggested that a regional goal should be to incorporate IAS into school curriculums. This in fact may be an appropriate pathway for long term improvement in public awareness in regards to invasive species, but such a concept should be evaluated, including receipt of local public input in each jurisdiction before extensive planning and implementation occur. Implementation of this goal, if appropriate, will require following guidelines and restrictions specific to each of the implementing jurisdictions.

E. Expected results/benefits

The development and implementation of a focused Invasive Species Awareness Campaign within each jurisdiction will increase the public's support for regional invasive species suppression. The support of an informed public will allow biosecurity efforts throughout Micronesia to move forward as jurisdictional campaigns will complement one another. In the long term these efforts will help protect the natural resources within Micronesia for future generations. Increased public awareness and local pride in natural heritage will assist with guarding against accidental or intentional releases of unwanted species, supporting maintenance of quarantine procedures and preserving pest-free areas.

F. Timeline

Approximate Start date: TBD 2015

Weeks 1 – 9

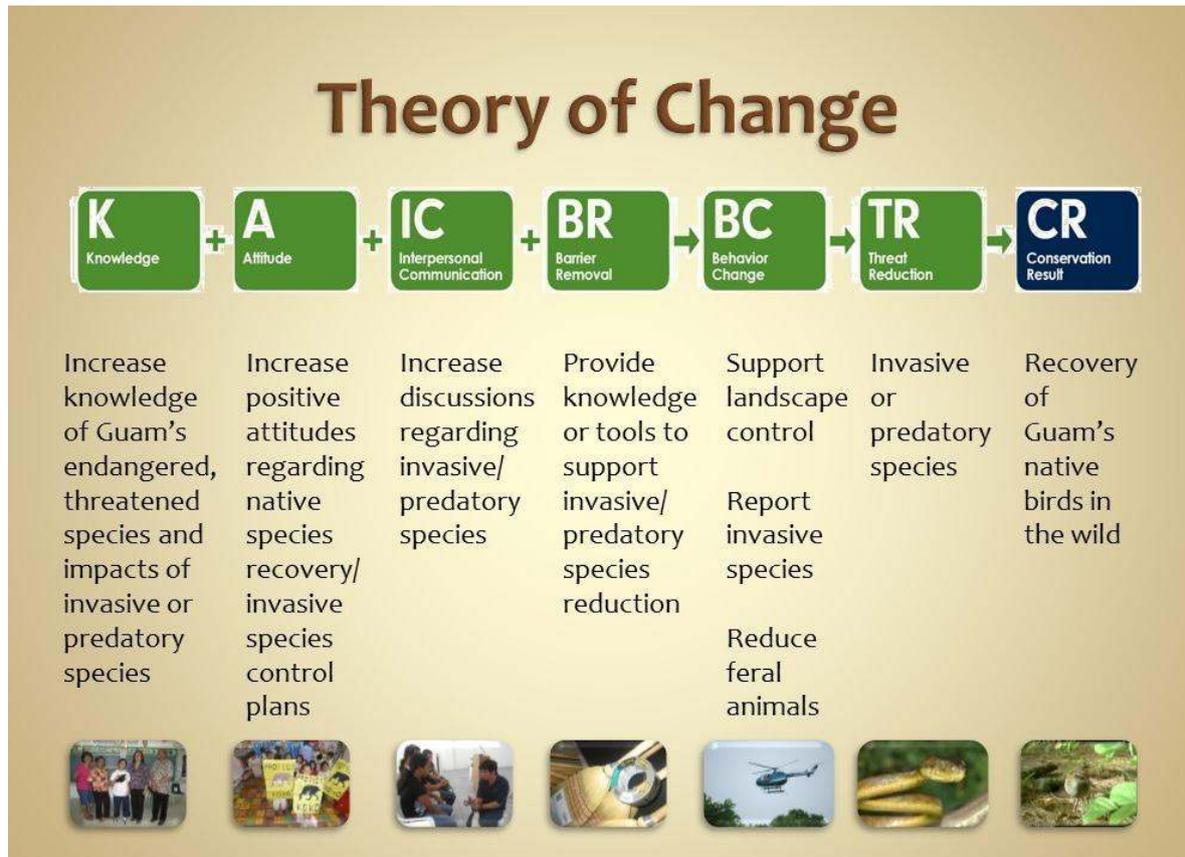

Build a comprehensive project plan, including ground truth concept models and threat ranking analysis, as well as identify potential solutions to barriers to invasive species suppression.

Weeks 10 – 35

Conduct pre-campaign survey, engage stakeholders, volunteers and technical experts, set objectives, build consensus, and finalize a draft campaign project plan for review and final approval.

Using the Go Native! Guam Social Marketing Campaigns as an example, the rationale or theory of change of a completed social marketing plan can be understood as follows:

“To protect and recover Guam’s native bird species, the threat of invasive or predatory species must be decreased by increasing the support of landscape control, reporting of invasive species and reduction of feral animals. This will be accomplished by providing knowledge or tools to support invasive species reduction in addition to increasing the knowledge, positive attitudes and interpersonal communication of biosecurity efforts within target audiences.”

(C. Calauastro, personal communication, April 7, 2014).

Weeks 36 – 40

Refine campaign plan and prepare for actual implementation, including marketing, media relations, design, advanced project management and measuring impact.

Weeks 41 – 148

Begin campaign implementation. With full technical support from agency partners, launch a multimedia public awareness campaign designed to change knowledge, attitudes and behaviors to increase support for broad-area invasive species prevention, control, and eradication.

For example, the Go Native! Guam Social Marketing Campaign utilizes a variety of mini and mass media as well as the Internet to engage target audiences:

(C. Calastro, personal communication, April 7, 2014).

Weeks 148 – 152

Conduct post-campaign survey.

Weeks 152 – 156

Prepare analysis of campaign results; build a long-term plan for sustaining impact.

Week 157 and beyond - Sustaining Impact

Seek support in the form of follow-up grants, regional networks, workshops, and peer mentoring. Work to sustain social and behavioral change in the long term with partners.

Approximate End date: TBD 2018

G. Examples Communication Vehicles (*Final marketing mix determined by pre-campaign survey*)

- Print newsletters/magazines/flyers
- Posters, banners, murals
- Web site; other web-based media: blogs, webinars, links to existing website, etc.
- News conferences
- Electronic newsletters
- Amnesty bins
- Video for airplanes
- Kiosks at airports
- Multi-media presentation to interested parties – Mayor’s Council, Village Chiefs
- Town/Village Meetings
- Lunch and learn events
- Face-to-face small meetings, workshops
- Field site events or trainings
- Special public events – concerts, free movies
- Digital advertising
- Radio spots
- General Swag: t-shirts, stickers, calendars etc.
- Use of a mascot

Awareness via Mass Media (recent videos):

Other specific examples of how jurisdictions and/or the region could improve IAS awareness are demonstrated in the following two scenarios. The first is a short film produced by CAB International in 2014 to create awareness of specific invasive plants in Africa. The video can be found at: <http://youtu.be/ggqseLRvlfY>. This is a clear example of the types of awareness elements that Micronesia and Hawaii should be developing. Clear, direct informational formats using mass media outlets, including the internet but also local TV, radio, and news print to build IAS awareness in the citizenry throughout the region. The second example is again a video, this one produced in Hawaii to build awareness of Little Fire Ant impacts. This video is an excellent example of awareness development to support biosecurity within the region. This video can be viewed at: <http://www.littlefireants.com/>.

New Zealand Biosecurity:

New Zealand is considered by many to have one of the best (if not the best) biosecurity system to date. The New Zealand system should be reviewed by the various jurisdictions covered in the RBP and potentially usable elements of this system should be further investigated as to the feasibility of incorporating the same or similar elements into the various biosecurity systems within the region covered by the RBP. Knowledge of functioning biosecurity models from other areas can be extremely useful and the review of biosecurity programs such as that utilized in New Zealand is encouraged, but ultimately, each jurisdiction will need to build the system that functions best for them, given their unique set of parameters. The New Zealand's biosecurity strategy can be found at: <http://www.biosecurity.govt.nz/files/biosec/sys/strategy/biosecurity-strategy.pdf>.

Perhaps a good place to start is with an understanding of what makes the New Zealand biosecurity system functional in New Zealand. And perhaps a clue to understanding the functionality of the New Zealand system is found in the opening pages of their strategy, where the importance of biosecurity to the country is clearly acknowledged. This statement, the importance of biosecurity to the country and its economy, is not just a conceptual notion. The fact is that this underlying foundational belief is born out in the support that the government and the citizenry of New Zealand provide for the protection of their country via their highly supported biosecurity system.

While buy-in from government and citizens is a big part of why the New Zealand biosecurity system functions successfully, there are other elements that contribute greatly to the overall functionality of this system. Among these other elements is a well thought-out and documented cost recovery component. Elements of the New Zealand biosecurity cost recovery component are available online and can be accessed at: <http://www.biosecurity.govt.nz/regs/fees-and-charges>. It is recommended that all jurisdictions review the clearly laid out funding strategy utilized by New Zealand to support biosecurity and consider how elements from this funding strategy can be incorporated into the biosecurity systems of Micronesia and Hawaii.

Attachment P: Biosecurity Officer Qualifications

Qualifications for biosecurity officers will vary depending on specific job duties and duty station. For example, biosecurity officers who work with detector animals, such as canines, will need additional training beyond general inspectors. But, there are minimal qualifications that all biosecurity inspectors should possess.

Minimal staff competency requirements:

1. Staff carrying out sampling should demonstrate ability to follow written procedures.
2. Inspection staff should be competent in the following areas:
 - a. Demonstrable ability to follow written procedures;
 - b. Demonstrable ability to detect pests or symptoms; and
 - c. Demonstrable ability to decide on the significance of the findings.

Along with the minimal qualifications, biosecurity inspectors should possess the following attributes: observant, tactful, reliable, and responsible. In addition, good communications skills and the ability to work with a wide variety of people from diverse cultures and backgrounds would seem highly beneficial.

While not strictly required for minimal qualification, professional experience and/or post-secondary training in an appropriate subject matter such as botany, ecology, agriculture, or marine science would be preferable.

Inspectors should have or should acquire with time in service both depth and breadth in the understanding of the basic concepts of biosecurity as well as detailed knowledge regarding specific elements of their position. Some of these skills which should be the focus of specific training for inspections follow (this list can obviously be expanded and should be for each jurisdiction):

- Taxonomic identification of specific high risk organisms
- Specimen collection and preservation
- Data collection and entry
- Professionalism
- Ability to interact appropriately and effectively with the public
- Ability to react appropriately and effectively to new situations as they arise
- A clear understanding of the critical nature of their position and how their specific duties fit into the larger biosecurity system framework

Attachment Q: Regional Biosecurity Plan Strategic Implementation Development Consultancy Visits*

26 – 30 November 2012, Majuro, Republic of the Marshall Islands (overlap with the Micronesia Chief Executives Summit and the Regional Invasive Species Council meeting)

21 – 28 May 2013, Republic of Palau

3 – 8 June 2013, Majuro, Republic of the Marshall Islands

17 – 22 June 2013, Kosrae, Federated States of Micronesia

22 – 29 June 2013, Pohnpei, Federated States of Micronesia

2 – 7 July 2013, Yap, Federated States of Micronesia

7 – 12 July 2013, Oahu, Hawaii

14 – 20 July 2013, Saipan, Tinian, and Rota, Northern Mariana Islands

24 – 27 July 2013, Chuuk, Federated States of Micronesia

2 – 6 September 2013, Majuro, Republic of the Marshall Islands (overlap with the Pacific Island Forum)

2 – 6 December 2013, Saipan, Northern Mariana Islands (overlap with the Micronesia Chief Executives Summit and Regional Invasive Species Council meeting)

9 – 15 December 2013, Oahu, Hawaii

15 – 17 January 2014, Washington D.C.

21 – 25 January 2014, Majuro, Republic of the Marshall Islands

25 – 28 January 2014, Kosrae, Federated States of Micronesia

28 – 30 January 2014, Pohnpei, Federated States of Micronesia

30 January – 1 February 2014, Chuuk, Federated States of Micronesia

4 – 9 February 2014, Republic of Palau

9 – 12 February 2014, Yap, Federated States of Micronesia

*Members of the Regional Biosecurity Plan development team reside within the Pacific Region many on the island of Guam and therefore no specific consultancy trips were made to Guam. Team members

have worked regionally with biosecurity and invasive species issues for many years and various additional site visits were made that are not listed as specific consultancy trips for this project. Additionally, much of the consultation work was conducted remotely via both email and phone conversation with stakeholders across the region.

Attachment R: Regional Biosecurity Plan for Micronesia and Hawaii Implementation Strategy Workshop Attendees List

19 - 21 May 2014

Office	Personnel
Chuuk State Chief of Staff, Office of the Governor	Wilfred S. Robert
Chuuk State Dept. of Agriculture Director, Office of the Governor	Kantito Kanas
CNMI Director of Agriculture, S\aipan	Manual A. Tenorio
CNMI Tinian Resident Department Head, Department of Lands & Natural Resources	Richard Farrell
Contractor	Else Demculinaek
Contractor	Lisa Chambers
Coordinator of the Hawaii Invasive Species Council	Joshua Atwood
Deputy Assistant Secretary of the Navy (DASN E)	Dan Cecchini
FAO	Viliami Fakava
Guam	Christine Camacho
Guam Customs and Quarantine	Jason Paulino
Guam Department of Agriculture	Brent Tibbatts
Guam Department of Agriculture	Russell Campbell
Guam DOA DAWR	Tino Aguon
Guam Legislature	Honorable Chris Duenas
Hawaii Department of Agriculture Acting Plant Quarantine Branch Chief	Darci Oishi
Hawaii Department of Agriculture Chairman	Scott Enright
Headquarters Marine Corps	Ryan Orndorff
Island Conservation	Raymond Nias
Kosrae Chief of Staff, Office of the Governor	Sweetiyona Tulensru
Kosrae Island Resource Management Authority Executive Director	Robert H. Jackson
Kosrae State Department of Resources and Economic Affairs	Mutanel Tolenna
LandCare	Phil Cowan
LandCare	John Parkes
United States National Invasive Species Council (NISC)	Phil Andreozi
Naval Facilities Engineering Command, Headquarters	Tammy Conkle
Naval Facilities Engineering Command, Marianas/Joint Region Marianas	Anne Brooke
Naval Facilities Engineering Command, Marianas/Joint Region Marianas	Steve Mosher
Naval Facilities Engineering Command, Pacific	Joel Helm
NAVFAC Marianas Commanding Officer/JRM J4 Regional Engineer	Captain Glenn Shephard
NOAA	VAL BROWN
Office of the Under Secretary of Defense - ATL	Gregory M. Beavers, CAPT USN OSD OUSD ATL (US)
Palau Chief of Staff, Office of the President	Secilil Eldebechel

Office	Personnel
Palau Minister of Natural Resources representative	King Malsol Sam
Palau National Invasive Species Coordinator, Bureau of Agriculture	Joel Miles
Pohnpei Agriculture Conservation Specialist, USDA-NRCS	Gibson Santos
Pohnpei Chief of Staff, Office of the Governor	Valerio Halens
Pohnpei Office of Economic Affairs Administrator	Kadalino Lorens
RMI Chief Fisheries Officer for the Coastal Fisheries, Marshall Islands Marine Resources Authority	Florence Edwards
RMI Chief of Agriculture & Quarantine, Ministry of Resources & Development	Henry Capelle
RMI Chief of Land, Coastal & Conservation Division, Environmental Protection Agency	Lani Milne
SPC	Josua Wainiqolo
SPC	Emil Adams
SPC	Radilaite Nawalowalo
SPC	Poasa Nauluvula
SPC	Ken Cokanasiga
The Nature Conservancy	Trina Leberer
UNDP	Johan Robinson
United States Department of Defense	Edward Lynch
United States Department of the Navy	Paul Wenninger
University of Guam	Tom Schils, Marine Lab
University of Guam	Ross Miller
University of Guam	Laura Biggs
University of Guam	President of the University of Guam Dr. Robert Underwood
University of Guam	Roland Quitigua
University of Guam	John Peterson
University of Guam	Ed Reyes
University of Guam	Frank Camacho
University of Guam	James Stanford

2 Volume II - Fresh Water Systems

Regional Biosecurity Plan for Micronesia and Hawaii

Volume II

Prepared by:

University of Guam and the Secretariat of the Pacific Community 2014

This plan was prepared in conjunction with representatives from various countries at various levels including federal/national, state/territory/commonwealth, industry, and non-governmental organizations and was generously funded and supported by the Commander, Navy Installations Command (CNIC) and Headquarters, Marine Corps.

Executive Summary

Prepared by the National Invasive Species Council

On March 7th, 2007 the U.S. Department of Navy (DoN) issued a Notice of Intent to prepare an “Environmental Impact Statement (EIS)/Overseas Environmental Impact Statement (OEIS)” for the “Relocation of U.S. Marine Corps Forces to Guam, Enhancement of Infrastructure and Logistic Capabilities, Improvement of Pier/Waterfront Infrastructure for Transient U.S. Navy Nuclear Aircraft Carrier (CVN) at Naval Base Guam, and Placement of a U.S. Army Ballistic Missile Defense (BMD) Task Force in Guam”. This relocation effort has become known as the “build-up”. In considering some of the environmental consequences of such an undertaking, it quickly became apparent that one of the primary regional concerns of such a move was the potential for unintentional movement of invasive species to new locations in the region. Guam has already suffered the eradication of many of its native species due to the introduction of brown treesnakes and many other invasive plants, animals and pathogens cause tremendous damage to its economy and marine, freshwater and terrestrial ecosystems. DoN, in consultation and concurrence with relevant federal and territorial regulatory entities, determined that there was a need to develop a biosecurity plan to address these concerns.

It is important to note that in February 2012, the United States (U.S.) Department of the Navy (Navy) initiated a Supplemental Environmental Impact Statement (SEIS) to evaluate the environmental consequences of establishing a live-fire training range complex (LFTRC) on Guam in support of the relocation of U.S. Marine Corps (USMC or Marines) forces to Guam (the "LFTRC SEIS"). Shortly thereafter, the U.S.-Japan Security Consultative Committee (SCC) issued a joint statement announcing its decision to adjust the plans outlined in the May 2006 Realignment Roadmap. In accordance with the SCC's adjustments (the "2012 Roadmap Adjustments"), the Department of Defense (DoD) adopted a new force posture in the Pacific, providing for a substantially smaller Marine Corps relocation to Guam.

As a result of the 2012 Roadmap Adjustments, the Navy expanded the scope of the LFTRC SEIS to also evaluate the potential environmental consequences from construction and operation of a main cantonment area, including family housing, and associated infrastructure to support the relocation of a substantially reduced number of Marines than previously analyzed. The SEIS will supplement the 2010 Final Environmental Impact Statement (EIS) for the Guam and Commonwealth of the Northern Mariana Islands (CNMI) Military Relocation. The need for a comprehensive plan to address biosecurity threats posed by the proposed action has not been eliminated as a result of the changes to the force posture.

To address this identified need, DoN has joined forces with partners in other U.S. federal agencies and with local, regional and international governments and organizations to develop a comprehensive Micronesia Biosecurity Plan (MBP). Invasive species are considered the second most significant driver of biodiversity loss worldwide and are by far the number one cause on islands. They also have significant, direct negative impacts upon other critical island issues such as food security, culture, natural resources, economic development and climate change adaptation. Invasive species are spread, intentionally or unintentionally, by trade, travel and tourism. All three of these activities are projected to increase significantly as a result of the USMC relocation to Guam. The projected growth will result in an increased potential to spread

invasive species which cause or are likely to cause economic or environmental harm or harm to human health. The development of the MBP is a proactive effort to determine how to best prevent and mitigate the risks of increased invasive species damages as a result of the build-up.

The MBP is unprecedented in its scope and covers invasive species risks from all major taxonomic groups (plants, animals and pathogens) and for all major ecosystems (freshwater, marine and terrestrial) for the vast majority of the region of Micronesia – including Palau, Guam, the Commonwealth of the Northern Marianas Islands, the Federated States of Micronesia and the Republic of the Marshall Islands. Nauru and Kiribati are part of Micronesia but are not included in this analysis because they will not be impacted by the build-up. The State of Hawaii is also being addressed in this effort – but only to the extent to which it will be directly impacted by invasive species concerns related to the build-up.

To develop the MBP, DoN has provided over \$3,700,000 in direct funding to scientists and invasive species experts from the Departments of Agriculture and Interior (USDA and DOI), the Smithsonian Institute (SI), the National Invasive Species Council (NISC) and the University of Guam (UOG). The cooperating federal partners (USDA, DOI, SI and NISC) and numerous local and regional cooperators have contributed, and continue to contribute, significant time, resources and expertise to this effort above and beyond the direct funding provided.

This comprehensive approach to biosecurity for the region of Micronesia is a multi-level, multi-disciplinary, collaborative effort, aimed at preventing the introduction and establishment of additional invasive species at both regional and jurisdictional levels. Such a holistic biosecurity plan considers implementation of pre-border (such as pre-clearance), at-the-border (such as inspection and quarantine) and post-border (such as monitoring, rapid response and eradication of invasive species) measures. While all three of these measures are considered critical to an effective biosecurity plan, preventing the establishment of invasive species is most effectively undertaken via pre-border and at the border efforts. Additionally, these efforts are significantly less expensive (in terms of both capital and negative impacts) than long-term control of established invasive species. For many invasive species there are no feasible long-term control options. Left uncontrolled, invasive species and their damage to environment and economy spread and intensify.

The development of the MBP is being conducted in two phases. The overall goal of Phase 1 of the MBP is (1.) to identify terrestrial, marine and freshwater biosecurity risks posed by changes associated with the build-up in transportation and commerce to and within Micronesia and to and from Hawaii, and (2.) to document prevention, control and treatment measures for invasive species that can be incorporated by civilian and military operations. Phase 2 is an ongoing effort with high levels of interest both within and outside of the Micronesia region. It includes the development of an independent scientific peer review of Phase 1 results and creation of a regionally vetted Strategic Implementation Plan (SIP), including extensive in-person consultation with regional invasive species experts and stakeholders. This unique effort will help address both invasive species threats to the military mission and invasive species concerns raised by the Micronesian Chief Executives and federal and regional partners. Phase 1 of the MBP has been completed and this summary is focused on that effort.

Phase 1 was prepared by federal scientists from three different federal departments working in partnership with a variety of other local, territorial, state, national and international invasive species scientists and experts. Experts from the U.S. Department of Agriculture's – Animal and Plant Health Inspection Service (APHIS) addressed terrestrial invasive species concerns and conducted a variety of port examinations. The Smithsonian Institution conducted all work on marine invasive species as well as invasive freshwater plant concerns for the region. Scientists from the U.S. Department of the Interior's – U.S. Geological Survey (USGS) examined invasive issues in regards to the regions freshwater fauna. The National Invasive Species Council (NISC) served as the overall coordinating body during the development of Phase 1. A primary NISC duty was to work closely with DoD counterparts to encourage regional engagement in the MBP process and to facilitate collaboration between local and regional invasive species experts, such as the members of the Micronesia Regional Invasive Species Council, and the federal scientists.

The development of Phase 1 of the MBP marks the first time that scientists from different federal departments have collaborated on such an effort at this scale. It represents a new level of inter-departmental collaboration in invasive species studies and planning that takes advantage of the various centers of invasive species expertise throughout the federal government. The geographic range and taxonomic scope of this effort, combined with the level of intra-federal cooperation and in-depth collaboration with local, territorial, commonwealth, state, and national governments as well as regional organizations truly makes the MBP a globally unprecedented effort. As is often the case when breaking new ground, unexpected challenges and delays arose, but thanks to laudable flexibility from partners and a commitment to the overall goal, these challenges were met and overcome.

Phase 1 of the MBP is composed of a series of documents totaling over 2,000 pages in length. This Executive Summary addresses the MBP Phase 1 document as it was written – breaking it out into its component parts, then providing a synthesis of common “Take Home Messages”.

FRESHWATER ECOSYSTEMS

Macrofauna:

The risk assessment analysis and summary of management alternatives for freshwater invasive animals and their pathways was conducted by a team of scientists from the United States Geological Survey (USGS) led by Drs. Stephen J. Walsh and Leo G. Nico. The USGS Team collaborated with local and regional scientists and experts, conducted numerous field surveys on multiple islands, and examined available data to summarize the status of native and nonindigenous freshwater macrofauna in Micronesia. Using this information, they assessed the introduction risk of new invasive freshwater species into the region, evaluated the pathways by which previous introductions occurred, and identified the species of most concern- i.e., those that have the greatest potential to become invasive in the inland waters of Micronesia. These evaluations and assessments informed the development of management alternatives to prevent or reduce the likelihood of invasion and mitigate the impacts of non-native species already in the region.

The USGS risk assessment used an original data set assembled from a quantitative analysis of fish introductions to the inland waters of Guam and Hawaii. This data set contains information that is much more complete than for any other freshwater taxa or islands in the tropical Pacific. Emphasis was given to the largest islands in Micronesia with the most freshwater resources (as opposed to small islands such as coral atolls with limited or no freshwater resources).

The USGS team found that 1) the aquarium trade, 2) aquaculture, and 3) the live-food trade are the general pathways posing the greatest risk of introduction and spread of invasive freshwater macrofauna. To address these pathways, the USGS summarized 25 specific management strategies, ranked from medium to high priority. The management alternatives are assigned to applicable parties (DoD, non-DoD management and regulatory agencies in Guam and the CNMI, and foreign entities) and are placed into four categories; Prevention/Pathway Disruption, Long-term Management, Early Detection, and Rapid Response.

The analysis by USGS scientists suggested that primary emphasis should be placed on management strategies that address prevention. In order to achieve that goal, a series of actions are suggested that would dramatically improve inspection and detection programs, improve training of inspectors, and establish robust monitoring and rapid response activities. Their assessment also draws attention to the critical need for additional biological surveys, research, and data compilation to allow fuller, more refined analyses of risk and to close data gaps.

Central to all management alternatives summarized by the USGS team is the need for flexibility in implementation. As gaps in the understanding of freshwater invasive species and their impacts in Micronesia are addressed, new technologies and methodologies are developed, and additional invasive species pathways and vectors are identified, biosecurity efforts will need to remain flexible enough to incorporate and take advantage of these advancements in knowledge. USGS identifies certain pathways of special concern, such as the availability of potentially invasive freshwater species for purchase over the internet, easy potential for shipment through both the U.S. mail system and private couriers. To close these and other high-risk biosecurity loopholes may require substantial policy and management practice modifications. Lastly, USGS emphasizes the need for broad cooperation and coordination between the U.S. Military, other U.S. Federal agencies, the territorial and sovereign island governments, universities and civilian sectors in Micronesia, and international partners to achieve the biosecurity goals put forth in this document.

Plants:

The risk assessment analysis and development of recommended management practices for freshwater invasive aquatic plant species (IAPS) and their pathways was led by a team of scientists from the Portland State University (PSU) Aquatic Bioinvasion Research and Policy Institute under the leadership of Dr. Mark Sytsma. The PSU risk assessment was conducted by Paul Champion and John Clayton of the New Zealand National Institute of Water & Atmospheric Research Ltd. The PSU team used the results of an exhaustive literature review, supplemented by data collected during field visits and surveys in multiple locations throughout Micronesia, and collaboration with regional experts to inform their risk assessment process and develop their management practice recommendations.

Field visits took place in early 2010 and included surveys of freshwater systems to determine which IAPS were established as well as plants available for sale in pet stores, markets and other commercial venues. As with freshwater animal studies, emphasis is given to the largest islands in Micronesia with the most freshwater resources (as opposed to small islands such as coral atolls with limited-to-no freshwater resources). A notable result of the field surveys was the first record in Micronesia of *Monochoria vaginalis*, a federally listed noxious weed, in a small stream in southern Guam.

Leading up to a detailed discussion of recommendations and specific actions to enhance regional biosecurity for IAPS, the PSU team provides an overview of specific IAPS of concern, susceptible freshwater habitats in Micronesia, IAPS treatment and control methods and current risk management efforts and limitations in the region.

PSU notes that geographic isolation of the islands of Micronesia present unique challenges to the management of IAPS, and that effective biosecurity will need to be coordinated across jurisdictions with understood roles, regulations and opportunities for collaboration. The importance of maintaining programmatic flexibility to be able to incorporate new data and state of the art technologies and methodologies into biosecurity planning is also stressed. The PSU recommended strategic actions to enhance IAPS regional biosecurity are divided into 5 separate Objectives - each objective containing multiple strategies and each strategy with individual actions.

Objective one is to coordinate and implement a comprehensive management plan. To accomplish this objective, PSU suggests strategies to effectively coordinate and strengthen biosecurity efforts across the region, enhance funding and resources, and maintain flexibility so that regional and international lessons learned, advances in understanding and new preventative methodologies can be incorporated into regional and local biosecurity planning.

Objective two is to prevent new freshwater IAPS introductions and spread of existing species. To accomplish this objective, PSU suggests strategies to address five critical pathways of IAPS introduction: internet/mail order, ornamental water features, tourism, military equipment and personnel and air and maritime cargo. Two additional strategies focus on improvement of detection and interception of IAPS as well as the development of plans to control high-risk IAPS already present in the region.

Objective three is to detect and monitor for freshwater IAPS. To accomplish this goal, PSU suggests a strategy to implement standardized IAPS surveys of regional freshwater habitats to enable more effective prevention, eradication and control efforts.

Objective four is to coordinate and implement a comprehensive early response plan. To accomplish this objective, PSU suggests strategies to enable swift identification and response to regional IAPS incursions and to develop efficient, coordinated eradication efforts based on accurate delineation, clearly stated management goals and informed selection of eradication methods.

Objective five is to inform public, policy makers, and user groups of risks and impacts of IAPS.

To accomplish this objective, PSU suggests strategies to enhance outreach and education to three targeted groups in the region. Effective public education can decrease intentional and unintentional IAPS introductions and outreach and training provided to natural resources personnel and networks of interested citizens can be important components to early detection and monitoring efforts.

MARINE ECOSYSTEMS:

A team lead by the Smithsonian Environmental Research Center (SERC) prepared the marine ecosystems component of Phase 1 of the MBP. The SERC document outlines risks of invasion and provides recommendations to reduce the introduction, establishment and spread of marine and estuarine invasive species. In preparation of this document SERC teamed with other Marine invasive species experts from Central Queensland University, Portland State University and the Bishop Museum.

The SERC document is composed of three basic parts. Part one presents information on the present understanding of vectors (such as vessels and live trade) by which non-native marine species are transferred into Micronesia and provides a summary of current regulations and management practices to address those vectors. Part two is a risk assessment of marine invasions for Micronesia and details likelihoods and consequences of invasion. Part three provides a marine biosecurity plan for the region including specific recommendations on actions, strategies and frameworks to be implemented to minimize damages to Micronesia from marine invasions. The SERC document focuses heavily on vectors of invasion and vector management is presented as a critical component of the marine biosecurity plan itself. The risk assessment focuses on biofouling organisms – i.e. those organisms known to foul the hulls and underwater surfaces of vessels - and incorporates information on shipping traffic patterns and history of commercial and U.S. military vessels. Critical information regarding a large proportion of U.S. Navy vessels was not made available to the SERC team to evaluate, due to its sensitive nature. Data for recreational and fishing vessels was also lacking..

Unique to the SERC document is a pilot study on Micronesian societal values towards invasive species impacts. The pilot study sought to identify known and perceived values (environmental, economic, social and cultural) that may be impacted by introduced marine species and then assess the perceived change in these values if invasive marine species were to occur in the region. Typically, and especially in the U.S., risk assessments do not incorporate social and cultural impacts. This preliminary examination shows that there is concern over social and cultural impacts of marine invasive species.

The SERC marine biosecurity recommendations start off with a review of general biosecurity and marine-specific plans that have been developed or proposed in the broader Pacific, within Micronesia and for U.S. military bases. SERC then provides a conceptual framework with four components (and the interactions among them) of marine invasive species vector management ((1). Vector analysis, (2). Vector strength, (3). Vector interruption (disruption) and, (4). Efficacy), noting that a successful biosecurity program must incorporate each of these components along with necessary policy, management and research to sustain them.

SERC provides 47 marine invasive species prevention recommendations for vector management broken out by particular vectors ranging from a variety of vessel types (military, commercial, fishing, recreational, etc.) to construction materials, diving and fishing equipment and live trade of marine organisms. Recommendations for vessels are categorized into the specific issues of ballast water, biofouling and compensating fuel tanks (the last for military vessels only).

For ballast water, SERC makes a variety of recommendations to ensure consistent and coordinated data collection and reporting, treatment requirements, field-based treatment validation surveys and education efforts to ensure familiarity with goals and requirements. Of note is the need for a clear policy that clarifies what ballast water practices are required for all military vessels, regardless of military branch or port of origin, as currently there is significant uncertainty and ballast water management and discharge practices are unknown for many military vessels. Also of note is the need for sufficient personnel, training and data management infrastructure to implement and evaluate ballast water management at commercial ports throughout Micronesia.

For biofouling, SERC recommends, as the highest priority, the need for DoD to inspect all military vessels with high likelihood of biofouling (due to high port residence times) and to effectively clean all military vessels that are heavily fouled before they are allowed to move into, out of, or within Micronesia. It is also recommended that DoD determine criteria for acceptable levels of hull biofouling for all military vessels (including amphibious) as well as any vessels under contract to the military (including barges, dredges, etc.). For commercial vessels (including barges, cruise ships, yachts and fishing vessels), SERC again recommends the establishment of requirements for acceptable hull biofouling and in-water cleaning methods as well as routine biofouling inspection, certification and reporting standards. SERC also recommends that targeted outreach efforts be initiated to inform both military and commercial vessel audiences of biofouling management requirements.

SERC stresses that commercial vessel biosecurity requirements must also apply to any commercial fishing vessels that operate in Micronesia. Outreach programs should be implemented to target DoD and civilian populations on guidelines and methods to minimize biosecurity risks associated with kayaks, outriggers, diving gear, and recreational fishing gear. Biosecurity requirements and practices should also be developed for grounded vessels, in-water structures such as dry docks, drilling rigs and fish aggregating devices because they can pose a very high, if infrequent, risk of marine organism transfer to and within the region. SERC also recommends the establishment of explicit biosecurity measures for aquaculture as well as the establishment of a formal risk assessment process, quarantine facilities and effective reporting, screening and enforcement capacity throughout the region to minimize risk of marine organism transfer from live organism trade.

In order to establish effective marine invasion detection capacity, SERC stresses the fundamental need to develop standardized, quantitative and repetitive field-based surveys of non-native marine species in harbors, bays and ports throughout the region. SERC recommends the establishment of a high-risk species watch list for the region and a detection and response plan focused on a few of these identified high-risk species. Further evaluation of economic and social

values (per the pilot study initiated in this report) would enhance and refine decision processes for management and priorities for response to invasive marine species incursions.

SERC's last comments address implementation of their recommendations and development of capacity necessary for that implementation. Implementation should, where possible, be addressed as a coordinated, integrated approach across disciplines and jurisdictions. This integrated approach would allow for more efficient use of resources and greater effectiveness and consistency of efforts. For example, although the document provided separate vector management recommendations for DoD and commercial vessels, many aspects of reporting, training, infrastructure and legal frameworks could be effectively and efficiently combined. Specifically, SERC recommends creating a single Micronesia-wide program – a Micronesia Marine Biosecurity Facility – to serve as a resource center to provide training, shared protocols, outreach initiatives and to help identify funding opportunities and build capacity. SERC also recommends formal Memoranda of Agreement (MOU) between Micronesian governments and DoD departments to establish plans and command structure to respond to incipient marine invasions. SERC also recognizes that development of capacity and resources should be a major focus of the implementation plan (MBP Phase 2).

SERC ends by discussing the visionary scope of the MBP effort, noting the advancement of regional biosecurity across multiple countries and cultures provides an important model that uses “an appropriate spatial scale at which invasions operate.” Successful implementation of a cohesive regional plan to address marine invasions would make “DoD and its partners across Micronesia...world leaders in advancing marine biosecurity, especially in tropical ecosystems.”

TERRESTRIAL ECOSYSTEMS

The U.S. Department of Agriculture, Animal and Plant Health Inspection Service (APHIS) prepared the entire terrestrial ecosystem component of the MBP. APHIS is a multi-faceted agency with a broad mission and a diverse set of expertise. To address the wide array of knowledge and disciplines necessary to comprehensively address invasive species threats to terrestrial ecosystems for the MBP, over 30 scientists and experts from three different APHIS agencies (Plant Protection and Quarantine (APHIS -PPQ), Wildlife Services (APHIS -WS) and Veterinary Services (APHIS-VS)) collaborated in developing this report.

There are multiple frameworks that scientists use to assess risks. Recommendations to prevent and mitigate invasive species risk can vary depending on the taxa under consideration and evaluation framework employed. Given the tremendous diversity and scope of evaluating all terrestrial invasive species risks, the APHIS document includes two separate sets of risk assessments and recommendations. The first risk assessment was conducted by APHIS-PPQ and informs the plant, pathogen and insect recommendations that were developed jointly by APHIS-PPQ, APHIS – VS, and APHIS-WS (wildlife disease scientists). APHIS – WS (terrestrial vertebrate scientists) conducted the second risk assessment and developed the terrestrial vertebrate recommendations. For the purposes of this Executive Summary, the work of all APHIS risk assessments and recommendations are synthesized together.

APHIS provides a thorough overview of operational considerations that should be addressed in route to developing a biosecurity program that integrates biosecurity activities in the Micronesia Region under single management framework. Cooperative, centralized management of biosecurity would improve efficiency and effectiveness of efforts by presenting opportunities for synergy, developing unified strategies and consistent outreach, and enhancing communication and cooperation amongst public, private and military sectors.

APHIS risk assessments examine impacts from the military relocation and provide evaluations and risk ratings for a variety of species of concern and pathways such as aircraft, maritime vessels, cargo, wood domestic and international mail, plant propagative material, livestock, pets and animal production. Different teams of APHIS scientists focused on different pathways and methodologies, depending on their area of focus, but all agreed that detailed information for making determinative rankings was limited – thus most risk rankings for pathways and species are qualitative.

The APHIS team developed over 200 recommendations to enhance biosecurity in the Micronesia Region. These recommendations are based on the specific risk assessments of each team and the observed state of biosecurity capabilities in the region. APHIS identifies a general lack of staffing, funding and biosecurity infrastructure in the region and recommends that sufficient funding be available at local and national levels and within the military to implement effective biosecurity region-wide. APHIS notes that user fees have been effectively used to generate funding for agriculture, wildlife disease and pest exclusion and recommends the legislative creation of a user fee structure similar to what is currently used by the USDA and the U.S. Department of Homeland Security.

APHIS draws particular attention to the need for sufficient numbers of well-trained staff and well-equipped biosecurity facilities and provides several specific recommendations to address these needs for both civilian and military attention. APHIS recommends several actions to enhance off-shore (pre-border) mitigation such as military pre-clearance facilities on Okinawa, weed risk assessments for importation of exotic plants and effective treatment of wood packing materials and imported timber products. Of particular note, APHIS recommends that military and civilian contracts include well-enforced requirements and provisions to minimize the risk of introduction of invasive species.

APHIS recommends a series of actions, including greater use of canine inspection teams and construction of necessary inspection, quarantine and wash-down facilities, to enhance point-of-entry biosecurity. APHIS also provides several recommendations in regards to the handling of cargo, mail and regulated garbage and export from and within the region which emphasize facilities, monitoring and inspection, and development of effective working relationships between regional, local, military and other U.S. Federal partners. Of highest priority is the need to maintain and enhance comprehensive brown treesnake (BTS) interdiction, control and eradication efforts on Guam. The BTS has caused massive direct and indirect impacts to the ecology and economy of Guam and APHIS provides numerous, specific recommendations, to both civilian and military sectors, to address this primary threat to the rest of Micronesia, Hawaii and other areas around the world.

In regards to regulations and compliance issues, APHIS recommends the military and civilian governments fully implement and take advantage of existing biosecurity guidelines and regulations. Specific to the military, APHIS suggests a revision of the DoN landscape plan to remove potentially invasive species from landscaping consideration and also recommends the development of a Memorandum of Understanding between DoD and all Micronesian countries to develop appropriate invasive species standard operating procedures for compliance when conducting activities in their respective jurisdictions. APHIS recommends outreach to pet stores, nurseries and landscaping companies to promote the adoption of a voluntary code of conduct to promote the use of native and non-invasive plants and to curtail smuggling of illegal, invasive pet species. APHIS also recommends that best management practices be developed for contractors and construction sites to prevent the introduction and spread of invasive plants and plant pests through their activities.

Several recommendations emphasize and support the development of invasive species training initiatives and outreach efforts to the public, military personnel and, particularly, to temporary workers who may come to the region as a result of the build-up. These efforts would raise general awareness of the potential harm that invasive species can cause and inform people of regulations, legal requirements and the consequences of violation. Outreach, effective communication and coordination are also critical components of successful monitoring and safeguarding efforts. APHIS recommends the development of an extensive biosecurity surveillance program for diseases, plants, plant pests and vertebrate invasive species that includes well developed processes and methodologies and incorporates expertise and capacity of other relevant entities in the region such as the Micronesia Challenge and other appropriate groups. APHIS highlights the need for background surveys to be conducted to establish baseline data for plants pests, invasive vertebrates, and diseases of livestock and wildlife throughout the region. This information would allow biosecurity plans to be refined and improved and should be completed as soon as possible.

Lastly, APHIS recommends a coordinated, centralized biosecurity effort for the region to maximize the effectiveness and efficiency of biosecurity activities, facilitate communication and cooperation between all public, private and military and other U.S. federal sectors involved and identify funding opportunities. Rapid or emergency response efforts should also be coordinated in a collaborative manner and APHIS recommends that rapid response capabilities as well as pre-export controls across the region should be improved – particularly at military and civilian airports and seaports on Guam, and the CNMI.

APHIS recommendations repeatedly emphasize the need for effective, meaningful collaboration amongst the various sectors, governments and partners to develop successful biosecurity efforts. Effective biosecurity requires sustained and managed funding and the flexibility to undergo regular reassessment and refinement as new information is obtained. APHIS asserts that the most cost-effective approach to protecting natural and economic resources in Micronesia is through implementing effective biosecurity measures before incursions or introductions occur.

TAKE HOME MESSAGES

In Phase 1 of the MBP, over 50 federal and university scientists collaborated with dozens of local and regional scientists, government officials and invasive species experts to develop a comprehensive set of invasive species risk assessments, recommendations and best management practices that are unprecedented in their size and scope. While the different teams of scientists used a diversity of methods and approaches to their evaluations and recommendations, a number of common themes became clear. These “Take Home Messages” are summarized below:

- **Sufficient Staffing and Facilities:** The need for sufficient numbers of well-trained staff and well-provisioned facilities is critical for all biosecurity activities. In general, staffing and facilities in the region are inadequate for current levels of need, let alone for the levels required during and after the build-up.
- **Coordination and Collaboration are Critical:** Effective biosecurity for the region will require constant, open collaboration between all levels of government in Micronesia, DoD, other U.S. federal departments, the private sector, non-profit sector and regional organizations. Coordinated efforts amongst all partners will allow the region to more efficiently address critical issues such as:
 - Strategies to identify funding opportunities and secure commitments to ensure long-term, consistent funding and capacity for biosecurity efforts in the region.
 - Adoption of Memoranda of Agreement between nations and other partners to harmonize and/or establish plans, command structures, roles and responsibilities in regards to specific biosecurity issues.
 - Establishment of clear policies and required best management practices to address a variety of marine, terrestrial and freshwater invasive species concerns.
 - Development and/or improvement of regionally coordinated efforts on:
 - Early detection and rapid response to invasive species.
 - Outreach and education to both civilian and military sectors on invasive species issues and biosecurity.
- **Information Needs:** New research and repetitive, systematic surveys are needed throughout the region to advance the science behind biosecurity and to establish baseline data on invasive species that is accurate, current and reflects the dynamics of changing situations. . . Accurate and current baseline data together with other pertinent information (such as economic analyses and societal and cultural valuation of invasive species impacts) will allow for higher quality risk assessments that will inform the development of more effective and efficient biosecurity measures.
- **A Flexible, Living Document:** The MBP must be frequently revised and updated to allow incorporation of new information (such as invasive species baseline data), technologies and methodologies that will increase the effectiveness and efficiency of biosecurity efforts.

NISC has been honored to be part of this worth-while effort. We thank our colleagues throughout Micronesia, the U.S. federal government and in the broader Pacific for their hard work and dedication in producing the MBP – an effort that will benefit all of Micronesia and set an example for other regions of the world.

Special attention needs to be brought to the role of the Micronesian Chief Executives and DoN in enabling this effort. The Micronesian Chief Executives have been proponents of the development of the MBP from its inception and publicly endorsed the effort and instructed their staffs to fully participate in its development and implementation in Resolution 17-7 of the 17th Micronesian Chief Executives' Summit. The development of the MBP also directly supports the “Green Guam” and “One Guam” pillars of the “four pillars that will shape the (build-up) strategy” – as stated by Undersecretary of the Navy Robert Work in 2011 and is prima facie evidence of DoN engaging in a meaningful way with regional partners to address issues of common concern. In supporting this effort and by acknowledging the critical role of cooperative relationships, the Micronesian Chief Executives and DoN have attempted to *proactively* address the invasive species implications of the build-up, not just for Guam and the CNMI where the build-up will happen, but for the entire region.

Regional Biosecurity Plan for Micronesia and Hawaii Freshwater Risk Assessment

The freshwater risk assessment is composed of edited elements of three reports prepared for DoN as part of the overall MBP development strategy. These reports in their entirety can be accessed at the DoN supported website.

The original reports titles are as follows:

- Assessing the risk posed to Micronesia by invasive aquatic weeds
- Biosecurity plan for freshwater invasive aquatic plants in Micronesia
- Risk analysis and management alternatives for the prevention and mitigation of nonindigenous fishes and other aquatic macrofauna in freshwater habitats of Micronesia

Introduction

Invasive alien species (IAS) are a significant threat to the integrity of freshwater systems throughout the world. Some of these threats include the alteration of ecosystem services, the loss of aquatic biodiversity, and the degradation of water quality for the human populations that rely on those waters. Identifying the pathways and vectors by which aquatic IAS may be introduced, understanding the factors that may contribute to the spread and establishment of IAS taxa is critically important to preventing the introduction of IAS and mitigating their ecological effects and ensuring that appropriate biosecurity measures are in place for the islands of Micronesia and the state of Hawaii in order to protect these jurisdictions from the negative cross-cutting effects of IAS.

Given their relative isolation, the islands of Micronesia and Hawaii may be particularly sensitive to the introduction of aquatic IAS taxa. Many of these islands are already host to a variety of non-indigenous fish, invertebrates, and macrophytes. To address these concerns, the Department of Defense has sponsored the development of risk assessments and management alternatives to minimize the introduction and spread of aquatic IAS throughout Micronesia and Hawaii.

This volume of the Micronesian Biosecurity Plan includes (1) risk assessments for invasive aquatic macrofauna and (2) management strategies to prevent the importation and spread of IAS between the different jurisdictions. The aquatic macrofauna risk assessment and management alternatives were developed by the U.S. Geological Survey (Section 1). The aquatic macrophyte risk assessment and biosecurity plan was developed by Portland State University (Section II) in partnership with the New Zealand National Institute of Water and Atmospheric Research, Ltd. (NIWA).

Prepared with cooperation and funding by the U.S. Department of the Navy

Risk Analysis and Management Alternatives for the Prevention and Mitigation of Nonindigenous Fishes and other Aquatic Macrofauna in Freshwater Habitats of Micronesia

Risk Analysis and Management Alternatives for the Prevention and Mitigation of Nonindigenous Fishes and other Aquatic Macrofauna in Freshwater Habitats of Micronesia

By Stephen J. Walsh¹, Leo G. Nico¹, Mark W. Miller¹, and Ronald A. Englund²

Executive Summary

This report provides an assessment of potential risks posed by the introduction and spread of nonindigenous freshwater organisms in Micronesia. The basis for this study is an anticipated increase of U.S. military and civilian activities on and around Guam and the Commonwealth of the Northern Mariana Islands. The focus of this effort is on invasive or potentially invasive freshwater animals, mainly fishes, and the pathways by which these aquatic organisms are introduced to regions outside their native ranges. The risk assessment analysis and accompanying management alternatives are provided as part of a biosecurity plan for the entire Micronesian region. The emphasis is on the islands of Guam, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia (specifically, Chuuk, Kosrae, Pohnpei, and Yap), and Palau, because these are the largest islands and those with the greatest extent of freshwater resources.

The objectives of this study were to (1) summarize available information on native and nonindigenous macrofauna of freshwater systems in Micronesia; (2) identify and evaluate pathways of introduction and assess the risk of introducing nonindigenous freshwater animals into new environments of Micronesia; (3) identify those aquatic and semiaquatic animals that have the potential to become widely established or invasive in inland waters of Micronesia, and; (4) provide management options with the goals of preventing or reducing the likelihood of introduction and spread of freshwater animals into and among the islands of Micronesia as well as mitigating risks. Emphasis is placed on freshwater fishes, because more is known about this group than the others, although information is also summarized for selected non-native taxa of other groups, mostly aquatic or semiaquatic mollusks, crustaceans, amphibians, and reptiles.

Micronesia is a heterogenous subregion of Oceania, comprising thousands of small tropical islands scattered across a vast expanse of the western Pacific Ocean, from the Mariana Islands and Palau in the west to Kiribati in the east. Micronesian islands and islets are extraordinarily diverse and complex in terms of geography, physiography, geology and biology. Although individual islands in Micronesia are surrounded by ocean, many contain a diverse array of natural freshwater habitats. Whether permanent freshwater habitats are present, and, if present, their type, diversity, and extent depends on a wide range of factors, including island location and size, geologic history, and physiography (e.g., elevation and topography). These factors and

¹ Southeast Ecological Science Center, U.S. Geological Survey, Gainesville, Florida

² Pacific Biological Survey, Bishop Museum, Honolulu, Hawaii

other characteristics vary widely among the many islands and islands groups of Micronesia and the Pacific. Many islands are quite distinctive in terms of their geomorphology and aquatic habitats. In general, larger islands, especially those with the greatest topographic relief, have more extensive and diverse inland freshwater ecosystems that include an array of streams, springs, wetlands, and natural lakes. Artificial freshwater habitats are also common, especially on islands populated by humans, and typically consist of reservoirs, ponds, ditches and small canals.

Freshwater habitats on Micronesian islands support moderately diverse and unique native biological communities. Although the total number of native freshwater species on any one island group is relatively low in comparison to continental faunas, native aquatic animals present are extremely important from a global perspective. This is due to a great degree of endemism in Micronesia—many species and community assemblages that are found nowhere else in the world. The most prominent freshwater animals are fishes and macroinvertebrates, and most of the native fishes, crustaceans, and aquatic mollusks (gastropods) are amphidromous species—that is, they are derived from marine ancestors and have a unique life history in which adults spawn in rivers and streams, eggs or larvae drift to the ocean, and juveniles then return to fresh water to complete their life cycle.

Invasive and other nonindigenous aquatic species have changed or otherwise affected all or most Pacific islands containing permanent freshwater habitats. Indeed, a wide variety and large number of nonindigenous fishes and various other nonindigenous aquatic animals have been introduced to freshwater habitats of Micronesia and other islands of Oceania. As a result, nonindigenous freshwater species are common on most islands in the region that have freshwater environments. Pathways are defined here as the general route or activity by which a species can be introduced into a new locale whereas vectors are considered to be the specific mechanisms or modes of introduction. The pathways and mechanisms by which these nonindigenous organisms were introduced are varied; some were brought intentionally by humans, and many others arrived accidentally. Guam, in particular, has more nonindigenous freshwater fishes and other aquatic fauna than any other island in Micronesia and is second only to Hawaii among islands in the tropical Pacific in this regard. However, all of the large islands have been affected to some degree by the introduction of freshwater species.

The risk assessment presented herein is based on a quantitative analysis of fish introductions to inland waters of Guam and Hawaii. This data set is used because it is derived from historical and current information that is far more complete and includes records of more nonindigenous aquatic taxa than any other group of islands in the tropical Pacific. The data used in the risk assessment are based on a total of 80 species or taxa, 49 (61%) of which are known to be established (that is, have reproducing populations) on Hawaii, Guam, or both. One dependent variable (prior establishment success) and 14 independent variables, including factors that relate to propagule pressure, life-history attributes, and physiological tolerances, were used to develop 21 *a priori* and 8 *post hoc* frequentist (logistic) models to determine probabilities of establishment success. The best model derived from this analysis included three primary factors used to predict establishment success: (1) a random family (taxonomic) effect; (2) prior invasion success on tropical islands or island groups globally, and; (3) hypoxia tolerance (i.e., tolerance to low dissolved oxygen using a categorical variable with three possible states).

Results of the risk assessment have utility in that the models can be used to assign probabilities of establishment success of species or taxa not currently established in Micronesia. For instance, the Guam Division of Aquatic and Wildlife Resources (DAWR) maintains a white (or “clean”) list of aquatic species (freshwater and marine fishes, invertebrates, and plants)

that are permitted for legal importation. Our risk assessment model could be used to evaluate relative risk for species that are currently on Guam’s white list, or species that might be under consideration in the future. Although the white list is a regulatory tool that DAWR uses to manage for potential introductions of invasive species (by limiting imports), there is currently no legislation that prohibits the possession of species not on the white list, including species considered potentially invasive or injurious. Establishment pathways of freshwater species were evaluated in our risk assessment, and are also addressed in the section on management alternatives. Although all pathways pose certain risks, the general pathways identified as posing the greatest risk for introductions (and spread) of freshwater species in Micronesia include: (1) the aquarium trade and commerce in ornamental species; (2) aquaculture, and; (3) the live-food trade.

As an objective, policy-neutral, science-based agency, the USGS has no management or regulatory authority. Therefore, the USGS refrains from making recommendations that target specific management or policy actions, and terminology such as “best management practice” or “BMP” is not used. Herein, management alternatives are provided with an implicit understanding that all options have not been thoroughly vetted and strategic actions may be warranted and modified over time as new information becomes available. Many existing sources provide baseline information on strategies for mitigating deleterious ecological or socioeconomic effects of invasive species; the information provided in this report is based on sources considered reliable.

Management alternatives for the prevention and mitigation of non-native freshwater species in Micronesia involve a variety of approaches and include, but are not limited to, the following:

- Continued monitoring of imports
- Improved inspection and detection programs
- Improved training of inspectors
- Improved knowledge about propagule pressure using surveys and other information-gathering approaches
- Expanded education and outreach programs
- Independent scientific review of DAWR white list of permitted aquatic species
- Improved management of aquaculture facilities
- Improved monitoring/detection of commodities in the live-food market
- Additional biological surveys
- Establishing robust monitoring programs based on appropriate statistical approaches that incorporate detectability and occupancy models
- Establishing a rapid response strategy and contingency plan for new introductions
- Additional scientific research and data compilation to assess more fully relative risk based on multiple factors (e.g., pathways, taxonomic groups, biological attributes) and data gaps

Implementation of management options should focus foremost on prevention and remain flexible enough to deal with changes in technology, transportation, and world markets. In particular, vigilance is needed to identify existing high-risk pathways or vectors and identify

potential future pathways and vectors. For example, a wide variety of potentially invasive freshwater animals are currently available worldwide for purchase over the Internet and there is ample and easy opportunity for a person living in Guam or elsewhere in Micronesia to obtain an aquatic animal not previously introduced to the island, including organisms whose import is illegal. Use of private shippers increases the possibility that such an import might proceed undetected by custom agents. Closing the loophole of such high-risk factors may require substantial modifications to existing practices, policies, or management structure and procedures. If introduction of a harmful non-native species is not successfully prevented, then eradication or containment efforts may result, both of which are strategies that require intensive, costly planning and logistics at many levels. Improved biosecurity for non-native freshwater species in Guam and the Commonwealth of the Northern Mariana Islands (CNMI), in particular, will require cooperation and coordination between the U.S. military, various island nations and states, and civilian sectors.

Overview

The purpose of this report is to provide an assessment of potential risks posed by the introduction and spread of nonindigenous freshwater organisms in Micronesia. Increased threats posed by nonindigenous species may accompany increased U.S. military and civilian activities anticipated in and around Guam and the Commonwealth of the Northern Mariana Islands. This report focuses on invasive or potentially invasive freshwater animals, mainly fishes and selected amphibians, reptiles, and macroinvertebrates, and the pathways by which these aquatic organisms are introduced to regions outside their native ranges. Included are mitigation measures to prevent or reduce the likelihood of introduction and spread of freshwater animals into and among the islands of Micronesia.

This report constitutes a component of a broader Micronesian Biosecurity Plan (MBP) that addresses a variety of non-native organisms, including terrestrial and aquatic (marine and freshwater) animals and plants, as well as parasites and pathogens. The MBP includes comprehensive information derived from risk assessments and review of existing conditions as provided by multidisciplinary teams of biologists and other scientists representing various agencies and institutions (USDA-APHIS 2010; ABRPI 2011; Zabin et al. 2011).

Micronesia is a heterogenous subregion of Oceania, comprising thousands of small tropical islands scattered across a wide expanse of the western Pacific Ocean, from the Mariana Islands and Palau in the west to Kiribati in the east. The more than 3,000 Micronesian islands and islets are extraordinarily diverse and complex in terms of geography, physiography, geology and biotas. All Micronesian islands combined have a total surface or land area that is estimated to cover anywhere from about 2,700 to 3,227 km² (1,042 to 1,246 mi²) (Crombie and Pregill 1999; Steadman 2006). Many of the individual island groups are relatively remote and separated by great distances from their nearest neighbors. Although most of the islands are far from continental land masses, a few are relatively close to the large island of New Guinea. Because of its size and complex geography, the nomenclature of Micronesian islands and island groups, including that of their political alliances, can be confusing and cumbersome.

Background

Introductions of non-native species to the islands of Oceania began with the earliest human inhabitants. Over the past several hundred years, and especially over the past few decades, the numbers and kinds of different nonindigenous species introduced have increased substantially. Although the introduction of freshwater aquatic animals to Pacific island habitats is relatively recent in comparison to the introduction of many non-native plants and terrestrial animals, over recent decades there have been multiple introductions and spread of freshwater species throughout islands of Oceania. Taxonomic groups introduced into freshwater habitats include fishes, amphibians, reptiles, and invertebrates (primarily crustaceans and mollusks). Current knowledge about the status of nonindigenous species in freshwater habitats varies with island or island group in Micronesia, and to a large extent, corresponds to degree of study by biologists or survey efforts by government agencies and nongovernmental organizations. In general, the most complete information exists about freshwater biotas for those islands with large human populations and extensive freshwater habitats, two characteristics that are closely linked. Thus, Guam, the Commonwealth of the Northern Mariana Islands (especially Saipan), Palau (Babeldaob and Koror), and the large, high islands of the Federated States of Micronesia (Pohnpei and Kosrae) have been the most intensively explored. Nevertheless, nearly all islands are considered to be inadequately surveyed.

A number of authors have assembled lists of what they consider to be the most detrimental invasive species—those introduced organisms that commonly are introduced, become established, and thrive and dominate in new places. For example, Lowe et al. (2004) produced a list of “100 of the World’s Worst Invasive Alien Species.” Of the eight fish species listed, seven have been introduced to islands in the Pacific. Similarly, Helfman (2007) provided a list of ten freshwater fish taxa whose introductions were considered to be especially controversial, largely due to their resulting ecological or economic impacts (Table 1). At least eight of the taxa on Helfman’s list have been introduced into Micronesia, and most are established there; additionally, a moderate number of other non-native fish species have been introduced and are considered established. To a lesser extent, other non-native freshwater animals have been introduced. However, there are notable examples of highly successful and even invasive and injurious aquatic or semiaquatic species of other taxonomic groups. For example, Guam is now host to a moderate number of frogs (Christy et al. 2007a, b), including the widespread and locally abundant cane toad, *Rhinella marina* (= *Bufo marinus*). In addition, the red-eared slider (*Trachemys scripta elegans*) is a freshwater turtle that has been introduced worldwide (Kraus 2009a), and wild populations are documented as established in Guam (Leberer 2003).

Table 1. Selected controversial freshwater fish species introduced in different regions of the world, based on Helfman (2007) and references therein. [Numbers of countries and states where established considered herein to be general approximations]

Species	Number of countries where established	Number of U.S. states where established	Native distribution	Purpose of introduction ^a
<i>Cyprinus carpio</i> , common carp	49	49	Eurasia	Food, ornamental
<i>Carassius auratus</i> , goldfish	>40	49	East Asia	Ornamental
<i>Ctenopharyngodon idella</i> , grass carp	? ^b	45	East Asia	Biocontrol
<i>Oncorhynchus mykiss</i> , rainbow trout	56	48	North America	Sportfishing, food
<i>Gambusia affinis</i> , <i>G. holbrooki</i> , mosquitofish	67	35	North America	Biocontrol
<i>Poecilia reticulata</i> , guppy	34	15	South America	Ornamental, biocontrol
<i>Micropterus salmoides</i> , largemouth bass	53	43	North America	Sportfishing
<i>Lates niloticus</i> , Nile perch	3	1	East Africa	Food
Tilapiine cichlids (many species)	94	13	Africa	Food, biocontrol
<i>Cichla</i> spp., peacock cichlids	6	2	South America	Sportfishing

^a Primary purpose(s) of introduction as provided by Helfman (2007), but the authors are aware of situations where some of these species were introduced for additional reasons.

^b Helfman (2007) gives number of countries as nine, considered here to be a significant underestimate.

Goals and Objectives

The principal objectives of this study were to (1) summarize available information about native and non-native macrofaunas of freshwater systems in Micronesia, with emphasis on Guam; (2) identify and evaluate pathways of introduction and assess the risk of introducing nonindigenous freshwater animals into new environments of Micronesia; (3) identify those freshwater species or groups that have the potential to become widely established or invasive in Micronesia, and; (4) provide management options for preventing unwanted introductions and for mitigating risks. Emphasis is placed on freshwater fishes, because more is known about this group than the other faunal groups mentioned in this report. Moreover, assessment and management practices for freshwater fishes have similar applicability to other groups of aquatic and some semiaquatic animals, including vertebrates and invertebrates.

Environmental Setting: Inland Aquatic Environments

The individual islands of Micronesia (Fig. 1) are surrounded extensively by ocean, yet many contain a diverse array of natural freshwater habitats. The presence or lack of freshwater habitats, and, if present, their type, diversity, and extent depend on a wide range of factors, including island location and size, geologic history, and physiography (e.g., elevation and

topography). These factors and other characteristics vary widely among the many islands and islands groups of Micronesia and the Pacific. Steadman (2006) recognized at least seven different types of Pacific islands: (1) active volcanic islands; (2) eroded volcanic islands (e.g., Babeldaob in Palau); (3) raised limestone islands; (4) atolls; (5) "almost atoll" islands; (6) sand cays or keys; and (7) composite islands (i.e., consisting of multiple types of exposed bedrock, such as Guam, which contains outcrops of limestone and volcanic rock).

In general, surficial freshwater habitats are few in number or absent on atolls and sand cays, as well as on many of the very small, low-elevation islands and islets. In contrast, larger islands, especially those with the greatest topographic relief, typically have more extensive and diverse inland freshwater habitats that include, depending on the particular island, small and large streams, springs, wetlands, and natural lakes. Artificial freshwater habitats are also common, especially on islands populated by humans, and typically consist of reservoirs, ponds, ditches and small canals. Most natural freshwater systems on Micronesian islands are linked to the ocean either directly or through estuarine or other brackish-water transition zones. Because of the association between fresh and salt water and the general isolation of the islands from continental areas, native fishes and invertebrates present in freshwater environments of these islands have evolved from marine ancestors, and nearly all depend on marine or brackish-water habitats for certain critical parts of their life cycle; for example, for food resources, nursery habitats, or spawning (Ford and Kinzie 1982).

This report focuses on a few of the major islands and island groups of Micronesia, mainly those with substantial freshwater resources: Guam, the Commonwealth of the Northern Mariana Islands (CNMI), the Federated States of Micronesia (FSM), and Palau. Brief descriptions of these select islands/island groups and their inland freshwater environments are presented in following sections. Additional information on inland aquatic environments of Micronesia is available from the Water and Environmental Research Institute of the Western Pacific (WERI), University of Guam (<http://www.weriguam.org/>), which conducts extensive research and monitoring of aquatic resources in Guam and throughout Micronesia. The WERI, in collaboration with other organizations and agencies, has produced or reprinted many important documents about the geology and freshwater resources of Micronesia. Most of these documents are available on the institute's web site and are the source of much of the information presented here.

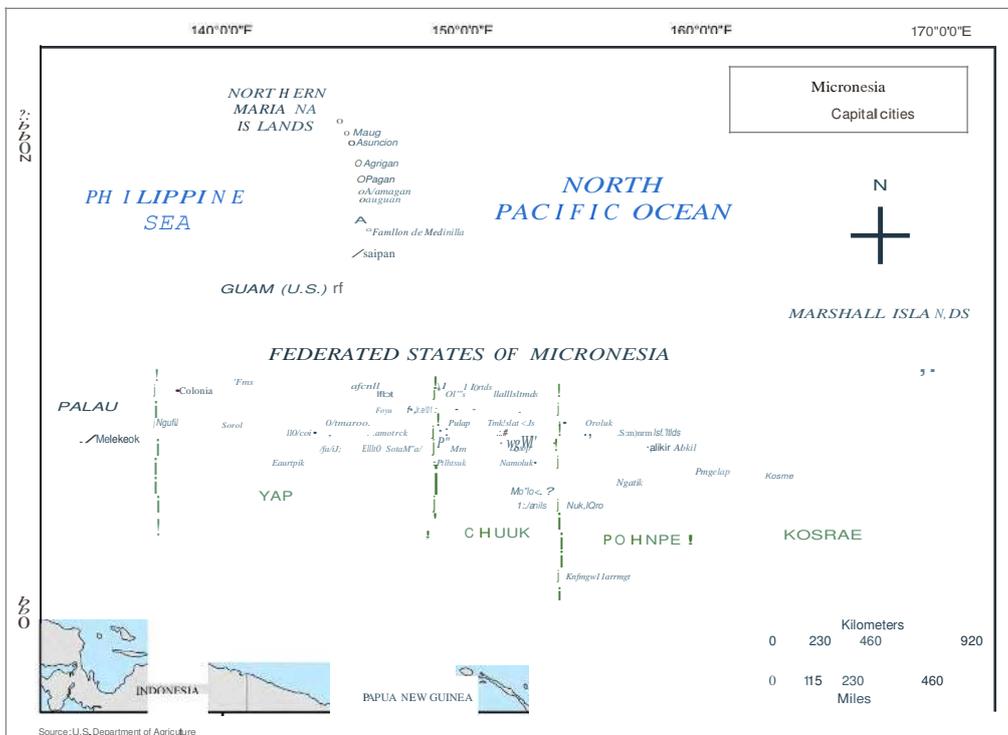

Figure 1. Map of Micronesia and political sovereignties.

Guam

Background

The climate of Guam is warm tropical, with air temperatures that are relatively uniform throughout the year; annual average temperature is about 26°C (79°F) and monthly means range from about 24° to 27°C (76° to 80°F) (<http://ns.gov.gu/climate.html>; Yeung 2005). Relative humidity ranges from about 65% during the day to 100% at night. Rainfall is the source of all fresh water in Guam and averages about 216-292 cm (85-115 inches) per year (Gingerich 2003). Rainfall recording stations differ in annual total by as much as 76 cm (30 inches) due to the island's orography and southern mountainous region. More rainfall occurs in the southern highlands in comparison to the central and coastal lowlands. Most (about 70%) of the rainfall for the entire island occurs during the wet season, from July through November or December; the pronounced dry season typically extends from January through May (Ward et al. 1965). Typhoons have historically resulted in episodic and prolonged rainfall events. In contrast, droughts in Guam are common and may be severe.

Guam has been the subject of extensive geologic and hydrogeologic investigation. The primary reference on the geology of Guam is that of Tracey et al. (1964). The first comprehensive hydrologic study of the island was by Ward et al. (1965). More recent synoptic publications that provide additional summaries of hydrogeologic research and syntheses of information about Guam's karstic features include those of Mink and Vacher (1997), Siegrist and Randall (1992), Taboroši (2000), Mylroie et al. (1999; 2001), and Taboroši et al. (2004, 2005). Karst topography is a landscape shaped by the dissolution of soluble bedrock, usually carbonate rock such as limestone or dolomite. The porous conditions commonly results in subterranean drainages with limited surface water. Guam's karst features are typically described in the framework of the Carbonate Island Karst Model (CIKM), a theoretical model that characterizes unique karstic terrain of relatively young limestones of small islands (Mylroie and Carew 1995; Mylroie and Jenson 2000).

Volcanic rock forms the foundation of Guam and is exposed over about 35% of the island; overlying this rock is limestone that is exposed over about 60% of the island. Seven major geologic units are represented, six of which lie in the southern half of the island (Fig. 2). A major fault line that extends approximately from Pago Bay on the east coast to Asan on the west coast divides the island into two basic physiographic provinces (Tracey et al. 1964; Kingston 2004; Taboroši et al. 2005). To the north of this fault is a limestone plateau consisting of carbonate island karst (eogenetic karst) that is broken by two volcanic intrusions (Tracey et al. 1964; Gingerich 2003; Taboroši et al. 2005). This limestone plateau lacks rivers or streams, but is porous, allowing percolation of rain water into an underlying freshwater-lens system that lies

above salt and brackish water (Gingerich 2003; Kingston 2004). Groundwater resources of the northern plateau provide the vast majority of freshwater supply for human use on the island. Consequently, there have been exhaustive hydrologic, geologic, and chemical studies of this region (Mink and Vacher 1997). The southern half of the island consists of seven primary physiographic provinces that can be classified into three categories: lowlands, limestone plateau, and volcanic uplands (Fig. 3).

The southern half of Guam is mountainous (Fig. 4) with a peak elevation of 406 m (1,332 ft) on Mount Lamlam. The southern mountains consist of exposed volcanic rock and soils that are relatively impervious to groundwater percolation, and karst features that are generally porous and similar to continental karst (Tracey et al. 1964; Taboroši et al. 2005).

Freshwater Habitats of Guam

Due to its more mountainous terrain, fewer exposed karst features, and wetter climate, southern Guam has many more freshwater habitats than the northern part of the island (Table 2; Appendix 1). The southern half includes about a hundred named rivers and streams (Fig. 5), 46 of which drain into the ocean (Best and Davidson 1981; DAWR 2006). The largest river system in Guam is the Talofofu River, draining an area of approximately 73 km² (28 mi²). The river originates on the eastern slopes of Mount Lamlam in southwestern Guam and flows to the northeast into the sea at Talofofu Bay. Nine of Guam's 46 rivers that drain into the ocean have true estuarine zones (DAWR 2006). A mountain ridge that extends along the western coast defines many of the drainages. With many small catchments draining directly to the ocean, watersheds of the island are grouped into 14 larger units (Fig. 5). Some of Guam's lotic systems are intermittent, with continuous flow only during periods of heavy rainfall. Extensive online spatial data and synoptic information about the natural resources of southern Guam are available on the WERI website (<http://www.hydroguam.net/watersheds-overview.php>).

Second in importance to rivers and streams in terms of their contribution to the total fresh water in Guam are habitats formed by springs, vegetated wetlands (both natural and artificial), impoundments, canals, and water-retention basins. Although dated, the review by Best (1981) provides a bibliography of inland aquatic resources of the Marianas archipelago, including documents relevant to the freshwater resources of Guam. Ellison (2009) gave a general summary of the wetland resources on islands throughout the western Pacific region. Agana Springs and Agana Swamp are two of Guam's best known spring and wetland habitats and are sites where nonindigenous aquatic species have been introduced. Hydrology of the downstream reaches of the Agana River were altered by efforts to drain the swamp as well as groundwater pumping (Randall et al. 1974); today, these sites are disturbed from encroaching development, runoff of sediments and contaminants, and invasive species.

The largest reservoir in Guam is Fena Reservoir (Fig. 5), a water-supply impoundment constructed for the U.S. Navy in 1950-1951, with a drainage area of approximately 15 km² (5.8 mi²) and surface-water area of 78 hectares (193 acres) (LaBaugh 1985). Fena Reservoir is situated on the Maagas River, a headwater tributary of the Talofofu River. The reservoir has been the site of introduction of various nonindigenous plants and animals (e.g., Brock and Takata 1956; DAWR 2006), some of which persist and others that never became established. In the past consideration was given to developing additional water-supply reservoirs, especially the

large basins of the Ugum, Ylig, Pago, and Inarajan (USACE 1979); no effort was made herein to ascertain the current status of proposed water-development projects in Guam. It is worth noting, however, that water impoundments and reservoirs are particularly susceptible to the introduction and establishment of nuisance aquatic species. Furthermore, these systems disrupt the flow regimes for native instream communities both above and below the impoundment. Thus, any planned water development projects should consider ways to mitigate against potential introductions and maintain the ecological integrity of the native instream communities.

A number of aquaculture facilities in Guam, currently inactive and active, have ponds that have also been sites where nonindigenous aquatic species have been introduced (B. Tibbatts, DAWR, oral commun., 2010). Additionally, a few golf courses have artificial impoundments that are inhabited by nonindigenous species.

Table 2. Freshwater habitats of Guam (DAWR 2006).

Habitat type	Location	Percentage of area	Relative condition	Needs
Freshwater swamps	Edges of marshes, along river courses, wet depressions in forests	0.06	Unknown	<ul style="list-style-type: none"> • Implement current management plans/laws • Control invasive species of vegetation and animals
Freshwater marshes	Common from central to southern Guam	0.29	Stable	<ul style="list-style-type: none"> • Implement current management plans/laws • Control invasive species of vegetation • Control BTS
Reservoirs	Widely through southern Guam	0.01	Unknown	<ul style="list-style-type: none"> • Implement current management plans/laws • Control invasive species of vegetation
Mangroves	Southern Guam	0.14	Stable	<ul style="list-style-type: none"> • Implement current management plans/laws • Control invasive species of vegetation • Prevent further habitat loss
Rivers	Southern Guam	0.13	Unknown	<ul style="list-style-type: none"> • Implement current management plans/laws • Reduce sedimentation • Control invasive species of vegetation

Commonwealth of the Northern Mariana Islands

Background

Surface-freshwater resources in the CNMI are limited primarily to the islands of Saipan and Rota. The only other island of CNMI with freshwater habitats of significance is Tinian.

Freshwater Habitats of the CNMI

Saipan

Although Saipan has no continuously perennial streams (permanently flowing to the ocean), several semi-permanent pools and perennially flowing stream sections support freshwater aquatic biota (Best and Davidson 1981). Additionally, there are several important wetlands situated largely along the Western Coastal Plain, the most significant of which is Lake Susupe, a mixed brackish and freshwater wetland approximately 17 hectares (42 acres) in surface-water extent during normal water levels; this system consists of a series of intermittent potholes that result in lake fluctuations depending on stage, but the wetland is perennial (Carruth 2003; McKagan et al. 2009). Lake Susupe and the large contiguous reed marsh and swamp on the western coastal plain of Saipan comprise over 60% of the freshwater wetlands in the CNMI (Stinson 1993).

The U.S. Geological Survey (USGS) recognizes eleven different watersheds on Saipan based on a 14-digit Hydrologic Unit Code (HUC) scale (CNMI-UWAWG 1998). Historical

information on freshwater habitats and associated aquatic fauna of Saipan is relatively limited (Best 1981; Best and Davidson 1981). A recent comprehensive survey documented the status of these habitats and the distribution and relevant biology of both introduced and native species (McKagan et al. 2009).

Rota

About five streams originate from limestone caves on the southern area of Rota, yet there is confusion about the names of some of these streams (Best and Davidson 1981). The maximum elevation of Rota is 491 m (1,612 ft) on Mount Manira. The karst geology and groundwater resources of Rota have been investigated (Stafford et al. 2002; Carruth 2005), but there appear to be few studies of surface water resources.

Tinian

Lake Hagoi is a natural open-water and wetland area with a surface area of about 17 hectares (36.3 acres) located near the northern end of the island. Other than Lake Hagoi, there are no perennial or intermittent streams or lakes on Tinian (Best and Davidson 1981).

Federated States of Micronesia

Background

Climate throughout the region is warm tropical and rainfall is generally abundant. Thus, climatic conditions combined with topography contributes to complex and diverse freshwater ecosystems. A series of hydrologic studies conducted by the USGS in cooperation with FSM institutions provide detailed baseline information about freshwater resources of the region (van der Brug 1983a, b, 1984a, b; Anthony 1991, 1992, 1993; Anthony and Spengler 1993; Hamlin and Takasaki 1996). A bibliography of FSM water resource studies was compiled by Winter (1993).

Surficial freshwater resources on these islands are primarily associated with those having high topographic relief, principally the main islands of each of the legislative states: Chuuk, Kosrae, Pohnpei, and Yap. The main freshwater resources of the FSM are rivers and streams. Wetlands of the FSM were reviewed by Dahl (1993) and include mangrove forests (85% of a total of about 100 km² [38.7 m²] for all islands combined), swamp forests (7%), freshwater marshes (6%), ivory nut palm forests (1.4%), and saline marshes (<1%).

Freshwater Habitats of FSM: Chuuk State

Within the five island groups of Chuuk State, the Chuuk Island group is the largest, and is a complex of volcanic, mountainous islands surrounded by smaller, low-lying islands; these mountainous islands contain the greatest extent of surficial freshwater habitats, mostly streams, with relatively small drainage areas. The highest elevation is the summit of Mount Winipot, at 445 m (1,460 ft) above mean sea level on the island of Tol. The other four major island groups are clusters of coral atolls that lack surface water runoff but have groundwater lenses that fluctuate with rainfall and freshwater infiltration (Hamlin and Takasaki 1996). Water supply on the inhabited outer islands is obtained through rainwater catchment systems and shallow wells that provide fresh to brackish water.

Freshwater Habitats of FSM: Kosrae State

The island has streams that drain radially from the interior, many with large drainage size relative to the area of the island. Data pertaining to drainage areas, elevation and geocoordinates of gaging stations, and discharge of rivers on Kosrae were summarized by van der Brug (1984a).

Freshwater Habitats of FSM: Pohnpei State

The topography of Pohnpei Island and heavy rainfall results in steep-gradient streams that flow to the coasts, and many of the streams have spectacular cascading waterfalls. Extensive data for air and stream temperatures, rainfall, and river discharge were summarized by van der Brug (1984b).

Freshwater Habitats of FSM: Yap State

Streams on Tomil-Gagil are perennial, but streams on Yap Island are dry about three months of the year. The dry season extends from December through April, and July through October is the wettest period. Hydrologic and other physical information for the island group was summarized by van der Brug (1983b). Nutrient characteristics of various inland water bodies of Yap Island were examined by Sanger and Hopper (1989).

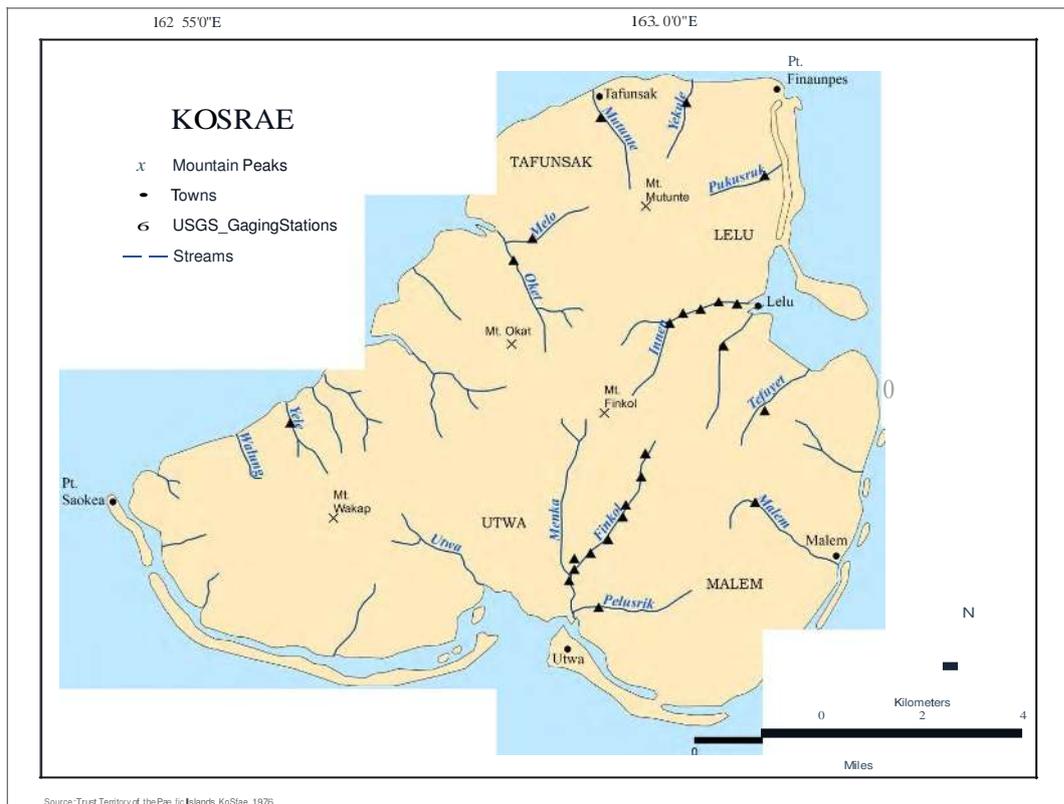

Figure 7. Streams of Kosrae and location of U.S. Geological Survey gaging stations where streamflow data were obtained as summarized by van der Brug (1984a).

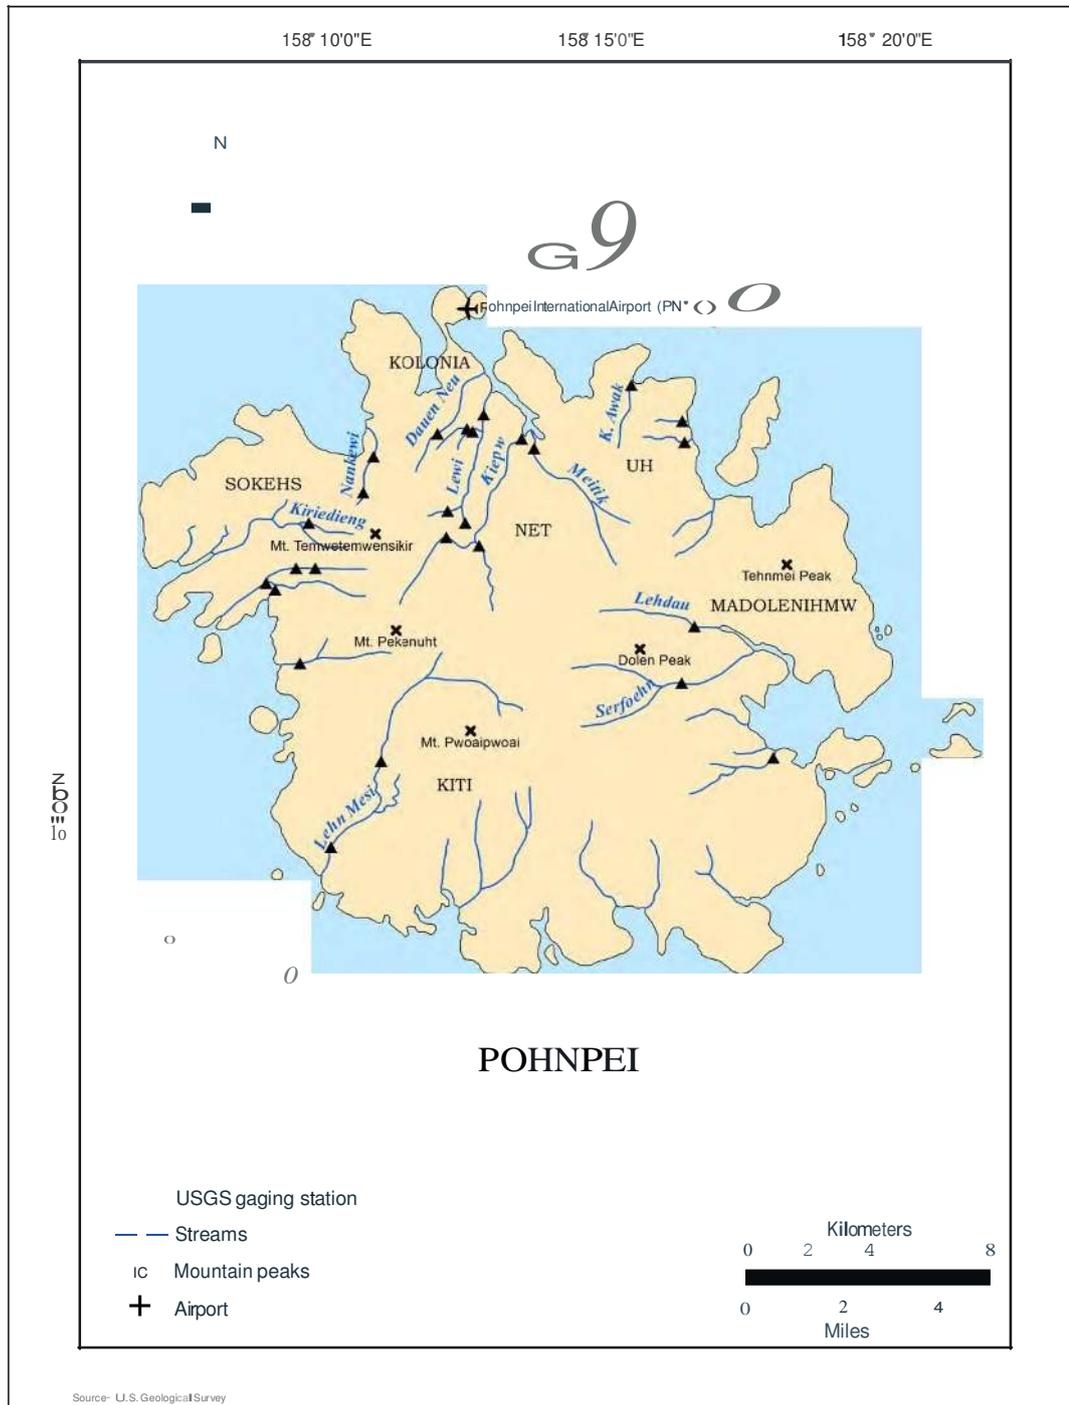

Figure 8. Major streams of Pohnpei and location of U.S. Geological Survey gaging stations where streamflow data were obtained as summarized by van der Brug (1984b).

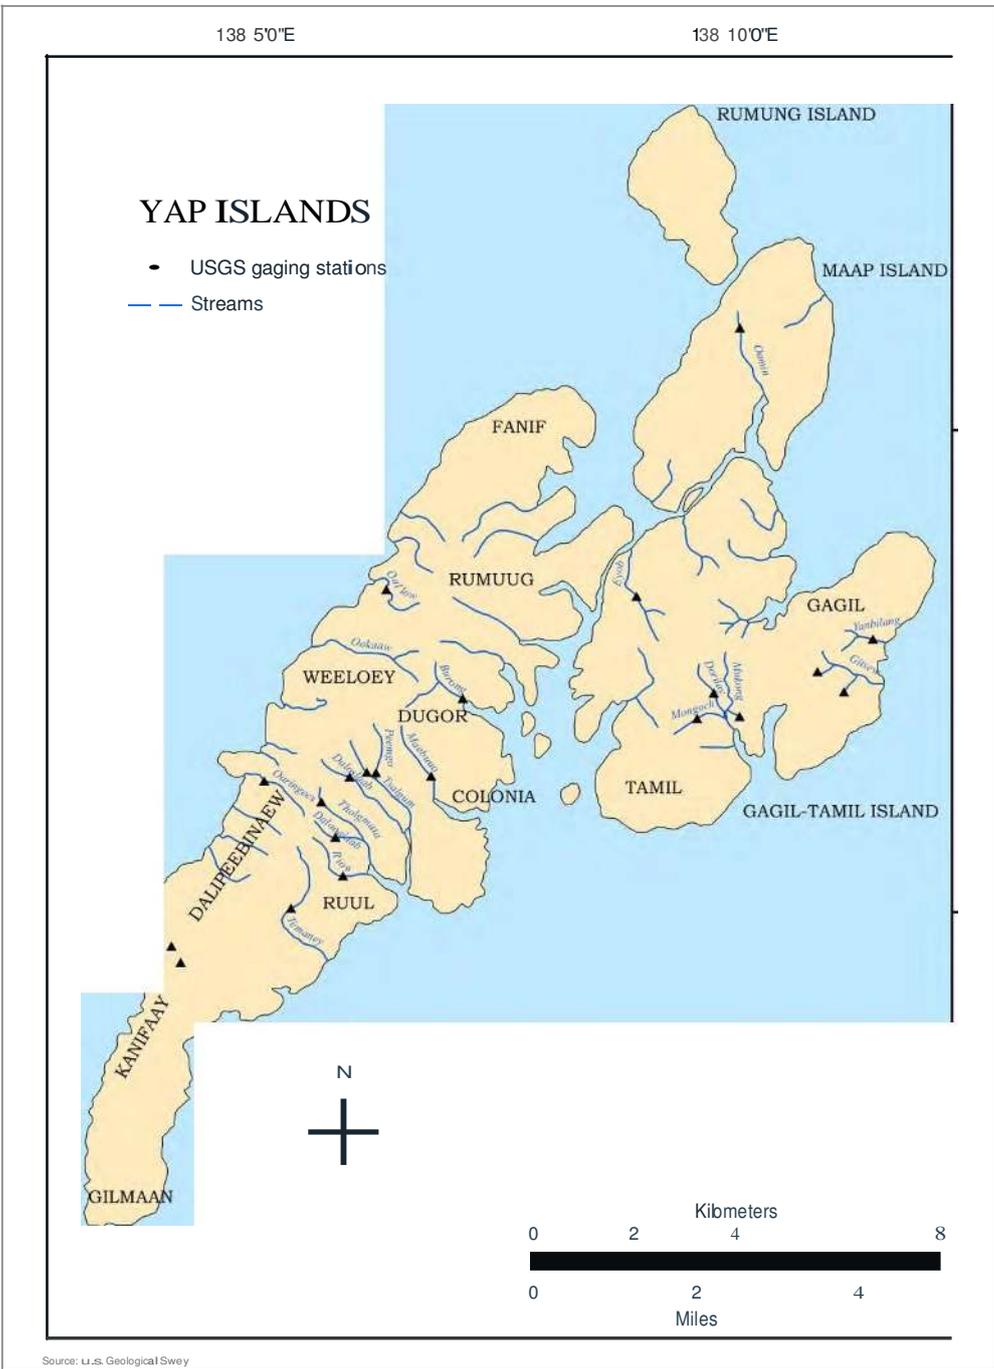

Figure 9. Yap Islands and location of U.S. Geological Survey gaging stations where streamflow data were obtained as summarized by van der Brug (1983b).

Palau

Freshwater Habitats of Palau

In Palau, streams are present only on the volcanic islands and are most highly developed on Babeldaob; streams on the other islands are small and usually dry part of the year. The largest lotic system is Ngerdorch River on Babeldaob, with a drainage area of about 47 km² (18 mi²). Lake Ngardok on the North Fork of the Ngerdorch River is the largest natural lake in Micronesia, with a length of about 732 m (2,400 ft), maximum width of about 183 m (600 ft), depth of about 2.7 m (8.9 ft), and a total surface area of about 493 hectares (1,218 acres).

Lake Ngardok and the surrounding streams, marshes, and swamp forests have been collectively designated as a Ramsar Convention on Wetlands international site (RCS 2006) and are part of a conservation reserve to protect indigenous species, including a small breeding

population of the Convention on International Trade in Endangered Species (CITES)-listed estuarine crocodile, *Crocodylus porosus*, numerous birds, fruit bats, freshwater fishes, aquatic plants, and other fauna and flora. The natural wetlands of Palau are diverse and include freshwater marshes, savannah wetlands, lowland swamps with low or high canopy, riparian wetlands, coastal saline marshes, mangrove forests, and cultivated wetlands used to grow taro (Scott 1993). There are also a number of artificial water bodies, including flooded bomb craters and phosphate quarries, roadside ditches, ponds, and reservoirs. The majority of the population in Koror is supplied by water from the Koror/Airai Public Water System (PWS) in southern Babeldaob; the main source of water is from the 75,000 m³ (20-million-gallon) capacity Ngerimel Dam and Reservoir (Kingston 2004).

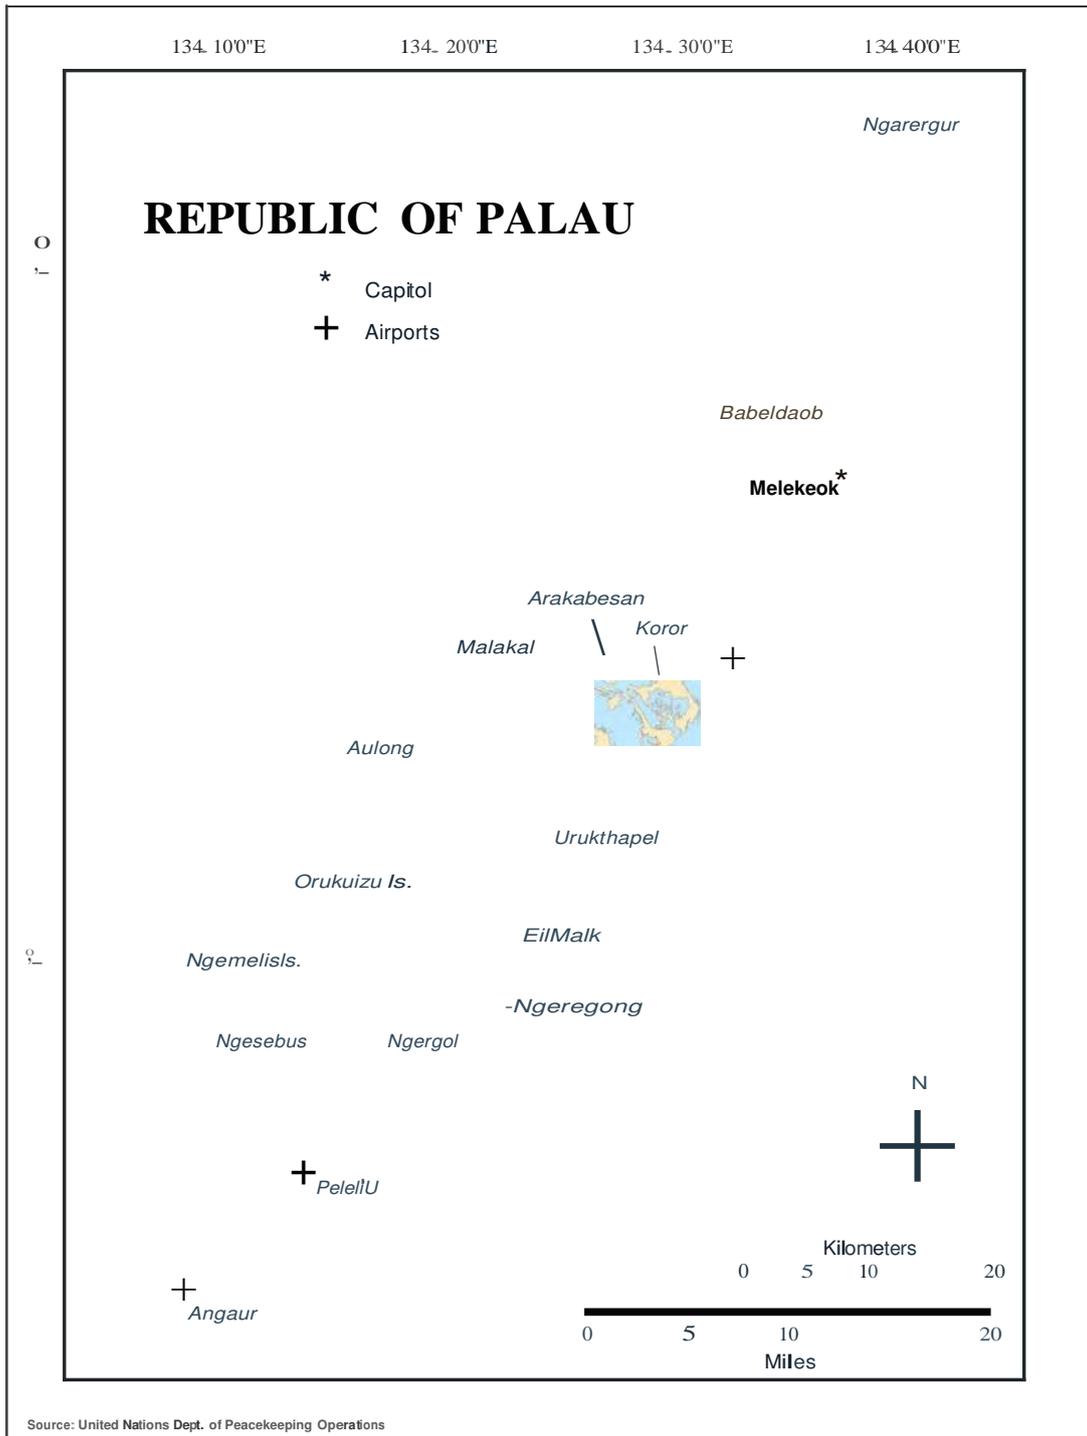

Figure 10. Republic of Palau, western Caroline Islands.

Native Freshwater Fauna

Natural freshwater habitats of Micronesian islands have relatively depauperate aquatic faunas in comparison to continental faunas, yet endemism is generally high. The most prominent freshwater animals are fishes and macroinvertebrates. The family Gobiidae is the most common and diverse group of native fishes present in freshwater streams of the Micronesian islands. This group is also the most species-rich fish family in the world, and one that has colonized many inland waters on islands throughout the tropical Pacific (Ryan 1991). The most diverse and abundant invertebrates in streams and rivers of Micronesian islands are primarily atyid and palaemonid shrimps, neritid and thiarid gastropods, and larval insects.

Most of the fishes, mollusks, and crustaceans inhabiting Micronesian inland waters are migratory, euryhaline, or primarily marine. Euryhaline species normally inhabit estuaries or the open sea, but commonly enter fresh water. In contrast, primarily marine species are those that only occasionally or very rarely enter fresh waters. Those species that complete part of their life cycle in freshwater are diadromous; they use both freshwater and marine or brackish habitats during their life cycle. Most of the diadromous fish, decapod crustaceans and gastropod mollusks in Micronesia exhibit a distinctive form of diadromy referred to as amphidromy. Amphidromous species have the following characteristics: adult reproduction in fresh water; downstream passage or drifting of eggs or newly hatched larvae to the sea; a period of feeding and growing at sea; and juveniles or adults that return to fresh water to spend additional time feeding, growing, maturing, and reproducing (e.g., McDowall 1988; Kinzie 1990; Keith 2003; McDowall 2004; Evenhuis and Fitzsimons 2005; Fitzsimons et al. 2007; Iguchi 2007; McDowall 2007).

In contrast to amphidromy, some diadromous species are catadromous, spawning at sea and migrating up streams and rivers as juveniles or adults where they feed and mature. Many of the amphidromous and catadromous species that inhabit the Pacific islands have exceptional abilities to ascend rivers, often reaching high elevations above waterfalls (Fitzsimons et al. 2007). However, lack of anatomical and behavioral specializations in some species precludes them from ascending above the first impassable waterfall of a system, thereby limiting their freshwater occurrence to downstream segments of streams or rivers.

The presence of a marine larval stage of development has profound implications for the genetic connectivity of Micronesian stream fauna within and between islands. Donaldson and Myers (2002) analyzed the native fish faunas of different Micronesian islands, comparing differences in taxonomic richness and faunal similarities relative to island size and topographic relief. Patterns of species richness and similarity were compared using cluster analyses with pooled groups of (1) amphidromous, catadromous, euryhaline, and marine (ACEM) species; and (2) amphidromous and catadromous (ACFW) species. The taxonomic richness of both ACEM and ACFW assemblages was found to be greatest on large islands with high elevations compared to smaller islands with high elevations and islands of all sizes with low elevations only (Table 3). A comparison of similarity indices for ACEM species revealed two faunal components consisting of high and low islands, with two additional components partitioned between a Mariana Islands cluster and a Caroline Islands cluster (Fig. 11). However, the analysis of islands based on ACFW species was more complex, consisting of a cluster of low islands and small high islands in the Carolines island chain, with limited freshwater habitat, and a second cluster partitioned into high islands and low islands that reflected the influence of both size and geography. In terms of their ecology, behavior, and distribution within the

river-sea continuum, the anadromous and catadromous fishes throughout Oceania (encompassing Hawaii and Micronesia) are quite similar and share taxonomic affinities (Fitzsimons et al. 2002).

Table 3. Species richness of fishes from insular localities in Micronesia (Donaldson and Myers 2002).

	Palau	Yap	Ifaluk/Woleai	Chuuk	Pohnpei	Kapingamarangi	Kosrae	Marshalls	Marianas	Total
Amphidromous and catadromous	55	8	2	4	21	1	19	19	0	77
Euryhaline	50	10	8	5	23	7	6	24	9	65
Marine	8	4	0	2	7	1	4	18	0	24
Total species	113	22	10	11	52	9	29	61	9	166

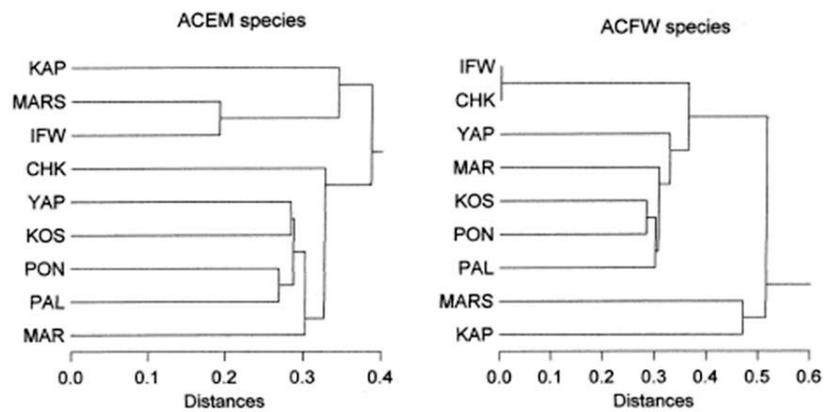

Figure 11. Cluster dendrograms among island groups indicating faunal similarities of native fishes occurring in Micronesian fresh waters, based on Sorensen Qualitative Similarity Index, a method robust for qualitative presence/absence data (Donaldson and Myers 2002). ACEM: amphidromous, catadromous, euryhaline, marine; ACFW: amphidromous and catadromous only.

Mariana Islands

Myers and Donaldson (2003) provided a comprehensive, annotated checklist of fishes of the Mariana Islands and adjacent territorial waters. They reported a total of 1,106 species, of which 1,020 were inshore or epipelagic, represented mainly by coral reef inhabitants. Only nine species were reported as occurring exclusively in fresh water as adults, representing four families (Anguillidae, Eleotridae, Gobiidae, and Kuhlidae), but when all sources are considered, 12 species of these groups are listed for freshwater habitats of the Mariana Islands (Table 4). Many additional species that primarily occur in marine or estuarine habitats occasionally or regularly penetrate streams within or beyond the tidal zone, in some cases, naturally dispersing as far upstream as the first major downstream waterfall. There is uncertainty as to how many different species require freshwater habitats as part of their life history, because it is unclear as to which and how many species of *Eleotris* may occur in these habitats in the Mariana Islands (Table 4, footnote). Of the freshwater species, two gobies (*Stiphodon* sp. and *Sicyopus* sp.) are distributed only in the southern Mariana Islands and one (*Stenogobius* sp.) has been reported only from Guam; the other species are likely distributed throughout the remainder of the Mariana Islands. *Awaous ocellaris* is included in Guam's Comprehensive Wildlife Conservation Strategy (DAWR 2006). However, Watson (1992) noted misidentifications of *Awaous* species associated with the Pacific Plate; *A. ocellaris* is known from French Polynesia westward to the Solomon Islands, whereas *A. guamensis* ranges from Hawaii and the Mariana Islands southward to Vanuatu, New Caledonia, and Fiji.

The crustacean fauna of freshwater habitats in the Mariana Islands is dominated by small (< 4 mm), amphidromous shrimps of the family Atyidae (nine species, although a few may not be valid taxa). Other decapod crustaceans inhabiting inland waters of the Mariana Islands include members of the shrimp family Palaemonidae (two species) and members of the crab family Varunidae (three species) (Chace 1983; Leberer and Cai 2003; Paulay et al. 2003) (Table 5). At least six atyid shrimp species are found on the island of Guam (Leberer and Cai 2003). Most of the atyids present on Guam and other Mariana Islands are also found on islands throughout the Indo-Pacific region. The atyids are herbivores or detritivores and occur in a wide range of habitats, including inland fresh water, brackish and anchialine sites (Leberer and Cai 2003). Species of *Atyoida* and *Atyopsis* occur in shallow-water areas with high current, whereas *Caridina* species are found in slow-moving, deeper waters (DAWR 2006). There are at least two hypogean atyids found in caves and sinkholes on Guam (including anchialine caves). The two native palaemonid prawn species known from fresh waters of the Mariana Islands belong to the genus *Macrobrachium* (Table 5). These shrimp are omnivores and capable of surviving in intermittent headwaters, often representing the only aquatic fauna in such locations. Crabs in freshwater habitats of the Mariana Islands are an under-studied and inconspicuous component of the fauna (DAWR 2006), but there appear to be at least three species representing the family Varunidae (Paulay et al. 2003).

The gastropods of Guam were reviewed by Roth (1976) and Smith (2003). Inland waters of the island have at least 17 species of native prosobranch snails in two families, the Neritidae and Thiaridae (Table 6) (Smith 2003; DAWR 2006). The neritids are amphidromous, and adults in freshwater are herbivorous, feeding on algae and diatoms growing on hard substrates. The thiarids are typically found on sand or soft substrates, are omnivorous and feed on both plant and animal matter, and complete their entire life cycle in fresh water.

During the course of this study, aquatic insects were surveyed from a variety of habitats on Guam; a total of 35 aquatic insect species were collected. Three species of aquatic Heteroptera collected are island endemics: *Limnogonus lundbladi*, *Microvelia mariannarum*, and *Saldula guamensis*. A complete list of species, collecting sites, and other summary information for this insect survey is provided in **Appendix 3**.

The Mariana Islands have no native amphibians or aquatic or semi-aquatic reptiles.

Table 4. Native fishes of inland waters of the Mariana Islands (Kami et al. 1968; Myers and Donaldson 2003; DAWR 2006).

Family	Species	Common name
Anguillidae	<i>Anguilla bicolor pacifica</i> Schmidt 1928	Indian short-finned eel
	<i>Anguilla marmorata</i> Quoy & Gaimard 1824	marbled freshwater eel

	<i>Sicyopus</i> sp.	red belly freshwater goby
	<i>Stenogobius</i> sp.	Marianas goby
	<i>Stiphodon percnopterygionus</i> Watson & Chen 1998	dark finned goby
	<i>Stiphodon</i> sp.	emerald river goby
Kuhliidae	<i>Kuhlia rupestris</i> (Lacepède 1802)	rock flagtail

^a Taxonomic identification and number of species of *Eleotris* occurring in fresh waters of Guam and elsewhere in Micronesia is in question (B. Tibbatts, DAWR, written commun., 2011). Most early accounts cite presence of *E. fusca*. Myers and Donaldson (2003) listed *E. fusca* as presumed misidentification under *E. acanthopoma* Bleeker 1853 but did not treat this species as occurring exclusively in fresh waters as adults.

^b Hypogean species reported from a single cave on Guam.

^c Collected from Guam during present study; provisional identification.

Table 5. Native decapod crustaceans of inland waters of the Mariana Islands (Leberer and Cai 2003; Paulay et al. 2003). [See footnotes for alternative nomenclature as provided by the Integrated Taxonomic Information System (ITIS; <http://www.itis.gov/>). Common names from ITIS database]

Family	Species	Common name
Atyidae	<i>Antecaridina lauensis</i> Edmondson 1935 ^a	Lauan anchialine shrimp
	<i>Atyoida pilipes</i> (Newport 1847) ^b	koros shrimp
	<i>Atyoida serrata</i> (Bate 1888) ^c	
	<i>Atyopsis spinipes</i> (Newport 1847) ^d	soldier brush shrimp
	<i>Caridina brachydactyla</i> (de Man 1908) ^e	
	<i>Caridina mertonii</i> Roux 1911 ^f	
	<i>Caridina typus</i> H. Milne-Edwards 1837 ^g	
	<i>Halocaridinides trigonophthalma</i> (Fujino & Shokita 1975) ^h	
	<i>Halocaridinides</i> sp. ⁱ	
Palaemonidae	<i>Macrobrachium lar</i> (Fabricius 1798)	monkey river prawn
	<i>Macrobrachium</i> sp. ^j

	<i>Ptychognathus</i> sp.	
	<i>Varuna litterata</i> (Fabricius 1798)	

^a A hypogean species in anchialine caves; widespread in Indo-Pacific region; name not included in ITIS.

^b Recorded from Mariana Islands in general; as *Atya pilipes* Newport 1847 in ITIS.

^c Dubious record possibly based on misidentification; name not included in ITIS.

^d Dubious record possibly based on misidentification; as *Atya spinipes* Newport 1847 in ITIS.

^e Previously recorded from Guam as *C. longirostris* H. Milne-Edwards 1837 and in need of further study; considered by some authors as a variety of *C. nilotica*; name not included in ITIS.

^f Previously recorded from Guam as *C. nilotica* (Roux 1833), *C. weberi* de Man 1892, and *C. serratiostris* de Man 1892; name not included in ITIS.

^g Recorded from Mariana Islands in general without specific island identified.

^h A hypogean species; Leberer and Cai (2003) speculated that individuals of this taxon reported by Maciolek (1983) likely represented the undescribed congeneric species; name not included in ITIS.

ⁱ A hypogean species under study (Leberer and Cai 2003).

^j DAWR (2006) listed *M. latimanus* (Von Martens 1868) for Guam, a widespread Indo-Pacific species; however, Nelson et al. (1996) reported that this species has not been recorded from either Guam or Palau.

Table 6. Native aquatic gastropods of inland waters of Guam (Smith 2003; DAWR 2006).

Federated States of Micronesia

The numbers of species of amphidromous and catadromous native fishes from islands groups of the FSM reported by Donaldson and Myers (2002) were as follows: Chuuk, 4 species; Yap, 8 species; Kosrae, 19 species; and Pohnpei, 21 species. However, these numbers are provisional, because information concerning taxonomy and life history is incomplete and some areas have been inadequately surveyed. As elsewhere in Oceania, gobiids and eleotrids are the most species-rich groups in inland waters. Eels of the genus *Anguilla* are the most conspicuous catadromous fish species.

The first comprehensive survey of stream macrofauna in the eastern Caroline Islands was conducted in the Nanpil Kiepw River of Pohnpei (Maciolek and Ford 1987). In that survey, 15 fish species representing five families were collected. Of seven species of Gobiidae reported by these investigators, five were previously undescribed scydiines of the genera *Sicyopterus* and *Stiphodon*, four of which were subsequently described (Parenti and Maciolek 1993). Additional surveys of Pohnpei improved documentation of the diversity, distribution, and ecology of gobies inhabiting streams of the island and revealed the presence of two others, including at least one as-yet undescribed species of *Lentipes* (Nelson et al. 1996; Buden et al. 2001b). At least three of the goby species on Pohnpei are considered endemic. The herbivorous *Stiphodon caeruleus* is the most abundant and widespread goby on the island. Nelson et al. (1996) found significant differences in density of gobies between rivers and habitats, but these investigators found no significant river-habitat interaction in their statistical analysis, indicating that fish were not randomly distributed among habitats but that their habitat use was similar between streams. Riverine fish faunas of other islands in the FSM have been less intensively studied than those of Pohnpei, but some endemism, particularly in the scydiine gobies, is known. Fish species occurring in streams and rivers of the large FSM islands are listed in Table 7.

Maciolek and Ford (1987) collected at least 28 species of invertebrates in their survey of the Nanpil Kiepw River, Pohnpei (11 crustaceans, 11 gastropods, five insects, and one annelid) (Table 8). A subsequent survey of headwater streams on Pohnpei yielded five different native shrimp taxa: two species of *Macrobrachium* and three species of atyids (Buden et al. 2001a). All of the species reported by Buden et al. (2001a) and many of those reported by Maciolek and Ford (1987) are widely distributed across the Indo-Pacific region. Maciolek and Ford (1987) noted additional insects known elsewhere on Pohnpei, typically occurring in quiet water habitats or stream areas less subjected to extreme flow fluctuations; these included odonates, caddisflies, dytiscid and hydrophilid beetles, mesoveliid bugs, and dipterans.

In recent years there have been a number of field surveys conducted on FSM islands to describe and document the odonate fauna (dragonflies and damselflies), especially of the winged adults (Buden and Paulson 2003; Paulson and Buden 2003; Buden 2004; Buden and Paulson 2007). A trend exists that corresponds with general island biogeography theory. Species richness of odonates decreases across the Micronesian archipelago from west to east (i.e., diversity diminishes farther from source areas), and larger islands have the greatest diversity (Paulson and Buden 2003). However, an exception is Pohnpei, to the east, which has high species richness, and is unique among the Caroline Islands in having six sympatric species of a single genus, *Teinobasis*. Eight of the 15 odonate species on Pohnpei are endemic (Paulson and Buden 2003). The odonate fauna of the large Micronesian island groups is summarized in Table 9.

Aquatic surveys of Yap Island provided information about native freshwater fishes, gastropods, crustaceans and insects (Nelson 1989a). At least eight native fish species representing seven families occur in Yap's streams and marshes: *Anguilla marmorata pacifica*, *Eleotris fuscus*, *Ophieleotris aporos*, *Periophthalmus vulgaris*, *Kuhlia rupestris*, *Scatophagus argus*, *Toxotes jaculator*, and *Ambassis* sp. (Nelson and Hopper 1989). Fourteen species of freshwater and brackish water gastropods were found in lotic and lentic habitats such as streams, ponds, taro plantations, mangrove swamps, and drainage ditches (Smith 1989). As throughout Micronesia, species of the families Neritidae and Thiaridae were dominant in freshwater habitats of Yap Island. *Neritina variegata*, *Melanoides plicaria*, and *Melanoides tuberculata* were the most abundant and widespread aquatic gastropods, occurring on rock, mud, and leaf-litter substrates. Likewise, the crustacean fauna of Yap Island includes at least eight species of atyid, palaemonid, and grapsid decapods. The atyid *Cardina typus* was found to be the most abundant and widespread decapod in freshwater habitats, typically occurring within about 1 to 2 km of the sea (Bright 1989). A survey of aquatic insects in freshwater habitats of Yap Island resulted in collection of about 50 species, with the greatest abundance and taxonomic richness present in lentic habitats and the lowest in streams (Schreiner and Nafus 1989). There appears to be relatively few, if any, endemic freshwater species on Yap Island, although there is need for additional surveys and critical taxonomic studies.

Freshwater faunistic studies of other FSM island groups are limited. General benthic surveys of some streams on Kosrae have been completed, but results have yet to be reported (B. Tibbatts, DAWR, and R.A. MacKenzie, U.S. Forest Service, oral commun., 2010). The freshwater faunas of the large islands of Chuuk remain poorly documented; surveys of these islands present special challenges for researchers due to logistics and various social and cultural impediments (B. Lynch, College of Micronesia, oral commun., 2010).

Table 7. Stream fishes of large islands of the Federated States of Micronesia (Maciolek and Ford 1987; Parenti and Maciolek 1993; Nelson et al. 1996; Buden et al. 2001b; Donaldson and Myers 2002). [A few species are omitted if their habitat occurrence is primarily mangrove, estuarine, or tidal reach within fresh water. Common names from FishBase® (Froese and Pauly 2011).]

Family	Species	Common name
Ambassidae	<i>Ambassis buruensis</i> Bleeker 1856	Buru glass perchlet

Palau

Fehlmann (1960) conducted a detailed study that provided information on the identification and distribution of fishes and invertebrates inhabiting Arakitaoch Stream on the island of Babeldaob. Based on faunal gradient and stream characteristics, four different reaches or zones were recognized: mangrove, lower graded, cascade, and source. Subsequent to Fehlmann's study, a synoptic checklist of the inland fishes of Palau was published in which a total of 43 native species representing 18 families were enumerated, including four introduced species (Bright and June 1981) (Table 10). Several of the species listed by these authors are primarily marine or estuarine; their occasional occurrence in rivers is confined to downstream tidal reaches and mangrove areas. Species richness was greatest for gobies (12 species) and sleepers (9 species). As noted by Bright and June (1981), the most extensive habitat suitable for diadromous or freshwater species in Palau are the streams and rivers of Babeldaob. However, there are also intermittent streams on Koror and Arakabesang, and on all three islands there are additional freshwater habitats that support aquatic communities.

An intensive, quantitative survey of freshwater fishes was conducted in the upper reaches of Babeldaob's Ngermeskang River, one of Palau's largest inland drainages (Nelson et al. 1995). These investigators obtained density estimates for 13 species, based largely on visual surveys conducted by snorkelers (although a few specimens were collected with nets and a backpack electroshocker) to aid in verifying visual survey identifications. Maximum densities of selected gobiid fish ranged from 0.4 individuals per m² for *Redigobius bikolanus* to more than 11.0 individuals per m² for female *Stiphodon elegans*, with the highest mean density of 5.2 individuals per m² for the latter. There was a distinct difference in community composition between river segments below and above the large Ngermeskang Waterfall (Table 11). Fishes (e.g., *Kuhlia* spp.) incapable of ascending steep waterfalls were confined to the downstream reaches. Nelson et al. (1995) provided quantitative evidence to support the qualitative observations of Fehlmann (1960) that habitat type defined by relative water column velocity (riffle, run, and pool) as well as substrate (cobble, boulder, and bedrock) are determinants of the distribution and abundance of native fishes in these high-gradient rivers and streams.

Fehlmann (1960) documented the invertebrate fauna of Arakitaoch Stream, principally in the mangrove, lower graded, and cascade sections. Several species of crustaceans and mollusks, including all bivalves collected, were only present in mangrove areas. As in other regions of Micronesia, the freshwater fauna was dominated by atyid and palaemonid shrimps and thiarid and neritid snails. The atyid shrimps present were composed of only one or a few species of *Atya* or a related genus, and these were found to be most abundant in the cascade zone (Fehlmann 1960). Palaemonids were identified as one or two species of *Macrobrachium* (most likely including *M. lar*). Gastropods in the lower graded zone were limited to *Neritina pulligera*, in moderate abundance, and *Thiara amarula* in low abundance. The cascade zone had the greatest snail species richness, which in decreasing order of abundance was as follows: *Neritina pulligera*, *N. cornea*, *N. variegata*, *Stenomelania* sp. cf. *hastula*, and *T. amarula*. Only *N. cornea* was found in the source zone and was in lower abundance than in the cascade zone.

During the course of this study, aquatic insects were surveyed from a variety of habitats on Palau, mostly Babeldaob streams; we collected a total of 28 aquatic insect species. We conservatively estimated that at least four island endemics were present, including three damselflies (*Drepanosticta palauensis*, *Pseudagrion palauense*, and *Teinobasis palauensis*) and

a gyrid (whirligig) beetle, *Dineutus (Spinodineutes) sp. cf. heterandrus*. An *Ischnura* damselfly found in lentic habitats on Palau was not identified conclusively, but, because it is not a widespread species such as *Ischnura aurora* or *Agriocnemus femina femina*, it is likely that it at least is indigenous if not possibly endemic to Palau. A complete list of species, collecting sites, and other summary information for this insect survey is provided in Appendix 3.

Palau has Micronesia's only native amphibian, the Palau frog *Platymantis pelewensis*, found throughout all but the southwest islands and endemic to the Palau archipelago, from Kayangel Atoll in the north to Angaur in the south. Although not considered to be aquatic (there is no tadpole stage and breeding is in terrestrial habitats), the species is common to abundant and is found in a variety of habitats, thriving in human-inhabited areas and often reaching very high densities in caves and abandoned war bunkers (Crombie and Pregill 1999). The Palau frog has direct development (Atoda 1950), but detailed information about reproduction and other aspects of its natural history is limited (Crombie and Pregill 1999).

The saltwater or estuarine crocodile (*Crocodylus porosus*) is native to Palau, although its numbers have declined in recent history. In the 1960s, there were systematic efforts to eradicate saltwater crocodiles from Palau as a result of attacks on humans. There have been persistent rumors that other crocodile species are present on Palau, presumably based partly on the possibility that some non-native crocodiles imported to the island in the 1930s may have escaped (Crombie and Pregill 1999). There are a few confirmed and some unconfirmed reports of saltwater crocodiles in the Caroline Islands outside of Palau. Their presence on these other islands is likely the result of natural dispersal (island hopping) across expanses of sea as waifs. Such events are considered rare; for example, there is a single record of a 380 cm (12.5 ft) male crocodile captured on the island of Pohnpei, about 1,360 km (845 mi) to the north of the Bismark Archipelago and 2,400 km (1,490 mi) to the east of Palau where this species is native (Allen 1974; Eldredge 1994; Crombie and Pregill 1999; Buden 2000).

^a Species described from Pohnpei (Parenti and Maciolek 1993); identification requires confirmation by qualified taxonomist.

Introduced Freshwater Fauna

Mollusks

A variety of nonindigenous aquatic mollusks, mostly gastropods (snails), have been introduced to inland waters of Pacific islands. Recent reviews of mollusk introductions to the region summarized information on both terrestrial and aquatic nonindigenous snails and on the single nonindigenous freshwater bivalve introduced to the region, the Asian freshwater clam (*Corbicula fluminea*) (Cowie 2000b, a). Considerable evidence indicates that many of the native Pacific insular gastropod faunas are being homogenized by the introduction and spread of invasive snails (Cowie 1998a, 2000b). Among nonindigenous species, some have been introduced intentionally and others accidentally. By virtue of their diversity, endemism, and limited dispersal capabilities, the native terrestrial gastropod faunas of tropical Pacific islands are disappearing, and are particularly threatened by nonindigenous mollusks. In contrast to native terrestrial snails, the native freshwater snail fauna of tropical Pacific islands consist of relatively few species and many have wider geographic distributions. Consequently, the native freshwater snail fauna is generally less imperiled overall than that of the terrestrial fauna; however, they also are threatened by introduced species and other factors.

The most notable introductions of freshwater gastropods in the Pacific are apple snails (Ampullariidae) of the genera *Pomacea* and *Pila*. Among terrestrial and aquatic mollusks, “channeled” or “golden” apple snail, *Pomacea canaliculata* is considered an especially harmful pest (Cowie et al. 2009). The taxonomy of ampullarids is inadequately resolved; some species are difficult to distinguish based on morphology, and species identifications of some introduced populations, when investigated closely, may reveal greater diversity and more complex history of introductions than initially recognized (Rawlings et al. 2007). Apple snails (especially *P. canaliculata*) have been widely introduced around the world as food and for aquaculture (Eldredge 1994; Cowie 1998b; Lach and Cowie 1999; Cowie 2000b; Cowie et al. 2007). They are also popular among aquarists (Perera and Walls 1996). Both aquatic and terrestrial species may also be associated with transport via the horticulture industry. When introduced to tropical areas outside of their native ranges, apple snails may become serious agricultural pests on cultivated crops such as taro and rice (Naylor 1996; Cowie 2002; Qiu and Kwong 2009). Apple snails in Micronesia are present on Guam and in the CNMI; on Guam they were first observed in the 1980s (Smith 2003). The ampullarid snail *Pila conica* was introduced to Palau in the mid-1980s, but was thought to have been eradicated by 1987 (Eldredge 1994). Both *Pomacea canaliculata* and *Pila conica* are intermediate hosts for several parasites of humans and their potential as vectors of human disease should not be overlooked.

Additional freshwater snail species have been introduced to Guam, including *Fossaria viridis* (Quoy and Gaimard) and at least one viviparid and two planorbid species (Eldredge 1994; Cowie 2000b). Most of these introductions are thought to have been accidental or intentional releases associated with the aquarium trade.

Invasive snails and other mollusks receive relatively little attention, but they can have important impacts on agriculture, biodiversity, and human health, and can become major public nuisances (Cowie et al. 2009). Negative impacts to native species on Pacific islands appear varied but are generally not well studied. Some predatory terrestrial snails have been intentionally introduced in misguided efforts to use them as biocontrol agents, resulting in severe depredation of native species (Cowie 1998b). Introduced snails in all habitats are also implicated in the decline of native snails through competition. Additionally, concerns often arise over

introductions of gastropods due to the fact that many species may serve as intermediate hosts for parasites that are transmissible to humans or livestock (Madsen and Frandsen 1989; Eldredge 1994).

No records were found to indicate that bivalve mollusks have been introduced to Micronesia. However, the freshwater Asiatic clam *Corbicula fluminea* is known from Hawaii (Cowie 2000b), and it has an extensive nonindigenous distribution in North America. Introductions of *C. fluminea* may have substantial ecological as well as economic impacts.

Crustaceans

A small number of freshwater decapod crustacean species have been introduced to inland waters of Pacific islands. At least five are considered established on at least one Pacific island: the giant river prawn (or giant freshwater prawn) *Macrobrachium rosenbergii* and giant Malaysian prawn *Macrobrachium lar* (both of the family Palaemonidae); the shrimp *Neocaridina denticulate sinensis* (Atyidae); the red swamp crawfish *Procambarus clarkii* (Cambaridae); and the Australian redclaw crayfish *Cherax quadricarinatus* (Parastacidae). To date, the only established wild populations are known from Hawaii (4 species) and New Caledonia (1 species). A few introductions have occurred on islands in Micronesia, including Guam and Palau, but without evidence of establishment in the wild (Eldredge 2000). The introduction of freshwater crustaceans to Pacific islands has typically been associated with aquaculture and the aquarium trade (Eldredge 2000).

The species of greatest interest in aquaculture has been the giant river prawn *Macrobrachium rosenbergii*, due to its large size and advanced culture technology. There has been long-standing confusion with its nomenclature that has been partly resolved by examination of morphological characters and use of modern genetic analyses (Wowor and Ng 2007; Iketani et al. 2011). Wowor and Ng (2007) recognized two distinct species for what has historically been regarded as the single species *M. rosenbergii* (and two subspecies according to some researchers), and distinguished them using discernible morphological characters. *Macrobrachium rosenbergii* (in the strict sense) occurs in Australia, Papua New Guinea, eastern Indonesia, and the Philippines. *Macrobrachium dacqueti*, an important food species extensively cultured in captivity and harvested from the wild, occurs throughout southern and southeastern Asia.

Eldredge (1994, 2000) provided a history of intentional introductions of *Macrobrachium* associated with aquaculture for Hawaii, Guam, Palau, and other regions of the Pacific. Movements of species have been in different directions. For instance, shipments of *M. rosenbergii* for aquaculture that originated in Hawaii (with original stock from Malaysia, and possibly elsewhere) were shipped to Guam, Palau, and a few South Pacific islands. Conversely, *M. lar*, which is native to Micronesia, was shipped from Guam to Hawaii, where it became established and now potentially competes with Hawaii's only native freshwater prawn, *M. grandimanus*.

Hawaii has other species of introduced crustaceans that are potentially of concern as possible risk to Micronesian islands. Atyid shrimps native to Southeast Asia are present on Oahu and likely escaped or were released by means of the aquarium trade (Englund and Cai 1999; Eldredge 2000). The freshwater crayfish *Procambarus clarkii* is also established in Hawaii, where it has had agricultural impacts (Eldredge 2000). Invasive crayfishes have had deleterious

ecological and economic impacts in places where they have been introduced outside of their native ranges (Gherardi 2007). Thus, from a biosecurity perspective for Micronesia, crayfishes should be considered high risk and subject to scrupulous monitoring.

Amphibians

Micronesia has only one native amphibian species, the Palau frog, *Platymantis pelewensis*, which is endemic to various islands of Palau where it is associated with freshwater environments, and reportedly, certain slightly brackish-water habitats (Crombie and Pregill 1999). However, a number of nonindigenous amphibians, mostly anurans (frogs and toads), have been introduced to Micronesia and several have become established, mostly on Guam (Table 12). The pathways by which nonindigenous amphibians have been introduced throughout many areas of the Pacific, as elsewhere in the world, are varied (Eldredge 1994; Pitt et al. 2005; Christy et al. 2007b; Kraus 2009b; USDA-APHIS 2010).

The first nonindigenous anuran to be introduced to the Pacific, and now one of the most widespread terrestrial vertebrates in the world, is the cane or marine toad, *Rhinella marina* (Easteal 1981; Eldredge 1994, 2000; Lever 2003; Kraus 2009a). In the Pacific, cane toads were first introduced to Hawaii, and were subsequently distributed extensively, and mostly intentionally, for biocontrol of various insect pests and garden slugs (e.g., *Veronicella leydigii*). Detailed historical accounts of introductions in Oceania have been summarized by various authors (e.g., Eldredge 1994; Crombie and Pregill 1999; Eldredge 2000; Lever 2003). The cane toad is now established virtually everywhere on the main island groups of Micronesia, and in some places it is extremely abundant. An extensive body of literature exists concerning the cane toad's global redistribution and its effects on native species and humans. The cane toad is not established on all islands within Micronesia and preventing its further spread may be valuable to consider.

There is general consensus that in many places where it has been introduced *R. marina* has had significant economic, ecological, and human-health impacts (Easteal 1981; Lever 2003). Ecological impacts include the following: (1) predation by cane toads on native invertebrates and vertebrates; (2) toxicity to native species that eat or come into contact with cane toads; (3) direct competition between cane toads and native species for food, spawning sites, and other resources; and (4) reduced native populations of species that provide natural controls of other pest species (Lever 2003). The list of impacts on human welfare is extensive, including, but not limited to the following: (1) pollution of potable water supplies, swimming pools, and other water resources; (2) blocking of drains by dead, decomposing toads; (3) death of domestic pets, and, although rare, humans; (4) erosion of earthen dams and berms by burrowing toads; (5) spread of human parasites, diseases, and other pathogens transmissible to humans (e.g., dysentery, *Salmonella*); (6) traffic hazards from dead toads on roadways; and (7) high costs of environmental monitoring, control, and mitigation programs.

Since 1937, at least 13 species of anurans have been introduced to Guam, six of which are known to have breeding populations. Eight species were reported for the first time from Guam between 2003 and 2005 (Christy et al. 2007a, b). The probable areas from which anuran species originated include Hawaii, Asia, Australia, the Philippines, and the continental United States. *Rhinella marina* is the only anuran that was intentionally introduced to Guam. The other species arrived by means of different vectors. Four species (*Kaloula picta*, *K. pulchra*, *Polypedates leucomystax*, and *Litoria fallax*) are known or suspected to have been transported on maritime or air-transport vessels. Two species that have direct development (i.e., with no aquatic

tadpole stage) are presumed to have been transported by means of the horticultural trade:

Eleutherodactylus coqui (not established) and *E. planirostris* (established). Specimens of *Pseudacris regilla* were recovered from shipments of Christmas trees and other agricultural products (it is also appropriate to note that other non-anuran amphibians [newts and salamanders] have reached Guam by means of this vector; D. Vice, DAWR, oral commun., 2010).

Analysis of commerce for the aquarium trade and for aquaculture suggested that the most likely means of introduction of five species, all of which are established on Guam, was by means of the aquaculture sector: *Fejervarya cancrivora*, *F. limnocharis*, *Microhyla pulchra*, *Polypedates megacephalus*, and *Rana guentheri* (Christy et al. 2007b). Most, if not all, of the introductions suspected to be associated with aquaculture likely arrived as unintended contaminants of broodstock fish or other aquaculture species, although the possibility of illegal introductions for use in the food trade cannot be dismissed.

Christy et al. (2007b) considered horticulture and aquaculture to be the primary pathways of concern for frogs arriving to Guam and potentially being disseminated to other Pacific islands. For these pathways, the life-history attributes of frogs may predispose them differentially to transport mechanisms and establishment success. Species without an aquatic larval stage may be readily transported as either eggs or adults in the absence of standing water (e.g. with horticultural products). Species with a tadpole stage could be transported in water (as eggs or larvae) as part of the transport vector (e.g., by means of the pet trade or aquaculture), and some of these could also be transported as adults on non-aqueous materials.

The Animal and Plant Health Inspection Service (APHIS) terrestrial wildlife team prepared a detailed risk assessment for nonindigenous frogs, other amphibians, and selected aquatic or semi-aquatic reptiles of greatest concern (USDA-APHIS 2010). In that assessment, the pet and food trade were identified as pathways of high risk for these taxonomic groups.

Reptiles

At least six species or subspecies of turtles that normally inhabit freshwater habitats have been introduced to Micronesia; most are confirmed as established on at least some islands (Table 13) (Leberer 2003). Mechanisms of introduction are varied; at least one species (*Pelodiscus sinensis*) was intentionally imported for food by means of the aquaculture pathway, whereas most others were likely released or escaped pets. Additionally, specimens of the terrestrial three-toed box turtle (*Terrapene carolina triunguis*), a species native to the southeastern continental United States, have been observed on Guam (McCoid 1992; Leberer 2003).

The most widespread nonindigenous turtle in Micronesia is the red-eared slider (*Trachemys scripta elegans*), a freshwater taxon native to the southern United States and subspecies of a species broadly distributed in the western hemisphere. The red-eared slider has become one of the most widespread reptiles in the world, largely as a result of its popularity, abundance, and broad dissemination in the pet trade (Lever 2003; Kraus 2009a). The first appearance of the red-eared slider in inland habitats on Guam is not clearly documented. Lever (2003), citing McCoid (1992) and Eldredge (1994), noted that it was first recorded from the municipality of Mangilao in 1991. However, McCoid (1999) speculated that it may have been introduced to Guam as early as the 1950s, whereas Leberer (2003) stated that this turtle may have been introduced to the island in the 1970s. Whether the authors were distinguishing between imported turtles versus occurrence in the wild is uncertain. Currently, the red-eared

slider is common in the wild throughout southern Guam, is regularly sold and traded as a pet, and even “used as prizes at island fiestas” (Leberer 2003). In addition to Guam, the red-eared slider is known from Lake Susupe on Saipan, where its status is uncertain (McCoid 1992; McKagan et al. 2009). A single specimen of this turtle subspecies was captured in the wild (at a dump site) on Pohnpei in 1997, without evidence of establishment (Buden 2000; Buden et al. 2001c). The red-eared slider has been present on the Hawaiian island of Oahu since 1980 where it is established in both lotic and lentic habitats (Devick 1991).

The Chinese softshell turtle (*Pelodiscus sinensis*; formerly known as *Trionyx sinensis sinensis*) was imported from Taiwan to Guam for aquaculture (FitzGerald 1982; Eldredge 1994; Leberer 2003; Lever 2003). The commercial venture to produce turtles for food failed within a year, and the surviving stock was either deliberately released or accidentally escaped. The species is now established in central and southern Guam (McCoid 1993; Eldredge 1994; Leberer 2003; Lever 2003).

There are reports, many unconfirmed, of other aquatic or semi-aquatic freshwater turtles from Guam, including common snapping turtle (*Chelydra serpentina*), Reeve’s turtle (*Mauremys reevesii*), Chinese stripe-necked turtle (*Mauremys sinensis*), and a mud turtle of the genus *Kinosternon*. These are presumed to have been pets that either accidentally escaped or were intentionally released (Leberer 2003); their status is unknown, and additional surveys are needed to determine if breeding populations exist on the island. A few other freshwater turtles are established or have been reported on other Pacific islands. For example, the wattle-necked softshell turtle (*Palea steindachneri*) is established on the Hawaiian islands of Kauai and Oahu (Yamamoto and Tagawa 2000; Ernst and Lovich 2009).

Possible negative ecological or economic consequences resulting from the presence of nonindigenous populations of freshwater turtles on Micronesian islands have not been fully assessed. However, based on what is known about the natural diets of the taxa involved, their presence in island inland waters could pose threats to native freshwater fishes and invertebrates (Lever 2003).

Kinosternidae	<i>Kinosternon</i> sp. Spix 1824	mud turtle	Guam	Not established	One record only in published literature (animal was in captivity in 2003); unverified specimen observed for sale in 2010 by roadside vendor (E. Wostl, USGS, oral commun., 2010)	Leberer (2003)
Trionychidae	<i>Pelodiscus sinensis</i> (Wiegmann 1834)	Chinese softshell	Guam	Established		Leberer (2003)

Fishes

A wide variety and large numbers of nonindigenous fishes have been introduced to freshwater habitats in Micronesia and other islands of Oceania. As a result, nonindigenous fishes are common on most islands in the region that have freshwater environments. In many areas nonindigenous fishes are the most abundant and visible group of introduced aquatic animals. Several publications have synthesized global or regional information on the distribution of nonindigenous fishes and other nonindigenous aquatic organisms. Most include annotated listings or accounts of species introduced to Micronesia or to specific island groups (Welcomme 1981; Maciolek 1984; Welcomme 1988; Nelson and Eldredge 1991; Munro 1993; Eldredge 1994, 2000). Additionally, databases exist that track distributional records of introduced species as reported in the literature or from other sources (Casal 2006; Froese and Pauly 2011). Hawaii has also had numerous introductions and establishment of freshwater fishes (Maciolek 1984; Devick 1991; Eldredge 1994; Yamamoto and Tagawa 2000; Mundy 2005). Some fishes were intentionally transported among many different Pacific islands, island groups, and mainland areas (e.g., Southeast Asia) and for many different reasons. For example, Nelson and Eldredge (1991) and Eldredge (1994) summarized intentional tilapia introductions to Pacific islands with putative sources and reasons for introduction, where known.

At least 25 nonindigenous freshwater or catadromous fish species or taxa have been introduced into the waters of Guam. Of these, 13 are known to be established (Tables 14-15). The source of these introductions is varied. Some species were intentionally stocked on Guam, especially in the Fena Reservoir and the Talofofu River, for sport fishing, as biological control agents, or both (e.g., *Oreochromis mossambicus*, *Micropterus salmoides*, *Cichla ocellaris*, *Ictalurus punctatus*, *Gambusia affinis*) (Brock and Takata 1956). Some species were initially held in aquaculture facilities and dispersed to inland waters and/or their spread was augmented by humans (e.g., *Clarias batrachus*, *Oreochromis mossambicus*, *Tilapia zillii*, and *Channa striata*). Other species may have been releases of aquarium fishes (e.g., *Betta pugnax*, *Astronotus ocellatus*, and *Poecilia reticulata*). Agana Springs and the adjacent marsh and swamp habitats are sites where aquatic pets and other nonindigenous species have been released or spread to (Randall et al. 1974; B. Tibbatts, DAWR, pers. comm.).

A recent survey for nonindigenous species on Saipan resulted in documentation of at least four different taxa of introduced fishes (McKagan et al. 2009) (Fig. 12; Tables 16, 17). Overall fish species richness at sites on Saipan was low, with most sites having two species or less. Moreover, native species appeared to have been displaced by nonindigenous species at disturbed sites.

In comparison to other island groups of the western and central Pacific (e.g., Hawaii and Fiji), there have been relatively few freshwater fish species introduced to Micronesian islands with the exception of Guam. Certain species or taxonomic groups (e.g., tilapiine cichlids and mosquitofishes) have been broadly introduced and in some areas have spread locally. In general there may have been fewer fish

introductions from west to east in the Carolines. At least five different nonindigenous fish species have been reported from inland waters of Palau (Table 10) (Bright and June 1981; Eldredge 2000; our own surveys). The most recent fish introduced to Palau was the Mozambique tilapia (*Oreochromis mossambicus*), to which the government responded by attempting to eradicate several localized populations that were discovered, in an effort that was partially successful (Nico and Walsh, in press). To date only two nonindigenous freshwater fish species (*O. mossambicus*, *Gambusia affinis*) are known from Pohnpei (B. Lynch and D. Buden, oral commun., 2010). A single species (*O. mossambicus*) has thus far been reported from Yap (Nelson and Hopper 1989).

Table 14. Nonindigenous freshwater fish species introduced to Guam. [Status codes: E = established in inland waters of Guam; NE = not established or insufficient information available. Known or presumed pathway of introduction: A = aquaculture (escapement or intentional release); S = stocked for sport fishing, biocontrol, and/or as forage; O = ornamental. Sources of data include Maciolek (1984), Eldredge (2000), and B. Tibbatts (DAWR, written commun., 2010)]

Pathways of Introduction

Increased rates of international trade, travel, and transport over recent decades have led to widespread introductions and frequent mixing of biotas from across the world (Pyšek et al. 2010). Introductions of nonindigenous species to new locations typically occur by means of three main mechanisms: importation of a commodity, arrival of a transport vector, or dispersal of previously introduced populations (Hulme et al. 2008). Pathways are defined here as the general route or activity by which a species can be introduced into a new locale whereas vectors are considered to be the specific mechanism, mode, or activity associated with that introduction. Often, individual species are introduced through multiple combinations of vectors and pathways.

The following types of pathways are the most common means by which freshwater animals (and plants) are introduced to inland areas outside of their natural ranges (Fuller et al. 1999; Nico and Fuller 1999; Kolar and Lodge 2002; Helfman 2007; Leung and Dudgeon 2008; Kolar et al. 2011):

- Releases of live animals previously maintained in aquaria, water gardens, and so forth (i.e., the ornamental pet trade)
- Escape from aquaculture or holding facilities
- Transport and release associated with the live-food industry
- Legal stocking, typically by government agencies (purposes may be varied; for example, to establish game or forage species, for biocontrol, for conservation of rare species, or for research or experimental purposes)
- Illegal or unauthorized stocking
- Bait-bucket release
- Transport and release through vessel ballast water, as hull-fouling organisms, or unintentional contaminants associated with other vectors
- Habitat modification (e.g., canals or artificial waterways that connect previously unconnected water bodies)
- Natural causes that aid in the dispersal of already existing nonindigenous populations (e.g., typhoons, transport by animals other than humans)

Regional patterns of invasion are complex, and shaped by a wide range of factors that vary over space and time (Pyšek et al. 2010). Over the years there has been an increasing number of studies published on pathways and the relative role that each has played in the establishment of nonindigenous aquatic species. Given the extensive and growing amount of literature on the subject, the list just presented should not be considered all-inclusive. Additional information about the role of

selected pathways in the establishment of freshwater species in Micronesia is

provided in the *Existing Conditions* sections of the *Management Alternatives* of this document.

Based on existing evidence, pathways that have contributed greatly to the introduction of nonindigenous freshwater fishes into inland waters of Micronesia—and that will likely remain a threat in the near future—include (1) intentional or unintentional releases associated with the ornamental species trade, (2) escape from aquaculture facilities, and (3) releases associated with the live food industry. Certain other pathways (e.g., ballast water, bait-bucket releases) appear to have posed little threat historically and presumably will present low relative risk in the future. However, other pathways (e.g., contaminants in other stocks) may currently and/or in the future pose relatively high risk, yet are inadequately documented and difficult to evaluate. Most threats are not mutually exclusive, and may act synergistically to increase risk.

Mechanisms of Spread

When a nonindigenous species becomes introduced into a novel environment, there are many factors that contribute to whether or not it will become established and the degree to which it will spread if established. An exhaustive review of these factors is beyond the scope of this study. However, a few generalizations provide insight into characteristics of aquatic species that contribute to their success at becoming established, and to some extent, the degree to which they spread or become invasive.

Ehrlich (1986; 1989) listed the following characteristics that are common to many species that successfully become established when introduced to places where they are not native:

- Large native range
- Abundant in native range
- Vagile
- Short generation time
- High genetic variability
- Gregarious
- Female able to colonize alone
- Larger than most relatives
- Broad diet
- Able to function in a wide range of physical conditions
- Associated with humans

As noted by Eldredge (2000), many of the nonindigenous freshwater species established on Pacific islands exhibit combinations of these characteristics, although one exception is body size, because most species introduced to these insular areas are relatively small.

Helfman (2007) examined these factors in more detail for fishes, and, drawing on selected literature sources, summarized the characteristics that favored successful invaders, characterized invulnerable habitats, and contrasted the first with opposing characteristics of vulnerable native species (Tables 18-19). Notably, many of the traits listed by Helfman (2007) are identical to those listed by Ehrlich (1986; 1989), thus indicating certain common factors across taxonomic groups and ecosystems. Many authors have invoked such species characteristics to analyze and attempt to better understand establishment and invasion success. Moreover, different factors may operate and affect success differentially and in unique combinations of ways during different stages of the invasion process (Kolar and Lodge 2001; Kolar and Lodge 2002). Some of these factors are addressed in greater detail in our risk analysis of establishment success for freshwater fishes introduced to Hawaii and Guam (see *Risk Assessment and Analysis*).

Table 18. General characteristics of successful fish invaders; see Helfman (2007) and references therein. [Different traits may affect success at different stages of invasion. Vulnerable native species were considered by the author to have characteristics contrasting to those indicated by asterisks]

Characteristic(s)
High reproductive rate; including high fecundity, short interbreeding interval*
Short generation time with rapid maturation*
Long-lived with rapid maturation
High dispersal rate*
"Pioneer" species; good colonists (with r-selected life-history traits)*
Biparental care unnecessary
Broad native range*
Abundant in native range*
High genetic variability and phenotypic plasticity*
Tolerant of wide range of water-quality criteria*
Ecological generalist with respect to habitat and trophic requirements (piscivores, detritivores, herbivores, some planktivores most successful)*
Previous history of successful invasions by the species or close relatives
Gregarious
Ability to breathe air
Medium body size; large size advantageous for predators
Human commensal

Table 19. General characteristics of highly invasible habitats and communities, after Helfman (2007).

Characteristic(s)
Human-modified habitat; such as with altered flow regime, impoundment, channelization, sedimentation, deforestation of riparian and uplands, urbanization, pollution
Decreased natural variability in hydrology or geomorphology
Relatively benign and physicochemically stable habitats, as opposed to those with extreme fluctuations (however, exceptions exist in which certain invaders may be more likely to become extirpated under such extremes)
Assemblages with vacant trophic representation, such as few or no predators or zooplanktivores
Low-diversity assemblages
Insular streams and lakes
Highland lakes
Tropical rivers

Existing Legislative and Regulatory Framework

Regulations governing the importation, stocking, and possession of nonindigenous species vary widely among different nations, states, and government agencies. Within the United States, more than 20 Federal agencies, as well as many State and local agencies are involved in the management of undesirable or invasive aquatic organisms (Kolar et al. 2011). The U.S. Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990 provided a strategic framework, through the establishment of an interagency committee, to coordinate and prioritize efforts and programs designed to control and manage aquatic nuisance species in U.S. waters. Federal efforts in the United States are coordinated by the National Invasive Species Council (NISC), established in 1999. A National Invasive Species Management Plan (NISC 2001, 2008) provides the guidelines for Federal agencies to engage authorities and coordinate existing programs to prevent introductions and spread of invasive species, apply rapid detection and response actions, mitigate for impacts, and restore native species and habitats. In practice, however, most fisheries management efforts for nuisance species in inland waters of the United States and its possessions are jointly administered across administrative levels, and for some activities done primarily at the local or state level. This general topic was reviewed by Kolar et al. (2011), who summarized some of the basic measures that management agencies invoke to prevent or reduce consequences of introductions (Table 20). There are also several international instruments that are available to Micronesian governments. These include binding international agreements (e.g., 1992 Convention on Biological Diversity) and guidelines to minimize the spread of non-native freshwater species (e.g., EIFAC Code of Practice for recreational Fisheries [EIFAC, 2008]).

Table 20. Common vectors by which nuisance fishes and other aquatic species are commonly introduced to inland waters, and methods used to minimize risks associated with intentional introductions (stocking by government agencies) or to minimize introduction events (all other vectors) within the United States (from Kolar et al. 2011). [Asterisk represents more common level of regulation.]

Vector of introduction	Prevention measures		
	Regulation	Management Options	Education and outreach
Ballast water	Federal*, State	X	
Aquaculture industry	Federal, State*	X	
Live food fish industry	Federal, State*	X	X
Stocking by government agencies	Federal, State*	X	X
Water garden and aquarium pets	Federal, State*		X
Unauthorized stocking	Federal, State*		X
Bait-bucket releases	State		X
Recreational activities	State	X	X
Research activities	State	X	X
Diffusion from neighboring waters			X

Initially, we attempted to review the legislative authorities and the existing regulatory framework governing management for nuisance freshwater species in Micronesia. However, the information obtained is incomplete because of the large number of different states and island nations, the complex nature of the subject, apparent or likely changes in regulations over time, and difficulty in obtaining verifiable data. Nevertheless, a brief summary of some of the relevant information obtained during the course of this study provides a basis for understanding how regional governments apply and administer rules and regulations designed to manage for invasive species. Most of this information is directly applicable to the primary pathways of interest in this document; that is, the pet trade, aquaculture, intentional stocking programs, and live-food animal trade.

Hawaii

The legislative and administrative policies for Hawaii have direct relevance to Micronesia due to the extensive trade of live animal and plant commodities across the Pacific. The Hawaiian Department of Agriculture (HDOA) maintains a web site (<http://hawaii.gov/hdoa>) that provides extensive information about regulations of the State of Hawaii governing the import and export of organisms by means of the live animal and plant trade. Most of the regulations, practices, and other management factors are similar for the individual types of trade involving aquatic species (i.e., common to the pet, live or fresh food, ornamental, bait, and aquaculture trades). HDOA requirements that pertain to the importation of live animals for food generally

emphasize nonaquatic organisms, specifically, domesticated livestock and other species. Hawaii's Administrative Rules establish the guidelines, limitations and parameters for specific types of actions within the context of the Hawaii Revised Statutes (<http://hawaii.gov/hdoa/admin-rules>). Certain types of animals, insects, microorganisms and plants are not allowed entry to Hawaii. For those that are allowed, import permits, letters of authorization, quarantine and/or health certificates may be required. A few examples of animals that are prohibited from importation or possession by private individuals in Hawaii include the following: alligators, bearded dragon lizards, coconut crabs, electric catfishes, hermit crabs, land snails, lionfishes, piranhas, snakes, and snapping turtles. All freight companies transporting agricultural items to Hawaii must notify a Plant Quarantine Inspector of these items and insure that all items, including cargo and mail, are available until the inspection is completed. The HDOA's Plant Quarantine Branch conducts pre-entry, entry, and post-entry inspections of regulated materials entering the State. All microorganisms and nondomestic animals and certain microorganisms and plants require permits prior to their importation.

Guam

Codified laws of Guam regulating the importation, care, conservation, and use of fish and wildlife are provided by the Guam Administrative Rules and Regulations, Title 9 (as of April 2004), available online at:

<http://www.justice.gov.gu/compileroflaws/GAR/09gar.html>. Most of these laws apply to domesticated livestock and feral animals. Rules governing aquatic organisms are generally listed under Title 9, Division 2 (Conservation, Hunting & Fishing Regulations), Chapter 12, Fishing Regulations. The General Guam Administrative Rules and Regulations home page is:

<http://www.justice.gov.gu/compileroflaws/gar.html>. The Guam Division of Aquatic and Wildlife Resources (DAWR) maintains a white list of permitted plants and animals; any animals or plants not present on the white list are prohibited from importation, but there is no existing legislation to prohibit possession of species not on the white list. The DAWR issues permits for the importation of any aquatic organism and requires scientific name, common name, number requested, point of origin, shipper, and receiving party. U.S. Customs maintains documents showing the number of organisms actually received. The DAWR does not allow the importation of any reptiles or amphibians. Freshwater fishes are permitted for the pet trade and for aquaculture. No fishes are currently allowed to be imported for biocontrol, bait, or sport purposes.

In Guam, the U.S. Department of the Interior, Law Enforcement Division, Fish and Wildlife Services (USFWS), has responsibility pertaining to the importation of reptiles, fish, and endangered species. A license is required for commercial imports or exports of fish and wildlife and/or their parts and products into or out of the United States and importers are also required to file a Declaration for Importation or Exportation of Fish or Wildlife (Form 3-177) at an authorized port of entry to receive clearance before U.S. Customs releases the shipment. Live aquatic animals and other wildlife are monitored through a system of national ports designated and managed by

the USFWS Office of Law Enforcement, U.S. Customs Service (USCS), and the U.S. Department of Agriculture (USDA).

The most detailed records pertaining to imports of live aquatic animals are those in the USFWS Law and Enforcement Management Information System (LEMIS). The USFWS compiles much of the information from U.S. Customs shipment declaration forms. Shipment records in LEMIS include information on number or weight of animals per container, scientific name, intended purpose, source, and country of origin; records are discarded every six years. Some data do not distinguish freshwater from marine species, and not all import declaration forms indicate source. Moreover, the country of origin is not always known with certainty because transshipments are common. Inadequate record keeping at ports makes it difficult to fully assess the diversity of live fishes imported, thereby hindering risk analysis and prevention programs.

Commonwealth of the Northern Mariana Islands

Codified laws of the CNMI are maintained by the Commonwealth Law Revision Commission (<http://www.cnmilaw.org/welcome.php>). The complete CNMI Administrative Code was not available to the authors. Regulations governing the importation of wildlife, permitting, law enforcement, and other management issues are under the jurisdiction of the CNMI Division of Fish and Wildlife (DFW): <http://www.dfw.gov.mp/Enforcement/Fishing%20Regulations.html>. The DFW enforcement section reviews all live imports, and often, dead, frozen imports. The DFW currently uses an Australian Quarantine and Inspection Service list to determine which species of fish to automatically admit and which to send for a more formal review by DFW biologists (S. McKagan, National Marine Fisheries Service, oral commun., 2010).

Federated States of Micronesia

The FSM National Government laws are summarized in the FSM Legal Information System: <http://www.fsmlaw.org/fsm/index.htm>. The FSM maintains official Plant & Animal Quarantine Regulations, which were not obtained during the course of this project. According to FSM law (Title 19, Chapter 4, Section 19.414), "No person shall export or import any live fish or viable fish eggs without the Director's prior written permission."

Republic of Palau and Other Micronesian Islands

Codified laws for Palau regarding importation, transport, distribution, or possession of nonindigenous aquatic species were not obtained. Likewise, no effort was made to obtain administrative rules and policies for those Micronesian islands or island groups with no significant freshwater resources.

Risk Assessment and Analysis

Introduction

Risk assessments are useful for estimating the risks associated with introductions of nonindigenous species. For instance, a risk assessment can be used to predict the likelihood that a particular nonindigenous species, if introduced, may become established and to what degree it may be invasive or cause ecological or economic harm (Pheloung et al. 1999; Bomford 2003; Daehler et al. 2004; Kolar 2004; Nico et al. 2005; Bomford 2008; Fujisaki et al. 2009). A variety of risk assessment techniques exist. Some of these methods are largely qualitative in nature; for example, relying on scoring relative values for species traits such as 0 or 1 (absent or present), or 'low/medium/high' (Pheloung et al. 1999; Orr 2003; Alfaro et al. 2009). Some authors have argued for use of more quantitative approaches to reduce subjectivity, more precisely, to identify gaps in knowledge and provide ways to statistically express uncertainty and variability (NRC 2002; Hayes 2003; Lockwood et al. 2007). Both qualitative and quantitative estimations of species-specific risk of establishment success may aid in screening species by identifying species that could be excluded or removed from permitted (white) lists, as well as species that could be considered for addition to prohibited (black) lists (Kolar and Lodge 2001, 2002; Marchetti et al. 2004a, b; Fujisaki et al. 2009; Bomford et al. 2010).

Among the many oceanic islands and archipelagos of the tropical Pacific, Guam is second only to the Hawaiian Islands in the numbers of nonindigenous fish introductions and establishments (Maciolek 1984). Our initial objective was to develop a purely quantitative model of establishment success of freshwater fishes in Guam. However, the number of nonindigenous fishes documented in Guam ($n = 25$), although large for an island of Oceania, was inadequate to develop a model useful for predictive purposes. To improve the power of the modeling approach to assessing establishment probability, we included data on fishes introduced and established in Hawaii. At least 46 nonindigenous freshwater fish species or taxa are documented as being established in inland waters of the Hawaiian Islands; additional nonindigenous fishes have been introduced, but apparently never formed permanent reproducing populations (Maciolek 1984; Eldredge 1994; Fuller et al. 1999; Yamamoto and Tagawa 2000; Mundy 2005; Nico et al. 2005).

A wide array of life-history traits have been correlated with the establishment and invasiveness of nonindigenous species (Kolar and Lodge 2001, 2002; Marchetti et al. 2004a, b; Bomford 2008; Bomford et al. 2009; Bomford et al. 2010). Blackburn (2009) summarized species traits into three categories related to persistence of small populations. Those authors argued that establishment success should be positively correlated with propagule pressure and with traits related to the ability to cope with novel environments, and correlated in some way with traits related to population growth rate and Allee effects (i.e., the positive correlation between population density and per capita population growth rate). We developed a model of establishment success of nonindigenous fishes in Guam and Hawaii using a set of variables related to propagule pressure, prior establishment success on tropical islands, and species traits. This model may be useful in screening freshwater fishes imported into Guam, Hawaii and other Pacific islands, thereby reducing the probability of additional invasive species becoming established on individual islands and in this region.

Nonindigenous Fish Taxa Included in Estimation of Establishment Success

For this analysis, nonindigenous fish data for the island of Guam and the Hawaiian islands are combined. Both share similar physiographic and climatic features and are subjected to fish introductions through similar pathways.

A total of 80 different nonindigenous fish taxa representing 33 fish families have been introduced to Guam and the Hawaiian Islands; this total includes species or taxa that are established as well as others that were reported as having been introduced but are not known to have formed permanent reproducing populations (Table 21) (Maciolek 1984; Eldredge 1994; Nico and Fuller 1999; Eldredge 2000; Yamamoto and Tagawa 2000; Mundy 2005). The list is composed mostly of fish recognized as distinct species. In addition, the list also treats as single taxa certain groups of closely related fish (e.g., *Channa striata* and *C. maculatus*; pacus of the genus *Colossoma* and *Piaractus*). This conservative approach was taken because members within these particular groups are very similar in appearance and records of their occurrence in Hawaii or Guam may have been based on incorrect identifications (e.g., recognizing two or more species, when only one species was actually introduced). Of the 80 total nonindigenous fish taxa

reported, 70 are recorded from Hawaii and 25 from Guam; 15 nonindigenous fish species are common to both regions.

An established species was defined as any taxon known to have a self-sustaining wild population in either Hawaii or Guam. Included in this analysis are species that are restricted to fresh water, species found in brackish and fresh water (e.g., mangrove goby, *Mugilogobius cavifrons*), and species that occur in marine, brackish, and fresh water (e.g., Gulf killifish, *Fundulus grandis*). Thirteen species identifications were not known with certainty; for these taxa, variables used in the analysis were scored based on the species most likely to have been introduced as evidenced from other introductions (e.g., Maciolek 1984; Fuller et al. 1999; Eldredge 2000; Mundy 2005) or species presumed to share similar life-history and ecophysiological attributes.

Table 21. Status of nonindigenous freshwater fishes known to have been introduced into Hawaii and Guam since the late 1800s (status: 1 = established, defined as a self-sustaining, wild population; 0 = introduced, not known to be established; blank cells indicate species not known to have been introduced into that region). [Species not identified with certainty indicated by use of “cf.,” “?”, “sp ?” or “complex.” Thirteen such species of uncertain identification were included among the 80 species used in quantitative risk analysis. Shading indicates air-breathing species; fitted values for best model (#23) of establishment success in risk analysis (see text)]

^a Only one taxon (*Channa* spp.) was used in risk analysis models since this is a functional guild and we were unable to verify species identifications.

Variables Used in Statistical Analysis

Many researchers have attempted to identify and describe the suite of characteristics important in determining the success and potential effects of invasive species (Moyle and Light 1996a, b; Kolar and Lodge 2001; 2002; Marchetti et al. 2004a, b; García-Berthou 2007; Hayes and Barry 2008; Bomford et al. 2009; Fujisaki et al. 2009; Bomford et al. 2010). Previous studies have suggested, for example, that many of the more successful fish invaders have the ability to reproduce rapidly, have a broad native distribution, and are habitat or diet generalists (Lodge 1993; Moyle and Light 1996a, b; Ricciardi and Rasmussen 1998). However, successful invasion also depends on the physical and biological characteristics of the receiving environment, given that some habitats appear to be more susceptible to invasion than others (Lodge 1993). Moreover, whether an introduction occurs and eventually results in establishment is heavily influenced by the types and availability of pathways and the corresponding number of individuals in the pathway that are then released into the region where they are not native; that is, propagule pressure (Lockwood et al. 2005; Wilson et al. 2009; Pyšek et al. 2010).

Based on previous studies of invasion success and our knowledge of many of the introduced fishes involved, a total of 15 different parameters (one dependent and 14 independent variables) were selected for analysis of the Hawaii and Guam nonindigenous fish dataset (Table 22). The dependent variable represented the establishment status of introduced taxa. Thirteen of the independent variables were as follows: family (taxonomic affinity); history (prior invasion success, based on the number of tropical islands or tropical island groups in which the taxon was introduced and became established); propagule pressure in the form of pathways of introduction; retail price; maximum body length; longevity; adult diet; trophic index; reproductive guild; spawning habitat; climate profile (based on the climate in a species' native range); salinity tolerance; and hypoxia tolerance). An additional independent parameter (variable 14) was developed that combined climate profile, salinity tolerance and hypoxia tolerance. These variables were scored based on (1) a survey of published literature; (2) other scientific and technical data, such as Fishbase® (Froese and Pauly 2011); (3) our own knowledge; or (4) closely related or similar species in cases where little information is available.

Certain types of biological variables are difficult to quantify precisely. Moreover, the ecology and life histories of many introduced fish species are not fully known; thus precluding assignment of exact values to some of the variables for many of the species in this analysis. Consequently, we relied primarily on categorical rather than continuous independent variables used in the predictive models. Each of the variables is summarized in Table 22 and described in greater detail in the following paragraphs.

Table 22. Variables pertaining to establishment success of nonindigenous fishes introduced to the Hawaiian Islands and Guam for use in risk analysis modeling. [Variables omitted from final model selections indicated by shading (see text)]

Parameter	Description	States
Dependent variable	Status on Hawaii and/or Guam (established versus introduced but not established)	Two (0=not established; 1=established)
Independent variable	Taxonomic affinity	
	1. Family	34 different fish families
Independent variable	Distributional attributes and history of introductions	
	2. History (prior invasion success, i.e., number of tropical islands/island groups where taxon was introduced and became established.	0-43
Independent variable	Propagule pressure	
	3. Pathways	Twelve (1=raised in aquaculture facilities/ponds; 2= in aquarium trade; 3=stocked as ornamental; 4=biological control; 5=stocked as food fish; 6=stocked as sport or game fish; 7=stocked as prey base; 8=used as bait; 9=present in live food markets; 10=ballast water; 11=contaminant with stocking of another species; 12=ceremonial release)
	4. Retail price (per individual fish in aquarium, aquaculture trade, or live food market)	Four (1=over \$50; 2=\$21-\$50; 3=\$5-\$20; 4=less than \$5)
Independent variable	Life-history attributes	
	5. Length (maximum adult size)	Four (1=small [<10 cm]; 2=medium [10-29 cm]; 3=large [30-100 cm]; 4=very large [>100 cm])
	6. Longevity	Three (1=short, less than 5 yr; 2=moderate, >5 to 10 yr; 3=long, >10 yr)
	7. Diet (trophic guild; adult diet only)	Seven (1=detrivore/algivore; 2=herbivore; 3=planktivore; 4=omnivore; 5=invertivore; 6=invertivore/piscivore; 7=piscivore/top predator)
	8. Trophic level index	2.0-4.5; values derived from FishBase

Table 22. Variables pertaining to establishment success of nonindigenous fishes introduced to the Hawaiian Islands and Guam for use in risk analysis modeling. [Variables omitted from final model selections indicated by shading (see text)]

Parameter	Description	States
	9. Reproductive guild (level of parental care, fecundity, and egg size)	Three (1=non-guarders, high fecundity, small egg; 2=guarder, medium fecundity and egg size; 3=bearer, low fecundity and large egg size ^a)
	10. Spawning habitat	Five (1=lotic; 2=lentic; 3=coastal/estuarine ^b ; 4=lotic and lentic; 5=lotic, lentic and coastal/estuarine)
Independent variable	Physiological tolerance	
	11. Climate profile (climate regions included in native geographic distribution)	Six (1=temperate; 2=subtropical; 3=tropical; 4=temperate/subtropical; 5=subtropical/tropical; 6=all)
	12. Salinity tolerance	Three (1=intolerant to salinity <1 ppm [stenohaline]; 2=moderately tolerant, >1 and <10 ppm; very tolerant, >10 ppm [euryhaline])
	13. Hypoxia tolerance	Three (1=intolerant of low O ₂ ; 2=moderately tolerant; 3=tolerant, air breathing)
	14. Environmental tolerance	3-11 (a compilation of the scores from variables 11-13 above)

^a Includes live-bearing species (e.g., *Poecilia*), species that carry eggs externally (e.g., *Oryzias*, *Ancistrus*), and species that brood eggs internally in their orobranchial cavity (e.g., *Oreochromis*, *Melanochromis*).

^b Includes species that spawn offshore or on reefs (e.g., *Anguilla marmorata*).

1. *Family (taxonomic affinity)*. This variable was included to account for effects of phylogenetic relationships among species (Kolar and Lodge 2002; Alcaraz et al. 2005; Ruesink 2005; Bomford et al. 2009; Bomford et al. 2010). Fish family designations were based on Eschmeyer (2011).

2. *History (prior invasion success)*. This variable is a measure of prior invasion success, defined in this study as the total number of tropical islands or island groups (excluding the Hawaiian Islands and Guam) where a species or taxon was introduced and became established. Prior invasion success is a parameter that has been identified as being positively correlated with the probability that a species will become established when introduced into a new area (Daehler and Strong 1993; Kolar and Lodge 2002; Marchetti et al. 2004a, b; Hayes and Barry 2008; Bomford et al. 2009; 2010). Data pertaining to the establishment of different fish taxa were based on review of published literature (important sources included Maciolek 1984; Welcomme 1988; Lever 1996; Eldredge 2000; Froese and Pauly 2000, 2011), consultation with subject-matter experts, and on original field work. Because information was limited to a taxon's history of establishment on tropical islands in the Pacific Ocean and other tropical regions of the world, this variable incorporates a form of climate matching (see Bomford et al. 2009; 2010).

3. *Pathways*. Principal pathways for introductions of freshwater fishes include aquaculture (Welcomme 1988; Fuller et al. 1999; De Silva et al. 2004), stocking of game fish (Fuller et al. 1999), releases of aquarium species (Courtenay and Stauffer 1990; Fuller et al. 1999; Rahel 2002; Padilla and Williams 2004), biocontrol of insects such as mosquitos, other fish species, or vegetation (Nelson and Eldredge 1991; Fuller et al. 1999), the live food industry (Fuller et al. 1999; Rixon et al. 2005), releases of bait fish (LoVullo and Stauffer 1993; Fuller et al. 1999), and ship ballast water (Ricciardi and MacIsaac 2000; Yamamoto and Tagawa 2000).

We distinguished 13 different pathway categories: (1) raised in aquaculture facilities or ponds; (2) used in the aquarium trade; (3) stocked for ornamental display; (4) used as biological control; (5) stocked as food fish; (6) stocked as sport or game fish; (7) stocked as forage for other fish; (8) stocked for conservation purposes to augment native populations or to establish new ones; (9) used as bait; (10) present in live food markets; (11) transported in ballast water; (12) contaminant unintentionally stocked with or instead of another species; and (13) used as part of religious or ethnic ceremonial release. It is worth noting that releases or stocking from research-related activities were not incorporated into the model but do occur.

The number and combinations of different pathways in which each taxon is known to have been introduced, either in Micronesia or any other part of the world, was determined based on the literature and other available information. Each pathway category was assigned a score of “1” and the number of pathways for each taxon was summed. Resulting values hypothetically could range anywhere from 1 to 13 and the summed value for each taxon was used for modeling. Frequency distributions by pathway for the data set of species included is depicted in Fig. 13.

We predicted that taxa with a higher pathway score would have a higher probability of establishment based on an *a priori* assumption that such taxa are more likely to have been introduced on multiple occasions or in large numbers over an extended time, reflecting high propagule pressure (Kolar and Lodge 2001; Lockwood et al. 2005; Ruesink 2005; Colautti et al. 2006; Duggan et al. 2006; Gertzen et al. 2008).

4. *Retail price*. This variable is the U.S. dollar value per individual fish in the aquarium fish trade, the aquaculture trade, or the live food market. We initially selected retail prices as a measure of propagule pressure, with the assumption that lower-priced animals would result in greater numbers of individuals in one or more pathways. However, it was not possible to obtain complete, accurate, or consistent retail pricing information for many of the fish species and the variable was later omitted from further consideration.

5. *Length (maximum adult size)*. This variable is a measure of the approximate maximum length that adult individuals achieve under good growth and survival conditions in the wild (Marchetti et al. 2004a). We elected to use only four different categories (mutually exclusive length size ranges), because (1) published and unpublished information on the size of fish in wild are often poorly documented, (2) some size data are probably associated with fish reared in captivity, and (3) methods of measurement vary (e.g., total length as opposed to standard length or fork length) and in some cases, are not reported. Information on maximum body length was obtained primarily from the online database FishBase® (Froese and Pauly 2011), Page and Burr (1991), and Fuller et al. (1999). Frequency distributions of the number of taxa in each size class are presented in Fig. 14.

According to Crawley (1986), species with a higher intrinsic rate of increase, r , are more likely to become established. Ruesink (2005) suggested that large species of fish may have a relatively low probability of establishment success based on the r - K continuum. However,

Crawley (1986) also suggested the effect of body size on establishment success might depend on the type of competition faced by an introduced species. Additionally, species held as pets that attain a large size may be more likely to be released by owners once the animals outgrow their aquaria (Gertzen et al. 2008), thereby resulting in higher propagule pressure and likelihood of establishment in the wild. Maximum length was not included in the best model of establishment success reported by Kolar and Lodge (2001) or by Marchetti et al. (2004b). However, maximum length was included in the best model of establishment success reported by Marchetti et al. (2004a), although slopes for maximum length were not reported in that study.

6. *Longevity*. Initially we categorically scored species for longevity. This variable was eventually omitted for three reasons: (1) maximum lifespans reported in the literature are highly variable and some values are suspect (e.g., for many species maximum age is derived from information on live fish maintained in captivity although it is widely known that captive individuals often live much longer than those in the wild); (2) for many species, this information is simply unavailable; and (3) general maximum adult length (variable 5) and longevity are assumed to be closely correlated. Frequency distributions of number of taxa in each lifespan category are presented in Fig. 14.

7. *Diet (trophic guild)*. This variable was a descriptor of the diets of adult fish. We recognized seven different diet categories or trophic guilds, ranging from detritivore/algivore (category 1) to top carnivore (category 7). The classification was based heavily on qualitative and quantitative information available in FishBase® (Froese and Pauly 2011), Goldstein and Simon (1999), and personal knowledge of the authors. For species for which there was little or nothing published, classification was based on information published for closely related or similar species. Frequency distributions showing the number of taxa in each trophic category are presented in Fig. 15.

Based on an analysis of terrestrial animals (mainly insects) in Europe, Crawley (1986) stated that herbivores are more likely to become established than carnivores or detritivores because herbivores experience less competition. In assessing fish invasions in California, Moyle and Light (1996a) also suggested that trophic status is an important predictor of establishment success, but they argued that piscivores and detritivores/omnivores appeared to have greater establishment success, with the caveat that such an outcome was most likely in aquatic habitats where there were low levels of human disturbance. Ruesink (2005) found that establishment success was higher for omnivorous fishes, which is consistent with the hypothesis that generalists are particularly well suited to invading new areas (Blackburn et al. 2009). However, Moyle and Marchetti (2006) reported finding no evidence of such relationships. Kolar and Lodge (2002) created a complex index of diet by combining diet breadth and foraging habitat, and found their resulting index to be correlated with establishment success.

8. *Trophic level index*. Trophic levels among fishes generally range from 2 for herbivores and detritivores to 4.5 or higher for certain top predators (Froese and Pauly 2000, 2011). We initially considered using a continuous trophic variable based on a quantitative index from FishBase® that combines diet composition with the trophic level of food items consumed (see http://www.fishbase.org/manual/English/fishbasethe_ecology_table.htm). We subsequently determined that the Fishbase® trophic level index values trended positively with our categorical classification (Fig. 16). Based on that comparison, we decided to omit the trophic level index from our models and, for fish trophic information, only the diet or trophic guild categorical variable (variable 7) was used in model analyses and to estimate separate slopes for each taxon.

9. *Reproductive guild (level of parental care, fecundity, and egg size)*. We recognized three general reproductive guilds for introduced fish, with each of the categories representing important life-history characteristics that tend to be negatively correlated; for example, the level of parental care compared to the number and size of eggs. Reproductive guild or parental care was examined as a factor of invasive success in fishes by Kolar and Lodge (2002) and Marchetti et al. (2004a, b). Annual fecundity and egg size were also included in the variable pool used by Kolar and Lodge (2002). We considered these variables to be closely related, and combined them into a single categorical variable based in part on Goldstein and Simon (1999) and on personal knowledge. Ruesink (2005) suggested that species with high fecundity may have higher establishment success. Moyle and Marchetti (2006) noted that species with intermediate or mixed life history characteristics are most likely to be successful invaders. We predicted that species with an intermediate score of our categorical variable would have highest establishment success. Frequency distributions of number of taxa in each reproductive guild are presented in Fig. 15.

10. *Spawning habitat*. We recognized five categories to distinguish the range of habitats used by island fishes for spawning. The ecological variable provides information on habitat type and distinguishes between species requiring a certain type of environment (e.g., lentic versus lotic) versus those species that are more flexible in their spawning requirements (e.g., lentic and lotic). Among the different types of habitats used by fish, it was assumed that spawning habitat would likely be the most important in determining establishment success. In the absence of appropriate spawning habitat, an introduced species might briefly survive and grow, but ultimately would fail to reproduce or persist. Marchetti and Moyle (2001) found that flow regime affected population persistence of nonindigenous fishes. Frequency distributions based on number of taxa in each spawning habitat category are presented in Fig. 17.

11. *Climate profile*. This variable is an indication of the types and numbers of different climate regions included in the species' native geographic range. We recognized six categories that provided information on the type of climate and also distinguished between species whose native range encompassed one or a few climate regions from those whose native range was much more widespread in terms of latitude and climate. Assignment of the different fish species to particular categories was based on information provided in the scientific literature, other sources (Froese and Pauly 2011), and our own observations and research. Climate profiles have been used in various species distribution models, including some (e.g., climate matching) intended for predicting the potential range of a nonindigenous species based on similarity to climates found in the species' native range (Peterson 2003; Franklin 2009). Frequency distributions of number of taxa in each size climate category are presented in Fig. 17.

The presence, absence, and relative abundance of a species in a climatic region are affected by their tolerance of, or preference for, ambient temperature. A general assumption is that climate is closely correlated with particular temperature ranges, and therefore, approximates a species' relative temperature tolerance. Those species that have broad thermal tolerance are generally considered to have a greater probability of establishment success (Kolar and Lodge 2002; Moyle and Marchetti 2006; Blackburn et al. 2009). Rather than attempt to estimate the range of temperatures suitable for survival and reproduction based on limited or nonexistent data for many species, we used a categorical classification of climate in the species' native range as a surrogate (i.e., distribution in temperate, subtropical, and/or tropical regions). This represents a qualitative form of climate matching used in some studies of establishment success (Bomford et

al. 2009; Fujisaki et al. 2009; Bomford et al. 2010). We predicted that tropical and subtropical species were most likely to establish successfully in Guam and Hawaii.

12. *Salinity tolerance*. As with temperature, a wide zone of salinity tolerance may increase probability of establishment success (Kolar and Lodge 2002; Moyle and Marchetti 2006; Blackburn et al. 2009). We used a categorical variable with three levels and predicted *a priori* that species tolerant to high salinities (euryhaline) would have highest establishment success. The classification scheme and assignment of the different fish species to particular categories was based on the scientific literature, other sources (e.g., FishBase®; Froese and Pauly 2011), personal knowledge, or inference from what is known about similar species. Species identified as intolerant to salinity (stenohaline) were predicted to have lowest establishment success. Frequency distributions of number of taxa in each salinity tolerance category are presented in Fig. 18.

13. *Hypoxia tolerance*. Hypoxia tolerance refers to the ability of a species to inhabit water with low dissolved oxygen levels. As with temperature and salinity, we created a categorical variable having three levels. The classification scheme and assignment of the different fish species to particular categories was based on the scientific literature, other sources (e.g., FishBase®; Froese and Pauly 2011), personal knowledge, or inference from what is known about similar species. Species that are very tolerant of low dissolved oxygen levels (i.e., air breathers and those capable of aquatic surface respiration) were predicted *a priori* to have the highest establishment success. Frequency distributions of the number of taxa in each hypoxia tolerance category are presented in Fig. 18.

14. *Environmental tolerance (climate profile + salinity tolerance + hypoxia tolerance)*. As an alternative to using three independent environmental tolerance variables, we combined climate profile (an approximation of temperature tolerance), salinity tolerance, and hypoxia tolerance. Their composite scores produced a new single variable that we referred to as “environmental tolerance.” For example, a temperate species that cannot tolerate salinity or low dissolved oxygen levels received an environmental tolerance score of 3 (equaling 1+1+1 for each factor) whereas a tropical species tolerant of high salinities and low dissolved oxygen levels received a physiological tolerance score of 9 (equaling 3+3+3). This variable was treated as an ordinal number to reduce the number of parameters in the most general model and to facilitate model convergence.

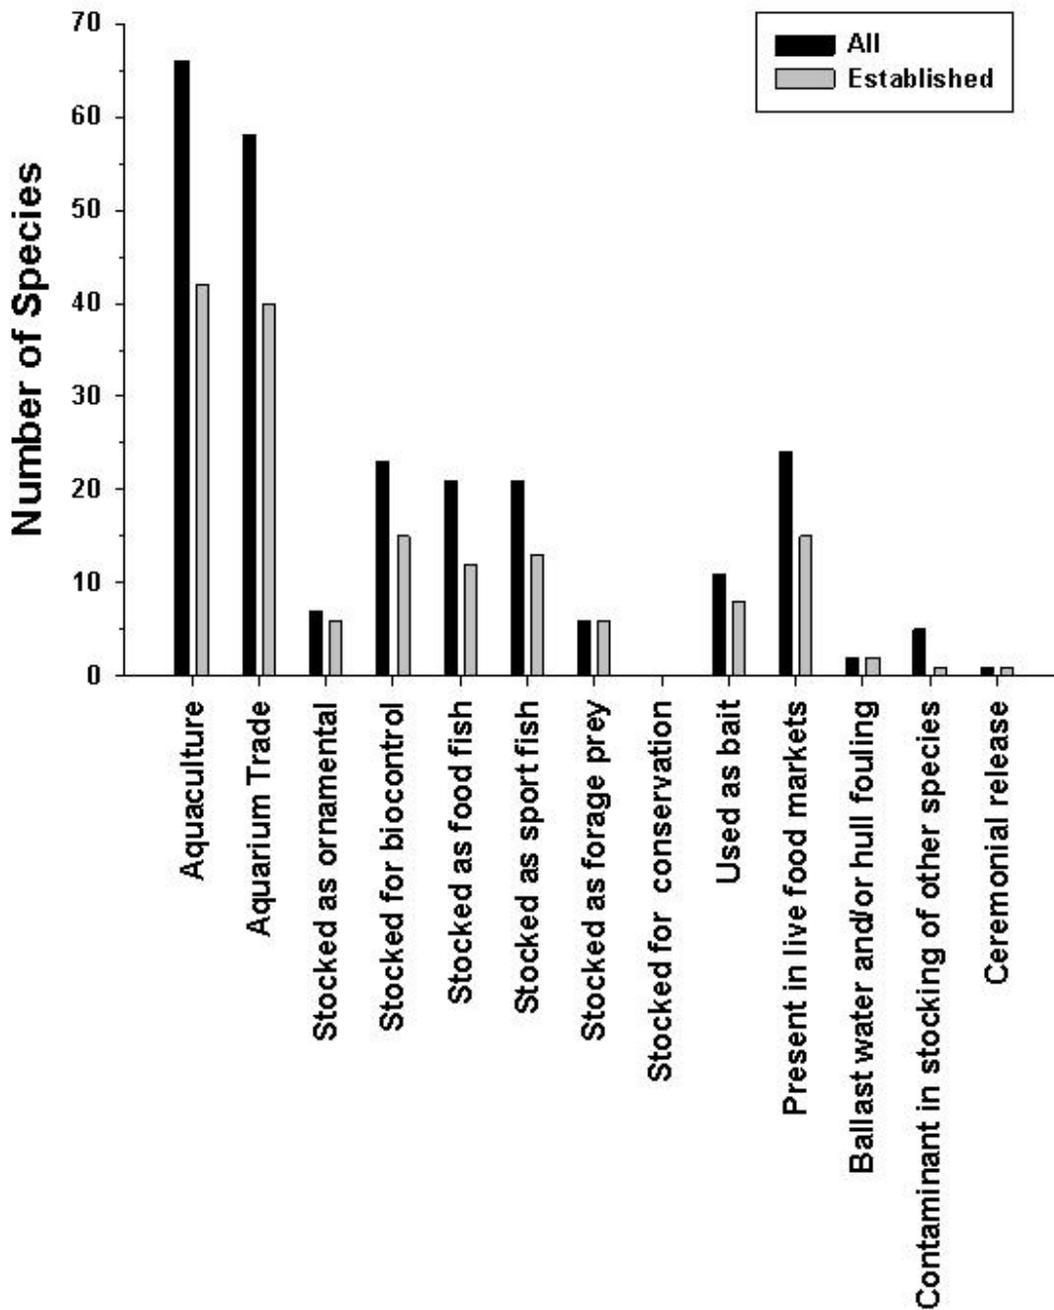

Figure 13. Number of nonindigenous freshwater fish species or taxa by known or presumed pathway of introduction in Hawaii and Guam. All = failed plus successful introductions (i.e., includes both established and non-established, nonindigenous fish species or taxa); established = only those known to have reproducing populations (graph based on data matrix used in model analyses and sources of data indicated in text).

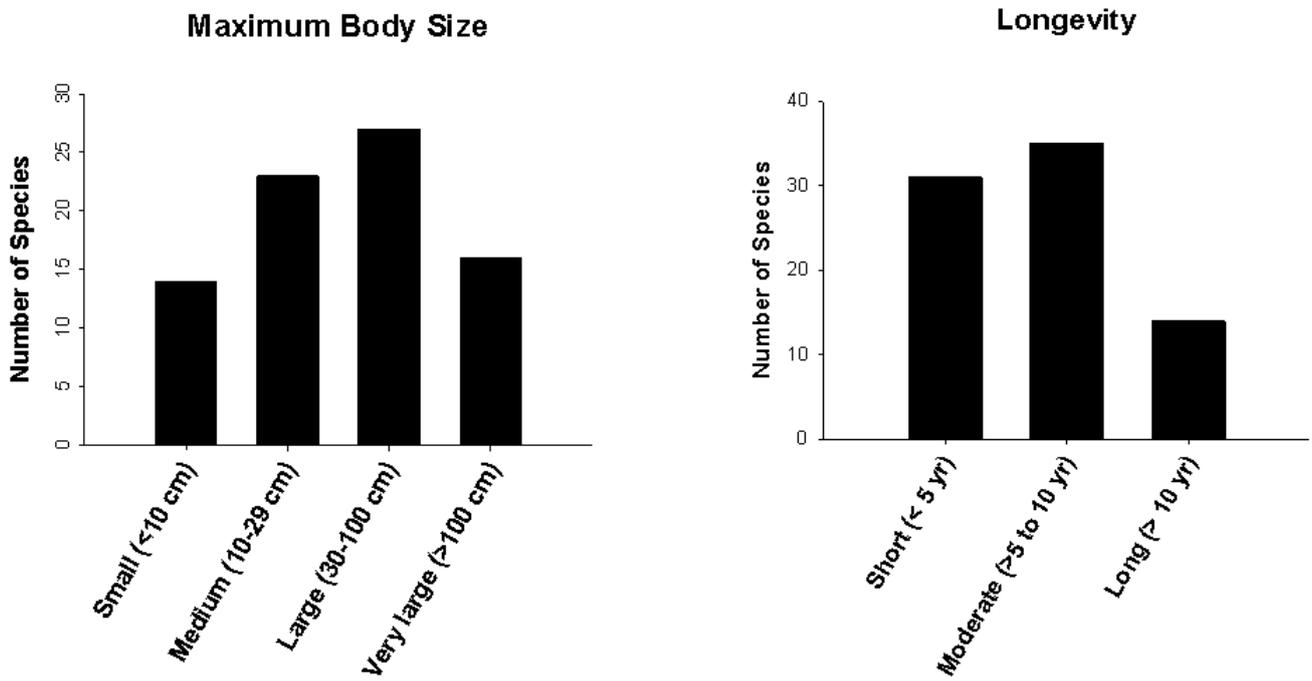

Figure 14. Frequency distribution by body size category and longevity of fishes scored for risk analysis (longevity was omitted from modeling; see text).

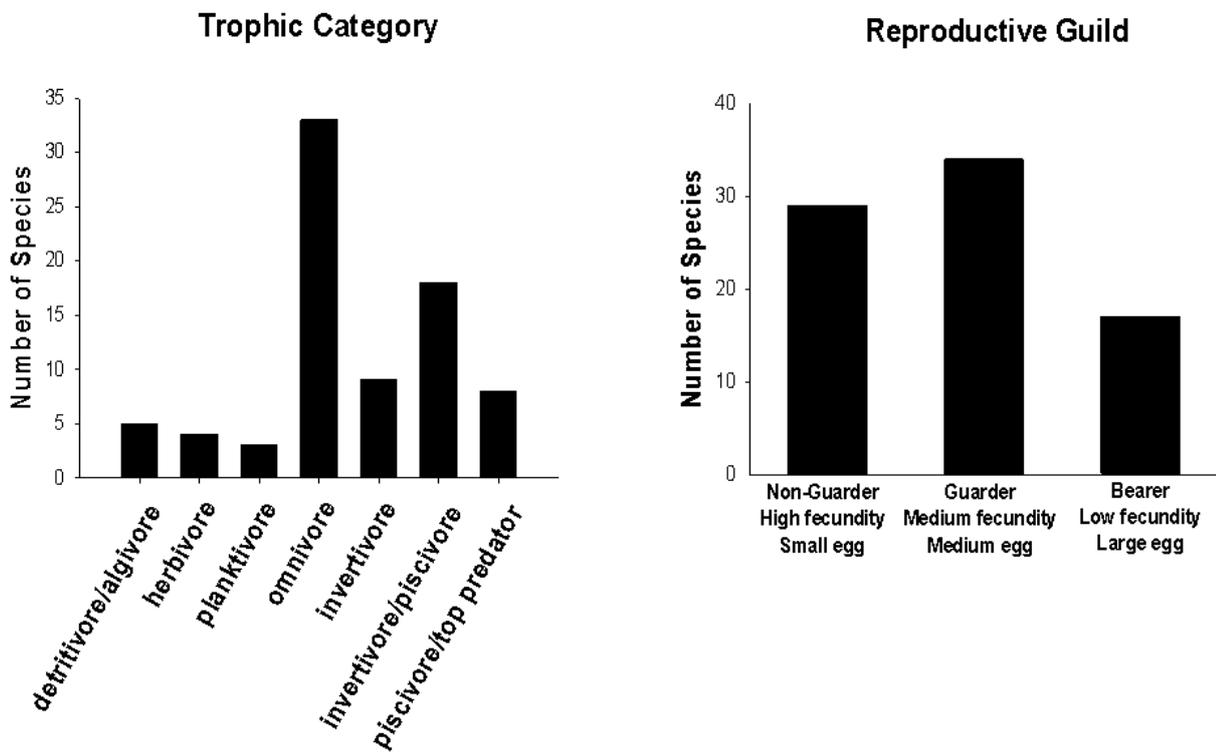

Figure 15. Frequency distribution by trophic category and reproductive guild of fishes scored for risk analysis.

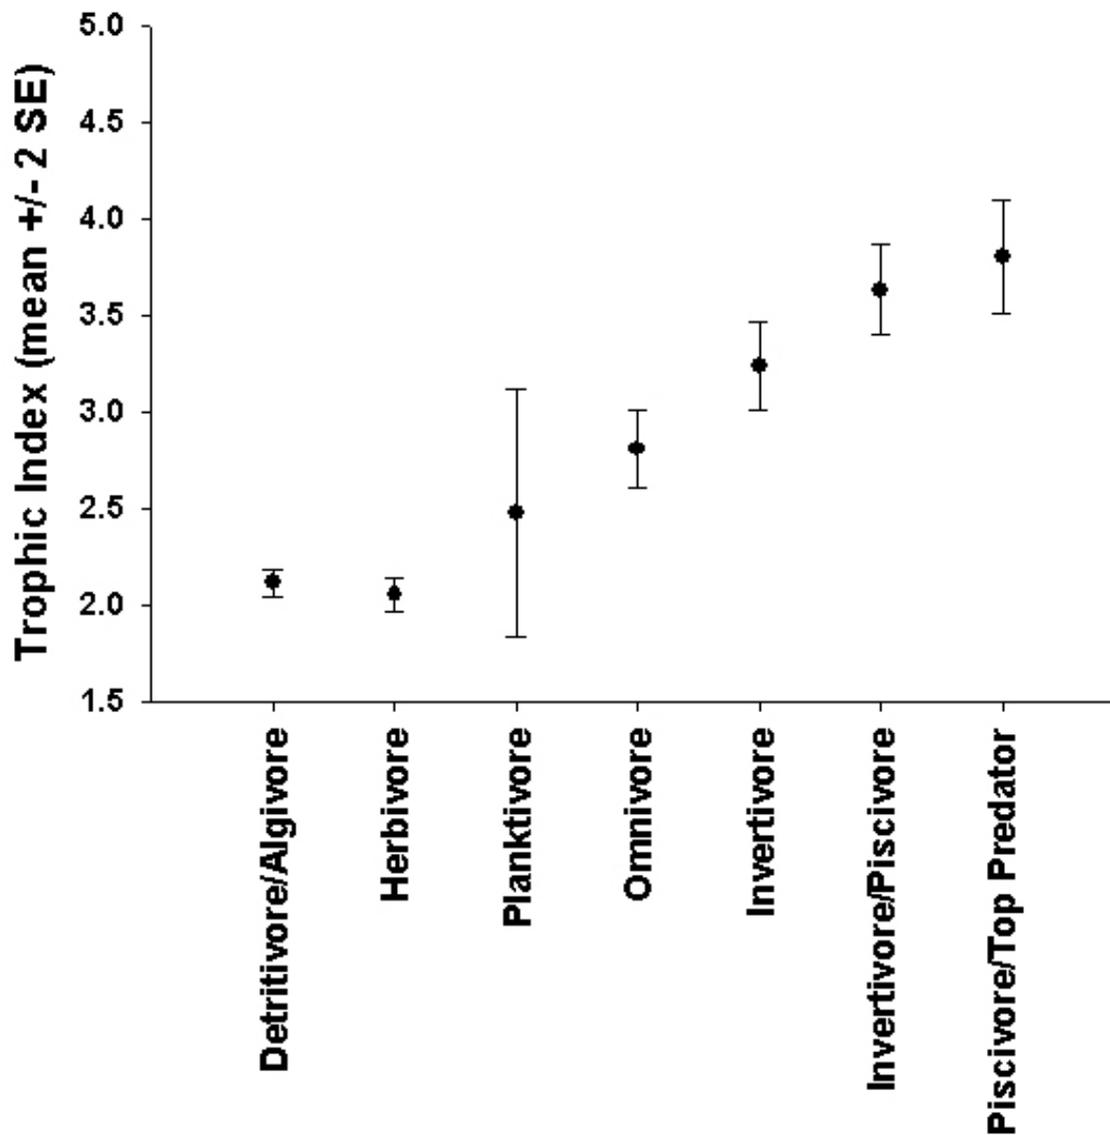

Figure 16. Relationship between trophic categories used in risk analysis versus trophic level index values appearing in species accounts of FishBase® (Froese and Pauly 2011). Mean +/-2Standard Error (SE) of species used in risk analysis matrix (for a few taxa not identified to species, mean trophic index from FishBase® was calculated as mean from congeners or family for available values).

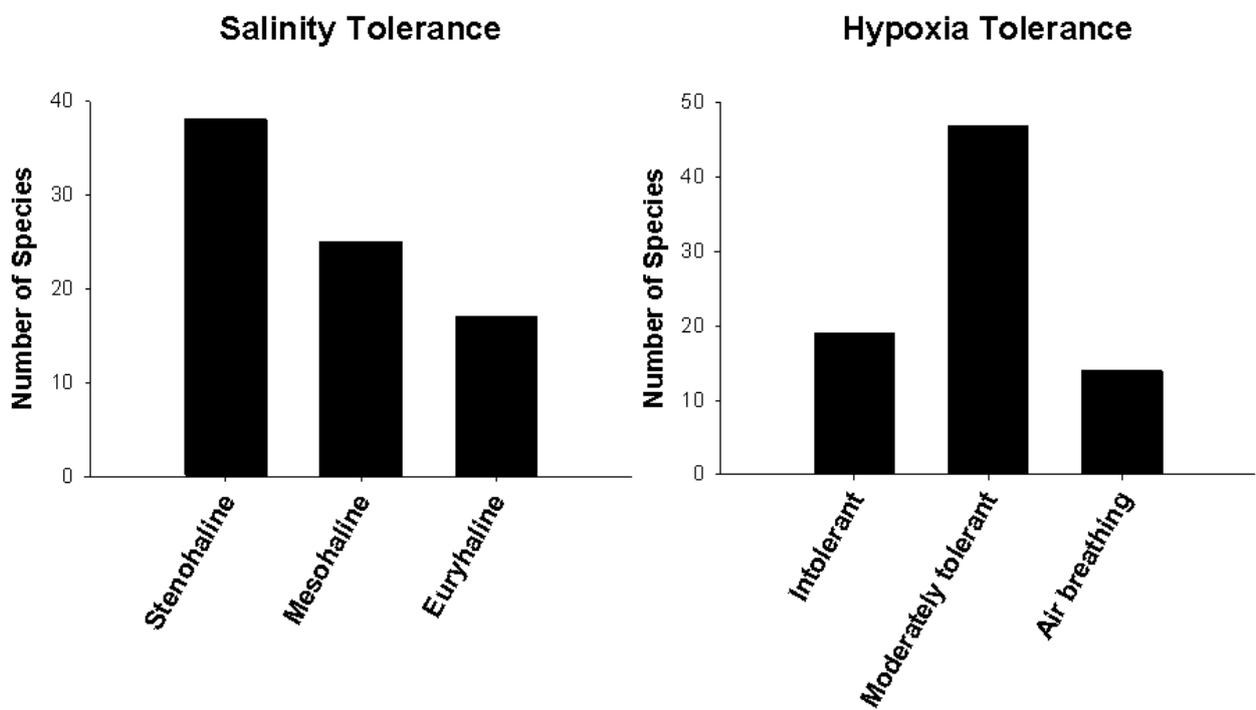

Figure 18. Frequency distribution by physiological tolerance categories of fishes scored for risk analysis.

Model Set

Establishment success was a binary response variable defined as equaling 1 for nonindigenous fish species with a self-sustaining reproducing population in the wild in Hawaii or Guam, and equaling 0 for nonindigenous fish species introduced but not known to be established in the wild in those two areas. We used logistic regression for our analysis because of the binary nature of our response variable (Agresti 2002). Our use of logistic regression followed methods of several previous authors who have predicted establishment success of nonindigenous species (Marchetti et al. 2004a, b; Ruesink 2005; Ribeiro et al. 2008; Bomford et al. 2009; Fujisaki et al. 2009; Bomford et al. 2010). The data matrix used in our analysis of establishment success is provided in Appendix 2.

We created a set of 21 competing *a priori* logistic regression models each representing a different hypothesis regarding establishment success (Table 23). This model set included our most general model, which contained eight independent variables. We included the composite variable (“environmental tolerance”) created by combining climate profile, salinity tolerance, and hypoxia tolerance, to achieve convergence of the most general model. The remaining 20 models in the set each included a unique subset of the independent variables in the most general model. Most of the competing models were created by reviewing the literature. Not all models from the literature could be reproduced exactly using our variable set. In such cases, we approximated published models as closely as possible with the variables in our set. A few additional competing models were added based on our hypotheses of possible combinations of variables that might have predictive power.

Each of the 21 *a priori* models in our model set were ranked using Akaike’s Information Criterion, AIC_c , adjusted for small sample size (Burnham and Anderson 2002). The best model has the lowest AIC_c . We calculated Akaike weights, w_i , to evaluate support for each model and for individual variables. These Akaike weights sum to 1.0, and indicate relative support for a given model. Climate, salinity and hypoxia were added to the best model in an exploratory *post-hoc* fashion by creating seven additional models to represent every possible combination of these three physiological variables. Summary output for all of the models and associated R code is available from the authors upon request.

Table 23. Set of competing models of establishment success for nonindigenous fishes introduced into Hawaii and Guam since the late 1800s and the hypotheses that each model represents. [The first 21 models were created *a priori*. Models 22-28 were *a posteriori* variations of the *a priori* model with the most support. Model 29 was an *a posteriori* version of the best model among models 1 – 28 in which the number of hypoxia tolerance scores were reduced from 3 to 2]

Model No.	Model name	Hypothesis	Reference
1	Family + history + pathways + length + diet + reproductive guild + spawning habitat + environmental tolerance	Our most general model	Present study

Model of Observations

To specify differences in establishment among species, we formulated the probability of establishment (on the logit scale) as a linear combination of Random and fixed covariates:

$$\text{logit}(p_{it}) = \beta' x_{sp} + \beta_3 \text{var}2_{sp} + \beta_4 \text{var}3_{sp} + \beta_5 \text{var}5_{sp} + \dots \dots + \beta_{20} \text{var}8_{sp}$$

where β' is a Random family effect and x_{sp} is the family for a given species, sp , (Bomford et al. 2009). Two parameters are estimated for this Random effect: a mean and a standard deviation. All other variables in the model are species-level fixed effects. The variable var2 represents number of tropical islands or island groups for a given species (sp), β_3 is the slope for that variable, var3 represents human-use score, β_4 is the slope for that variable, var5 is a binary, dummy variable used to codify one level of our maximum length variable, β_5 is the slope for that variable, var8 represents the composite environmental tolerance, and β_{20} is the slope for that variable. Model parameters were estimated using the “lmer” function for linear mixed models (Gelman and Hill 2007) in Program R (R Development Core Team 2004). Each of the 21 *a priori* competing models included a Random family effect. When no Random effect is supported by the data the lmer function estimates a constant intercept with a variance of zero, essentially removing the Random family effect from the model.

After identification of the best model, we assessed fit of that model by estimating its error rate (Gelman and Hill 2007). The error rate is the proportion of observations in the data set for which the fitted value > 0.5 and species status in the study area = 0, or fitted value < 0.5 and status = 1. We compared the error rate of the best model to the error rate of the null model. The null model is simply the proportion of observations in the data set for which species status is one. The error rate of the null model is 1; that is, the proportion of observations in the data set with a species status of one. Ideally, the error rate of the best model is low and substantially lower than the error rate of the null model.

We also assessed fit of the most general model by creating 1,000 simulated data sets based on that model (Gelman and Hill 2007). We used the proportion of observations in the data set with a species status of 0 as our test statistic and compared the value of that test statistic to the same proportion for each of the 1,000 simulated data sets. A two-sided p -value was used to estimate whether the actual test statistic differed significantly from values obtained by means of simulation.

Results

Table 24 includes summary information on the numbers of introduced and established nonindigenous fishes on Guam and the Hawaiian Islands, as well as selected information on the variable “history,” a measure of their invasion success (establishment) on other tropical islands. The 80 nonindigenous fish taxa included in this analysis include only those species and taxa known to have been introduced into inland waters of Guam, Hawaii, or both, regardless of whether their introduction resulted in establishment (i.e., 49 taxa established and 31 not established).

Many of the nonindigenous fish taxa introduced to Guam or Hawaii (42 of the 80 taxa; 52.5%) are considered established on other tropical islands or island groups. However, most (72 taxa, 90%) of the 80 Guam/Hawaii nonindigenous taxa are either not established on other tropical islands or are established on relatively few islands (eight or fewer) (Fig. 19). A few species are widely established among different tropical islands or island groups. The most extreme examples include (1) Mozambique tilapia, *Oreochromis mossambicus*, recorded as established in as many as 43 other tropical islands or island groups; and (2) three different members of the family Poeciliidae: the guppy *Poecilia reticulata*, established in 30 other tropical islands or island groups; the mosquitofish *Gambusia affinis/holbrooki*, established in 23 other tropical islands or island groups; and the swordtail *Xiphophorus hellerii*, established in 15 other tropical islands or island groups. All four of these taxa are also established in Guam and Hawaii.

Of the 80 nonindigenous fish taxa, 26 are established both in Hawaii or Guam and on at least one other tropical island. Among those 38 species not established on any other tropical islands, 20 (51%) are documented as established in Hawaii or Guam. Twenty-two of the 23 species (96%) introduced into Hawaii or Guam and established on at least three other islands or island groups also are established in Hawaii or Guam. *Osphronemus goramy* was established in seven other tropical islands or island groups, but did not become established after being introduced into Hawaii.

The 80 nonindigenous fish taxa (including grouped forms) in our analysis represented 30 families (Table 21). Family Cichlidae was represented by the most species (18), followed by Poeciliidae (8), Cyprinidae (7), Centrarchidae (4), Loricariidae (4), and Salmonidae (4). Of the 30 total families, 22 (73%) were represented by only one species. Inclusion of families with only one species does not present a problem when using a Random family effect (Gelman and Hill 2007). Overall, 50 of 81 (62%) introduced species were considered established. For the purpose of model simulation, the two species of *Channa* were treated as one taxon (i.e., *Channa maculata* on Hawaii, *C. striata* on Guam, neither identification of which was verified). Because of continued taxonomic confusion and problems in positive identification, all members of certain other genera (e.g., *Hypostomus*) were also treated as one taxon even though records could actually have been based on more than one member of that group.

The number of species introduced through means of each of the 12 pathways described earlier (and the percentage that became established) was as follows: raised in aquaculture facilities/ponds, 64 (63%); used in the aquarium trade, 58 (68%); stocked as ornamental, 7 (86%); biological control, 22 (64%); stocked or transported as food fish, 20 (55%); stocked as sport or game fish, 20 (60%); stocked as prey base (forage), 6 (20%); used as bait, 11 (73%); present in live food markets, 23 (61%); transported in ballast water, 2 (100%); contaminant with other stocking, 5 (20%); and used for ceremonial release, 1 (100%) (Fig. 13). We did not score any species as having been introduced for conservation purposes; although *Kuhlia rupestris* has been stocked in Australia to restore populations (Hutchison et al. 2002); we did not score it as such because its introduction to Hawaii would not have been for this reason.

The best model (#23) of establishment probability included a Random family effect with a nonzero standard deviation ($SD = 2.61$), an effect of history (i.e., prior invasion success on tropical islands or island groups), and an effect of hypoxia tolerance (Table 25). This model had substantial support (Akaike weight = 0.59, evidence ratio = $w_{25}/w_{27} = 6.4$). No other model had an Akaike weight > 0.09. The second, third, and fourth best models were the only other models with an Akaike weight > 0.05, and these three models were minor variations of our best model.

Effect of history variable in our best model had a positive slope, as expected ($\hat{\beta}_{\text{history}} = 0.45$, $\hat{SE} = 0.19$), suggesting establishment probability in Hawaii and Guam was higher for species established on a large number of islands or islands groups other than Hawaii and Guam. According to our best model, air-breathing fishes (hypoxia score = 3) were most likely to become established ($\hat{\beta}_{\text{hypoxia } 3} = 2.36$, $\hat{SE} = 1.71$). Fourteen air-breathing species were included in our study, and 11 of these species (79%) are established (Table 21).

Point estimates for the Random family effect in our best model ranged from -3.48 to 3.76 (Table 26). Of the nine families represented by ≥ 2 species, Cichlidae (3.76), Centrarchidae (2.54), and Poeciliidae (2.11) had the highest point estimates, representing high establishment probability. The families Osphronemidae (-3.48), Salmonidae (-1.76), and Anguillidae (-0.88) had the lowest point estimates, indicating low establishment probability.

We plotted probability of establishment based on our best model using a fixed intercept that incorporated the history variable as the x-axis (Fig. 20). Equations for each of the lines in Fig. 20 are as follows:

Species with hypoxia tolerance score of 1:

$$-0.2399136 + 0.4597635 * (\text{number of islands})$$

Species with hypoxia tolerance score of 2:

$$-0.2399136 + 0.4597635 * (\text{number of islands}) + (-2.562265)$$

Species with hypoxia tolerance score of 3:

$$-0.2399136 + 0.4597635 * (\text{number of islands}) + (2.355279)$$

Species that are intolerant of low dissolved-oxygen levels (hypoxia tolerance score of 1) had a 0.44 probability of becoming established if they were not established on any other tropical islands or island groups. The probability of establishment increased to 0.66 if these species were established on two other tropical islands or island groups. Species with a hypoxia tolerance score of 2 had only a 0.06 probability of becoming established if they were not established on any other tropical islands or island groups. Their probability of becoming established increased to 0.38 if they were established on 5 other tropical islands or island groups, and increased to 0.49 if they were established on 6 other tropical islands or island groups. Air-breathing species (hypoxia tolerance score of 3) had a 0.89 probability of becoming established if they were not established on any other tropical islands or island groups. Probability of establishment increased to 1.00 for all species as the number of tropical islands or island groups on which they were established elsewhere increased. We created one more *a posteriori* variant of our best model in which species with a hypoxia tolerance score of 1 or 2 were grouped and given a new hypoxia tolerance score of 1, while the hypoxia tolerance score for air-breathing species was changed from 3 to 2. However, that new model had only half as much support as the best model reported in Tables 25-26.

We also plotted estimated probability of establishment for individual fish families represented by more than 3 species based on our best model (Fig. 21). Species in the family Cichlidae had a 0.77 probability of establishment when not established elsewhere. All species in

that family had a hypoxia tolerance score of 2. Species in the family Salmonidae had only a 0.15 probability of establishment when not established elsewhere. All salmonids had a hypoxia tolerance score of 1. Species in the family Poeciliidae had a 0.40 probability of establishment when not established elsewhere. Snakeheads (Family Channidae) had an estimated establishment probability of 0.90 when not established elsewhere; as previously noted, the two species of snakeheads recorded for Hawaii and Guam were treated as a single taxon in our model. Species of Channidae are established on at least seven other tropical islands or island groups, and the fitted value of establishment probability for that taxon was 1.0.

Using our best-fit model we scored parameters for a set of nine taxa representing eight families not known to be currently established in Hawaii or Guam to predict probability of future establishment. These taxa were selected based on their known or presumed likelihood of presence in pathways under consideration, primarily popularity or novelty in the aquarium trade and species used for aquaculture, food, bait, or as biocontrol agents. The establishment probability for four of these taxa was greater than 70% and two were greater than 90% (Table 27). The remaining three taxa had an establishment probability of 25% or less. There was considerable imprecision in some of these estimations, given the relatively high standard deviations of predicted probability of establishment. This was due in large part to greater relative importance of hypoxia tolerance scores and low numbers of tropical islands/island groups on which they are established (0 for six taxa, 1 for two taxa, and 2 for one taxon). Nevertheless, this procedure illustrates how the modeling method can be applied to provide a general estimate of establishment likelihood for taxa of potential concern.

Table 24. Summary of the numbers of introduced and established nonindigenous fishes on Guam and the Hawaiian Islands.

Island or island group	Number of nonindigenous fish introduced ^a	Number of nonindigenous fish established (percentage of total introduced) ^b	Number established on "other tropical Pacific islands" ^c	Number established on "other tropical islands" ^d
Guam	25	13 (52%)	15	18
Hawaii	70	46 (66%)	31	37
Guam and Hawaii ^e	80 ^f	49 ^g (61%)	35	42

^aTotal number of nonindigenous fish species or taxa reported as introduced into inland waters, including those that are considered established combined with those that have been documented as introduced or occurring in the wild, but not known to have established (reproducing) populations.

^bThese values represent total number of nonindigenous fish species or taxa that have one or more populations in inland waters that are considered established (reproducing).

^cThese values represent total number of nonindigenous fish species or taxa that are known to have been introduced (established and not established) to the location identified in column #1 (i.e., either Guam, Hawaii, or both) that are also documented as having been introduced and currently considered established on one or more other tropical Pacific islands. (Note: additional nonindigenous fish species, never introduced to Guam or Hawaii, are established on other tropical Pacific islands, but these additional taxa are not considered in this tabulation).

^dThese values represent total number of nonindigenous fish species or taxa that are known to have been introduced (established and not established) to the location identified in column #1 (i.e., either Guam, Hawaii, or both) that are also documented as having been introduced and currently considered established on one or more other tropical islands throughout the globe. (Note: additional nonindigenous fish species, not known to have been introduced to Guam or Hawaii, are established on other tropical islands, but these additional taxa are not considered in the tabulation).

^eTreating Guam and the Hawaiian Islands as a single geographic unit; the values in this row relate to the total number of nonindigenous fish species or taxa documented from either Guam, Hawaii or both (e.g., a species that may have been introduced to Guam, but not to Hawaii, would be treated as introduced to Guam and Hawaii)

^fIt was determined that 15 of the 80 introduced nonindigenous fish species/taxa tallied have been introduced to both Guam and Hawaii.

^gIt was determined that 10 of the 49 total number of established species/taxa are established on both Guam and Hawaii.

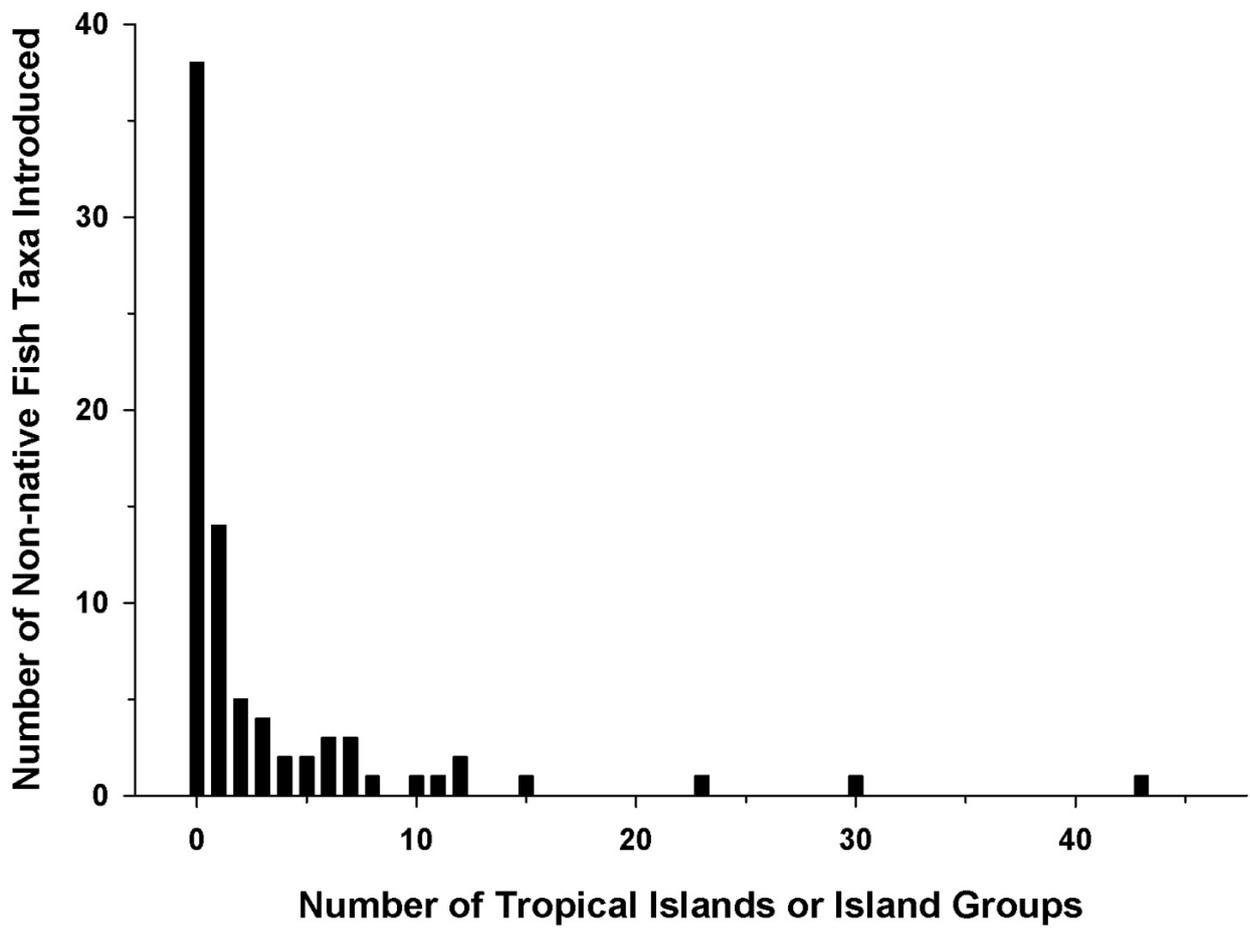

Figure 19. Frequency distribution of nonindigenous freshwater fish species introduced to Guam, Hawaii, or both, and the number of other tropical islands where they are established globally. This graph relates to the history variable used in risk analysis, i.e., prior establishment success.

Table 25. Models of establishment success of nonindigenous inland fish species introduced into Hawaii and Guam since the late 1800's were compared using an information-theoretic approach. [The model with the lowest AIC_c and highest Akaike weight had the most support. AIC_c balances model precision and bias. Akaike weights indicate relative support for each model and sum to one. Only models with an Akaike weight ≥ 0.01 are shown. The best *a priori* model included an effect of taxonomic affinity (family) and prior establishment success on tropical islands or island groups other than Hawaii and Guam (history). Seven *a posteriori* models were created, each containing a unique combination of the variables climate profile, hypoxia tolerance, and salinity tolerance added to our best *a priori* model. The new best model included effects of taxonomic affinity (family), prior establishment success on tropical islands or island groups other than Hawaii and Guam (history), and hypoxia tolerance. The second, third and fourth best models were minor variations of our best model. The third best model overall was our best *a priori* model. We did not include Model 29 from Table 23 in this model comparison since that model was two steps removed from being *a priori*.]

Model number	Model	Number of parameters in model	Log-likelihood	AIC_c	ΔAIC_c	Akaike weight
23	Family + history + hypoxia tolerance	5	-39.2382	89.28725	0	0.587

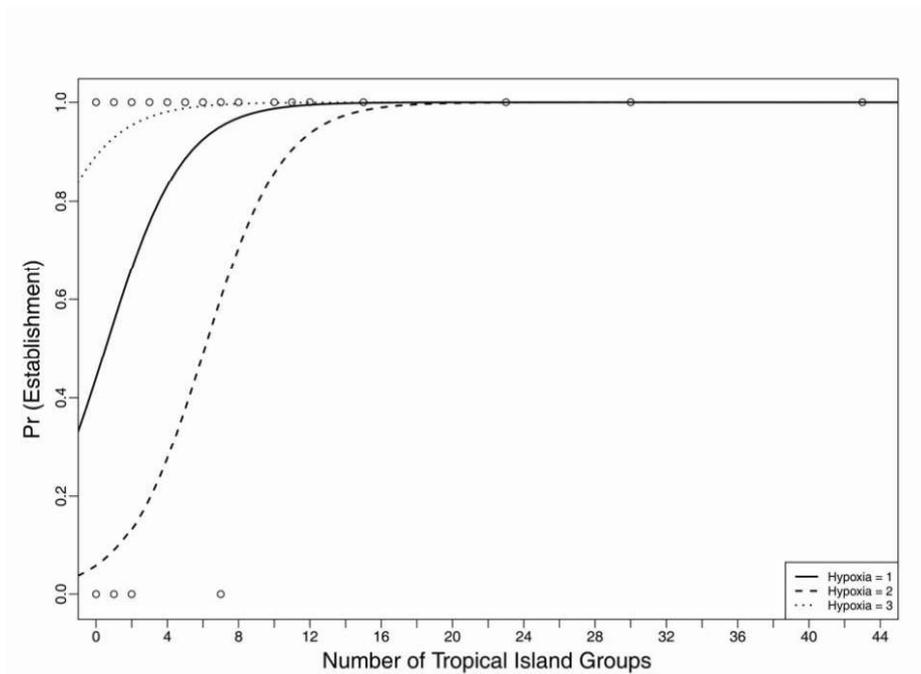

Figure 20. Probability of establishment of nonindigenous inland fishes introduced into Hawaii and Guam as a function of (1) number of tropical islands or island groups, excluding Hawaii and Guam, on which a species is established and (2) hypoxia tolerance. A fixed intercept is used to remove family effect. Species or taxa with a hypoxia tolerance score of 1 (solid line) are intolerant of low oxygen levels; species with a score of 2 (dashed line) are moderately tolerant, and species with a score of 3 (dotted line) are air-breathers. Open circles represent the number of tropical islands or island groups on which a species is known to be established. Number of islands or island groups on which a species was established, excluding Guam and Hawaii, ranged from 0 to 43. Of the 80 nonindigenous fish species or taxa introduced into Guam and Hawaii, 38 were not established on any other tropical islands, 14 were established on one other tropical island or island group, five were established on two, four were established on three, and 19 were established on > 3 other tropical islands or island groups.

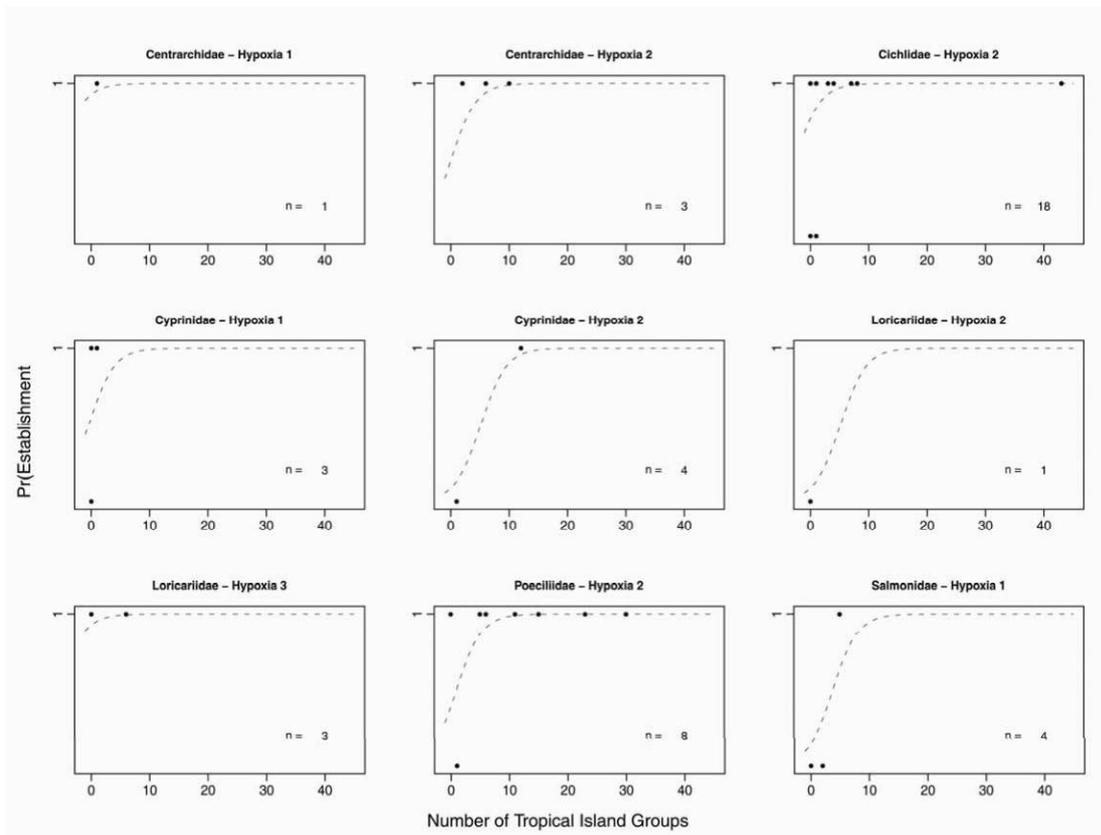

Figure 21. Probability of establishment of nonindigenous inland fishes introduced into Hawaii and Guam as a function of (1) number of tropical islands or island groups, excluding Hawaii and Guam, on which a species is established and (2) hypoxia tolerance, with family effect used as intercept. Only families represented by > 3 species are shown (n = the number of species for a given family:hypoxia tolerance combination).

Discussion

Our best model of establishment success can be used to predict establishment probability of nonindigenous fish species or taxa introduced or likely to be introduced into Hawaii or Guam in the future. Such an application of the model would require that data be gathered for each particular taxon to be tested. This would include data necessary to reliably assign a score for each of the variables in our best model: (1) history (number of tropical islands or island groups on which the species is established excluding Hawaii and Guam), (2) hypoxia tolerance score, and (3) family (taxonomic affinity).

Ultimately, authorities (e.g., resource managers, legislators) must define an acceptable level of risk that considers the benefits of importing or using a nonindigenous fish against the likelihood that it may become invasive and the potential magnitude of its unintended environmental, economic, and social costs. Once an acceptable level of risk is determined and the necessary data gathered to reliably score model variables, the model could be used to estimate whether the predicted probability of establishment was above, below, or equal to the accepted level of risk. Species above an accepted level of risk might be considered for removal from a permitted (white) list or added to a prohibited (black) list. For example, if the accepted level of risk was an establishment probability of 0.44, perhaps all air-breathing fish species would be prohibited (based on Fig. 20); species intolerant to low dissolved oxygen levels (hypoxia tolerance score of 1) might only be permitted if they were not established on any other tropical island or island group; and species with a hypoxia tolerance score of 2 might only be permitted if they were established on fewer than 6 other tropical islands or island groups.

Our results, which estimated a higher establishment probability for species with a hypoxia tolerance score of 1 than for species with a score of 2, were counterintuitive. We expected species with a score of 1 to have the lowest establishment probability. Perhaps the reason species with a score of 1 had a higher estimated establishment probability is that most stream habitats in Hawaii and Guam may have high dissolved oxygen levels because of swift currents. Restated, an abundance of habitats with high dissolved oxygen levels may provide plentiful opportunities for establishment of species that require high dissolved oxygen levels.

Nevertheless, the counterintuitive results related to hypoxia tolerance might also reflect a shortcoming of the model or the data. Some of the assigned variable scores used in the model were heavily based on expert opinion, perhaps influenced by knowledge of similar species rather than rigorous published research about a particular target species. Modeling efforts historically have (and perhaps always will) serve to highlight gaps in existing knowledge of systems and the ecology and precise life-history attributes of various organisms. Our model was no different in that regard. Available information on many fish species makes it difficult to clearly distinguish between a species' physiological tolerance limits compared to environmental preferences and requirements, much less their ecological optima. Consequently, the ecological or physiological variables incorporated into a model may reflect absence of knowledge about species-specific values for certain life-history and ecological variables rather than absence of a relationship between these variables and establishment success. A history of being established on other tropical islands or island groups did appear to be strongly correlated with establishment success and similar relationships have been reported by other authors for various taxa. The relationship we detected here is likely real, albeit not as revealing or enlightening about the biology of the species and the system studied as we might prefer. That air-breathing species have a high

estimated establishment probability was also expected, and lends additional support to our model.

An additional problem in attempting to model and predict establishment is the fact that there is a fair amount of uncertainty with regard to basic knowledge about fish introductions and the status of nonindigenous fish populations. For example, it is likely that some nonindigenous fish species have been introduced to Hawaii and Guam that were never documented. In addition, such unrecorded nonindigenous species could be established in Hawaii and/or Guam, but as yet remain undetected. Relative to the many hundreds to thousands of fish species in the ornamental fish trade, few have been documented as introduced into the wild in Hawaii and Guam, and even fewer of these have become established. That only two fish species in our analysis (both estuarine) that were documented to have been introduced into Hawaii by means of ballast may seem somewhat unexpected given the volume of ship traffic to these islands. Perhaps other fish species have been introduced by means of this vector but failed to establish and were never detected (or if established remain undetected or at least unreported). However, because most ballast water transported to these insular areas is of high salinity, relatively stenohaline freshwater or brackish water species would likely have low levels of survivorship during long periods of transport in this medium. Historical records of fish species introduced intentionally along other pathways, such as stocking for sport fishing, are presumed to be known with a greater degree of certainty than introductions by means of accidental pathways (e.g., ballast water and contaminants).

Propagule pressure has been reported as an important variable in estimating establishment success (Marchetti et al. 2004a, b; Lockwood et al. 2005; Rixon et al. 2005; Colautti et al. 2006; Duggan et al. 2006; Moyle and Marchetti 2006; Copp et al. 2007; Gertzen et al. 2008). Propagule pressure may be generally defined as the number of individual fish of a given species introduced into an area (although life-history attributes such as fecundity or parental care can also be correlates). Probability of establishment is expected to increase as the number of individuals that are released increases. Unfortunately, in most cases for freshwater fishes in Hawaii and Guam, few data exist on the number of individuals of a given species that have been released into the wild for some of the most likely pathways of introductions that lead to establishment (e.g., the aquarium trade). To better assess risk of species and pathways, a suggested approach for future analyses would be to gain greater knowledge about propagule pressure, especially for areas where important information gaps exist (e.g., prohibited importations that are undetected, contaminants in legal shipments, etc.).

Screening of nonindigenous species imported into Hawaii and Guam using a predictive model such as ours may reduce the likelihood of additional invasive species becoming established in either locale. Aquaculture and the aquarium trade are the primary pathways of introduction for nonindigenous fishes in Hawaii and Guam. These pathways reflect the intentional importation of fish. As such, they may be under greater management control than some other pathways and more conducive to regulation by means of a white list guided by a predictive model.

Management Alternatives, with Preexisting Conditions, Potential Actions, and Mitigation Measures for Micronesia

Background

In the U.S., the term “best management practice” (BMP), as applied to environmental management (specifically, pollution control), originated in the Clean Water Act of 1972, although it was not explicitly defined in that legislative document. BMPs have been widely applied to complex environmental problems, generally in a context-specific manner and often lacking imperfect knowledge about the outcome of management actions under different settings. By definition, BMPs are transitory; although in principle there can only be one “best” practice, many are likely to be “better” than a range of others, and incremental improvements may occur over time as new knowledge is attained and protocols, procedures, or practices change (Clay 2008). Increasingly, the term BMP refers to “better management practices.” Conceptually, for complex problems (such as prevention or mitigation for invasive species), BMPs are best regarded as an adaptive learning process rather than an exclusively prescriptive approach (Measham et al. 2007).

As an objective, policy-neutral, science-based agency, the USGS has no management or regulatory authority. Therefore, the USGS refrains from making recommendations that target

specific management or policy actions, and terminology such as “best management practice” or “BMP” is not used. Herein, management alternatives are provided with an implicit understanding that all options have not been thoroughly vetted and strategic actions may be warranted and modified over time as new information becomes available. Many existing sources provide baseline information on strategies for mitigating deleterious ecological or socioeconomic effects of invasive species; the information provided in this report is based on sources considered reliable (e.g., Wittenberg and Cock 2001; Tucker and Hargreaves 2008; Henderson and Bomford 2011).

This document provides management alternatives intended to help prevent, limit, or mitigate impacts of invasive freshwater animal species in the region of Micronesia, with emphasis on fishes, turtles, frogs, and macroinvertebrates. New practices or modifications of existing ones are intended to compliment other management options provided by Federal agencies to address additional organisms representing different taxonomic groups, their habitats, and associated pathways (e.g., terrestrial and marine plants and animals, pathogens, and diseases).

Summary of Management Alternatives

Management can best focus on the following aspects of the sequential invasion process: (1) preventing introductions from occurring; (2) detecting incursions at an early stage; and (3) rapidly eradicating newly found nonindigenous organisms and/or mitigating the worst effects of established or reproducing invasive populations (Kraus and Duffy 2010).

(1) Prevention requires the identification of all pathways and then screening major pathways so as to exclude importation of species most likely to become invasive. This is typically accomplished by screening for animals at the port of origin, and also port-of-entry screening of pathways or products thought or known to be at high risk for harboring nonindigenous aquatic animals.

(2) Rapid-response programs typically involve systematic attempts to detect new incursions followed by programs to eradicate (or at least contain) the worst species so detected.

(3) Long-term mitigation is usually focused on areas of high value or importance that need protection, such as national parks, undisturbed natural streams, or other unique ecosystems. For Guam and other Pacific islands, areas needing protection may best be identified through “ecosystem prioritization” (Jenkins et al. 2009). Long-term mitigation may also involve attempts to control particularly harmful species over much of their invaded ranges.

The following list (Table 28) provides management alternatives that are intended to assist in the prevention, limitation, or mitigation for possible impacts of invasive and other nonindigenous freshwater animals, with specific emphasis on Guam (although many of the items might equally apply to other governments of Micronesia, as well as other commercially linked regions). The subsequent discussion addresses the following main strategies and topics: (1) prevention/pathway disruption; (2) early detection; (3) contingency plans/rapid response; (4) long-term management; and (5) research needs. Action-specific recommendations and priority levels are not implied in keeping with the aforementioned policy and management-neutral position of the USGS. The list is followed by more detailed information and the rationale for each of the strategies. These management options are provisional in the sense that the science of invasive species is a growing and rapidly changing field. Moreover, local conditions are

dynamic. For example, relevant information may become available in the future, or events and field conditions may change that necessitate adjustments of how to best manage certain nonindigenous species or groups of species and particular pathways of introduction. Globally, bioinvasions are highly complex and management strategies require sophisticated levels of coordination (Ruiz and Carlton 2003; Henderson and Bomford 2011). As such, management alternatives as outlined here are considered to be only general guiding principles, and implementation of precautionary as well as post-invasion approaches will require a substantial degree of cooperation among all sectors involved in commerce throughout Micronesia.

Table 28. Summary of management alternatives for nonindigenous freshwater animals. [DoD, Department of Defense; Non-DoD, local, territorial, and other civilian regulatory and/or management agencies in Guam); Foreign, other sovereign governments of Micronesia]

No.	Management Alternative	Category	Applies to		
			DoD	Non-DoD	Foreign
1	Inspection program: Development of an international inspection and monitoring program in which nations coordinate monitoring for invasive species and attempts to prevent their export as well as import.	Prevention/pathway disruption	X	X	X
2	Inspection program: Improvement and expansion of existing documentation and record keeping on the types and numbers of imported aquatic species, including imports from both domestic and foreign sources. Such documentation requires complete and accurate identification of animals to species level, numbers of specimens, purposes, sources, and pathways.	Prevention/pathway disruption	X	X	
3	Inspection program: Assurance that border agents and wildlife inspectors have necessary training and knowledge to identify all or most aquatic animal families, genera, and species, including those prohibited by Federal laws and also taxa permitted under Guam's White List.	Prevention/pathway disruption	X	X	
4	Inspection program: Additional personnel and training of wildlife inspectors and/or implementation of a quarantine system so that most shipments of live wildlife can be inspected.	Prevention/pathway disruption	X	X	
5	Inspection program: Augmentation, expansion, and/or replacement of existing radiographic equipment used to screen imports for live aquatic animals.	Prevention/pathway disruption		X	
6	Inspection program: Inspection of all international packages and increased efforts to inspect a greater percentage of domestic mail.	Prevention/pathway disruption	X	X	

Table 28. Summary of management alternatives for nonindigenous freshwater animals. [DoD, Department of Defense; Non-DoD, local, territorial, and other civilian regulatory and/or management agencies in Guam]; Foreign, other sovereign governments of Micronesia]

No.	Management Alternative	Category	Applies to

7	Survey questionnaires: Survey(s) of incoming military and construction workforce to learn about aquatic animal pets. Questions might include the types and numbers of aquatic animal pets currently owned; which pets, if any, are intend to be transported to Guam; and, regarding unwanted pets, if owners would be likely to release animals into the wild or would they be willing to relinquish pets to pet shops or other authorities.	Prevention/pathway disruption	X	X	
8	Education/outreach—international conferences: Such venues provide a means to maintain open communication and improve diffusion of knowledge of new advances in invasive species biosecurity, covering such themes as prevention/pathway disruption, early detection, management, eradication and control. To increase participation, various Pacific island governments and institutions could be engaged by encouraging different venues among the major islands.	Long-term management	X	X	X
9	Education/outreach: Development and distribution of brochures, posters, bumper stickers, and other forms of print and mass media that provides information on invasive aquatic animals, their identification, the harm that these animals can cause, warnings against releasing pets into the wild, and warnings against transporting illegal or potentially harmful aquatic species. Target groups might include military and civilian families intending to move to Guam, as well as current Guam residents, private businesses, public organizations, schools, and others.	Prevention/pathway disruption & early detection	X	X	X

			DoD	Non-DoD	Foreign
10	Education/outreach: Development of a short video describing potential harm caused by nonindigenous invasive species and warning against their transport or release. Such a video could be shown on incoming commercial and military passenger flights and passenger ships.	Prevention/pathway disruption	X	X	
11	Education/outreach: Development of education programs that target children by providing interactive school presentations that illustrate the impacts that nonindigenous species can have and discouraging release of pets.	Prevention/pathway disruption		X	
12	Education/outreach: Encouragement to pet stores and garden retail outlets to participate in the Habitattitude program (http://www.habitattitude.net/), a partnership between commercial industry and the Aquatic Nuisance Species Task Force that increases consumer awareness and engages businesses and the public to prevent the release of invasive species.	Prevention/pathway disruption	X	X	
13	Education/outreach: Assistance and encouragement for pet stores to identify captive stocks with valid scientific names, including provisioning vendors with printed material on the subject and consultation with qualified experts.	Prevention/pathway disruption		X	
14	Survey questionnaires: Surveys of pet store customers that include questions about the types and numbers of pet aquatic animals currently owned, whether any unwanted pets have ever been released into the wild; and, regarding future unwanted pets, would owners be likely to release animals into the wild or be willing to turn pets over to pet shops or other authorities.	Prevention/pathway disruption	X	X	
15	Education/outreach: Website development to disseminate information about native and invasive species.	Prevention/pathway disruption	X	X	

Table 28. Summary of management alternatives for nonindigenous freshwater animals. [DoD, Department of Defense; Non-DoD, local, territorial, and other civilian regulatory and/or management agencies in Guam]; Foreign, other sovereign governments of Micronesia]

No.	Management Alternative	Category	Applies to		
			DoD	Non-DoD	Foreign
16	Education/outreach: Establishment of programs that provide information on alternatives to releasing unwanted pets, possibly including arrangements for pet stores to accept unwanted pets and/or establishing periodic “Amnesty Days” for the public to surrender unwanted or illegal pets.	Prevention/pathway disruption	X	X	
17	Expert panel(s): Panel(s) of experts to periodically assess operations at borders that involve screening of imported aquatic animals, identification of any existing or potential needs and problem areas in the screening process, assessment of inspector training issues and needs, and review of permitted species.	Prevention/pathway disruption	X	X	X
18	Management/regulation of aquaculture industry: Establishment and maintenance of a database of active and former aquaculture facilities that can be used by management resource agencies and invasive species researchers. Database to include location and contact information of all facilities, types and numbers of aquatic species held, and how and where live animals are distributed.	Prevention/pathway disruption		X	X
19	Management/regulation of aquaculture industry: Routine inspections of aquaculture facilities and farms to assess biosecurity features, focusing on escape risk and type(s) of stock being cultured. This may include evaluation of design and condition of facilities and ponds (e.g., pond location, status of perimeter berms and fences, inlets and outlets); assessment of live aquatic animals cultured, health and status of breeding stocks, and whether any are contaminated by unwanted or harmful species; assessment of equipment; and evaluation of personnel training and determination if additional training is needed.	Prevention/pathway disruption		X	X

Table 28. Summary of management alternatives for nonindigenous freshwater animals. [DoD, Department of Defense; Non-DoD, local, territorial, and other civilian regulatory and/or management agencies in Guam]; Foreign, other sovereign governments of Micronesia]

No.	Management Alternative	Category	Applies to		
			DoD	Non-DoD	Foreign
20	Management/regulation of aquaculture industry: Promotion of the use of triploid, sterile, male fish or only native species in aquaculture. Higher priority for any stock that is distributed live to less secure facilities.	Prevention/pathway disruption		X	X
21	Management/regulation of live food markets: Enforcement of existing regulations and/or establishment of new procedures to minimize allowing retail live food markets on Guam and other Pacific islands to supply customers with live, potentially invasive non-native aquatic animals; encouragement to have vendors provide food fish or other aquatic animals fresh, on ice, at time of sale.	Prevention/pathway disruption	X	X	
22	Establish or strengthen existing programs for monitoring and sampling inland water bodies on Guam and other Pacific islands for the purpose of detecting new or expanding populations of invasive and other nonindigenous aquatic animals. Form and support teams to regularly visit markets and seafood restaurants to document presence of live nonindigenous aquatic animals, including any illegal species. Samples of nonindigenous aquatic species collected, preserved, and voucher specimens deposited in repositories of major scientific museums (e.g., the University of Guam in Mangilao; Bishop Museum in Honolulu). Discoveries of new nonindigenous populations reported to a rapid response team and, if appropriate, information provided to news outlets to inform and advise the public.	Early detection	X	X	X
23	Development and advertisement of a reporting process for military personnel and private citizens who suspect that they have captured or detected a new or uncommon nonindigenous aquatic species.	Rapid response	X	X	X

Table 28. Summary of management alternatives for nonindigenous freshwater animals. [DoD, Department of Defense; Non-DoD, local, territorial, and other civilian regulatory and/or management agencies in Guam]; Foreign, other sovereign governments of Micronesia]

No.	Management Alternative	Category	Applies to		
			DoD	Non-DoD	Foreign
24	Establishment of team(s) led by qualified experts who can rapidly respond and attempt to eradicate any newly discovered wild populations of invasive aquatic species. This requires training, adequate equipment, and development of appropriate protocols for control or eradication.	Rapid response	X	X	X
25	Ecosystem prioritization: Assessment of drainages and water bodies within and outside military reserves so as to prioritize aquatic and wetland ecosystems in terms of their biological significance. Such information is useful for determining areas to focus monitoring, control, and/or eradication efforts.	Long-term management	X	X	

Pathways Assessment with Existing Management Practices

In this section we provide an assessment by pathway of the current status of conditions on Guam and elsewhere in Micronesia, relevant practices currently in place, and the prognosis for future change that may be directly or indirectly associated with the military buildup.

In the following pathway assessment, the prognosis for each pathway includes a qualitative rating or estimation of the overall risk, including the level of uncertainty using criteria

established by the Risk Assessment and Management Committee of the Aquatic Nuisance Species Task Force (RAM-ANSTF 1996). Estimated level of risk of each element or pathway is rated as “low,” “medium,” or “high,” and levels of uncertainty are “very certain,” “reasonably certain,” “moderately certain,” “reasonably uncertain,” and “very uncertain.” The analysis relies on the current state of available information, and resulting risk assessments are intended only as general guidelines for what to expect for future conditions pertaining to each pathway, and how the implementation of alternative management actions may help to mitigate by preventing further establishment or spread of nuisance aquatic species.

Aquarium Trade and Related Commerce in Ornamental Aquatic Animals

Ornamental commerce involves the aquarium trade industry, which includes retail merchants, regional wholesalers, import and export wholesalers, and related businesses that raise or sell aquatic animals for captivity as pets or “ornamentals” (e.g., koi for private and public water-garden ponds.), and consumers, mainly pet hobbyists, who buy and maintain live aquatic animals in captivity. A large number and wide diversity of freshwater fishes and other aquatic organisms (e.g., crustaceans and mollusks) are distributed and marketed worldwide as ornamentals. As a result, this pathway is one of the primary means by which aquatic nonindigenous species have become introduced and established in both freshwater and marine environments throughout the world (Courtenay and Stauffer 1990; Courtenay 1999; Fuller et al. 1999; Eldredge 2000; Fuller 2003; Padilla and Williams 2004; Rixon et al. 2005; Calado and Chapman 2006; Duggan et al. 2006; Gertzen et al. 2008). Padilla and Williams (2004) estimated that perhaps one-third of the world’s worst aquatic invasive species are aquarium or ornamental species.

The aquarium pet trade is the pathway by which a large number and variety of different nonindigenous fishes and other aquatic animals are imported to Guam (Table 14) and to other Pacific islands. Over the last several decades, this pathway has also (and will likely continue to) lead to the introduction of certain fishes into the wild in Guam and other Pacific islands, and was the primary pathway of introduction for many aquatic animals now established in Hawaii (Maciolek 1984; Eldredge 2000; Yamamoto and Tagawa 2000). The aquarium trade is complex and is closely tied to other major pathways, such as aquaculture and stocking contaminants. For example, some fishes, crustaceans, and mollusks, especially snails, may be transported and enter new areas accidentally as contaminants or stowaways in shipments of other aquatic ornamental animal and plant species that are being purposely imported (Lin et al. 2006).

With the aquarium trade considered as the general pathway, there are different sub-pathways or vectors by which aquatic animals and plants become introduced to new places. One of the more common modes by which ornamental species become established is direct release of animals by pet owners. Reasons for the disposal of pet fish are varied and include the following (Gertzen et al. 2008):

- Aggressive behavior
- Large size
- Frequent illness
- Rapid reproduction
- Other reasons, such as owner(s) that are moving, bored with pets, or tired of maintenance

Other pathways and vectors that are either a subset or closely linked to the aquarium pet trade include escapement from holding facilities, especially outdoor ponds, raceways, or other structures used for holding or captive breeding. Sites where such escapements of fish commonly occur are commercial ornamental fish farms. For example, in Florida and other warmer parts of the United States, a number of species are known to have become established or probably became established in this manner (Courtenay and Stauffer 1990; Courtenay 1994; Courtenay 1999; Fuller et al. 1999).

Present Condition: Aquarium Pet Owners

Aquarium pet owners and other pet hobbyists are consumers, private citizens that commonly play important and varied roles in the aquarium trade pathway. Functioning as vectors, pet owners are known or reputed to hand carry or otherwise transport a small number of live freshwater fish or other aquatic animals to Guam and other Pacific islands. Citizens may be residents or nonresidents. This pathway may include any live aquatic animals considered to be personal pets or gifts provided to friends or family members. Animals are typically transported in this pathway by one of the following methods: (1) hand-carried or with checked-in luggage on airlines or by maritime vessel; or (2) packaged and shipped by means of private-sector couriers or the U.S. Postal Service. This pathway is distinguished from the commercial retail industry because it is small-scale, relatively sporadic, and typically not-for-profit.

The current number of private citizens that carry or send pet aquatic animals to Guam is unknown, as is information pertaining to the degree to which non-commercial shipments containing live animals arrive through this pathway. It is assumed to represent a small proportion, relative to the aquarium industry, of the total number of aquarium fishes and other aquatic pets that enter Guam or other Pacific islands. The extent to which any nonindigenous freshwater fishes and other aquatic animals established in the wild on Guam that may have been introduced by means of this pathway is unknown.

Present Condition: Retail Sales

A few nonindigenous freshwater fishes and other aquatic animals established in the wild on Guam—because of their wide distribution and popularity as pets—are presumed to have originated by means of the aquarium or ornamental pet trade. These particular species may have escaped from holding facilities or, more likely, were intentionally released.

Many freshwater fishes and other aquatic animals imported and sold in the aquarium trade are misidentified, partly because many taxa are difficult even for experts to positively identify to species level. In addition, some species that are legal to import are similar in appearance to species that are illegal. Consequently, lists of imported species maintained by government agencies and businesses associated with the aquarium industry likely contain incorrect species identifications. This situation increases the risk that certain harmful or illegal aquatic animals will be imported, unintentionally and without the knowledge of regulators. According to Gertzen et al. (2008) there is little regulation of the aquarium trade in terms of restricting potentially nuisance nonindigenous aquatic species. Molecular tools may be useful for identification and may also serve to recognize taxa in the live animal or plant trade that are mislabeled (Thum et al. 2011).

Guam currently has two retail pet stores that import and sell live freshwater and marine fishes, invertebrates, plants, and locally caught turtles: Little Wangz Petlife in Harmon, and

Feathers 'n Fins (<http://www.feathersnfins.com/>) in Hagåtña. Additionally, a vendor who does not have a physical retail shop occasionally sells live aquarium fish, plants, snails, and turtles at the flea market in Dededo. The garden center at the U.S. Naval Base was also visited and, at the time of our visit, had live freshwater plants for sale; a few fish (*Poecilia reticulata*) and snails were observed in some of the containers, but appeared to be contaminants of the water and plant stock. Most freshwater ornamental fishes for sale in the stores are imported. The primary sources of aquarium fish shipped to Guam are in Malaysia, but fish are apparently also shipped directly from both Florida and Japan (Christy et al. 2007b). Additionally, a clerk at one shop told us that they obtain a few locally-reared fishes (guppies and platyfish) from one or a few individuals who culture the fish in outdoor ponds, but this information is unverified.

Customs records and statistics maintained by the U.S. Fish and Wildlife Service indicate that the volume of imports to Guam is moderate. However, due to a variety of reasons, we were unable to obtain detailed information on types and numbers of ornamental freshwater fishes imported into Guam annually or volume of sales. Augmenting the available information, our visits to both of the “brick-and-mortar” pet stores on the island confirmed that a wide variety of species were for sale. Based on visits to the stores in 2010, we compiled a partial list of the types of live fish available for sale (Table 29). This list includes approximately 80 to 90 species or strains representing about 18 families. We suspect that the number of different species imported varies among years and certain seasons, depending on availability of stock and changing consumer demand. The typical method for commercial shipment of live ornamental fish is by means of airplane flights, with fish confined within polyethylene bags containing oxygen-saturated water; multiple bags with fish are then densely packed into insulated boxes or shipping containers (Cole et al. 1999).

In early 2010, a USGS biologist residing in Guam observed a street vendor selling live freshwater turtles, presumably intended as pets rather than for food (E. Wostl, U.S. Geological Survey, oral commun., 2010). We presume that the nonindigenous turtles were taken from an established wild population. In fact, freshwater turtles, typically red-eared sliders, are offered for sale by street vendors on a semi-regular basis in at least one village on Guam. How many turtles and the variety of species which are sold is unclear. It is assumed that these turtles are being harvested locally. This type of unauthorized pet trade increases the risk that the range of already established populations will more rapidly expand with the aid of humans.

The senior author of this report visited a pet shop in Saipan; the owners had converted part of their dwelling to a retail sales shop, plumbed it with aquaria, and were selling a small assortment of tropical freshwater aquarium fish. We are unaware if there are additional pet shops in Micronesia.

We are unaware of any outdoor facilities used for the propagation of aquarium or other ornamental species on Guam or elsewhere in Micronesia. However, there are various types of ornamental ponds and other outdoor holding facilities, some of which may have the potential to allow for escape or dispersal. For instance, some hotels on Guam and Saipan maintain water gardens with live ornamental fish (mostly koi, *Cyprinus carpio*, and milkfish, *Chanos chanos*). The senior author observed swordtails (*Xiphophorus helleri*) in an aquarium in the gift shop of the Etpison Museum in Koror, Palau; when asked about the source of fish, an employee responded that the fish had been brought to the museum by the director, who had maintained (and presumably bred) the fish in a pond on her private property.

Current Management Practices

Live animals brought to Guam legally must be declared. Individuals arriving in Guam from foreign ports must complete a U.S. Customs and Border Protection (CBP) Declaration Form 6059B, which is handed to the CBP inspector upon approaching the CBP area. If a traveler is transporting live animals, the cargo must be indicated on the form, which may result in additional questioning and possible inspection of the traveler's articles. Because airline passengers are not permitted to transport substantial volumes of liquids in carry-on luggage, there is a low probability that travelers typically carry live fish or other aquatic animals. Regulations pertaining to checked luggage and other transport or shipment of live aquatic animals apparently vary among the different passenger and freight air carriers.

The U.S. Department of the Interior, Law Enforcement Division, USFWS, has responsibility pertaining to the importation of reptiles, fish, and endangered species. A license is required for commercial imports or exports of fish and wildlife and/or their parts and products into or out of the United States (USFWS 2010) and importers are also required to file a Declaration for Importation or Exportation of Fish or Wildlife (Form 3-177) at an authorized port of entry to receive clearance before U.S. Customs releases the shipment. Live aquatic animals and other wildlife are monitored through a system of national ports designated and managed by the USFWS Office of Law Enforcement, USCS, and the USDA.

The Port of Guam in Agana is one of a number of United States ports designated to handle commercial traffic of live wildlife (see: <http://www.fws.gov/pacific/lawenforcement/portag.html>). The Guam office is overseen by the Pacific Islands Resident Agent in Charge subdistrict office which includes Hawaii, the CNMI, the territories of Guam and American Samoa, and other central and western Pacific islands subject to the jurisdiction of the United States (see: <http://www.fws.gov/pacific/lawenforcement/RAC%20Honolulu.html>).

The most detailed records pertaining to imports of live aquatic animals are those in the USFWS Law and Enforcement Management Information System (LEMIS) (Smith et al. 2008). The USFWS compiles much of the information from Customs shipment declaration forms (Form 3-177), which are completed for each shipment that arrives or exits a given U.S. port of entry (Chapman et al. 1997; Adams et al. 2001). LEMIS shipment records include information on number of animals (or their weight) per container, scientific name, intended purpose (e.g., commercial, personal), source (e.g., captive bred, wild caught), and country of origin; import records are discarded every six years (Smith et al. 2008). Some data do not distinguish freshwater from marine species, and not all import declaration forms indicate source. Moreover, country of origin is not always known with certainty since transshipments are common (Chapman et al. 1997; Adams et al. 2001). According to Smith et al. (2008), inadequate record keeping at ports makes it difficult to fully assess the diversity of live fishes imported, thereby hindering risk analysis and prevention programs.

Augmenting regulations and requirements of the USFWS, DAWR applies its white list of aquatic species—mostly aquarium fishes—that can be legally imported live into Guam. Importation of aquatic animals not present on the white list is prohibited; requests for exemptions to the list are reviewed on a case-by-case basis. The most recent version of the white list (provided to us in early 2010 by Brent Tibbatts, DAWR) includes a mix of 448 different genera, species, and hybrid freshwater fishes, saltwater fishes, and aquatic invertebrates. Since 1981, DAWR has not issued any permits allowing the importation of any turtle species into Guam for personal or commercial use (Leberer 2003). All reptiles and amphibians are currently prohibited from importation into Guam. Only saltwater fish species native to Guam can be legally imported.

Prognosis

The primary mechanisms by which future introductions and spread of nonindigenous aquatic species through the aquarium pet and ornamental species trade are likely to occur include: (1) unauthorized imports and subsequent (intentional) release to the environment; (2) organisms legally imported, purchased by consumers, and subsequent (intentional) release to the

environment; and (3) organisms legally or illegally imported and accidentally escaping from holding facilities into the environment:

(1) It is anticipated that an increase in the human population on Guam will result in an increase in the number of freshwater aquarium fishes and other aquatic pets carried or sent to Guam by private citizens outside of the normal retail trade vector. Thus, there will be increased probability that fish and other aquatic species may be transported and subsequently released through this pathway. Future risk potential for establishment of new species by means of this pathway is *medium/moderately certain*.

(2) The anticipated increase in human population in Guam is also expected to result in increased consumer demand, which will likely increase the volume of legal imports, sales, and ownership of freshwater aquarium fishes and other aquatic pets. This increases propagule pressure by increasing the likelihood of unwanted pets being released into natural waters. It is unknown if increased demand will result in the opening of any additional retail pet stores in Guam. Future risk potential for establishment of new species and/or spread of species currently established by means of this pathway is *medium-to-high/reasonably certain*.

(3) Given that at present there is little indication that ornamental species are commonly held in outdoor facilities on Guam and elsewhere in Micronesia, future risk potential for establishment of new species and/or spread of species by escapement by means of this pathway is *low-to-medium/reasonably uncertain*.

Freshwater Aquaculture Industry

Freshwater aquaculture is the farming of freshwater species in ponds and tanks for subsequent sale as food, either live, fresh, or frozen, for human consumption (in our assessment, it excludes aquaculture associated with the aquarium pet trade and other ornamental species). The freshwater aquaculture industry is a pathway that includes a variety of aquatic animals (principally finfish and shellfish). Included are eggs and fry of various fishes that are imported and subsequently reared to marketable size at aquaculture facilities. In addition, aquaculture facilities commonly hold fishes and other aquatic animals in captivity to replenish their stocks. Personnel at some facilities, usually intending to improve the marketability of their stock, experiment in an effort to produce new strains and hybrids. The mechanism by which nonindigenous aquatic species become introduced into natural water bodies by this pathway typically involves escapement from captive holding facilities, often through accidental, unintended, or natural events (e.g., failure of containment structures, hydrologic alterations, floods, tropical storms). In some Asian countries, freshwater fishes are raised in cages placed in open lakes and rivers, but we are unaware of this practice in freshwater habitats in Guam or other parts of Micronesia. Worldwide, large numbers of commercially important species, both freshwater and marine, have been introduced, established, and spread in association with the food aquaculture sector.

Present Condition

Aquaculture has long been an active and viable commercial enterprise in Micronesia and elsewhere in Oceania (Fitzgerald and Nelson 1979; FitzGerald 1982; Nelson 1988, 1989b), and continues to flourish (Prasad 2003; NMC-CREES 2011). A substantial amount of food-based aquaculture in the region is of marine species, more strictly referred to as mariculture. Common

marine seafood organisms that are cultivated include giant clam, trochus, milkfish, and sea cucumber. The Secretariat of the Pacific Community (SPC) promotes and coordinates much of the aquaculture activities throughout the western Pacific (<http://www.spc.int/aquaculture/>). The SPC headquarters are in Noumea, New Caledonia, with regional offices in the Fiji Islands, FSM (Pohnpei), Papua New Guinea, Solomon Islands, and Vanuatu. Increased interest in mariculture of marine species for the ornamental trade is expected as demand grows (e.g., live corals and other invertebrates, reef fishes).

Within Micronesia, freshwater aquaculture is most highly developed on Guam and in the CNMI. Aquaculture facilities and personnel associated with the University of Guam (UOG) and Northern Marianas College (NMC) support the industry through basic and applied research and extension service. The Guam Aquaculture Development and Training Center (GADTC) of the Western Pacific Tropical Research Center, also known as the Fadian Hatchery, is the largest and oldest aquaculture center in the western Pacific (<http://www.wptrc.org/section.asp?secID=7>). Originally built as a private facility to supply aquaculture products to Asia, the GADTC was transferred to the Government of Guam in 1986 and subsequently to the University of Guam in 2001. The hatchery is located on five acres in the east-central side of Guam and is equipped with indoor laboratories, office buildings and living quarters, ponds and raceways, and sources of sea water and fresh water. A recent effort to organize a Guam aquaculture development working group as a means to facilitate interactions between government agencies and commercial producers was unsuccessful, and instead an improvised process was adopted (CTSA 2010).

Aquaculture in the CNMI is based at the NMC Cooperative Research Extension and Education Service (<http://www.crees.org/sec.asp?secID=1>), which is mandated by public law 15-43 (effective 2007) to be the lead authority for aquaculture development in the CNMI. As part of that legislative directive, the NMC-CREES recently produced an aquaculture development plan based on extensive input from stakeholders throughout the region (NMC-CREES 2011). The NMC-CREES facilities currently include an inland hatchery composed of an assortment of recirculating systems equipped with both fresh and salt water. This facility is used for producing tilapia seedstock for distribution, and for commercial-scale grow-out trials of a variety of species. There are plans to build an additional hatchery. The location for that hatchery has yet to be finalized, but priority factors that are under consideration include (1) access to both fresh and salt water; (2) isolation of the hatchery for biosecurity and security against human intrusion, and; (3) ease of distribution of seed stock to other islands (NMC-CREES 2011).

Most of the current aquaculture production on Guam and in the CNMI involves tilapia (mainly Mozambique tilapia (*Oreochromis mossambicus*), Nile tilapia (*O. niloticus*), and hybrids) and penaeid shrimp (mostly two marine species, the Pacific white shrimp (*Litopenaeus vannamei*) and black tiger prawn (*Penaeus monodon*)). Government-sponsored aquaculture facilities typically conduct research and produce seedstock for distribution to private fish farms, where fish are then raised and eventually distributed to retail food markets.

There is evidence that tilapia fry were imported to Guam from Taiwan as *O. aureus* x *niloticus* hybrids, and permits may have been issued to import genetically pure *O. aureus* (CTSA 2010), but we were unable to independently confirm this. Historically, a number of species were investigated for their aquaculture potential (FitzGerald 1982), and there is also growing interest in experimenting with and utilizing additional species, including native species (M. Ogo and R. Manglona, oral commun., 2010). A list of commodity species for research and production at the NMC-CREES has been prioritized (Table 30). Diseases pose serious problems in aquaculture in

general, including the Pacific region, especially with shrimp. The GADTC has been a leader in research to understand and develop guidelines for managing aquaculture-related disease problems (J.W. Brown, oral commun., 2010).

Both facilities at UOG and NMC follow careful biosecurity protocols and staff members are conscientious of the risks involved in holding and culturing nonindigenous species in the vicinity of natural waters. At the GADTC research facility, for instance, all circulating water passes through a filtration system and is eventually dispensed onto dry volcanic rock and then channeled directly to the sea.

The CNMI aquaculture development plan specifically addresses biosecurity issues (Table 31). There is no evidence, to the best of our knowledge, that there have been any recent breaches or escapes from these facilities. The giant river prawn (*Macrobrachium cf. rosenbergii*), a taxon of interest in the past, escaped accidentally and may have also been intentionally released into natural waters on Guam. However, this species apparently failed to become established (Eldredge 2000), perhaps from being outcompeted by the native *M. lars* (J.W. Brown, oral commun., 2010). It is unclear to us whether *M. rosenbergii* escaped from government-managed or private aquaculture facilities, or both.

We are unaware of other major freshwater aquaculture facilities throughout the rest of Micronesia. However, mariculture is a growing economic enterprise in Palau and to a lesser extent in the FSM (Prasad 2003; Sakuma and Ueranant 2007; Lindsay 2008). The mariculture industry in Palau and the FSM involves production of species for food (e.g., giant clam, trochus, crab, grouper, rabbitfish, and milkfish), ornamental trade (e.g., live corals), and baitfish (e.g., milkfish for recreational and commercial tuna fishing). The best developed facility in those regions is the Palau Mariculture Demonstration Center (PMDC) on Malakal, originally established in the 1970s as the Micronesian Mariculture Demonstration Center (MMDC). The PMDC is the largest clam factory in the world and mass produces several species of giant clams that are supplied locally and also to many other island nations in the Pacific region, marketed for food, aquaculture, the aquarium trade, and for natural stock replenishment. There was a limited attempt to mass produce freshwater giant prawns (*Macrobrachium cf. rosenbergii*) at the PMDC (http://www.spc.int/aquaculture/index.php?option=com_countries&view=country&id=14).

Table 30. Priority list of species/groups in production or of interest for aquaculture by the Northern Marianas College Cooperative Research Extension and Education Service (NMC-CREES 2011).

High Priority	Medium priority	Low priority	Emerging
Tilapia	Marine finfish	Sea cucumbers/sea urchins	Coconut crabs
Marine shrimp	Freshwater crustaceans (e.g., <i>Macrobrachium cf. rosenbergii</i> , <i>Procambarus clarkii</i>)	Corals	Trochus (<i>Trochus</i> spp.)
	Giant clams (<i>Tridacna derasa</i>)	Marine ornamental fish	Sponges
	Milkfish (<i>Chanos chanos</i>)	Freshwater ornamental fish	Turban shells (<i>Turbo</i> spp.)
		Mangrove crabs (<i>Scylla serrata</i>)	

Table 31. Strategies identified to overcome biosecurity challenges for aquaculture in the Commonwealth of the Northern Mariana Islands (NMC-CREES 2011).

Objective	Action Strategies	Measures
Minimize risk of disease import	<ul style="list-style-type: none"> • Laws and regulations reducing potentially harmful imports such as fresh or frozen shrimp. • Increase public awareness of biosecurity issues through media such as posters or TV ads. • Establish a quarantine facility. • Improve disease diagnostic and observation capacity. 	Biosecurity threats to aquaculture from imported products are eliminated within five years.
Minimize risk of harmful invasive species	<ul style="list-style-type: none"> • Risk assessment of any exotic species importation into CNMI. • Publish and publicize a list of potentially invasive species for CNMI. 	Biosecurity threats to aquaculture from potentially invasive species are eliminated within five years.

Current Management Practices

As a territory of the United States, Guam is subject to Federal regulations that restrict the importation of certain live aquatic animals intended for aquaculture food production. For example, under the injurious wildlife provisions of the Lacey Act (P.L. 97-79 as amended), the USFWS prohibits the importation and interstate transport of certain injurious terrestrial and aquatic animals, including various species of mammals, birds, fish, amphibians, reptiles, mollusks, and crustaceans. All or most fish species and other taxa currently listed as prohibited under the Lacey Act are associated with the aquaculture industry or the live food industry and includes members of the families Salmonidae (salmon), Clariidae (walking catfishes), Channidae (snakeheads), and four Asian carp species and their hybrids: the largescale silver, silver, bighead, and black carp (Table 32).

Although government programs that support and promote finfish and shellfish aquaculture in Micronesia are generally proactive in implementing established biosecurity protocols, it is less clear how engaged the commercial and private sector is in doing so. Consequently, there are known cases of nonindigenous species becoming established or being spread into natural waters through this pathway. For instance, the chevron snakehead (*Channa striata*) population now established in the Ajayan River in southern Guam is thought to have resulted from the escape of fish from a local fish farm. A number of other nonindigenous fishes and other freshwater animals (e.g., walking catfish, *Clarias* spp., and turtles) were previously imported for use in aquaculture, and are established or reported in the wild. Similar to snakeheads, the source of some or all of these wild populations is possibly due to escapes or releases from aquaculture facilities.

Table 32. Aquatic species listed under the injurious wildlife provisions of the U.S. Lacey Act (<http://www.fws.gov/fisheries/ans/ANSInjurious.cfm>).

Scientific Name	Common Name
Family Salmonidae	salmon ^a
Family Clariidae	walking catfish (about 13 genera; ~100 species)
Genera <i>Channa</i> and <i>Parachanna</i>	snakeheads (2 genera; 28 species)
<i>Hypophthalmichthys harmandi</i>	largescale silver carp (and hybrids)
<i>Hypophthalmichthys molitrix</i>	silver carp (and hybrids)
<i>Hypophthalmichthys nobilis</i>	bighead carp (and hybrids)
<i>Mylopharyngodon piceus</i>	black carp (and hybrids)
Genus <i>Eriocheir</i>	mitten crabs (three species)
Genus <i>Dreissena polymorpha</i>	zebra mussel

^a Except those accompanied by proper health certification

Prognosis

It is anticipated that any increase in the human population in Guam will also result in increased demand for food animals produced through aquaculture. It is possible that such demand will also increase the likelihood of development of additional aquaculture facilities, as well as species of interest for aquaculture. Future risk potential for establishment of new species as well as the spread of already established species by means of this pathway is **medium/moderately certain**.

Live Food Industry

This pathway includes freshwater fishes or other aquatic animals that are imported live into Guam and other Micronesian islands to be sold as food, as well as freshwater fishes or other aquatic animals that are raised in aquaculture facilities on the islands and distributed live to local stores or markets where they are sold as food. The mechanism by which animals are introduced into natural water bodies by means of this pathway is typically through intentional release or unauthorized release with the intent of establishing populations for subsistence harvesting.

Present Condition

Except for some live marine animals (e.g., lobsters, crabs, clams), most aquatic animals imported to Guam for human consumption arrive dead as chilled, frozen, dried, or preserved products (Christy et al. 2007b). In contrast, some tilapia that are raised on aquaculture farms in Guam are distributed live to markets on the island where they are sold as food. During our visit to Guam in 2010, we visited at least three stores that were selling small-, medium- and large-sized Nile tilapia (*Oreochromis niloticus*), including both wild and red-color morphs, as well as live shrimp for consumption. Some stores and the farmer's market in Dededo also had live walking catfish for sale. Live animals, presumably supplied entirely by aquaculture facilities, were held in indoor tanks within each store. Based on our observations, consumers are allowed, if desired, to carry fish away live, although it is likely that most purchasers have vendors supply fresh fish or shellfish on ice, either whole or cleaned. It is unknown how many localized

populations of popular food species may have been introduced into natural water bodies by means of this pathway.

It is likely that tilapia were introduced to Palau and the FSM with the intent to be stocked locally, possibly illegally and presumably for food. Tilapia (provisionally identified as *O. mossambicus*) were first detected in Palau in 2003, and the Bureau of Agriculture promptly responded with a concerted effort to eradicate fish from four sites using rotenone (Nico and Walsh 2011). However, fish persisted at one site as of 2010, and we were informed that management authorities planned to continue efforts to eradicate fish from this site. Recently, in contrast to previous actions, a legislative bill was under consideration in Palau that was intended to promote tilapia farming in the islands. Senate bill 8-173, dated 9 December 2010, proposed the following:

“Encourage the development of Tilapia fish farms by providing Palauan citizens with training on developing Tilapia fish farms, and providing local Palauan citizens with seedlings to develop Tilapia fish farms; encourage Palauan citizens to raise, breed, consume, and sell Tilapia fish raised on Tilapia fish farms.”

This action prompted knowledgeable scientists and other experts to express concern, on behalf of the Secretariat of the Pacific Regional Environment Programme (SPREP), about potential impacts of tilapia introductions to Palau. Recently we were informed that this issue appears to be resolved and there are currently no further plans to promote tilapia farming in Palau (J. Miles, invasive species coordinator for Palau, written commun., 2011).

We are aware of the interdiction of at least one shipment of swamp eels (*Monopterus* sp.) in Saipan that was presumably imported illegally to be used for food (S. McKagan, oral commun., 2010).

Current Management Practices

Other than prohibitions against possession or sale of certain species, we are unaware of any management practices related to the distribution of live food fish within Guam. It is unknown to us whether retail markets selling live food fish are required to have permits, if food fish must be killed prior to sale, or if there are regulations in place for the handling and distribution of live or fresh animal products. At the market in Dededo we observed vendors selling live fish and shrimp to customers with no apparent sanitary precautions.

Prognosis

It is anticipated that any increase in human population in Guam will also result in an increase in the numbers of live fish and other freshwater species provided to food markets on the island. Increased consumer demand may also result in more markets distributing live food products. Future risk potential for establishment of new species as well as the spread of already established species by means of this pathway is **medium-to-high/moderately certain**. Greater risk may be likely depending on the demographic and ethnic composition of the workforce associated with the military buildup on Guam.

Recreational Freshwater Fishing

This pathway is associated with sport fishing or casual angling and typically involves government stocking as well as illegal or unauthorized stocking of sport and game fishes and the intentional or accidental release of bait fishes or other aquatic animals or invertebrates used as bait. In freshwater systems, bait releases are typically associated with anglers who release any unused, live bait fishes or other aquatic animals used as bait.

Present Condition

Guam and other areas of Micronesia have been sites where species have been historically stocked by government agencies, in most cases to establish game species (e.g., sport fishes), food species, and/or as biocontrol agents. For instance, various fish species were intentionally stocked in Fena Reservoir after its construction with the intent to establish them for sportfishing purposes (e.g., *Micropterus* spp., *Ictalurus punctatus*; Table 14) (Guam 1964, 1967). The following excerpt from Guam's Department of Agriculture 1969 annual report (Guam 1969) describes the introduction of Neotropical sportfish of the genus *Cichla*, a group commonly known as peacock bass or tucunare:

“A South American fresh water game fish called Tucunare, introduced into the 175-acre Fena Lake in February 1968, have spawned and appeared to be firmly established in the lake. By November 1968, at least three distinct sizes of Tucunare were seen in the lake and spillway catchment basin. To develop the fresh water game fishing potential of the island, young Tucunare were also transplanted into one of the large stream systems in the south-central part of the island.”

However, stocking of *Cichla* in Fena Reservoir may have also been motivated in part to control tilapia (*Oreochromis mossambicus*), a nonindigenous omnivorous fish that was stocked previously in an attempt to control nonindigenous plants (Brock and Takata 1956). Although the source of populations of some poeciliids currently established on Guam and on other islands in Micronesia may have been through the pet trade, there is also evidence that introductions of some of these species occurred through intentional stockings as biocontrol agents for insect pests (Eldredge 2000) or, in the case of *Poecilia reticulata*, to “balance” the aquatic fauna represented by previously stocked species (Brock and Takata 1956).

Fishing with live bait is a common practice throughout the world and the dispersal and introduction of nonindigenous aquatic species have often been attributed to the release or escape of baitfish and other biota from anglers (Ludwig and Leitch 1996; Fuller et al. 1999). The vector usually involves one or more anglers either accidentally or intentionally dumping the contents of a live-bait well into a water body. On some Pacific islands (e.g., Hawaii), tilapia are used as bait, although perhaps more commonly as cut bait rather than used live (Maciolek 1984). However, we are unaware of any nonindigenous freshwater fish species on Guam or elsewhere in Micronesia having become established by this vector.

Current Management Practices

In the past, intentional stockings were an important pathway by which nonindigenous species became established on Guam and other Micronesian islands. However, some agencies now recognize the adverse effects of previous stockings that resulted in the establishment of

injurious or harmful species. It is our impression that DAWR, and presumably other government agencies in Micronesia, currently undergo a thorough vetting process to evaluate the potential risks associated with fishes or other aquatic species that might be under consideration for intentional stocking in either natural or artificial water bodies. Except for aquaculture interests, there appears to be a prevailing attitude to utilize native species intended for consumptive purposes, at least for recreational fishing.

DAWR does not permit the importation of nonindigenous fishes for use as bait fish (B. Tibbatts, oral commun., 2010). DAWR is currently involved in restoration of the Masso reservoir by removing nonindigenous species, restocking with native species, and providing recreational fishing opportunities. Presumably, anglers will be allowed to fish with live bait, but we are unaware if there will be any regulations or policies implemented to govern the use of such animals. Our assumption is that use of live bait for any type of fishing (saltwater or freshwater) is limited to native species.

Prognosis

An increase in the human population on Guam will likely result in an increase in the numbers of individuals on the island interested in freshwater fishing, a situation that might lead to the introduction or spread of nonindigenous sport or bait fish or other animals. Given the abundant fishing opportunities for marine species, relatively limited freshwater sportfishing pressure, and regulations prohibiting importation of freshwater bait species (at least on Guam), there is relatively low probability that this pathway will lead to additional introductions of nonindigenous freshwater fishes in Micronesia for the foreseeable future. DAWR promotes use of native species for recreational angling purposes. Although the possibility exists of people moving freshwater game and/or bait species from one water body to another, the overall current low interest in angling in inland water bodies on Guam suggests that this situation is not likely to change substantially in association with the planned military buildup. Future risk potential for establishment of new species as well as the spread of already established species by means of this pathway is expected to be *low/reasonably uncertain*.

Ballast Water and Hull Fouling

Present Condition

Transport and release of organisms by means of this pathway is a widespread problem and has led to the establishment of numerous invasive and injurious aquatic species worldwide. This pathway has been cited as the leading cause of introductions of nonindigenous species to navigable coastal waters and inland waterways, and a few natural water bodies such as the Laurentian Great Lakes (Ricciardi and MacIsaac 2000; Fofonoff et al. 2003; Ruiz and Carlton 2003; Drake and Lodge 2004; Drake et al. 2005). Consequently, many practices and policies have been proposed and/or adopted to detect, monitor, and mitigate for translocations of organisms by means of this pathway and associated vectors (Wasson et al. 2002; Drake and Lodge 2004; Fernandez 2008; Hulme et al. 2008; Buck 2009; GWADF 2009). Ballast water and hull fouling differ as vectors in that the first usually involves benthic or free-swimming organisms whereas the second typically involves sessile or attached organisms.

We are unaware of any confirmed cases of established nonindigenous freshwater or diadromous species in Micronesia transported by means of this pathway. Two brackish-water

species used in the quantitative risk analysis for this study, the fang-toothed blenny (*Omobranchus ferox*) and the mangrove goby (*Mugiligobius cavifrons*), were assumed to have been introduced to Hawaii by means of ballast water (Englund 2002).

Current Management Practices

Current procedures and policies of either the DoD or the commercial and private shipping sectors was not reviewed to determine existing practices or policies intended to prevent or minimize introductions or spread of nonindigenous species by means of this pathway.

Prognosis

The volume and network of maritime traffic in and around Micronesia is likely to result in this pathway providing a much greater likelihood for nonindigenous marine organisms than freshwater ones. Future risk potential for establishment of new species as well as the spread of already established species in freshwater habitats of Micronesia by means of this pathway is expected to be **low/reasonably uncertain**.

Biological Control

Present Condition

Several freshwater fish species present on Pacific islands were introduced for the purpose of biological control (Maciolek 1984). The introduction of peacock cichlid (*Cichla* sp.) to Guam was not only for sportfishing purposes, but also to control feral tilapia (see *Recreational Freshwater Fishing—Present Condition*) (Nelson 1988). The mosquitofish (*Gambusia* sp.) and sailfin molly (*Poecilia latipinna*) were introduced into Hawaii for the biological control of mosquitoes (Van Dine 1907; Yamamoto and Tagawa 2000). It is likely that some poeciliids and certain other small nonindigenous fishes were also stocked on other Pacific islands in the past with the intention of using them to control insect pests. The cane toad *Rhinella marina* was intentionally introduced to various Pacific islands as a biological control agent. For example, it was introduced to the Micronesian island of Pohnpei (in FSM) by occupying Japanese forces during the Second World War to control mosquitoes and grasshoppers and to Fiji in the early 1930s to control beetle (coleopteran) pests of agriculture (Lever 2003). In Guam, the cane toad was first introduced to Agaña Spring in 1937 for insect and slug control (Eldredge 1994, 2000).

Current Management Practices

DAWR serves as the main agency to permit the importation of nonindigenous fishes or other aquatic animals for use in biological control. This would likely require careful review and vetting of any plans for such use of nonindigenous species and consideration of possible consequences.

Prognosis

We are unaware of any current activities or plans involving introductions of nonindigenous aquatic animals for the purpose of biological control agents. Thus, future risk potential for establishment of any new species by means of this pathway is considered to be **low/very uncertain**.

Research

Present Condition

We are unaware of any past or current activities involving the introduction of nonindigenous aquatic vertebrates or macroinvertebrates to Pacific islands for the explicit purpose of conducting scientific research, other than those species of interest for aquaculture.

Current Management Practices

DAWR serves as the main agency that issues permits for the importation of nonindigenous fishes or other aquatic animals for use in scientific research. This would likely require careful review and vetting of any plans for such use of nonindigenous species and consideration of possible consequences.

Prognosis

Future risk potential for establishment and/or spread of nonindigenous species by means of this pathway is *unknown*.

Natural Dispersal from Neighboring Waters

This pathway involves the natural dispersal or spread of nonindigenous freshwater aquatic animals. Within freshwater bodies of Pacific islands, this includes natural movement from one island to another, and within a single island, from a drainage where the species is established to an adjacent drainage where it previously did not occur.

Present Condition

We are unaware of any evidence to indicate that nonindigenous freshwater animals have naturally dispersed to Guam from neighboring islands. However, it is likely that some nonindigenous aquatic animals introduced into one or a few drainages subsequently dispersed naturally into adjacent drainages, as evidenced by their current distribution. For example, the widespread presence of tilapia among Guam drainages suggests that they may have naturally dispersed as well as been intentionally stocked. Peacock cichlids introduced to Fena Reservoir reportedly dispersed to streams downstream of the reservoir (B. Tibbatts and F. Camacho, oral commun., 2010).

Current Management Practices

We are unaware of any specific management practices on Guam or other Micronesian islands currently aimed at preventing the natural dispersal of nonindigenous aquatic animals.

Prognosis

Future risk potential for dispersal of nonindigenous species, both those already established on Guam, and/or other Micronesian islands, as well as those with significant probability of becoming established in the future, is *medium/moderately certain*. This pathway can be affected by different factors, some of which may act in synergy. For example, episodic

natural events such as floods or typhoons can create physical conditions that favor dispersal for some species. Moreover, the physiological tolerances of many species may predispose them with the ability to move through habitats (e.g., brackish or full-strength sea water) that would preclude other less-tolerant species.

Detection

The chance of eradicating a new introduced species decreases the longer one remains undetected (McNeely et al. 2001; Wittenberg and Cock 2001). Early detection of new introductions of nonindigenous fish species will require increasing public awareness plus surveys to monitor sites. Although surveys can and should be used to detect new introductions, the public should be engaged because the sheer size of the human population on Guam greatly increases the likelihood of early detections. The population of Guam was projected as 180,692 in 2010 (Guam Bureau of Statistics and Plans 2009, p. 290). The key is educating the public to recognize new invasive species.

Methods to increase public awareness are described in greater detail below, and emphasize possible use of posters and other media to illustrate native freshwater species in Guam, which may help the public to recognize nonindigenous species by default. In effect, if a member of the public buys or finds a freshwater fish in Guam and that fish is not recognized as being native, then it should not be released. Any fish (or other aquatic species) collected in the wild that is not recognized as native, or not known to be an established nonindigenous species, should be promptly reported to DAWR. Similar posters and other media products that illustrate native and nonindigenous species could be created for other taxonomic groups, such as turtles, frogs, snails, and crustaceans. Reporting could be enhanced by a telephone or text messaging hotline (such as is currently used by DAWR and publicized for reporting occurrence of coqui frogs), and by an online reporting form.

Any specimens of newly detected or introduced species should be preserved as vouchers and added to the museum collection at the University of Guam or another appropriate institution, where specimens could be examined by taxonomic experts to confirm identification. Local newspapers should be encouraged to report any new introductions, together with photographs to document new species on the island, and local biologists are encouraged to publish information about any such specimens in the peer-reviewed literature. The University of Guam publishes the scientific journal *Micronesica* that focuses on the natural sciences and is an appropriate outlet for the publication of new reports of the occurrence, establishment, or spread of introduced species.

Documenting Imports: Propagule Pressure

To thoroughly understand the potential risks to Micronesia of invasive species originating by means of the pet trade and other pathways requires that the types and numbers of each species imported into Guam and other islands be regularly documented. Currently this information is only partially available. Having this information available would allow for better estimation of propagule pressure (Kolar and Lodge 2001; Lockwood et al. 2005; Colautti et al. 2006; Duggan et al. 2006; Conover et al. 2007; Gertzen et al. 2008). Some information regarding species imported into Guam is recorded by USFWS personnel on Guam (animals from foreign sources) and some information is maintained by DAWR personnel (animals from domestic sources); we were unable to locate or obtain either of these sources of information. The LEMIS data for Guam

have been obtained from the USFWS. However, that database generally does not identify aquarium fish to species. In particular, many shipments of fish generally are lumped into a category termed “tropical fish.” The estimated number of freshwater “tropical fish” imported into Guam over the 2007-2009 period totaled 149,650 (67,213 fish in 2007, 60,263 in 2008, and 22,174 in 2009). These numbers only represent fish imported into Guam from foreign sources, not those shipped from Hawaii or the mainland United States. Tracking of imports could be improved if foreign exporters were to list the types and numbers of each species of fish in each shipment arriving in Guam, and if such information were to be recorded by border agents and retained in an electronic database. Additionally, tracking could be further improved if the types and number of each species imported into Guam from domestic sources also were monitored, recorded, and available in an electronic database.

Border agents and wildlife inspectors likely cannot be trained to identify all aquarium animals and plants that are or potentially can be imported into Guam. However, agents are encouraged to receive sufficient training to identify most of the approximately 265 freshwater fish species or species groups and 45 species of aquatic invertebrates (most of which are marine) on the island’s white list (see below), a list of permitted, nonindigenous species that are putatively safe to import insofar as not to pose serious threats of becoming invasive.

Currently the wildlife inspector on Guam apparently inspects about 30% of shipments brought to his attention. Perhaps this percentage could be increased by hiring an additional wildlife inspector or by requiring that live fish be held in quarantine for a brief period to provide inspectors more time to examine each shipment. Photographic documentation of containers and contents might speed the process. Any quarantine would likely increase costs for the government and the private sector. In a quarantine system some fish would need to be housed and fed while in quarantine, and a few of these animals might die from stress or other factors. However, such costs might be offset by preventing the importation of potentially invasive species that otherwise would not have been stopped. Also, diseased fish in quarantine might be identified and any pathogens prevented from spreading to wild populations.

Documenting Imports: Detecting Imports

Radiograph machines at A.B. Won Pat International Airport, the commercial airport in Guam, may be inadequate to thoroughly screen materials arriving by air; at the onset of this study, equipment was in disrepair as well as insufficient to pass large items (USDA-APHIS 2009). This indicates that contraband materials could enter the island relatively easily. Trained security dogs are used for luggage inspection at Guam’s airport, but we presume that dogs are not trained or are incapable of detecting live aquatic animals. Detection could be improved by repair or replacement of radiograph equipment and increased screening of commercial shipments arriving by air.

Even with increased inspection of known live-animal shipments to Guam, border agents cannot detect all incoming wildlife. The detection probability of live freshwater fishes and other potential nuisance aquatic species could be estimated by conducting controlled trials in which live fish are imported into Guam in known containers, along known pathways, following a predetermined schedule. In a hypothetical scenario, investigators would record the percentage of such packages and fish detected by agents who are unaware of the trial schedule or package characteristics. This information could then be used to estimate the actual number of fish

imported annually into Guam by means of each pathway. This would allow for the identification of porous pathways of introduction that subsequently could receive additional attention by inspectors.

Postal Service

By law (U.S. Code Title 39, Section 404[c]) domestic mail in the United States is protected and sealed against inspection except under exigent circumstances such as to protect human life or safety, as authorized for intelligence purposes, or if executed by Federal Search Warrant. The postal inspector in Guam currently does not allow domestic mail to be inspected unless the postal inspector is present, and this individual is frequently unavailable (USDA-APHIS 2009). Approximately 95% of mail arriving in Guam is considered domestic mail. Aquarium fish and other aquatic species can be transported by mail services, with some ordered by means of the Internet. As a result, even if customs inspectors documented every aquarium organism transported as ship or air cargo or transported by passengers, an undetermined and potentially large number of nonindigenous animals could be imported into Guam by means of other pathways, including the postal service and private courier services such as Federal Express or the United Parcel Service. Ideally, all mail entering Guam could be inspected by radiograph to establish probable cause for search warrants for undeclared live-animal packages. However, radiograph equipment at the main U.S. sorting facility in Guam was inoperative at the onset of this study (USDA-APHIS 2009). Moreover, it is unknown to us how much domestic mail is inspected.

Currently, most international mail destined for Guam enters the United States in Hawaii where it can be inspected relatively easily (USDA-APHIS 2009). From that point, such mail is considered domestic U.S. mail and a search warrant is required to inspect it once it reaches Guam. Perhaps in the future postal workers in Guam may have the capability to inspect a larger percentage of such mail than is done by workers in Hawaii.

Australia inspects 100% of international mail using visual inspection, dogs and radiograph machines (Pheloung 2003). As part of New Zealand's integrated biosecurity system, officials inspected 84% of approximately 51 million pieces of international mail within a year ending 30 June 2000; of those, 94,000 items were opened, of which 30.7% contained risk goods (Hayden and Whyte 2003). Increased interdiction of contraband live animals would result if similar measures were implemented for all mail arriving to Guam from both domestic and international sites of origin. Further improvements at intercepting live-animal shipments could be achieved if efforts were expended to better estimate detection probability, and the results used to help design the most efficient system of mail inspection.

Currently, mail that arrives at Andersen Air Force Base is not inspected (USDA-APHIS 2009). As with commercial shipments, increased inspection of military mail arriving in Guam from off the island would improve detection of undeclared live-animal shipments.

Permitted and Prohibited Species

White List Review

A white list (Simberloff 1998) or a clean list (Case Study 2.5 in Wittenberg and Cock 2001) is a list of nonindigenous species that are considered to be non-invasive and safe to import

(McNeely et al. 2001). This concept is considered to be stricter and safer than relying upon a black or “dirty list” list (Wittenberg and Cock 2001) of species that are prohibited from a given region. A white list follows the precautionary principle (Case Study 3.3 in Wittenberg and Cock 2001) of the idea of guilty until proven innocent (Ruesink et al. 1995; McNeely et al. 2001; Wittenberg and Cock 2001); in other words, of evaluating the tradeoffs by considering those species to be permitted as posing less potential invasive risk. Some researchers have proposed a third category, a “gray list,” to include taxa provisionally prohibited (or provisionally permitted) pending further information (the three-list approach has been called “white/black/gray” or “green/red/amber”) (Jenkins 2005).

DAWR has developed a white list of freshwater and marine plants and animals that are permitted to be legally imported for the aquarium trade, aquaculture, water gardens, and other uses. Species that are not on the white list are prohibited from being legally imported, with limited exceptions (for example, species allowed to be displayed by the commercial aquarium in Tumon). The white list is made available to those businesses that regularly import plants and animals, mainly pet shops and a small number of aquaculture facilities. A preliminary review of the freshwater fish species included on the white list revealed a few discrepancies in currently accepted nomenclature; the white list is included here with revisions to scientific names and the addition of taxonomic authorities and vernacular names commonly used in the aquarium trade (Table 33). A similar review was not completed for the permitted marine fishes, invertebrates (mostly marine), and the small number of allowable freshwater plants (Tables 34-36).

An independent review of DAWR white list may be warranted, including a process to ensure flexibility in omitting or adding species to the list based on recommendations by experts. Some immediate considerations were proposed from our preliminary review of the list and site visits to pet shops in Guam. For instance, we suggested in an earlier (2010) draft of this document that the legal importation of all armored suckermouth catfishes of the genus *Pterygoplichthys* and related species and genera (various taxa of the family Loricariidae) be reconsidered in Guam. Several species in the genus *Pterygoplichthys* are popular in the aquarium trade and are sold widely, and individuals commonly grow to become quite large. Owners of pet fish are more likely to release fish that become too large to house easily (Gertzen et al. 2008), and the suspected repeated release of aquarium specimens of *Pterygoplichthys* has resulted in their widespread establishment in Hawaii, Florida, Texas, Mexico, Southeast Asia, and elsewhere (Nico et al. 2009). Once released, colonies of fish in the genus *Pterygoplichthys* can cause extensive damage to stream banks by their excavation of numerous nesting burrows (Nico et al. 2009). Some populations that have become established out of their native range reach extraordinary densities. We were recently informed that, effective 31 December 2010, DAWR no longer permits the importation of armored catfishes of the family Loricariidae into Guam (B. Tibbatts, written commun., 2011). Another example of a species that likely should be removed from the list is the bighead carp, *Hypophthalmichthys nobilis*, which was recently listed as injurious by the U.S. Fish and Wildlife Service and is now prohibited from transport between U.S. states and any of its territories (USFWS 2011). The white list also contains other species known to be invasive on Pacific islands (including Guam) and elsewhere, including various cichlids and poeciliids. Some species reach relatively large body size and/or are predatory and thus likely to pose threats to native species, others may be suspected or known superior competitors, and for yet others possible ecological or interspecific impacts remain unknown. A regular review of this list, perhaps on a 5-year basis, would allow incorporation of new

information as it becomes available to assess the potential risks associated with the importation of permitted fish.

Faunistic Surveys and Monitoring

Wittenberg and Cock (2001) describe three types of surveys designed for early detection of new introductions of nonindigenous species: general surveys, site-specific surveys and species-specific surveys. Such surveys must be repeated regularly to be effective.

As a general survey, one possibility is an occupancy survey (MacKenzie et al. 2006) similar to the North American Breeding Bird Survey (Sauer et al. 1994; <http://www.pwrc.usgs.gov/bbs/>), the Swiss Breeding Bird Monitoring Program (Kéry et al. 2005), the Swiss Butterfly Monitoring Program (Kéry et al. 2009), or the U.S. Geological Survey's North American Amphibian Research and Monitoring Initiative (<http://armi.usgs.gov/>). Details of survey design could be established through consultation with appropriate experts. For aquatic surveys of freshwater sites in Guam and elsewhere in Micronesia, sampling could utilize different methods, such as minnow seines, dip nets, passive fish traps, and visual observation (Hankin and Reeves 1988), depending on the knowledge and experience of personnel conducting surveys.

Site-Specific Surveys

These types of surveys are intended to target areas that have high conservation value (e.g., ecosystem prioritization) or are near high-risk entry points (Wittenberg and Cock 2001; Jenkins et al. 2009). Examples of the latter would include areas near human population centers, aquaculture facilities, and/or ports of entry. DAWR currently has a routine river and wetland survey and monitoring program in place that includes targeted sites as well as new ones; additional aquatic surveys are conducted by University of Guam researchers and the U.S. National Park Service. A review of these sites and consideration of additional sites to target specifically for monitoring potential new introductions requires careful consultation between agency biologists and cooperators. Perhaps 20-50 randomly-selected survey sites could be chosen in or near each area as listed above. Potential sites to be targeted in Guam could include: Apra Harbor, Guam International Airport, Andersen Air Force Base, Agana Swamp (Guam's largest natural freshwater marsh), Fena Reservoir (the main reservoir in Guam), Sasa Bay Wetland (102 hectares of estuarine and freshwater wetland), Atantano Wetland (130 hectares of estuarine and freshwater wetland), the Talofofu River Valley (the largest contiguous water body in Guam), and current and former aquaculture facilities.

Species-Specific Surveys

In Guam, these surveys would overlap substantially with site-specific surveys, but potentially could target species currently known to be present, such as snakeheads (*Channa* spp.), tilapia (*Oreochromis* spp., hybrids, and *Tilapia zillii*), peacock cichlids (*Cichla* sp.), walking catfish (*Clarias* spp.), as well as other taxa of special concern, such as swamp eels (Synbranchidae). Species-specific surveys might focus more on ponds, current and former aquaculture facilities, Guam's reservoirs, Agana Swamp, golf courses, and river mouths rather than focusing on stream reaches, at least if the aforementioned species were targeted.

Volunteer Surveyors

Conducting regular surveys likely would require more effort and resources than are currently available to DAWR and other Micronesian agencies. Elsewhere, some large-scale intensive surveys are volunteer-based; use of volunteers to survey for invasive species in Guam

could enhance early detection. Such efforts would be further enhanced with sufficient funding to support a survey coordinator and adequate training of volunteers.

A potential pool of volunteers might involve government biologists, military personnel in charge of managing natural resources, park personnel, students at the University of Guam, local naturalists, interested anglers, and high school students. Such volunteer groups could adopt one or more sites to survey on a regular basis. Guam might also benefit from the allure of ecotourism to recruit volunteers from off the island for commitments to survey or monitor selected sites.

Funding to Support Surveys

The government of Guam could benefit from implementing a fishing license, if a portion of any generated revenue were used to support surveys and management efforts for aquatic invasive species. Fees assessed to those who wish to profit from importing nonindigenous species is a demonstrated mechanism to advance management efforts (McNeely et al. 2001). Additional potential funding mechanisms are discussed below under *Management*.

Intercepting Animals Illegally Shipped for Food

Early detection of new introductions of nonindigenous species could be accomplished using the above approaches regardless of the pathway of introduction. Additionally, improved detection of species with potential to be intentionally introduced for food could be accomplished by means of periodic visits to markets and restaurants that sell live fish and other aquatic animals.

In cases of suspected illegal live or fresh animal products or species of questionable identity, DAWR personnel and other authorities are encouraged to collect whole-animal and tissue samples (for possible genetic analysis) using appropriate preservation techniques, and to have these samples examined and identified by qualified experts. If qualified experts cannot be found to accept specimens immediately, good-quality photographs of live animals will improve the chances that accurate identifications can be made. Freezing of any specimen(s) is preferable to discarding or releasing it (them).

Management

Prevention

Preventing transport or import of potentially harmful species so as to thwart their possible introduction or spread into new areas is generally considered to be the most efficient and cost effective way to manage invasive species (Simberloff 1998; Wittenberg and Cock 2001; Lodge et al. 2006).

Cooperation among nations in the western Pacific, whereby preventive measures are enacted to reduce the probability of exporting or importing invasive species, may benefit each nation by reducing the probability of additional nonindigenous taxa becoming established (McNeely et al. 2001). Such an approach has been implemented by Australia and its neighbors, as the North Australian Quarantine Strategy (Pheloung 2003), which involves surveillance and monitoring by all participating nations. A proactive, precautionary approach is preferred, requiring effective and coordinated efforts together with sufficient resources and networking (Henderson and Bomford 2011). Similar cooperation is encouraged between Guam, the

Commonwealth of the Northern Mariana Islands, the Federated States of Micronesia, the Republic of Palau, the Republic of Kiribati, the Republic of the Marshall Islands, the Republic of Nauru, Japan, Wake Island, Hawaii, and the U.S. mainland. There currently exists heightened awareness of invasive species in insular regions of the Pacific; consequently, a certain degree of networking and coordination is already in place.

Prevention requires that all pathways of introduction be identified and evaluated. For Guam and other insular areas in the western Pacific, the primary human-mediated dispersal pathways of nonindigenous aquatic animals are thought to be the ornamental pet trade and the aquaculture industry. The risks associated with different pathways vary among the various islands, depending in part on the scope and effectiveness of existing legal measures already in place.

Dispensing of Unwanted Aquarium Pets

Wittenberg and Cock (2001) describe options of what to do with aquarium fish that are no longer wanted by their owners. A few of the options include returning unwanted fish to the pet store of origin, donating to another hobbyist or a corporate or public aquarium, or giving unwanted animals to a public institution such as a school, nursing home, hospital, or prison.

If none of these options are available, fish may be euthanized by placing them in a container of water and putting the container in a freezer. Humane treatment can be accomplished by exposing fish to carbon dioxide (released by use of effervescent antacid tablets such as Alka-Seltzer®) or clove oil prior to freezing. Instructions for humane lethal treatments could be included in educational materials. Another alternative would be for DAWR to establish a program whereby the agency could accept unwanted fish or other aquatic life and humanely dispose of animals or distribute them to other owners who are capable of providing proper care. As an example, the Florida Fish and Wildlife Conservation Commission holds Non-native Amnesty Days at which time pet owners can relinquish unwanted pets (http://myfwc.com/wildlifehabitats/non-native_amnestydayevents.htm). DAWR is encouraged to consider adopting a similar program and to offer adequate numbers of sites, annual dates, and to sufficiently publicize events to ensure success.

Eradication

Eradication of an established freshwater fish population in a stream or river system is often difficult, and in many situations, impossible. Most successful eradication attempts rely heavily on the use of fish toxicants, mainly rotenone, but these chemicals must be used judiciously because they are largely non-selective and result in loss of both native and nonindigenous species (Kolar et al. 2011; Nico and Walsh 2011). In Guam, rotenone could possibly be used to eliminate nonindigenous fishes from certain closed systems; for example, abandoned aquaculture facilities or small ponds on golf courses where native species are absent. Reviews of eradication projects targeting invasive fishes, including eradication attempts on Pacific Islands, are included in the publications cited above.

Containment and Control

Containment is a means to prevent the spread of a nonindigenous species. Containment in a river system may be achieved by preventing a species from passing upstream or downstream beyond a natural or artificial physical barrier, or preventing the species from passing from one watershed to another. Salinity may naturally prevent a freshwater species from dispersing among river basins. Drainage alteration that connects two or more previously separated watersheds during land development or flood control is one way in which a contained species might spread. Consideration of this possibility should be given during the construction phase of the U.S. military build-up in Guam.

Control of nonindigenous species involves reducing the density and abundance to acceptable levels. For nonindigenous species in river habitats, control and eradication may simply be matters of degree, as the methods used will largely be the same. However, control measures can sometimes fail and result in increased abundance of a target species if density-dependent population mechanisms are present (Zipkin et al. 2009). These authors stated that “species with high per capita fecundity (over discrete breeding periods), short juvenile stages, and fairly constant survivorship rates are most likely to respond undesirably to harvest.”

Legislative Actions

DAWR white list only permits those species that are allowed to be legally imported into Guam. It is our understanding that no legislation currently exists that prohibits ownership of species that are not permitted for legal importation. It is possible that Guam authorities may wish to review existing legislation and consider possible benefits of laws that could apply to possession of live animals that are otherwise illegal to import (especially given the “leaky” pathways by which undeclared shipments can potentially bypass ordinary inspection procedures). Exclusionary precedents exist; for instance, the commercial aquarium in Tumon receives official permission to maintain certain prohibited species for display and educational purposes. Legislative actions could include incentives for disclosure of potentially invasive captive-held species, such as establishing the aforementioned “amnesty” program whereby live animals could be voluntarily surrendered.

Aquaculture Industry

Species introduced for aquaculture may escape and become established in the wild. Flooding of aquaculture facilities, in particular, may allow animals to escape (Nico et al. 2005). Nonindigenous species used for aquaculture may also carry nonindigenous disease organisms that can reduce populations of native species as well as captive animals (Funge-Smith and Briggs 2005). The following measures may help to prevent animals from escaping from aquaculture facilities (Fuller 2003; Tucker and Hargreaves 2008):

- Careful inspection to ensure that stock is not contaminated with unintended species (see also Nico et al. 2005).
- Avoid placing facilities within areas prone to flooding (e.g., 100-year floodplain).
- Install perimeter berms and fencing to secure the facility.
- Use strong and durable construction materials.

- Use appropriate mooring systems.
- Use closed circulation systems so that no water leaves the facility, or install other barriers to prevent escapement.
- Use nets or other devices to prevent birds and other predators from transporting fish away from the facility.
- Regularly inspect containment facilities.

Some species, especially those that pose the greatest threat if they escape into the wild, may be best maintained in aquaculture facilities or farm ponds as entire stocks of certified triploids or sterile hybrids. Triploid fish contain three sets of chromosomes in cell nuclei instead of the usual two sets and are considered sterile (Nico et al. 2005). Use of native species is also encouraged.

Triploid carp are commonly used for biocontrol and other purposes so that the stocked carp do not form wild reproducing populations. However, this approach may not be 100% effective at preventing carp from establishing wild breeding populations because some individuals presumed to be triploid may actually be diploid and capable of breeding (Nico et al. 2005). Possibly, triploid tilapia (Hussain et al. 1991; Byamungu et al. 2001; El-Sayed 2006) could be used in aquaculture facilities in Guam and elsewhere in Micronesia outside of government controlled, biosecure, closed-circulation breeding facilities. However, use of triploids for some species could increase production costs to the point that rearing of these species becomes economically unfeasible.

In addition to the above measures, facilities that are located at isolated sites with no connection to natural waterways reduce chances of accidental escapements of undesirable species. This may be considered a form of closed circulation. Facilities that are inspected regularly, followed with routine repairs and maintenance, provide greatest biosecurity. Data regarding the number and location of all existing and recently closed aquaculture facilities in Guam were not available to the investigators. A database containing the locations and information about the owners or former owners of these facilities would improve tracking of aquaculture activities. Facilities that are no longer in operation may remain a risk for nonindigenous species introductions if stocked animals were not previously removed and/or if perimeter barriers are no longer maintained.

There are many sources of information readily available that provide biosecurity guidance for the aquaculture sector, such as the review by Tucker and Hargreaves (2008). Local and regional regulatory authorities are encouraged to provide summaries of these resources, and recommended management alternatives, to private and commercial aquaculturists.

Intentional Introductions for Food

Freshwater fish and other aquatic species form a large part of the diet of some ethnic groups living in Guam and elsewhere throughout Micronesia. It is likely that some nonindigenous species have become established on Pacific islands after being imported and intentionally released to provide a source of live food favored by particular ethnic groups. The population of Guam currently consists of people from many different ethnic backgrounds, and that trend is likely to continue with new immigrants (Table 37).

Table 37. Projected ethnic background of human population of Guam for 2011, 2015, and 2020. Figures in parenthesis under Native Hawaiian and other Pacific Islander include Chamorro population. Those under Asian refer to Filipino population (Guam Bureau of Statistics and Plans 2009).

Ethnic Origin	2011	2015	2020
Native Hawaiian and other Pacific Islander	81,649 (67,763)	85,762 (71,176)	90,629 (75,215)
Asian	59,522 (48,168)	62,520 (50,594)	66,068 (53,466)
White	12,429	13,054	13,795
Black or African American	1,854	1,948	2,058
Other, single race or ethnic group	2,137	2,245	2,372
Other, mixed race or ethnic group	25,490	26,774	28,293
Total	203,216	192,302	183,081

The likelihood of additional nonindigenous species being illegally brought to Guam and/or elsewhere in Micronesia for live food may in part depend on the ethnic composition of the construction work force that will be involved in the military build-up. Thus, projections by the government of Guam and the DoD on the anticipated ethnic composition of the civilian workforce may be beneficial in assessing risk associated with this pathway of potential introductions.

As nonindigenous fish species are not allowed to be released in Guam, the best measures to prevent intentional introductions of nonindigenous species for live food will be enforcement efforts by border control and customs inspectors, and public education, similar to the approaches described above for aquarium species.

Baitfish

No nonindigenous freshwater fish species are sold legally as bait in Guam (B. Tibbatts, oral commun., 2010). Any future consideration of importation of baitfish should be thoroughly vetted.

Biocontrol

No nonindigenous freshwater fish species are currently used legally for biocontrol in Guam (B. Tibbatts, oral commun., 2010). In the past, some species were introduced into Fena Reservoir on the U.S. Naval Magazine for aquatic plant control. Additionally, various poeciliid fishes may have been released in the past in Guam and other Micronesian islands to aid in insect control. As with baitfish, any considerations to introduce aquatic species as biocontrol agents should be thoroughly vetted, drawing on the expertise of scientists and government agencies to fully assess all possible consequences that would ensue through such introductions.

Contingency Plan and Rapid Response

A contingency plan is a course of action to be taken when a new introduction has been detected or suspected (Wittenberg and Cock 2001). The first step in Guam likely would be for any person finding a fish or other aquatic species to contact one of the island's recognized authorities (e.g., Mr. Brent Tibbatts, Fisheries Biologist with DAWR, or Dr. Frank Camacho or Dr. Terry Donaldson, University of Guam). Any specimens that are available should be provided to DAWR or deposited into the biological collections at the University of Guam or another appropriate institution. Once a specimen has been positively identified or a report of a suspected new introduction has been received, personnel must then decide upon the most appropriate and effective management action to be taken. The four main management strategies described by Wittenberg and Cock (2001) are eradication, containment, control, and mitigation. These strategies will likely be the same regardless of the pathway of introduction except for intentional introductions for food, which might involve law enforcement. Officials of DAWR and other agencies are encouraged to develop a rapid response program for the early detection and management strategy for new introductions of aquatic species.

Liability

Individuals responsible for releasing an invasive species can bear responsibility to pay all or a portion of the resulting economic costs (McNeely et al. 2001). However, individual(s) responsible have to be identified. Also, endorsement of such punitive action requires public support. In practice, costs may be so high as to bankrupt many individuals. Businesses that import or use invasive species may need to carry liability insurance (McNeely et al. 2001). The cost of such insurance could potentially render aquaculture to be economically unfeasible. Perrings et al. (2005) suggested using tariffs to have exporters of nonindigenous species pay costs incurred by those species that become invasive. Jenkins (2002) suggested fees charged to intercontinental importers and cited California's Ballast Water Management and Control Program as a possible model (www.boe.ca.gov/sptaxprog/bllstweb12.htm).

As the population of Guam increases, the popularity of home aquaria is expected to increase proportionally. Therefore, propagule pressure in the form of greater numbers of nonindigenous organisms in the pathway, and greater numbers of people likely to release fish to the wild, will also increase proportionally. The most successful management actions to mitigate for this increased propagule pressure will likely require improved public education, refinement of permitted species, and increased inspections and monitoring of imports.

Education

The mainland U.S. chain pet store PetsMart discourages buyers of pet fish from releasing their pets by printing slogans directly on the bags in which customers transport their purchased fish home. This is done as part of a national campaign called “Habitattitude” (<http://www.habitattitude.net/>). This program is a partnership between the pet and aquarium trade (Pet Industry Joint Advisory Council), nursery and landscape trade, the U.S. Fish and Wildlife Service, and the National Sea Grant Program. Pet stores in Guam that sell aquatic animals and plants could be encouraged to participate in this program and to use similar bags. We asked personnel at two pet stores in Guam what measures they currently take, or would be willing to take, to discourage their customers from releasing pet fish, but staff at neither store responded.

Aquarium fish are often sold under non-standardized names. We suggest that pet stores consider labeling their stock with current valid scientific names in addition to whatever trade names they use. Scientific names could be placed on aquaria containing each species and could be visible to customers and potential inspectors. Qualified personnel of DAWR, inspection agents, and university faculty are encouraged to work closely with pet stores to achieve this and to ensure that names are kept up to date. Regular workshops could be conducted or on-site visits made to pet stores to educate store managers and their employees.

Pet store customers could be surveyed to estimate their likelihood or history of releasing animals that they purchase(d) and the reasons they do so (Gertzen et al. 2008). This information could be used to estimate the number of nonindigenous species released into Guam annually, another measure of propagule pressure, and directly related to the probability that a nonindigenous species will become established in Guam. Polled individuals could be provided with assurances of complete anonymity to prevent any possible fear of recrimination and to ensure that information is provided openly and honestly.

A website could be constructed with information about invasive aquatic species and the threats that they pose to native species and habitats. Through such a web site, the aforementioned posters and videos could be made freely available for downloading and printing. Such a website could be designed so that it appears at, or very near, the top of the list of links returned by casual searches conducted by means of Internet search engines by use of strategic key words.

Research Needs

Some authors have reported that little evidence exists concerning the negative effects of nonindigenous fish species on native species in their regions or countries, or that relatively little

research has been directed in this area (Luu and VanThanh 2005; Nuov et al. 2005; Win 2005). However, there are many well documented cases that illustrate how introduced freshwater fishes have negative consequences on native faunas—in some examples on a community level or large landscape scale (e.g., the Laurentian Great Lakes, the Colorado River basin, and Lake Victoria). In the case of Micronesia, we are aware of few studies that have directly examined interactions between nonindigenous and native species. McKagan et al. (2009) reported results of an extensive survey for nonindigenous aquatic species on Saipan, and included information from FishBase (<http://www.fishbase.org>) that summarized potential threats. MacKenzie and Bruland found that introduced poeciliid fishes posed threats to wetland habitats in Hawaii. Tilapias, which were intentionally introduced to many Pacific islands to provide food (Devambeze 1964), are now commonly regarded as pests in many places and may have impacts on native species broadly across aquatic habitats from fresh water to coral atolls (Gillett 1990; Nelson and Eldredge 1991; Canonico et al. 2005). We suggest that additional research into effects of nonindigenous species on native species in Micronesia would be helpful in prioritizing management efforts, albeit a precautionary approach is best in the absence of scientific evidence of effects (Bartley et al. 2005). Other authors have similarly suggested the need for additional empirical research on the general topic of how nonindigenous species affect native species in areas where they become invasive (Hager and McCoy 1998; Gurevitch and Padilla 2004; Didham et al. 2005).

Acknowledgments

Completion of this study would not have been possible without the generous assistance of many individuals (see pages *x-xi* for institutional or affiliation acronyms for the following people). We would especially like to thank Brent Tibbatts (DAWR) for providing extensive information and valuable assistance in the field. Phil Andreozzi (NISC) kept the project and the teams focused and greatly facilitated progress, always with a positive attitude and understanding of the challenges. For providing logistical support that enabled us to conduct fieldwork in Guam and other assistance, we are very grateful to Shane Siers, James Stanford, Eli Wostl, Gordon Rodda, and Howard Jelks (all USGS). Additional assistance with field work was provided by Jamie Barichivich (USGS), Jennifer Staiger (USGS), and Frank Camacho (UOG). Diane Vice (DAWR) kindly gave us a tour of DAWR facilities and assisted with meeting logistics and other matters. Earl Campbell (USFWS), Richard MacKenzie (USDA-FS), and Joel Miles (Palau) contributed valuable scientific insights. Steve McKagan (NMFS) was very helpful in arranging to meet with Mike Trianni and Mike Tenorio (both CNMI-DFW) to discuss issues pertinent to invasive species in the CNMI, and facilitating site visits in Saipan. Fred Sengebau (PBOA) issued a collecting permit for Palau, and Chipper Tellei (Palau) provided very helpful field and logistical support. Emil Edesomel (PEQPB) supplied us with information about eradication efforts for tilapia on Malakal. Don Buden and Brian Lynch (both College of Micronesia, Pohnpei campus) contributed valuable information on native and nonindigenous species in Pohnpei. Site visits to aquaculture facilities and discussions about biosecurity protocols were facilitated by John Brown (GADTC), Michael Ogo, and Ross Manglona (both NMC-CREES). Art Taimanglo (USFWS) answered questions about imports and inspections. Jill Nishimura (USGS, Pacific Islands Water Science Center) informed us of numerous sources of hydrologic data for Pacific islands. The Smithsonian team contributed important information and discussions and facilitated in other ways for which we are thankful: Gregory Ruiz, Chela Zabin (both SERC), Mark Sytsma, Rich Miller, Lynda Moore, Vanessa Howard (all PSU-ABRPI), Chad Hewitt, and Marnie Campbell (both CQUA-CEM). We especially thank the following members of the USDA-APHIS team who assisted in countless ways: Robert Ahearn, Dallas Berringer, Cheryl Berthoud, Alan Franklin, Julie Gauthier, Janet Grimes, Daniel Jimenez, Lisa Kohl, Ingrid Kotowski, Heike Meissner, Will Pitt, Joan Sills, Michael Simon, Randal Stahl, Kristyn Stone, and Dan Vice. We are grateful to Patterson Shed (CSP), Gibson Susumu, and John Wichep (both FSM-DEA) for answering questions pertinent to the FSM. John (Bart) Lawrence and Jackie Flores (both USDA-NRCS) provided useful contact information. The following people representing Naval Facilities Engineering Command Pacific (NAVFAC PAC) assisted in numerous helpful ways: Anne Brooke, Cory Campora, Patrick Chee, Lisa Fiedler, Joel Helm, Jeffrey Herod, Taylor Houston, Vanessa Pepi, and Paul Wenninger. Maps were improved from an earlier draft of the manuscript by Andrew Horan and Ann Foster (both USGS).

1. Introduction

The purpose of this document is to guide the Department of Defense (DoD), as well as civilian government and non-governmental organizations working within the region, in identifying risk associated with the potential introduction of freshwater invasive alien plant species (IAPS) in Hawaii and Micronesia. It is one component of a larger effort to address all invasive species issues in that region. The intent of this component of the Micronesia Biosecurity Plan or MBP is to provide guidance to countries and territories in the region on how to protect their natural resources and economies from freshwater IAPS by recommending management actions that will 1) reduce the risks for new introductions 2) provide early warning of new introductions and 3) minimize the spread of new infestations and 4) control, or if possible, eradicate infestations.

This effort is necessary due to the U.S. Military relocation to Guam and Commonwealth of the Northern Mariana Islands (CNMI) (the Buildup) and the associated Environmental Impact Statement (DoN 2010). The planned Buildup activities will increase the risk for IAPS and other invasive species through increased movement and trade within and outside the region and increased habitat disturbance (DoN 2010). The Buildup as envisioned in 2009 would involve the relocation of approximately 8,600 U. S. Marine Corps forces and their approximate 9,000 dependents from Okinawa, Japan to Guam; the development of existing and construction of new infrastructure and facilities to support these Marines; the construction of a new wharf and infrastructure in Apra Harbor (Guam) to support transient nuclear powered aircraft carriers; and the relocation of approximately 600 U.S. Army personnel and their approximately 900 dependents to establish and operate an Air Missile Defense Task Force in Guam (DoN 2010). DoD expected a total of approximately 30,000 people, including active duty members, civilian personnel, and dependents of both to relocate to Guam as a result of the Buildup. At the peak of construction, DoD projected the population of Guam would increase by as much as 80,000 people due to the associated military and construction work related to the Buildup. Since 2010 the overall size of the Buildup has been in question and it is no longer clear exactly how many troops, civilian and transitory workers will be required.

Regardless of its ultimate size, the Buildup will have an indirect impact beyond Guam and CNMI, the geographic scope also includes the Republic of Palau (Palau), the Federated States of Micronesia (FSM), the Republic of the Marshall Islands (RMI), and Hawai'i (hereafter referred to as the Region) (Figure 1-1).

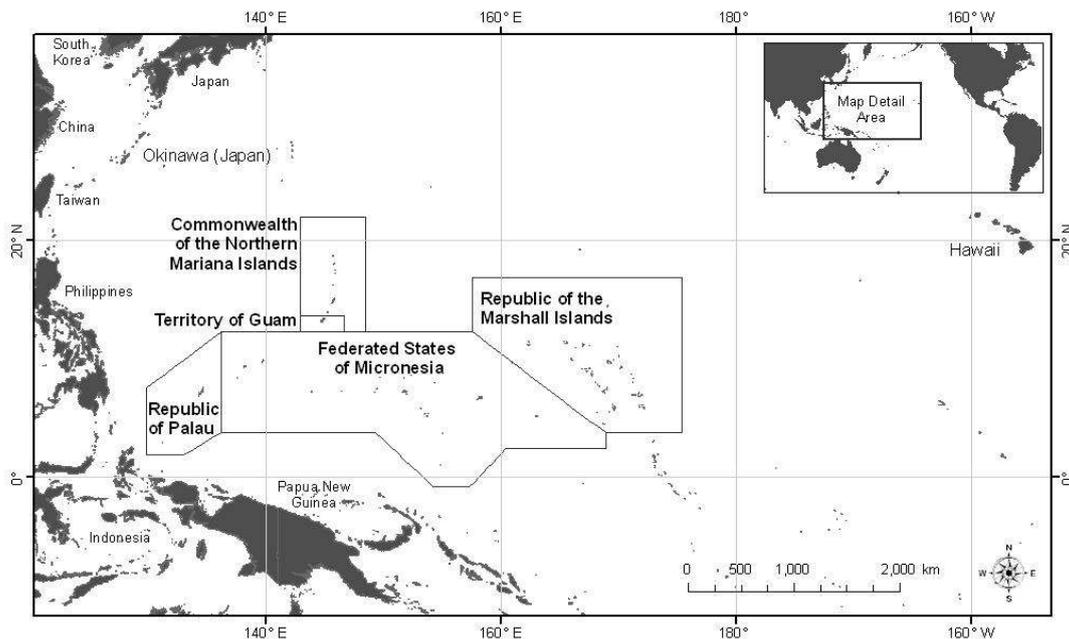

Figure 1-1: Geographic scope of the MBP Region.

1.1 Impacts of IAPS on Freshwater Habitats

Establishment and spread of IAPS in freshwater habitats often leads to considerable ecological, economical, and cultural harm. IAPS can reduce species richness and abundance of native plants (Boylen et al. 1999), affect utilization of drinking water supplies (Newroth 1985), increase water loss through evapotranspiration (Boyd 1987), retard water flow (Carpenter and Lodge 1986), and disrupt hydropower generation. IAPS can consume large amounts of oxygen during rapid senescence (Godshalk et al. 1977) creating fish kills, decrease land values (Halstead et al. 2003, Rockwell 2003), and diminish recreational opportunities such as boating, waterskiing, and fishing (Van Nes et al. 1999). Toxigenic blue-green algae associated with IAPS have been implicated in bird mortality (Wilde et al. 2005) and have the potential to affect human health. Conservative estimates of annual costs associated with IAPS in the United States (U.S.) are \$10 million in losses and damages and \$100 million in control (Pimentel et al. 2005). Flood control and recreation benefits associated with IAPS control in the U.S. are estimated to be over ten times higher (Rockwell 2003). Although IAPS can be dispersed by natural water currents, wind patterns, and animal movements; anthropogenic factors have substantially increased the rate and geographic range of invasions (Muirhead et al. 2009). In particular, increased globalization of trade has been correlated with higher rates of biological invasions (Levine and D'Antonio 2003) and establishment success is often greater in disturbed habitats (Chytrý et al. 2008).

1.2 The Freshwater IAPS Invasion Process

Although the islands in the Micronesia region are relatively isolated, they are susceptible to IAPS introduction. In fact, the low native freshwater aquatic plant species richness on the islands (there are only three native submersed species) may make the freshwater habitats on the islands particularly vulnerable to IAPS due to the available “niche space” for invaders (Kueffer

et al. 2010). This available “niche space” is just one of many factors that determines whether an IAPS will successfully invade an ecosystem after introduction. Catford et al. (2008) provides a useful framework for describing the components or factors in the invasion process (Figure 1-2). These components which are summarized below include the transport and introduction to an ecosystem followed by interactions between IAPS propagule pressure, abiotic characteristics of the ecosystem, and biotic characteristics of the IAPS and invaded community.

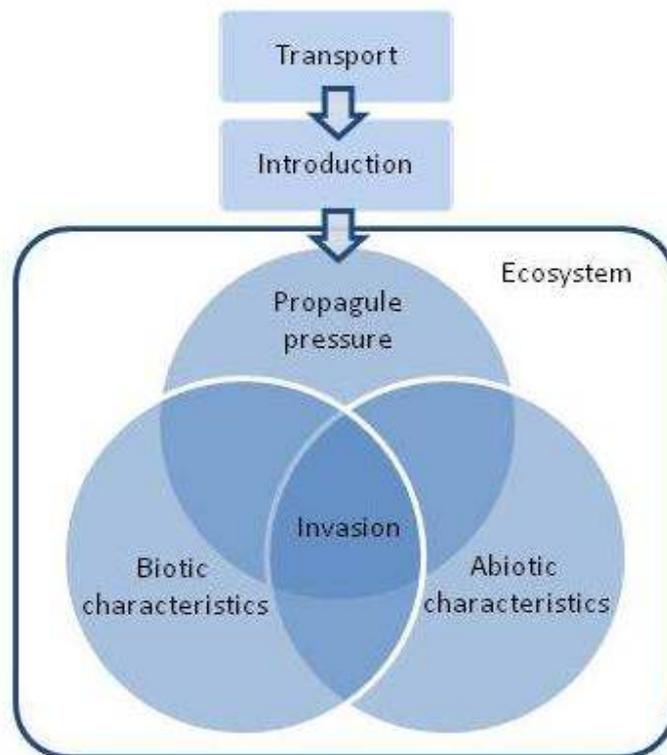

Figure 1-2: Schematic of how the transport and introduction of IAPS to an ecosystem influences propagule pressure; and how propagule pressure, abiotic characteristics, and biotic characteristics interact to determine invasion success (adapted from (Catford et al. 2008)).

IAPS are transported to new regions through natural pathways such as wind and water currents, and anthropogenic pathways such as ballast water or the pet and aquarium trade. The likely pathways of freshwater IAPS invasions to the Region are described below in Section 2. Once transported to a new region, IAPS can be released to the environment by accident or intent.

Once an IAPS is released to the environment, propagule pressure, the number of individuals released during an event and the frequency of events, are key characteristics in determining invasion success. Although a single individual can lead to successful invasion for some IAPS, higher propagule pressure is important for the continued invasion success of most IAPS.

The abiotic characteristics of an environment can also determine which IAPS successfully invade. The abiotic characteristics of freshwater aquatic environments include temperature, salinity, nutrient concentrations, light availability, soils, water flow, water depth, and the seasonality of water levels. In addition, disturbance of environments by both natural and

anthropogenic means can also promote invasion success. Characteristics of the Region's invulnerable freshwater aquatic habitats are described in Section 4.

Biotic characteristics of the IAPS and the native species also influence invasion success. Some of these biotic characteristics include a species competitive ability, dispersal modes, and reproductive capacity. The biotic characteristics of the Region's potential invaders are included in the Aquatic Weed Risk Assessment (Appendix B) and are summarized in Section 3.

2. Micronesia Region Invasion Pathways

Geographic isolation of islands is thought to limit the natural transport of viable freshwater and other IAPS via pathways such as wind patterns, water currents and animals (MacArthur and Wilson 1967). The islands of Micronesia are indeed isolated (Table 2-1); however, in a study of island plant invasions at a global scale, (Kueffer et al. 2010) found that human development (measured as gross domestic product) and habitat diversity are much more important factors than geographic isolation in determining the number of IAPS present. Kueffer et al. (2010) noted that human activity is the most important invasion pathway and that most IAPS were introduced intentionally.

2.1 Aquarium and Pet Trade

The aquarium plant trade is an important pathway for the spread and introduction of invasive species (Keller and Lodge 2007; Strecker et al. 2011) and is the primary driver of biosecurity risks associated with electronic commerce (Derraik and Phillips 2010). The aquarium trade is responsible for the introduction of several freshwater IAPS into the U.S., including Eurasian water milfoil (*Myriophyllum spicatum*), giant salvinia (*Salvinia molesta*), and Brazilian egeria (*Egeria densa*) (Reichard and White 2001). Many aquarium enthusiasts purchase fresh plant material for their aquaria online. The growing use and increasing speed and efficiency of postal/shipping delivery increases the probability that healthy invasive plants will reach appropriate climates for establishment and invasion (Reichard and White 2001).

Species misidentification, “hitchhiking” species, and disregard for regulations are major concerns with the aquarium and pet trade. Maki and Galatowitsch (2004) found that 93% of pond-plant shipments contained plant or animal species that were not ordered, and that 100% of shipments were contaminated with plants that were not ordered. Aquarium and pet trade vendors fulfilled 13 of 14 orders for species that were prohibited by either U.S. federal or state regulations, demonstrating that ignorance of or disregard for rules and regulations for the plant trade is commonplace (Maki and Galatowitsch 2004).

Nine of the first ten freshwater aquatic plant distributors returned by a U.S. internet search conducted by us during 2010 were U.S. companies. Seven of these top ten internet vendors made no mention of regulations pertaining to live plant transport. One vendor indicated that they verified the legality of shipping a plant to the customer, and two indicated that they placed the responsibility for determining the legality of the shipment on the customer.

After aquarium and water gardening species are imported, they are often discarded to ponds, ditches, streams, and lakes (Kay and Hoyle 2001; Maki and Galatowitsch 2004). Risks posed by the aquarium trade can be reduced through education regarding the dangers of improper disposal

of aquarium plants (Cohen et al. 2007). Use of scientific rather than common names of plant species (Kay and Hoyle 2001; Keller and Lodge 2007), and regulation of the intentional sale and transport of prohibited species will reduce the risk of IAPS introduction (Maki and Galatowitsch 2004).

Shipments of IAPS are likely to go undetected by both USPS and USCBP under current management practices due to U.S. Federal regulations, the large number of vendors, and discrete labeling. U.S. domestic mail is protected by being sealed against inspection (Title 39, United States Code, Section 404(c)); therefore, a U.S. Federal Search Warrant is required to open domestic mail including letters, packages, Express Mail packages and envelopes, and U.S. Priority Mail packages and envelopes. Domestic mail to Guam and the CNMI passes first through Honolulu, Hawai'i, but its inspection is not part of the Hawai'i Plant Protection and Quarantine pre-departure inspection program (D. Berringer, APHIS-PPQ, pers. comm.). All Domestic mail shipped to Guam through Honolulu is subject to an agricultural inspection in Honolulu, however, data on the number of parcels subjected to inspection was unavailable to us.

2.2 Ornamental Aquatic Plant Trade

The ornamental aquatic plant trade includes a diverse array of plants that are easy to grow, require minimal maintenance, and reproduce quickly (Bell et al. 2003, Peters et al. 2006) – all characteristics of successful invasive plants. In a global study of IAPS in island habitats, Kueffer et al. (2010) found that half of IAPS are ornamental plants. Ornamental ponds and water features are common within hotel, resort, and casino landscaping in Micronesia. Some hotels propagate and grow their own nursery stock on site for use in landscape features. Risks associated with these features include the distribution of plant propagules during flooding events or typhoons, distribution by birds, and intentional dispersal by staff, guests and other island residents.

2.3 Medicinal and Culinary Aquatic Plant Trade

Temporary and permanent workers from a diverse range of cultures, including the Philippines, China, and Korea are expected to constitute a large proportion of the work force associated with the Buildup (DoN 2010). These workers could bring along their culinary and medicinal cultures which may include freshwater IAPS. *Ipomoea aquatica* (water spinach) is a notable example of an IAPS introduced as a vegetable that is currently widespread and consumed throughout the region. Up to 80% of the populations in some Asian and African countries depend on traditional medicine for their primary health care (WHO 2003). The aquatic plant *Monochoria vaginalis* is traditionally used in the Indian State of Tamil Nadu to treat toothaches and as a dentifrice (Ganesan 2008). Alang-ilang (*Cananga odorata*) is a Tongan herbal medicine which has naturalized on numerous Pacific islands (PIER 2010). Weedy species may serve dual purposes; acapulco (*Senna alata*) is a ringworm treatment and is also occasionally planted to improve taro fields (PIER 2010).

2.4 Tourism and Business Travel

Tourism accounts for 40 to 90% of the visits to some Micronesian islands (Table 2-2Table 2-1). Risks associated with tourism include movement of passenger cargo and the unintentional introduction of plant material stuck to vessels or vehicles. Between 1984 and 2000, 62% of the 725,000 plant-pest interceptions recorded by USDA APHIS were associated with passenger

baggage. Most interceptions were at airports (73%), followed by interception during land based border crossing (13%), and finally interception at marine ports (9%). Seven percent of the interceptions were weed species (McCullough et al. 2006).

Table 2-2: Visitors that declared “tourism” as reason for visit to FSM, RMI, and Palau. No data available for CNMI.

	FSM	RMI	Palau
Year of survey	2006	2005	2006
Total visitors	19,136	9,173	87,206
Tourism	13,345	3,658	78,252
% of total	70	40	90
Country of residence of tourists (% of total)	U.S. (43) Japan (20) Europe (16)	U.S. (28) Other Pacific Islands (22) Japan (17)	Japan (35) Taiwan (17) Korea (16)

Source: Federated States of Micronesia Division of Statistics, Republic of Palau Office of Planning and Statistics, Republic of the Marshall Islands Planning and Statistics Office.

2.5 Movement of DoD Equipment and Personnel

Unintentional movement of IAPS may occur when plant propagules (vegetative fragments, seeds, capsules, roots, etc.), including those of aquatic plant species, adhere to equipment, hulls of boats, and in standing water moved from site to site. There is a risk that the relocation of equipment to Micronesia and routine deployment and training activities could increase the potential for accidental movement of plant propagules. It is worth noting that Cofrancesco et al. (2007) did reviewed some of the existing guidelines for inspecting and sterilizing military equipment from invasive species.

2.6 Movement of Cargo

Cargo is imported and exported from Guam by several methods including surface shipping containers, break-bulk (cargo packed in cases, bales, cartons, etc.), roll on-roll off (vehicles), barges, fishing vessels, private yachts and air transport. The vast majority of the cargo imported and exported from Guam (over 97% by weight) has been transported via surface shipping methods rather than via air transport (Table 2-3).

During the Buildup, the original number of commercial cargo containers handled by the Port Authority of Guam was expected to increase by about 25% between 2008 and 2018 while the number of military containers will increase to a peak of about 400% above 2008 levels (currently it is difficult to say how realistic these figures remain as the Buildup planning is under consideration and may change significantly before the efforts are completed). Following the Buildup the number of military containers could stabilize at approximately 38,000 per year until at least 2027 (DoN 2010) (again at this time more updated and realistic numbers are not known and will depend on the final true make-up of the proposed DoD Buildup). Break-bulk cargo shipments to Guam are projected to follow a similar trend to container shipments, but peak several years earlier.

Table 2-3: Guam surface and air cargo imports and exports from 2006 to 2009.

Movement type	2009	2008	2007	2006
Surface cargo (revenue tons) ^a ^b				
<i>Unloaded (Import)</i>	1,213,400	1,269,600	1,226,300	1,139,200
<i>Loaded (Export)</i>	194,700	213,700	213,500	194,900
<i>Transship</i>	447,700	576,500	629,000	579,800
<i>Total surface cargo</i>	1,855,800	2,059,800	2,068,800	1,913,900
Air cargo (metric tons) ^c				
<i>Unloaded (Import)</i>	16,539	17,528	15,380	16,904
<i>Loaded (Export)</i>	9,046	11,616	12,998	15,022
<i>Total air cargo</i>	25,585	29,144	28,378	31,926

^aRevenue tons are equal to either metric tons or cubic meters depending on cargo type. ^bSource: Port Authority of Guam and the Guam International Airport Authority, Government of Guam. ^cSource: Guam International Airport Authority, Government of Guam

All DoD air cargo is received at Andersen Air Force Base and all DoD surface cargo is received at the Naval Base Guam. Household goods associated with military personnel constitute the largest volume of cargo moving on and off of Guam (D. Vice, USDA Wildlife Services, pers. comm.). When military personnel undergo a permanent change of station their household personal goods can be shipped via air or surface. Plant propagules can lodge in tires of vehicles, in equipment, or they can adhere to hulls of boats, kayaks, personal watercraft, or other watercraft. The risk of IAPS transport is not limited to the initial re-entry into water; it persists until either the propagule becomes dislodged or dies, potentially placing multiple water bodies at risk.

In a study of the risk for transport of non-native insect species to the U.S. via foreign cargo trade, (Work et al. 2005) found that risk was highest for refrigerated maritime containers followed by non-refrigerated maritime containers, air cargo, and finally overland transport.

Approximately 2% of cargo arriving at U.S. maritime ports, border crossings, and airports has been inspected since 1972 and the number of plant pests intercepted is a linear function of the number of inspections conducted (Work et al. 2005). The volume of imported goods and inadequate funding and staffing contribute to these overall low inspection rates.

3. Freshwater IAPS of concern

IAPS of concern to the Micronesia Region include those species that:

- are already present within the region
- are likely to occur in high risk invasion pathways
- have biotic characteristics that could potentially lead to successful invasions such as ecological versatility, competitive ability, reproductive output and dispersal mechanisms, ability to colonize undisturbed habitats and similarity of climate from source to new habitat
- have known negative environmental impacts
- and have known negative impacts on economic and social uses of water and the environment

3.1 The Aquatic Weed Risk Assessment Model (AWRAM) (Champion and Clayton 2000, 2001) was used to assign risks of individual IAPS to the Region see Appendix B for details.

3.2 Field Survey Results

Field visits were conducted in January and April 2010 to survey freshwater aquatic plants established in the region (Table 4) and plants available for sale in commercial settings, such as open-air markets and aquarium stores (Table 5). Sites were visited on Guam (Figure 3-1), Saipan, CNMI (Figure 3-2), Yap, FSM (Figure 3-3), Pohnpei, FSM (Figure 3-4), and Palau (Figure 3-5). Survey sites were selected based on previous USFS vegetation surveys (Cole et al. 1987; Falanruw et al. 1987; MacLean et al. 1986) and local knowledge provided by natural resource staff and guides on the islands. Detailed survey methods and results are available in Appendix B.

Significant findings included the first record of *Monochoria vaginalis* within Micronesia in a small stream on the southern coast of Guam. *M. vaginalis* is an ornamental emergent to floating species from Indonesia (Horn 2002), Malaysia, Japan (including Okinawa), and Taiwan (Wagner et al. 1999). It has naturalized in rice fields of California (Horn 2002) and invasive populations are known in Fiji and several of the Hawai'i islands (Smith 1979, Wagner and Herbst 1995, Wagner et al. 1999). This species is considered edible, medicinal and has an attractive flower, suggesting that it was a likely intentional introduction (Yang et al. 2008). *M. vaginalis* and its congener, *M. hasata*, are listed noxious weeds by the U.S. Federal Government (7 CFR § 360.200).

Previously abundant populations of hydrilla (*Hydrilla verticillata*) and curly-leaf pondweed (*Potamogeton crispus*) in Fena Valley Reservoir, Guam were not found, apparently due to grazing by two introduced Tilapia species (*Oreochromis massambicus* and *Tilapia zillii*). *H. verticillata* was present, however, in tributaries to, and downstream of, the reservoir and was found in numerous other streams throughout southern Guam.

Eichhornia crassipes was widespread in the region. *E. crassipes* is native to the Amazon River basin in South America, but has been widely distributed as an ornamental floating leaved plant. It was found naturalized in Agana Swamp, Guam, where it was also observed in an individual's bucket; it was apparently collected there for transport. On Pohnpei, *E. crassipes* and *Pistia stratiotes* were naturalized in numerous ditches. On Yap, *E. crassipes* and *Ipomoea aquatica* were found in similar habitat. It was reported that *E. crassipes* flowers were brought to church each week on both these islands.

H. verticillata, *E. crassipes*, *P. stratiotes* and *I. aquatica* were available for sale in open-air markets in at least one location visited within Micronesia. These species, as well as *Salvinia* spp., *Nymphaea* spp., *Nelumbo* spp. were also offered for sale at numerous nurseries with ornamental pond plants. *I. aquatica*, a floating-leaved plant native to China, was widely cultivated and sold as an edible plant on all islands visited, as it is throughout many regions of the Pacific, Africa, South America, and Australia (Fang and Staples 1995).

In addition to these findings during field sampling, two websites of local flora and habitats indicated a population of *Salvinia natans* may be naturalized within the Malojloj watershed (Pauliluc River), Guam. This species was observed for sale at a nursery within this watershed.

<i>Salvinia spp.</i>	watermoss
<i>Spirodela polyrrhiza</i>	greater duckweed, common duckweed

4. Susceptible Freshwater Habitats

An essential requirement for the establishment of invasive plants in any region is the availability of suitable habitat. For freshwater IAPS, suitable habitats include permanent and intermittent freshwater wetlands, lakes and other standing waters, and rivers and streams. In Micronesia these habitats are primarily limited to high volcanic, raised atoll, and raised continental shelf islands, which include Guam; most islands in CNMI; Kosrae, Pohnpei, Yap, and some of the islands of Chuuk State in FSM; and several islands in the Republic of Palau (Stemmermann and Proby 1978b). Freshwater habitats on low atoll islands in the region are restricted to cultivated wetlands, although there is one small freshwater pond in the center of Lib Island, Republic of the Marshall Islands (Dahl 1980). Land-cover data from a variety of sources were analyzed to characterize the freshwater habitats in the region (Table 4-1). Vegetation surveys conducted for the U.S. Army Corp of Engineers (USACE)¹ and the USFS² describe wetlands and their distributions throughout the Micronesian region. Wetland habitats were classified into categories including lowland swamp forests, upland wetlands, cultivated and other ruderal wetlands, riparian wetlands, lakes, reservoirs, and ponds³. Pictures of representative habitats are presented in **Error! Reference source not found.** Mangrove swamps and other habitats with salinities greater than 5‰ (parts per thousand) were not included in this assessment. Although the percentage of land area covered by freshwater is low throughout region (Table 4-2 and **Error! Reference source not found.**), freshwater areas are important for fish, wildlife, food production, recreation, and drinking water.

Forested marsh accounted for the greatest area of freshwater habitat in the region as estimated using C-CAP and USFS land cover data (Table 4-2). Palau and Guam have the most forested marsh area followed by Kosrae and Pohnpei. Non-forested marsh is the next most extensive freshwater habitat followed by lakes, ponds, and reservoirs. Although stream length data is not necessarily comparable across the different data sources with great confidence, Palau, Guam, and Pohnpei have more stream kilometers than other islands.

¹ Moore et al. 1977; Stemmermann and Proby 1978a; Stemmermann and Proby 1978b

² Cole et al. 1987; Falanruw et al. 1987a; MacLean et al. 1986; Whitesell et al. 1986

³ These classifications are similar but more detailed than classification schemes used by the NOAA Coastal Change and Analysis Program (C-CAP) and the USFWS National Wetlands Inventory (NWI) to characterize more recent conditions.

Table 4-1: Primary data sources used to summarize freshwater resources¹.

Region	Data source	Image date(s)
Territory of Guam	NOAA C-CAP (NOAA-CSC 1995-)	2005
Commonwealth of the Northern Mariana Islands	NOAA C-CAP (NOAA-CSC 1995-)	2003-2005
Federated States of Micronesia		
<i>Kosrae State</i>	USFS (Whitesell et al. 1986)	1976
<i>Pohnpei State</i>	USFS (MacLean et al. 1986)	1976
<i>Yap State</i>	USFS (Falanruw et al. 1987a)	1976
<i>Chuuk State</i>		
<i>Tol, Paata, Polle, Fanapanges, Romanum, Udot, Eot, Pwipwi, and Totiw Islands</i>	USFS (Donnegan et al. 2010)	2006
Republic of Palau	USFS (Cole et al. 1987)	1976
Republic of the Marshall Islands	Dahl 1980	No data

¹Data sources used to characterize freshwater habitats in the region included NOAA C-CAP land cover data for Guam and CNMI derived from 2000s era satellite imagery and ground verification and USFS vegetation surveys based on 1970s era aerial photographs and 1980s era ground verification. USFS Forest Inventory and Analysis Program (FIA) vegetation survey data, which is based on satellite imagery and ground verification, was used for several of the Chuuk Islands since C-CAP and USFS vegetation survey data were not available (Table 2). Although the FIA vegetation survey data is available for much of the region, and is more recent, it was only used when other data sources were unavailable because the FIA wetlands classification scheme is relatively coarse compared to the earlier USFS vegetation surveys and recent C-CAP land cover data. For example, the FIA survey data does not differentiate between fresh and brackish water.

Table 4-2: Land area of selected islands within the Micronesia, percent of land covered by freshwater habitats, and stream density.¹

Island	Land area (ha)	Percent of land covered by freshwater habitats ¹	Stream density (m/ha) ²

Figure 4-1: Representative freshwater habitats in the Micronesia Region (clockwise from upper right): large stream on Pohnpei; upland savannah wetland with *Phragmites vallatoria* on Yap; ruderal roadside seep with *Eichhornia crassipes* on Pohnpei; cultivated taro wetland on Guam; Fena reservoir on Guam; and a small bomb crater reservoir with *Utricularia gibba* on Palau.

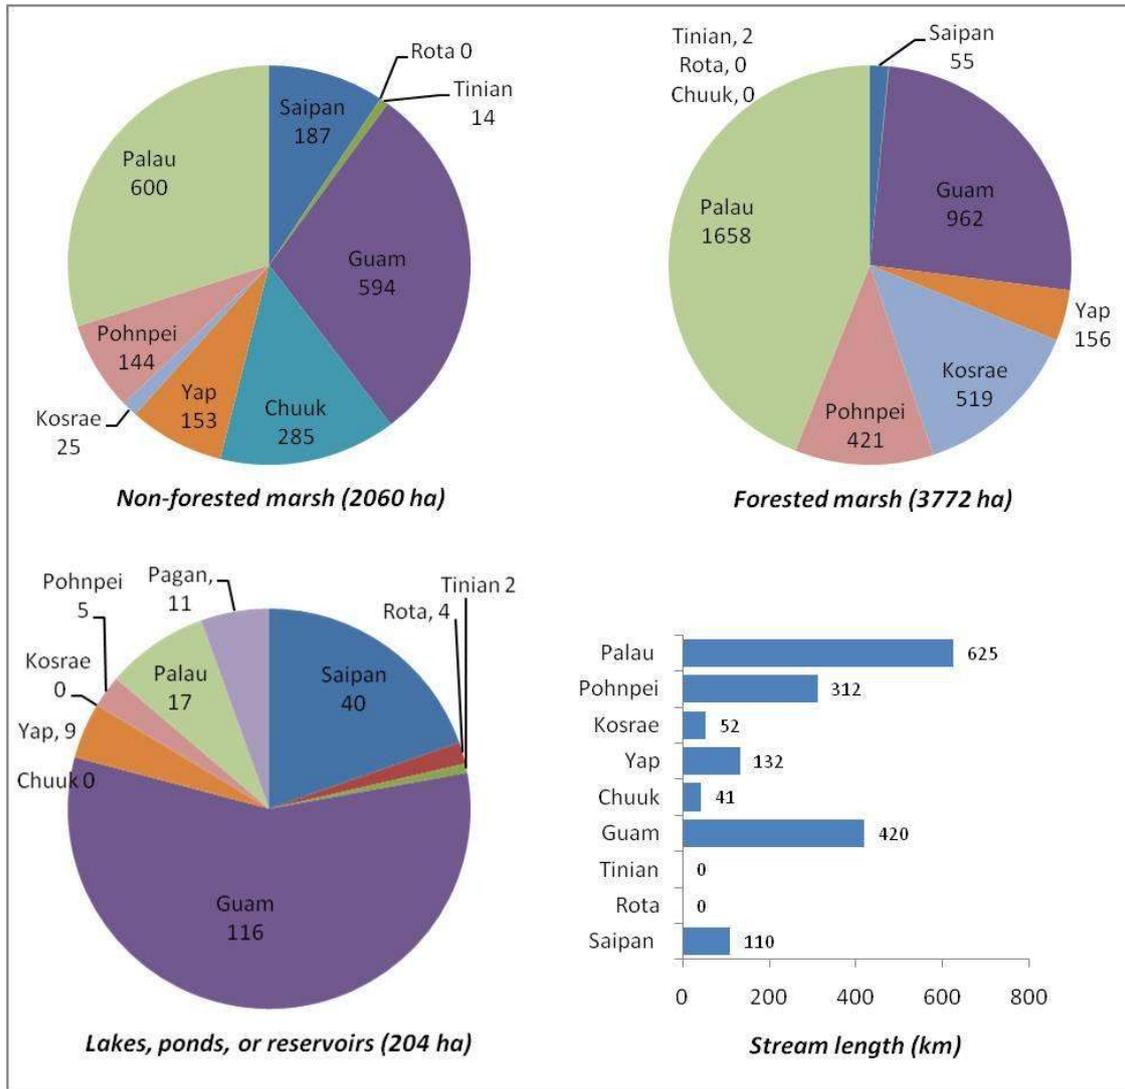

Figure 4-2: Summary of freshwater habitats in the Micronesia Region.

4.1 Freshwater wetlands

4.1.1 Lowland swamp forests

Swamp forests are by far the most extensive type of freshwater wetlands in the region and cover large areas of Palau, Kosrae, Pohnpei and Guam. Swamp forests are often to the landward side of mangrove swamps where brackish water is diluted by fresh water. Canopy cover in swamp forests ranges from high to low. Swamp forests with low canopy cover and sufficient light penetration are ideal for growing taro; consequently forest cover has been thinned or cleared in many areas for agriculture. Typical tree species present in high-canopy swamps vary across the region but include *Camposperma brevipetiolata*, *Terminalia carolinensis* (Ka tree), *Horsfieldia nunu*, and *Calophyllum cholobtaches*. Forests with low canopy cover include *Hibiscus tiliaceus*, *Barringtonia racemosa* (powder-puff tree), and *Scirpodendron ghaeri* (Stemmermann and Proby 1978a).

4.1.2 Open canopy swamps and wetlands

Several types of non-forested wetlands are common throughout the region including wetlands dominated by the tall reed *Phragmites vallatoria* (Khagra reed), wetlands with low sedge, grass, and herb species; and savannah wetlands with scattered trees such as *Pandanus spp.* (Stemmermann and Proby 1978a). Many of these wetlands are seasonally dry.

4.1.3 Cultivated and other ruderal wetlands

Wetland cultivation of the taro species *Cryptosperma camissonis* (giant or swamp taro) and *Colocasia esculenta* (soft taro) is an important component of Micronesian food production and culture (Manner 2008). In Kosrae, FSM, for example, about 97% of households cultivate taro in wetlands (Drew et al. 2005). Creation of swamp taro patches often involves clearing or thinning swamp forests, destruction of open canopy marsh, conversion of brackish mangrove swamps to freshwater, or creation of new marsh by excavating pits. Excavated taro pits are the only types of freshwater wetlands present on the numerous atolls throughout Micronesia (Stemmermann and Proby 1978b).

Swamp taro cultivation in Micronesia is declining due to increased reliance on dry-land crops such as sweet potatoes and cassava, imported foods such as rice, and the time and labor constraints associated with a more urbanized lifestyle (Manner 2008). Furthermore, human emigration from the outer islands has led to an increase in abandoned or neglected taro pits. These pits have been found to be susceptible to invasive aquatic species, such as water hyacinth. Other disturbed-area wetlands include roadside ditches, seeps, and construction areas. Although these ruderal areas are not as extensive as other wetland types (Stemmermann and Proby 1978b), their accessibility puts them at high risk for invasion.

4.2 Rivers and streams

The extent of streams and rivers in Micronesia varies considerably from island to island based on watershed size, soil permeability, rainfall amounts, and season. Because many of the islands are small and composed of permeable limestone, surface flows are typically limited to high rainfall events. Permanent rivers and streams occur on the large islands of Saipan, Kosrae, Pohnpei, Chuuk, Palau and the southern half of Guam that are composed of less permeable geological materials and where precipitation is high.

Precipitation patterns vary across the region. On a large scale, there is an east-west zone of high annual precipitation from 4-8°N across Micronesia. Precipitation drops off steadily north of this zone and the dry season becomes more prolonged. The islands of Kosrae and Pohnpei experience over 150 inches of rain annually with no appreciable dry season (Figure 4-3). Further north, annual rainfall drops to 80 inches and there is an extended dry season at Saipan, CNMI. Rainfall decreases to around 40 inches per year north and east of Saipan (Lander and Guard 2003). The result of the observed rainfall patterns is larger and more permanent streams in Kosrae, Pohnpei, and Palau than on islands to the north.

Most streams and rivers in the region are heavily shaded, which limits the potential for growth of freshwater aquatic plants. Riparian areas in urban and suburban areas are often denuded of vegetation and have more light available for the growth of aquatic plants. Riparian vegetation in upland forested areas of the wetter islands and riparian vegetation along rivers running through swamp forests is also similar to surrounding vegetation (Stemmermann and Proby 1978b). Grass

species such as *Ischaemum polystachyum* are often found along riverbanks. Where light is sufficient for aquatic plants to survive, other factors may limit establishment and growth. For instance, high stream flow can scour streambeds and remove freshwater aquatic plants such as *Hydrilla verticillata* (Brent Tibbatts, Guam DFW, pers. comm.) and the sediments necessary for rooting.

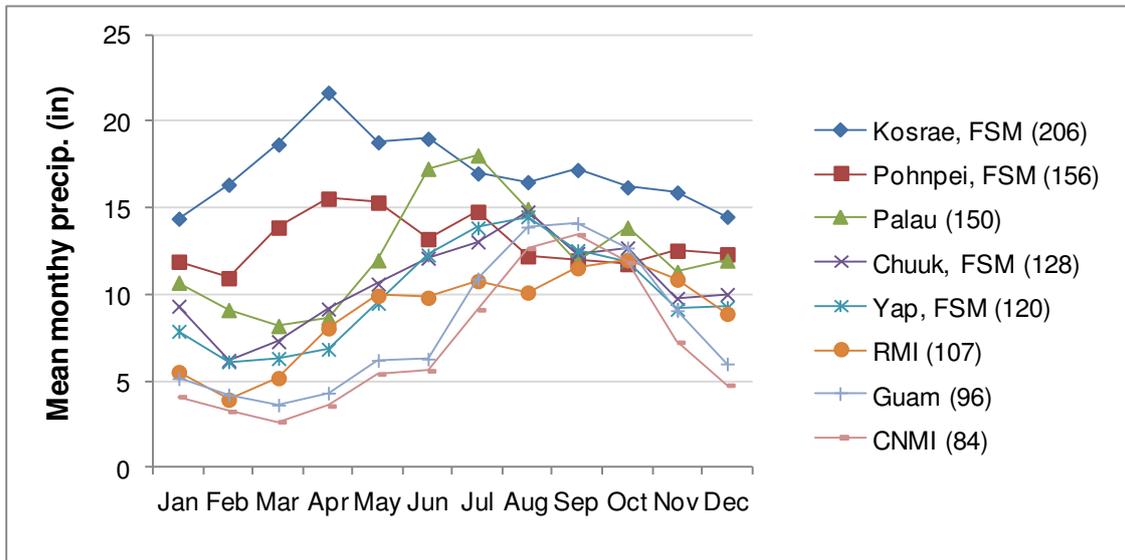

Figure 4-3. Mean monthly precipitation and annual precipitation (in parentheses) measured throughout the Micronesia region. Data are from U.S. and cooperating Government of Guam agencies (Lander and Guard 2003).

4.3 Lakes, reservoirs, and ponds

Lakes and reservoirs are not common in the region. Some notable examples include Fena Reservoir, Guam; Lake Susupe, CNMI; and Ngardok Lake, Palau. Fena Reservoir is the largest freshwater body and constitutes nearly half of the total surface area of lakes, ponds and reservoirs in the region. The non-native freshwater plant species hydrilla (*Hydrilla verticillata*) and curly leaf pondweed (*Potamogeton crispus*) were historically abundant in Fena Reservoir but are now sparse due to grazing pressure by introduced tilapia (Brock and Takata 1956; Nelson and Eldredge 1991). Lake Susupe is the second largest water body in the region, however, the lake is brackish (Wong and Hill 2000) and therefore not suitable for many species of freshwater aquatic plants. The largest natural freshwater lake in Micronesia is Lake Ngardok on the island of Babeldaob, Palau (Yeung and Wong 1999). The most numerous standing water bodies in the region include bomb crater ponds, golf course ponds, and municipal water supply reservoirs. Freshwater aquatic plant species common to many of these water bodies include *Utrichularia* spp. and *Chara* spp.

5. Aquatic Plant Treatment and Control Methods

There are numerous mechanical, physical, biological, and chemical methods available for managing emergent, floating and submersed aquatic plants. An integrated approach to aquatic plant management requires consideration of the abundance and distribution of the plants present, management goals, site-specific characteristics, legal and economic constraints, and possible impacts of management activities. Although there are limited examples of AIPS eradication and control efforts in the literature or the popular media, Simberloff (2009) argues that this is not a reflection of reality for two reasons: resource managers are more focused on management rather than publication of success stories, and unsuccessful efforts receive more interest in the media.

5.1 Mechanical Control

Mechanical techniques have been utilized for many years to control nuisance aquatic vegetation. A variety of mechanical methods exist, including hand tools; cutting, harvesting, chopping, and rotovation machines; and diver-operated suction harvesting. Mechanical methods often provide immediate results, cause little shoreline damage, are amenable to use in isolated areas, and can be used for large or small scale projects. Drawbacks to mechanical control include potentially high costs, the necessity of repeated treatments during the year, and the disposal of the collected plant material. More importantly, these methods may also promote fragmentation and, as a result, subsequent proliferation of certain species of macrophytes.

5.1.1 Hand removal

Hand removal, using cutters, rakes, or bare hands to remove plants, is the most common method of weed removal. This labor-intensive technique works best on small infestations or for small areas such as around docks. With hand cutting, plant shoots are cut below the water's surface, but roots are not removed. A simple design for a cutter uses two single-sided blades forming a "V" shape, connected to a handle with a rope. The cutter can be thrown from the shore, dock, or other floating structure. As the cutter is pulled through the water, it cuts a swath of vegetation. Raking involves tearing the plants from the sediment with a regular garden or thatch rake; the rake-head may be attached to a rope, allowing removal from deeper waters. Any type of hand removal is likely to create plant fragments, which should be removed from the water and disposed of away from the shoreline to prevent recolonization. Hand removal methods are likely to disturb sediments and increase turbidity and require repeated application during the year to maintain adequate control.

5.1.2 Harvesting

Mechanical harvesters are large specialized machines that cut and collect aquatic plants. The cut plants are removed from the water by a conveyor system and stored on the harvester or a barge following the harvester, until they can be disposed of on shore. Harvesting can target specific areas in a lake, creating boat channels for example, while leaving other areas untreated. In removing the plants from the water column, the nutrients stored within the plants are also removed. Since harvesting only removes the upper portion of the plant, some plant material remains as habitat for fish and other organisms (Gettys et al. 2009). The large size of most harvesters limits access to shallow areas or around structures such as docks. Bottom obstructions

such as logs or stumps may make harvesting difficult and shallow lakes with loose organic sediment are not suitable for harvesting.

5.1.3 Cutting

Cutter or shredder boats are specially designed to cut aquatic vegetation below the water surface. Unlike harvesting units, however, cutting equipment does not remove plant fragments from the water. Fragments generated from cutting or shredding are allowed to flow downstream on river currents or with tidal action and may spread an infestation of IAPS. Cutting is used in situations where removal of fragments is not feasible for logistical or economic reasons.

5.1.4 Rotovation

A rotovator is an aquatic rototiller, with blades that till the sediment and dislodge plants and roots. Floating booms may be placed around the treatment area to collect plant fragments created in this process; these fragments may then be removed from the water mechanically or by hand collection. This method is not species specific and since it disturbs the sediment, it may increase turbidity and negatively impact benthic organisms and fish-spawning areas.

5.2 Physical Control

Physical control methods to control existing plants involve modifying the environment to limit or eliminate conditions favorable to plant growth. Physical methods include benthic barriers, drawdown, aeration, nutrient inactivation, sediment agitation, steepening of banks, water column dyes, and others. Many physical control measures are technically simple to implement, leave little to no chemical residue, and can be very site specific. These benefits are weighed against the fact that the treatment time required to achieve the desired result can be long, often require intensive personnel resources, and are rarely species specific.

5.2.1 Benthic barriers

Benthic barriers are gas-permeable sheeting materials installed directly on the lake sediments and held in place by sandbags, pins, rocks, bricks, or other objects. Growth of rooted aquatic plants is prevented by light limitation and physical contact with the sediment. A variety of materials may be used as benthic barriers including burlap, PVC, or woven synthetics such as geotextile fabrics. The material should be gas permeable to allow for the escape of gas produced during plant decomposition beneath the barrier and sediment respiration; alternatively, the material may be strategically cut to allow venting of gases. Plants typically die within a few months, but barriers may be installed for longer periods around high-use areas such as boat launches in order to prevent recolonization. Barriers require periodic cleaning to remove sediment deposition to prevent plants from rooting on top of the barrier.

5.2.2 Drawdown

Where water control structures are in place, strategic lowering of water levels can control certain emergent or rooted aquatic plants. Siphoning or pumping can be used if gravity draining is not an option.

Effectiveness is maximized when the depth of the drawdown exceeds the maximum depth of colonization of the target species and the sediments are dried for a sufficient time to kill aquatic

plants (Nichols 1991); time required for drying varies with the local climate and substrate, but generally ranges between 4-8 weeks. Drawdown may not be effective for free-floating aquatic species, e.g., *Pistia stratiotes* or *Salvinia* spp., that retreat with diminishing water levels unless the entire water body can be dewatered. Species with desiccation-resistant propagules (seeds or resistant vegetative structures) like *Hydrilla verticillata* are adapted to seasonal drying and can persist or even increase following periods of drawdown (Gettys et al. 2009).

5.2.3 Aeration/mixing

Aeration/mixing devices that destabilize the water column and can alter nutrient concentrations in lakes and ponds. Physical disruption of water column stability can alter the phytoplankton community by increasing mixing depth and consequently the light regime that phytoplankton experience. Destabilization of the water column and increased mixing can also reduce the competitive advantage of cyanobacteria that can regulate their buoyancy. Induction of surface currents by aeration/mixing devices can reduce the cover of free-floating plants, like duckweeds; however, this method will not eliminate or effectively control rooted aquatic plants.

5.2.4 Nutrient inactivation

Applications of alum (aluminum sulfate), iron salts, or calcium (lime) reduces water column concentrations of phosphorus, which commonly limits phytoplankton abundance in lakes and ponds, resulting in reduction in phytoplankton abundance in the water column (Bellaud 2009). Nutrient inactivation may reduce growth rates of floating aquatic plant species that obtain all their nutrients from the water column, but rooted plants have access to sediment phosphorus, so the method is not effective on rooted plants (Nichols 1991). Increased light penetration due to reduction in phytoplankton abundance in the water column may actually increase growth of macrophytes (Bellaud 2009).

5.2.5 Sediment agitation

Mechanical devices like weed rollers, lake sweepers and beach groomers mechanically disturb the lake bottom within a well-defined area to remove aquatic plants and prevent regrowth. The machines sweep, roll, or drag repetitively over plants and the sediment. They must be attached to a post, dock or other structure and require a source of electricity. This method may dislodge plant fragments that could spread to new areas or re-colonize the same area when the agitation device is not in use.

5.2.6 Dredging

Dredging is usually not performed solely for aquatic plant management (Madsen 2000). It is more often used to deepen lakes subjected to sediment infill, remove high-nutrient surface sediments, increase the volume of the pelagic and hypolimnetic zones, or remove toxic substances (Peterson 1982). Lakes that are shallow due to sedimentation typically have abundant aquatic plant growth. Dredging reduces aquatic plant problems directly by removing the plants, bottom sediment, and associated nutrients.

Dredging for aquatic plant control is most effective when the depth is increased to exceed the maximum depth of colonization (Collett et al. 1981, Tobiessen et al. 1992). Shallow dredging (one meter) has been found to be effective for a few months (Engel and Nichols 1984).

Dredging is effective when nutrient-rich sediments are removed and when the increased depth decreases the light available for plant photosynthesis and growth.

Dredging has several drawbacks. It produces high turbidity due to suspended sediments and can harm benthic organisms and other wildlife that overwinter in the sediments. It also has extensive permitting issues, high costs, and sediment disposal issues.

5.2.7 Shading/Light Attenuation

Use of aquatic dyes or surface covers can effectively limit light and restrict submersed aquatic plant growth. Both dye applications and shading covers are non-selective processes and thus control growth of native and introduced plants and algae. Commercially formulated natural or synthetic aquatic dyes are considered non-toxic to aquatic animals. They are generally used in small water bodies where outflow can be controlled, such as ornamental ponds or golf-course water hazards (Gettys et al. 2009).

Surface covers made of fabric or plastic can be installed to control plant growth; these may be held above or just below the surface. Covers are typically used only on small scale control projects, like boat docks or narrow streams or canals (Nichols 1991).

5.3 Biological Control

Biological control involves the intentional release of one species in an effort to control another species. Biological control agents undergo rigorous screening on a large suite of plants including the target and its relatives. Testing includes feeding specificity (including choice/no choice and exploratory feeding) as well as the agent's ability to complete its life cycle on plants other than the target (McFadyen 1998).

Insects are commonly used in biocontrol because their coevolutionary relationship with plants has led to highly species-specific relationships, but pathogens and animals are used as well. Establishment of biocontrol agents may be complicated by source-population climate tolerances as well as by parasitism and predation by native insects, fish or other animals. Some macrophytes are also chemically or structurally resistant to herbivory. Most agents have provided insufficient control to be used as a stand-alone management tool, but they can be an important component of integrated pest management strategies.

A variety of insect control agents have been released in the U.S. for control of aquatic plants, including the salvinia weevil (*Cyrtobagous salviniae*) alligator weed flea beetle (*Agasicles hygrophila*), mottled water hyacinth weevil (*Neochetina eichhorniae*), and most recently a water hyacinth plant hopper (*Megamelus scutellaris*). Milfoil weevil (*Euhrychiopsis lecontei*) is apparently an endemic weevil to North America that has emerged as an effective control of Eurasian milfoil (*Myriophyllum spicatum*). In most cases, damage done by biological agents controls, but does not eradicate, plant populations. Insects may limit vegetative propagules and their feeding scars or entry holes can facilitate secondary damage by naturally occurring pathogens (Gettys et al. 2009).

The grass carp (*Ctenopharyngodon idella*), native to rivers of East Asia, was introduced into the U.S. in 1963 for submersed aquatic weed control (Guillory and Gasaway 1978). Although they exhibit some species preference, grass carp are typically considered a generalist herbivore that can damage native aquatic plant communities. Triploid grass carp, which have a low probability of successful reproduction and are functionally sterile (Bronson 2008), were developed to limit

natural reproduction and population size of the fish. Use of grass carp in aquatic plant control is complicated by difficulty in developing stocking plans; they often prefer native plants over IAPS and either supply inadequate control of weedy species or complete eradication of all submersed aquatic plants (Gettys et al. 2009).

5.4 Chemical Control

Aquatic herbicides are an effective and inexpensive IAPS management tool. For example, the state of Florida reduced the area of water hyacinth (*Eichhornia crassipes*) infestation from a high of 51,000 ha in the 1960s to 2000 ha primarily using the herbicide 2,4-D (Schardt 1997). The use of aquatic herbicides, however, is often controversial. In the past 20 years, the use and review of herbicides has changed significantly to accommodate human and environmental health concerns; and no herbicide can be labeled for aquatic use if it is shown to have unreasonable adverse effects on human health or the environment (Gettys et al. 2009). Because of the unique characteristics of aquatic systems and the relatively small size of the aquatic herbicide market, there are a limited number of effective, EPA-approved herbicides currently available for aquatic use (Table 5-1).

Table 5-1. Selected contact and systematic herbicides approved for aquatic use by the U.S. EPA, their mode of action, and comments on use (modified from Getty's et al. 2009).

Compound	Primary use			Mode of action
	Submersed	Floating	Emergent	
Copper	X	X		Contact, plant cell toxicant
Endothall	X	X		Contact, inhibits respiration and protein synthesis
Diquat	X	X	X	Contact, inhibits photosynthesis and destroys cell membranes
Carfentrazone		X	X	Contact, inhibits plant specific enzyme
2,4-D	X	X	X	Systematic, plant growth regulator
Triclopyr	X	X	X	Systematic, plant growth regulator
Glyphosate		X	X	Systematic, plant enzyme inhibitor
Imazapyr			X	Systematic, plant enzyme inhibitor
Fluridone	X	X		Sytematic, plant enzyme inhibitor
Penoxsulam	X	X		Sytematic, plant enzyme inhibitor
Imazamox	X	X	X	Sytematic, plant enzyme inhibitor

There are positive and negative aspects to use of herbicides for aquatic plant management. Modern application technology focuses on matching contact time and chemical concentration in the water to the target species to allow for selective control. Used appropriately, systemic herbicides can selectively remove IAPS without major, long-term impacts on native plant communities. When used inappropriately aquatic herbicides can lead to nontarget impacts on native plants, fish, and invertebrates and development of herbicide tolerance in IAPS. Effective permitting and proper training of applicators can alleviate problems with aquatic herbicides.

Acknowledgements

This project was conducted under a subcontract between Portland State University and the Smithsonian Environmental Research Center through the Portland State University/Smithsonian Environmental Research Center Aquatic Bioinvasion Research and Policy Institute. Funding for the project was provided by the U.S. Department of Defense.

John Clayton and Paul Champion conducted the AWRA weed risk assessment and provided assistance with field surveys. We would like to thank Brent Tibbatts from Guam DAWR and Paul Wenninger from DoD for guidance in the field and discussion of freshwater resources in Guam; Steve McKagan from NOAA Fisheries for guidance and Michael Trianni and Michael Tenoria from CNMI DFW, and Lisa Eller and Aric Bickel from CNMI DEQ for discussion of CNMI's freshwater resources; Dr. Rufino Mauricio, John P. Wichep, Gisbon Santos, Majoriko Victor, Rosendo Fredrick, and Konrad Englberger for guidance and discussion in Pohnpei, FSM; Pius Liyagel for guidance and Tamdad Sulog, John Runman and Margorie Falanruw for discussion of freshwater resources and aquatic plants on Yap, FSM; and Chipper Tellei for guidance and discussions in the Republic of Palau.

1. Introduction

The freshwater resources of Micronesia and Hawaii are critically important to the human populations and natural ecosystems these waters support. Introduced invasive aquatic macrophytes, algae, and cyanobacteria represent an important threat to the integrity of these aquatic systems. Understanding the potential pathways and vectors by which these taxa may be introduced is essential for creating sound management strategies to minimize their introduction and spread in Micronesia and abroad.

The New Zealand National Institute of Water and Atmospheric Research Ltd (NIWA) was contracted by Portland State University (PSU) to prepare aquatic weed risk assessments for a range of species including those locally present on Micronesia (Guam, Northern Mariana Islands, Federated States of Micronesia and the Republic of Palau) or potentially imported from Hawaii, South East Asia (Philippines, Indonesia, Malaysia, Taiwan and Japan) or from other risk sources (mainland USA and Australia), which threaten ecological, social and economic values of Micronesia.

Weed risk assessment models have been developed to predict the invasiveness of potential new weeds to a country by quantifying biological and ecological traits of the plant, their geographical origin and previous introduction history. These models then provide a decision support tool to managers as a basis for future management actions. These may include determining which cultivated freshwater plants should be banned from entry (black list), prevented from deliberate dispersal through the nursery trade, targeted for control/eradication and conversely which species are suitable for importation and pose little threat to the country to which they are imported. Examples of weed risk assessment protocols and their use to manage weed species include Esler et al., (1993), Pheloung et al., (1999), Dahler et al., (2004), Champion (2005), Parker et al., (2007), Csurhes (2008) and IFAS (2010).

NIWA has developed a risk assessment model specifically for aquatic weeds - AWRAM (Champion & Clayton 2000; 2001), based on the failure of general weed risk assessment models (e.g., Pheloung et al., 1999; Daehler et al., 2004) to adequately discriminate the level of impact caused by aquatic plant species. These general models recognise that aquatic species often become weedy, giving an assessment score of 5 to any aquatic species (generally the questions answered in the assessment only score 1 or 2). Any species exceeding a threshold score of 6 is recommended for rejection by these models, and hence the vast majority of aquatic species evaluated exceed this threshold. Although aquatic species rank highly, there is little separation between species with differing levels of impact. For example, the submerged Hydrocharitacean weeds *Elodea canadensis*, *Lagarosiphon major*, *Egeria densa* and *Hydrilla verticillata* (all invasive alien species in New Zealand) were scored 24, 23, 23 and 22

respectively using the model of Pheloung et al., (1999). AWRAM scored 46, 60, 64 and 74 respectively, out of a total possible score of 152, reflecting their relative management importance (Champion & Clayton 2000).

AWRAM has been used to determine which aquatic species are prohibited for sale and distribution and to prioritise national eradication strategies in New Zealand (Champion 2005; Champion & Hofstra 2006). AWRAM has also been modified for other countries and used to recommend weed management initiatives in Australia, The U.S. states of Indiana and Florida, and potentially in Europe (Champion et al., in press; Petroschevsky & Champion 2008; Gordon et al., 2010; Champion et al., 2010).

This report outlines the selection criteria used to select aquatic plant species prior to weed risk assessment and outlines a modified AWRAM used to score these species and identify the species of greatest concern.

2. Methods

2.1 Selection of species for assessment

Two field visits were undertaken by PSU and NIWA staff to identify aquatic plants, including introduced weeds either naturalised or in cultivation, and assess the range of freshwater aquatic habitats present on the following islands:

Guam	22-26 & 28 January; 19-20 April 2010.
Saipan, Northern Mariana Islands	26 & 27 January 2010.
Pohnpei, Federated States of Micronesia	22 & 23 April 2010.
Yap, Federated States of Micronesia	25-27 April 2010.
Palau	28 & 29 April 2010.

The jurisdictions covered by the Micronesia Biosecurity Plan but not visited as part of this initiative include Kosrae, Chuuk, Marshall Islands, and Hawaii.

Plants were identified using a variety of literature including Cook (1996), Di Tomaso et al., (2003), Hussey et al., (2007), Koo et al., (2005), Lorence & Flynn (2009), Morita (1997), Sainty & Jacobs (2003), Sharpe (1986), Stephens & Dowling (2002) and Whistler, W.A. (1995). Habitat types were taken from Fosberg (1960), Falanruw (2002) and Ellison (2008).

A review of literature and web-based data was undertaken to:

- Determine the known distribution of aquatic plants in Micronesia.
- Identify risk species traded as aquarium and pond plants that could pose a threat to Micronesia.
- Identify the weed history and distribution of other risk species with an emphasis on species known to be present in Hawaii, South East Asia (including Philippines, Indonesia, Malaysia, Taiwan and Japan), mainland USA and Australia.

Distribution data for Micronesia were sourced from Fosberg et al., (1979; 1982; 1987), Lorence & Flynn (2009), Raulerson (2006), and the Hawaii Ecosystems at Risk (HEAR, 2010) and Pacific Islands Ecosystems at Risk (PIER) website.

A list of aquarium species permitted for importation into Guam was provided by Brent Tibbatts (Government of Guam, Department of Agriculture Division of Aquatic and Wildlife Resources) and these species were also assessed. A list of species traded

internationally were collated based on Kasselmann (2003) and Champion & Clayton (2000; 2001).

Preliminary assessments of risk weeds, including aquatic species were compiled for Micronesia or various component states by Space et al., (2000a & b; 2003; 2009), Space & Falanruw (1999) and Meyer (2000). Aquatic weed species from adjacent areas were obtained from Barrett & Seaman (1980), Champion & Clayton (2000; 2001), Csurhes & Edwards (1998), Kadono (2004), Lancar & Krake (2002), Moody (1989), Pancho & Soerjan (1978), Parsons & Cuthbertson (2001), Pieterse & Murphy (1990), Staples et al., (2000) and Waterhouse (1993), with additional web-based resources HEAR (2010) Pacific Islands Ecosystems at Risk and ISSG (2010) Global Invasive Species Database, Invasive Species Specialist Group, IUCN.

A composite list of aquatic plants, mostly species, but in some cases genera or sub-specific taxa were compiled along with synonyms used in the literature, family affiliation and life-form type (Table 1). Life-form groups used were marginal (rarely growing in water), erect emergent, sprawling emergent, amphibious submerged, obligate submerged, free-floating and floating leaved - bottom rooted (water lily type). Table 2 compiles the known distribution of these taxa including additions to the flora found during the two field visits.

2.2 Aquatic weed risk assessment (AWRAM)

2.2.1 Information sources used for weed assessment

Over 100 references have been used to score the candidate weed species, ranging from specific papers on one aspect of a species ecology or management to general books on aquatic weed impacts or management. Table 3 gives the relevant information sources used for each taxon.

Two invaluable general references provide a valuable insight into the weed history of the potential aquatic weeds. Holm et al., (1979) reports the number of countries in which that weed is regarded as an economic weed. It is rather outdated and some serious weeds are either not recorded (e.g., *Cabomba caroliniana*) or underrepresented (e.g., *Mimosa pigra*) based on current information. Countries where the weed occurs are ranked (based on submissions from weed experts from each country) in 5 categories from highest to least impact:

- Serious – one of the 3 worst species.
- Principle – the next worst 10 species.
- Common.
- Present, but not widespread as a weed.

- Present in the flora but not assessed.

Randall (2002) and a web-accessible link (see Section 6) is essentially a catalogue of information on weedy species, with the number of references referring to that weed a good indication of its importance. Key words used to describe each species are:

- Agricultural weed.
- Environmental weed.
- Naturalized weed.
- Noxious weed.
- Cultivation escape (also with the term garden thug for some).
- Quarantine weed.
- Sleeper weed (or potential weed still in the lag phase of invasion).
- Unspecified weed.
- Casual alien.

Table 4 summarises information from the two references with the number of countries with each of the Holm et al., (1979) economic weed classifications, total number of Randall (2002) weed references (with tropical or sub-tropical references in parentheses), and Randall's (2002) weed classifications.

2.2.2 Weed risk assessment model

The weed risk assessment model used to score the species selected in Section 2.1, has three main component sections:

- Assessment of entry pathways to Micronesia, including the likely volume of propagules and likelihood of survival and successful establishment.
- Weed potential based on ecological versatility, competitive ability, reproductive output and dispersal mechanisms, ability to colonise undisturbed habitats and similarity of climate from source to new habitat.
- Impact based on types of impact on economic and social uses of water, environmental impacts, ease of management and weed history within indigenous and introduced ranges.

Entry Pathways

Potential weed sources and introduction routes to Micronesia are as follows:

- Present on N. Mariana Islands, FSM or Palau (internal spread).
- Present on Guam (most likely source of spread to other Micronesian islands).
- Present on Hawaii (most likely source of spread to Guam).
- Present in Philippines, Taiwan or Japan (most likely sources through military support personnel).
- Present in other SE Asian countries i.e., Indonesia, Malaysia, Thailand, Singapore, Vietnam (less likely sources of spread).
- Not in region but present in USA or Australia (even lower risk, but direct flights from Australia to Micronesia and Hawaii may alter risk profile).

Entry pathways from these sources are as follows:

- Aquarium trade of aquatic plants. Known importation to Guam is regulated, but importation of non-permitted species may occur through the mail services due to inability to inspect mail/courier from U.S. mainland. Mainland mail is likely the highest risk pathway at present due to the inability to appropriately inspect these items. Species with seeds or spores that resist desiccation and can be mailed may be particularly difficult to interdict.
- Trade in plant nurseries, markets and other sales of aquatic plants for ornamental use. This pathway is of slightly less risk because permits are required for importation and shipments are inspected.
- Food and medicinal plants introduced by various ethnicities associated with U.S. military build-up or otherwise (especially Philippines and Taiwan). It is likely that most high demand food plants (e.g., *Ipomoea aquatica*) have already been introduced into at least part of Micronesia or Hawaii but even these species may not be spread throughout the region and therefore appropriate protections both for the region and within the region should be in place to reduce the likelihood of their spread, either accidentally or on purpose.
- Deliberate introduction to 'improve' fodder etc. (e.g., recommendation to Yap to import *Azolla* (M. Falanruw pers. comm.) and apparent introduction of *Salvinia molesta* from Australia to SE Asia to improve rice cultivation). Probably a low risk especially if the production of a blacklist of prohibited species will inform responsible agencies. But for most of the jurisdictions of

Micronesia these types of blacklist either do not currently exist or are in need of updating.

- Non-commercial ornamental spp. (e.g., plants imported from Philippines) brought in by individuals for their gardens/ponds etc. Another high risk pathway, although propagule pressure would be much less than the aquarium/nursery pathways.
- Contaminants or hitchhikers with other species that are permitted for sale (e.g., duckweeds (*Lemna*, *Landoltia* and *Spirodela*), *Utricularia* and *Azolla* spp.). This pathway also includes introductions through aquacultural shipments and transport. A low risk but requiring thorough inspection of imported material for these species.
- Contamination of U.S. military equipment from wetlands and aquatic sites overseas (*S. molesta* was spread in Australia from Queensland to Victoria (>1000 km) by military vehicles (authors pers. obs.). This would be a very low risk pathway because the only marsh area the U.S. military is planning to use in Micronesia is the cleaning station by Apra Harbor. Training exercises may take place in Hagoi lake/marsh on Tinian; however, the lake is mesohaline.

If a plant is already indigenous or naturalised within Guam or elsewhere in Micronesia it is assigned the maximum score of 30.

If cultivated in Micronesia then the number of propagules and likelihood of establishing a naturalised population is assessed as relatively high (see later).

If outside of the region, then the number of likely pathways is recorded; scoring 1 for each. For each pathway, the likely number of propagules (minimum 1 to maximum 10) and the likelihood of establishing a naturalised population (minimum 1 to maximum 10) are assigned. These are multiplied and then divided by 10 to give a maximum score of 10 for each pathway. The maximum score cannot exceed 30.

Maximum Entry Pathway score = 30.

Weed potential

The scores for this section approximately follow previous AWRAM models (Champion & Clayton 2000; Champion et al., 2008) with the scores of the following parameters based on characteristics of the species and the aquatic habitats available in Micronesia:

- Habitat versatility (maximum of 13)

- Range (minimum 1 to maximum 3), maximum if able to grow from aquatic to dry land, or from margin to > 5 m deep.
- Water level fluctuation (minimum 0 to maximum 3), maximum if able to tolerate one month dewatering.
- Nutrient (minimum 1 to maximum 2), maximum if able to tolerate high or low enriched waters.
- Shade tolerant (minimum 1 to maximum 3), maximum if able to grow from full sun to deep shade.
- Salinity (minimum 0 to maximum 2), maximum if able to grow in fully saline (35 ppt) water.
- Habitat range (maximum of 9)
 - Flowing water (minimum 0 to maximum 3), maximum if dominant in this habitat.
 - Still water (minimum 0 to maximum 3), maximum if dominant in this habitat.
 - Wetland with ephemeral standing water (minimum 0 to maximum 3), maximum if dominant in this habitat.
- Competitive ability (maximum of 20)
 - Within growth form (minimum 1 to maximum 16), maximum if excludes all other species (e.g., *Eichhornia crassipes*, *Hydrilla verticillata*, *Phragmites vallisneria*).
 - Between growth form (minimum 0 to maximum 4), maximum if excludes all other life-forms (e.g., tall emergent spp.).
- Propagule dispersal (maximum of 10)
 - Natural agents (minimum 0 to maximum 5), maximum if adapted for spread by waterfowl (e.g., *Najas* spp.- Agami & Waisel 1986) or wind (e.g., *Phragmites vallisneria*).
 - Accidental human spread (minimum 0 to maximum 5), maximum if spread by 3 methods (e.g., boat trailers, machinery, fishing nets).

- Deliberate spread (minimum 0 to maximum 1), maximum if attractive to humans.
- Effective dispersal within a water body (minimum 0 to maximum 1).
- Propagule output (maximum of 10)
 - Seed quantity (minimum 0 to maximum 3), maximum if >1000 seed produced /plant or m².
 - Seed viability/persistence (minimum 0 to maximum 2), maximum if viability > 1 year.
 - Clonal spread (minimum 0 to maximum 5), maximum if spreads by fragmentation.
- Establishment (maximum of 5).
 - Existing vegetation (minimum -5 to maximum 0), maximum if able to invade unmodified vegetation.
 - Disturbance (minimum 0 to maximum 5), maximum if able to aggressively colonise following vegetation clearance, newly constructed water bodies or nutrient enrichment.
- Suitable climate (minimum 0 to maximum of 5), maximum if source and destination have same climate.

Maximum Weed Potential score = 72.

Impact

These scores follow previous AWRAM models (Champion & Clayton 2000; Champion et al., 2008) with the following parameters scored:

- Obstruction (maximum of 10)
 - Recreation (minimum 0 to maximum 1), maximum if major nuisance.
 - Access (minimum 0 to maximum 2), maximum if major nuisance.
 - Flow (minimum 0 to maximum 1), maximum if major nuisance.
 - Irrigation (minimum 0 to maximum 5), maximum if able to prevent effective irrigation.

- Aesthetics (minimum 0 to maximum 1), maximum if visual and smell problems.
- Environmental damage (maximum of 10)
 - Biodiversity (minimum 0 to maximum 5), maximum if completely displace all other species.
 - Water quality (minimum 0 to maximum 3), maximum if deoxygenation/nutrient enrichment.
 - Physical processes (minimum 0 to maximum 2), maximum if promoting flooding or siltation.
- Other undesirable traits (maximum of 10)
 - Human health (minimum 0 to maximum 2), maximum if 2 impacts such as drowning risk, mosquito habitat, thorns, etc.
 - Agricultural weed (minimum 0 to maximum 8), maximum if major impact on taro culture.
- Resistance to management (maximum of 10)
 - Ease of implementation (minimum 0 to maximum 2), maximum if dense impenetrable thickets.
 - Recognition (minimum 0 to maximum 1), maximum if cryptic (e.g., submerged spp.).
 - Control methods (minimum 0 to maximum 2), maximum if no control methods (e.g., deep water species, tolerant to available herbicides).
 - Effectiveness (minimum 0 to maximum 2), maximum if ineffective (unable to reduce impact).
 - Duration (minimum 0 to maximum 2), maximum if no control >1 month.
- Weed history (maximum of 10)
 - Indigenous range (minimum 1 to maximum 5), maximum if serious or principle weed of many tropical/sub-tropical countries.
 - Invasive alien range (minimum 0 to maximum 5), maximum if serious or principle weed of many tropical/sub-tropical countries.

Maximum Impact score = 50.

Thus the maximum and minimum theoretical scores would be:

Component	Maximum	Minimum
• Entry	30	1
• Weed potential	72	0
• Impact	50	1
• Total	152	2
• Presentation of AWRAM results		

Table 5 and 6 present the weed risk assessment scores for the 95 taxa. Table 5 presents the taxa ranked on total AWRAM score, also listing component Entry, Weed potential and Impact scores and combined Weed potential and Impact scores. Table 6 presents the taxa ranked on combined Weed potential and Impact scores and also presents the habitat types where it is likely to grow.

Habitat types discerned on the field trips can be divided into seven groups:

- Shaded ‘jungle’ streams and rivers.
- Open drains, streams and rivers.
- Reservoirs, ponds and natural lakes.
- Savannah wetlands.
- Lowland wetlands (e.g., *Phragmites vallatoria* dominated areas).
- Cultivated wetlands (e.g., taro cultivation – disturbed wetlands formerly dominated by *P. vallatoria*).
- Swamp forest.

3. Results

Table 1: List of species (or other taxa) assessed for weed potential in Micronesia, with synonyms used in recent literature, family and life-form (as - amphibious submerged;

<i>Vesicularia dubyana</i>	Likely to be widespread within SE Asia and Pacific Islands				J	A	U

- 1 Possibly present at Lake Ngardok.
- 2 First identified on Hawaii as part of this project.
- 3 Only reference to this distribution Lancar & Krake (2002).
- 4 Recorded as native by Fosberg et al., (1979), found in cultivation on Guam.
- 5 Guam plants sometimes regarded as the endemic *C. gaudichaudii* (Masuyama 2008).
- 6 First identified in cultivation on Guam as part of this project.
- 7 Reported from Guam, but name misapplied to *Hydrilla verticillata* (Fosberg et al., 1987).
- 8 Reported once from Hawaii, material destroyed (HEAR 2010).
- 9 In cultivation, Manoa University Campus.
- 10 Recorded as native by Fosberg et al., (1979).
- 11 Formerly regarded as *M. crenata*, but now assigned to *M. minuta* (Whitten & Jacono 2009).
- 12 *M. quadrifolia* misapplied to *M. mutica* in Australia.
- 13 Reported as naturalized as part of this project.
- 14 *Nymphoides* sp. recorded as present on Palau by Fosberg et al., (1979).
- 15 Found on Babeldaob as part of this project; only previously reported from Koror (Fosberg et al., 1987).
- 16 This species is likely native throughout the Mariana Islands
- 17 Reported in cultivation (M. Falanrw pers. comm.) but not seen by authors.
- 18 Reported as *S. latifolia* in error from SE Asia. Plants referred to as *S. trifolia* are synonymous with *S. sagittifolia*.

Table 3: References used to carry out weed risk assessments on potential weeds of Micronesia (numbers refer to references as in Section 5).

Table 4: Weed history for potential weeds of Micronesia, based on Holm et al., (1979), which reports the number of countries in which that weed is regarded as an economic weed (ranked in 5 categories from highest to least impact: serious, principle, common, present as a weed, present in the flora but not assessed); and Randall (2002) with the number of references referring to that weed (tropical or sub-tropical references in parentheses), and where a weed is classified g = agricultural, e = environmental, n = naturalized, x = noxious, c = cultivation escape, q = quarantine, s = sleeper weed, w = unspecified weed, c = casual alien).

4. Discussion and recommendations

4.1 Dealing with uncertainty

As with any type of prediction, there is a degree of uncertainty regarding the validity of the weed risk assessment scores. In this case there are three main issues; identity of plant taxa, quality of weed records and lack of relevant information for non-weedy species.

There are problems with the identity of some taxa, e.g., the water lilies (*Nymphaea* species especially where these are of hybrid origin), and then relating this to weed information on these species in their naturalized or indigenous ranges. Where this confusion has occurred, taxa have been grouped (e.g., *N. nouchali* and *N. stellata* records have been grouped with *N. caerulea* and *N. pubescens* grouped with *N. lotus*). In the case where genera have historically had problematic taxonomy (e.g., *Vallisneria* and *Trapa*) all species weed information has been collated under that genus.

Ideally all information used to assess potential weeds would be based on scientifically validated data (i.e., peer-reviewed journals and other publications). However, much of the information is only available as ‘grey’ literature, and several of the primary references used for this weed risk assessment either use ‘expert weed assessment’ (Holm et al., 1977; 1979; 1997) or all available information regardless of validation (Randall 2002). Both of these approaches are seen as valid, with the resulting weed risk assessment information based on a wide collection and weight of information that major weed species should generate. This is evident from Tables 3 and 4, where the world renowned weeds such as *Eichhornia crassipes*, *S. molesta*, *Pistia stratiotes* and *Hydrilla verticillata* are represented by the greatest volume of references.

Conversely, information on potential weeds yet to show weedy characteristics, or those with limited weed potential, is often lacking. Champion et al., (2008) and Petroschevsky & Champion (2008) regarded the lack of information on naturalization and weed impacts of aquarium and other ornamental species that were internationally traded in high volumes (therefore with high propagule pressure) over decades as a very good indication of lack of weed potential. Length of time and volume in the trade were scored negatively if a taxon had been traded for over 30 years without naturalising.

4.2 High ranked aquatic weeds

The top 12 AWRAM scores were assigned to species that were already naturalized, or native to at least some part of Micronesia (Table 5). Three native species were amongst the nine species with scores >100, comprising *Phragmites vallatoria*, a widespread and dominant wetland species, and also *Panicum repens* and *Ceratophyllum demersum*, both regarded as indigenous by Fosberg et al. (1979; 1987). These species were of very limited distribution, with only one site of *P. repens* seen

during the field visits. Their indigenous status could be questioned. The remaining six species were all apparently limited in distribution, with the first record of *Monochoria vaginalis* in Micronesia and the first naturalized records of the highest and third-highest ranked species *E. crassipes* and *Pistia stratiotes* from Pohnpei made during field work contributing to this report. Of the 33 species scoring ≥ 80 , ten were found or reported to be in cultivation in Micronesia, and either not naturalized or of limited distribution, including the first naturalized population of *Salvinia natans* in Guam (R. Miller pers. comm.). Clearly the greatest risk from potential weeds comes from aquatic species that have already arrived across the Micronesian border. Although such species could be regarded as no longer a border issue for the Region, they do represent a more immediate economic, social and ecological risk and their management is advocated (see later).

Of the 33 species scoring ≥ 80 , only ten have not been recorded from Micronesia. These were (in decreasing order of risk) *Mimosa pigra*, *Azolla pinnata*, *Alternanthera philoxeroides*, *Salvinia molesta*, *Eichhornia azurea*, *Azolla filiculoides*, *Myriophyllum spicatum*, *Typha angustifolia*, *Limncharis flava* and *T. latifolia*. The risk of entry of the *Azolla* species is seen as much more likely than the other species (each scoring 24/30 compared to scores of ≤ 5 for the other species).

By excluding the likelihood of entry score, a measure of weed potential and impact can be used to rank species (Table 6). Of the 12 highest ranked alien species (scores ≥ 80), six are not known to occur in Micronesia (*M. pigra*, *A. philoxeroides*, *S. molesta*, *E. azurea*, *M. spicatum*, *T. angustifolia* and *L. flava*).

The species in Table 7 are not known from Micronesia and all have combined scores higher than 50 (weed potential and impact score). These species are distributed via international aquarium and/or ornamental plant trades and are therefore recommended for inclusion of a 'black list' of imports to the jurisdictions of Micronesia (Table 7).

Additionally, there are a number of species that are sparingly naturalized or only known from cultivation in Micronesia and that rank higher or within the same range as the species in Table 7. These species are recommended for preventative measures prohibiting their sale and distribution (Table 8). Species listed in table 8 include the highest ranked species *E. crassipes*.

Management programs are advocated for a number of very high risk species (weed potential and impact score ≥ 70) that have very limited naturalized ranges in Micronesia (Table 9). These include some species previously regarded as indigenous, as discussed above. Additional to these species, the recently recognized naturalized population of *Salvinia natans* should also be assessed. Thorough surveys for their presence in cultivation and naturalized populations in each jurisdiction are recommended, with eradication programs advocated should their populations be rated as eradicable.

Table 7: High risk aquatic plant species not present in Micronesia recommended for inclusion in a ‘black-list’ of species prohibited from importation, with combined weed potential and impact score, and ranking out of 95 taxa assessed.

Species	Combined weed potential and impact score	Ranking/ 95
<i>Myriophyllum spicatum</i>	82	10
<i>Typha angustifolia</i>	81	11

<i>Nymphaea caerulea</i>	53	=57
<i>Nymphaea lotus</i>	53	=57

Table 9: Very high risk aquatic plant species present in Micronesia recommended for evaluation for possible eradication programmes, with combined weed potential and impact score, and ranking out of 95 taxa assessed.

Species	Combined weed potential and impact score	Ranking/ 95
<i>Eichhornia crassipes</i>	97	1
<i>Pistia stratiotes</i>	87	6
<i>Panicum repens</i>	85	=7
<i>Ceratophyllum demersum</i>	83	9
<i>Melaleuca quinquenervia</i>	77	=14
<i>Schinus terebinthifolius</i>	77	=14
<i>Salvinia natans</i>	56	=48

4.3 Species currently permitted for importation as aquarium plants

All the plants currently permitted as aquarium imports to Guam scored in the low range of the AWRAM, with combined weed potential and impact score < 45.

The highest ranked species (#78) was *Echinodorus cordifolius*, a native of central- and south-eastern USA, included as a quarantine weed in Western Australia (Randall 2002), but still traded in the aquarium/pond plant trade there (Champion et al., (2008). It was recently recognized in a photograph taken of a canal in Hawaii, but its status there is uncertain. It is present in cultivation in Guam, but unlikely to be a weed of much consequence.

Cryptocoryne species were the next highest group (#80), with *C. ciliata* and *C. spiralis*, both commonly traded species, reported as rice weeds (no indication of level of impact) in India (Moody 1989) and *C. beckettii*, *C. wendtii* and *C. undulata* naturalized in the San Marcos River, Texas and other U.S. localities (NAS 2010). These species are very popular in the aquarium trade and pose a minor risk to natural habitats, especially forest streams, in Micronesia.

Aponogeton species (excluding the warm temperate, water-lily like *A. distachyos*) were ranked #87. *A. crispus*, *A. natans*, *A. robinsonii* and *A. undulatus* are all reported as rice weeds (no indication of level of impact) in India and Southeast Asia (Moody 1989), with these species often occurring in seasonal pools, regrowing from tubers once these pools are flooded. Several species are included as a quarantine weed in Western Australia (Randall 2002), but they are still traded in the aquarium/pond plant trade there (Champion et al., (2008). These species are very popular in the aquarium

trade and pose a minor risk to natural habitats, especially open streams and ponds and potentially savanna wetlands in Micronesia.

Other *Echinodorus* species (excluding *E. cordifolius*) are ranked #88, with Randall (2002), reporting 14 species, including *E. osiris* recorded in pond cultivation in Guam, as weeds within their native range of South America. *E. berteroi* is a native rice weed of California (Barrett & Seaman 1980; Di Tomaso & Healy 2003), but are likely to pose minor risks to Micronesia.

The remaining taxa permitted for importation occupy the bottom four rankings (ranks #92 -95). These are *Anubias* spp. (African aroids - Kasselmann 2003), *Microsorium pteropus* (a fern native to tropical Asia and New Guinea - Kasselmann 2003), *Vesicularia duyana* (a moss native to the Philippines - Kasselmann 2003, and possibly Micronesia) and the lowest ranked South American aroid *Spathiphyllum tasson* (not included as an aquatic plant by Kasselmann 2003). All are forest stream species and are unlikely to cause any impact on habitats in Micronesia.

The inclusion of these taxa on a 'white-list' for importation as aquarium plants is supported.

5. Acknowledgements

We would like to thank Mark Sytsma and Rich Miller (PSU) for assistance in the field and also helpful discussions on approaches to weed risk assessment. Data on aquatic plant species was also provided by Linda Moore and Vanessa Howard (PSU). Rohan Wells provided a helpful critique of this report.

3 Volume III - Marine Systems

Regional Biosecurity Plan for Micronesia and Hawaii

Volume III

Prepared by:

University of Guam and the Secretariat of the Pacific Community 2014

This plan was prepared in conjunction with representatives from various countries at various levels including federal/national, state/territory/commonwealth, industry, and non-governmental organizations and was generously funded and supported by the Commander, Navy Installations Command (CNIC) and Headquarters, Marine Corps.

**Marine Invasive Species Risk Assessment for the
Commonwealth of the Northern Mariana Islands,
Guam, Hawai'i, Palau, the Federated States of
Micronesia, and the Republic of the Marshall Islands**

Edited version of the original document

Preface

This document presents a risk analysis for the marine systems of Micronesia, providing a framework and recommended actions to reduce the risks (probability of establishment, spread, and impacts) of invasions by non-native species in marine habitats.

The work presented in this document is primarily a synthesis and review of information available on the processes, spatial and temporal patterns, and existing management (regulations, guidelines and practices) for invasions by non-native marine species. Micronesia was the primary focus of this analysis, and information was also included from other regions, where relevant to understanding invasion dynamics and current (and emerging) management practices.

Most of the information presented in this document was obtained from extensive literature review, analysis of reports and documents, existing datasets (especially on ships and commerce), and interviews and correspondence with experts across a diverse range of topic areas. As conceived by the sponsoring agency, the project scope was constrained to what could be accomplished in one year of effort. Thus, the available time and resources were insufficient to complete any new major research effort, such as conducting field-based surveys to document existing biota in Micronesia or associated with vectors operating in the region. The resulting document indicates therefore what data and data gaps exist in this respect. An exception to this approach was an opportunistic field-based survey of a small number of supply ships in Guam, providing some preliminary data that begin to assess the extent and taxonomic diversity of marine organisms associated with the hulls (underwater surfaces).

It is important to recognize that the information presented in this report represents a snapshot in time. The work for this project began in late 2009, and most of the information collection and analyses were done in 2010. Unfortunately, due to delays in obtaining data for vessel traffic patterns (as discussed in Chapter 1), the final report was not completed until early 2012. While the authors attempted to include new information as it became available through February 2012, it also was not possible to accomplish this in a comprehensive way. Management of marine invasions is a very dynamic field that is undergoing rapid changes, and new policy changes emerged during the report drafting. For example, since this project began, new regulations have emerged for ballast water on a national level, for ballast water discharges by commercial ships operating in U.S. waters (including Guam). The U.S. Environmental Protection Agency published draft regulations (Federal Register, Volume 76, Number 236, December 8, 2011), and the U.S. Coast Guard published a final rule for ballast water treatment (Federal Register, Volume 77, Number 57, March 23, 2012). In fact, the latter rule did not become final until after this report was completed, and reference to it was added as a footnote in a revised version. Additional regulations are pending at state levels, as seen in California for management of biofouling organisms on commercial vessels operating in state waters (http://www.slc.ca.gov/spec_pub/mfd/ballast_water/Ballast_Water_Default.html).

Finally, we are greatly indebted to the many people who generously shared their time, expertise, insights, and information concerning the invasions, management, policy, culture, and history of Micronesia and Hawai'i. This project would not have been possible without the enormous assistance and advice provided from those who shared their knowledge (at regional, national, and local scales) in resource management, customs and quarantine, commercial and military maritime transportation, port operations, fisheries, aquaculture, recreation, tourism, conservation, policy, and marine species distributions and inventories. Large numbers of people, agencies, and organizations were involved in this regard from many different parts of Micronesia and elsewhere. Rather than attempt a comprehensive list and unintentionally omit some participants, we simply acknowledge the important information contributed to this report by many people throughout Micronesia and Hawai'i.

PART I.

Overview: Introduction to the Report and Analysis of Marine Invasion Mechanisms and Management in Micronesia

Chapter 1: Introduction to the Report and Marine Biological Invasions

By Gregory M. Ruiz, Chela J. Zabin, and Paul W. Fofonoff

1.1 Purpose of the Report

Recognizing existing concerns about biological invasions, the U.S. Department of Defense (DoD) has requested development of a Biosecurity Plan for Micronesia to minimize the risk of introduction and spread of non-native species in the region. This plan is in response to the proposed relocation of Marine Corps, Navy and Army operations from Okinawa, Japan to Guam (hereafter referred to as the Buildup), as outlined in the Draft Environmental Impact Statement (DEIS; DoD 2009) and Final Environmental Statement (FEIS; DoD 2010). Overall, the U.S. military originally anticipated the relocation to Guam of 24,713 military employees and dependents. This was expected to result in construction of ~3,000 buildings and major infrastructure improvements, including the creation of a new deep draft wharf that could accommodate a transient nuclear powered aircraft carrier. During the construction phase, the population of Guam was projected to (a) increase by 79,178 people at its peak, in order to provide the infrastructure and services in existing plans and (b) level off at 33,608 (including the military personnel and dependents). These estimates are subject to changes, and current plans are to lower the estimated size of the Buildup and extend the time of completion (U.S.-Japan Security Consultative Committee 2012). The increased demand for equipment (e.g., dredging equipment, silt curtains, etc.), vessels, construction materials, household goods, food, and other supplies regardless of the ultimate size and nature of the buildup will result in increases in commercial and military shipping and air traffic activity.

This increased flux could increase the risk of introduction and establishment of non-native species to Guam and, once established, increase their potential to spread to other parts of Micronesia. Currently there are connections between islands in the region via commercial shipping, military and private ship/boat traffic, and airline and helicopter traffic, which move goods and people. Spread within the region could be potentially further facilitated by the DoD's plans to use Tinian in the Commonwealth of the Northern Mariana Islands (CNMI) for military operations, by more frequent military ship traffic to other locations within Micronesia, and by increased tourism by military personnel and dependents within Micronesia and Hawai'i.

For this reason, the DoD has called for a Risk Assessment and Biosecurity Plan, which is required as part of the FEIS and the Record of Decision for the Buildup. The Risk Assessment and Biosecurity Plan are intended to have two phases, as specified in the Statement of Work. The first phase uses a science-based analysis and assessment to characterize potential mechanisms and associated risks of non-native species transfers. The second phase develops a biosecurity plan that identifies best management practices (BMPs) and responses needed to reduce the likelihood and potential effects of new invasions by non-native species. While this effort focuses on Guam as the center of increased military activity, the DoD has specified that the Risk Assessment and Biosecurity Plan include

analysis of the Micronesian region more broadly and also the linkages (opportunities for species transfers) between Micronesia and Hawai'i.

This document is intended to (a) outline risks of marine invasions to Guam and Micronesia, as well as those in Hawai'i associated with the Buildup, and (b) provide recommendations for practices that can reduce the likelihood of introductions, establishment, and spread of non-native marine species. Below, we provide a more detailed description of the process, structure, and content for this report.

1.2 Context, Timeline, and Limitations of the Report

The issue of biological invasions was largely absent from the DEIS , released by the DoD in November 2009, with an understanding that the current analysis (findings of the Risk Assessment and recommendations in the Biosecurity Plan) would be incorporated at a later date, as available. This project was initiated in September 2009, when funds became available to implement the analysis for coastal marine ecosystems.

In anticipation of a 2011 construction start date, especially for facilities at Apra Harbor in Guam, the DoD requested preliminary recommendations for BMPs prior to the completed Risk Assessment, focusing primarily on port facilities and operations in Guam. A set of draft BMPs were submitted to the DoD in March 2010 to serve as general guidelines while this RA and the overall MBP were completed. The recommendations contained in the current document build upon and refine those made in March 2010.

The findings and recommendations from this risk analysis support the regional biosecurity implementation plan. The U.S. Navy and University of Guam entered into a cooperative agreement in September of 2011, whereby the university has agreed to create a strategic implementation plan using this analysis, as well as those for freshwater plants, freshwater fishes, and terrestrial organisms (see above). Thus, the current report aims to highlight the current understanding about marine invasions, identify key data gaps, and recommend management strategies to include in the implementation plan, in order to reduce invasion risks to the region. However, this report does not identify the necessary resources, possible timeline, or the institutional framework and coordination required to fully implement and sustain an effective biosecurity program. These latter elements are inter- dependent upon each other, representing critical aspects of the implementation planning process.

Importantly, the time period specified by DoD in the Statement of Work limited the analysis to relying primarily on the collection and synthesis of existing data as available to us, through efforts to identify and obtain relevant information for Guam, the Commonwealth of the Northern Mariana Islands, Palau, the Federated States of Micronesia, the Republic of the Marshall Islands, and Hawai'i. It is evident that significant data gaps exist, and many of these are identified throughout the report in particular chapters, which discuss (a) the implications for risk assessment, (b) how these gaps are addressed within the analyses, and (c) approaches to address these gaps.

One of the conspicuous data gaps merits brief mention at the onset, because it is a core component to assessing invasion risk as outlined in the Statement of Work. Access to vessel movement data or hull information for U.S. Navy combatant ships was not provided,

due to concerns about the sensitive nature of these data with respect to national security and potential public release. In consultation with DoD, we sought data on both U.S. Navy combatant and supply ships, in order to assess the current connectivity among global regions and the potential opportunity for transfer of non-native species by vessels. In the summer of 2011, we received data on the supply ships, and DoD requested that analyses proceed without data for the combatant ships. Consequently, U.S. Navy combatant ships arriving to Guam or elsewhere were not included in the risk assessment (see Chapter 5). In the absence of vessel movement data, there is no reliable way to constrain the potential ports visited (and non-native species contacted) by this classification of vessel, and the potential risk of invasions associated with combatants remain undefined in this analysis.

1.3 Structure and Rationale of the Report

The report is divided into three different parts, most with multiple chapters, to address different topics associated with marine invasions and biosecurity. Part I characterizes the current status and knowledge of human-mediated transfer mechanisms (vectors) for non-native marine species into Micronesia, summarizing available information on their operation, scope, and management (including regulations and practices) in four separate chapters. Part II (one chapter) provides an assessment of risks of marine invasions for Micronesia. Part III (one chapter) outlines a biosecurity plan, providing recommendations for specific management actions, strategies, and frameworks to minimize impacts of marine invasions for the jurisdictions covered by the Micronesia Biosecurity Plan (MBP).

This first introductory chapter (Chapter 1) provides a brief overview of the report and background information regarding the patterns and mechanisms of marine invasions across multiple geographic regions. This chapter also highlights the importance of particular vectors for the introduction of marine species, including especially (a) the movement of organisms associated with vessels and (b) trade of live organisms associated with aquaculture, restocking efforts, food, bait, and home aquaria.

A focus on vectors, as described in the introductory chapter, is used as a general framework for the organization of the report. This framework serves multiple purposes; first, focusing on vectors places primary attention on understanding and preventing unwanted species transfers in order to reduce the likelihood of invasions. A pre-border (prevention) approach to biosecurity is widely considered more desirable, effective, and predictable than post-border interventions, after species have arrived or established populations (Meyerson and Reaser 2002; Wittenberg and Cock 2005). This approach is also consistent with guidance for U.S. federal agencies (see Section 2.1). Second, guidelines and management strategies to advance pre-border biosecurity are organized primarily by vector, recognizing that this is the operational unit for both (a) invasion opportunities and (b) particular segments of industry, military, commercial, and public activities. Any pre-border strategy or policy must have an explicit vector-based component, whether for particular types of organisms or habitats, addressing the transfer mechanism(s) of concern. In short, this organizational framework will underscore vector management as a critical component of the biosecurity plan, aiming to reduce the risk (probability) of future invasions.

In Chapter 2, the report reviews current regulations, guidelines, and practices used to reduce marine invasions associated with vessels. Of particular relevance are practices for

vessels arriving to Guam, other parts of Micronesia, and Hawai'i. We also consider the practices that are applied to vessels in other global regions, discussing the rapid changes that are now underway on an international scale. The analysis in Chapter 2 focuses on commercial and U.S. military vessels, including military supply vessels. Although recreational and fishing vessels also pose potential invasion risks, biosecurity guidelines and regulations are largely undeveloped for these vessels at the present time.

Chapter 3 reviews what is known about the current and projected future flux (number) of vessels arriving to Guam and Micronesia, as well as the magnitude of vessels moving between this region and Hawai'i. We focus particular attention on commercial and military vessels, evaluating what is known about the previous ports of call, since these are the potential source regions of species transfers. We also summarize available information across all types of vessels and other in-water structures and equipment which may transport organisms. In some cases, there are significant gaps in knowledge regarding vessels, in-water equipment, and various other equipment types. These information gaps are identified and discussed.

Live trade as a possible vector for non-native species introductions to Micronesia is addressed in Chapter 4, providing information available on (a) existing regulations and practices and (b) current activities, and (c) anticipated future activities.

A risk assessment for marine invasions associated with vessels is presented in Chapter 5. This uses information from several different areas, including: (a) a detailed analysis of shipping traffic for commercial and U.S. Navy vessels (specifically Navy supply ships, as data from combatant ships were not made available), indicating the connectivity to various geographic regions; and (b) a list of some of the non-native marine species known to occur in these various geographic source regions. These data are combined to assess the opportunity for transferring species with a known invasion history from areas of known occurrence, thereby posing some invasion risk to Guam, other jurisdictions of Micronesia, and Hawai'i. The analysis focuses solely on biofouling organisms, or those species that are known to occur as biofoulers on the hulls and underwater surfaces of vessels, and does not distinguish between biofoulers originating from tropical regions (which have a higher likelihood of establishment in Micronesia and Hawai'i) versus biofoulers from temperate and colder waters (which have a lower risk of establishment). Moreover, only species that have been reported thus far to be invasive were considered. A similar analysis of biofouling for other vessel types (i.e., fishing vessels, recreational vessels, and barges) was not undertaken; neither were environmental parameters accounted for in the risk assessments. Also omitted were analyses of other important vectors such as ballast water and the live trade. Such analyses were deemed to be not yet possible, due to lack of sufficient data on geographic sources and fluxes, as discussed in Chapter 3.

One of the challenges in conducting a risk assessment is to identify the potential hazards or impacts associated with invasions. As an extension of Chapter 5, a small pilot study was conducted to explore what is now known about values in Micronesia and possible implications for risk analyses. This is presented in Appendix B and begins to characterize the environment, economic, social and cultural core values that people in these locations hold and how they perceive that introduced species will affect these values.

Chapter 6 presents a biosecurity plan for Guam, Commonwealth of the Northern Mariana

Islands, Palau, the Federated States of Micronesia, the Republic of the Marshall Islands, and Hawai'i. Following a brief overview of existing regional plans and programs, this chapter outlines recommendations for management practices to (a) prevent new invasions as well as (b) detect and respond to such incursions that may occur. It is evident that there are currently many gaps in meeting these recommendations for marine biosecurity in the region. Thus, beyond the practices themselves, regional coordination and capacity are discussed and must be considered explicitly to implement various elements of the biosecurity plan.

1.4 Terminology for Non-Native Species

In general, we avoid the use of the term “invasive,” because in regards to tropical marine systems it is an imprecise term that is functionally difficult to define in a robust fashion. It is important to recognize that (a) the impacts, or potential impacts, of most non-native marine species have never been evaluated (e.g., Ruiz et al. 1999, 2011a; see also Chapter 5), and (b) such impacts can vary greatly in space and time. Thus, it is currently not possible with any confidence to divide non-native marine species into those that are “invasive” and those that are not, based on impact criteria. In the absence of data, a precautionary approach would assume that most non-native species have the potential to cause harm under some circumstances. For this report, use of the term “invasive” is restricted primarily to cases where specific negative effects are perceived or recognized, and “non-native” and “invasive” are used as synonyms.

Finally, following Carlton (1996), species that occur in a specific region are considered to fall into one of three categories: native, non-native, or cryptogenic. The latter are species of uncertain origin, reflecting a poor state of knowledge about taxonomic identity and/or biogeographic origin of an organism. A large number of species in a region may be cryptogenic, as is the case with many locations with limited historical data, such as tropical marine ecosystems (Paulay et al. 2002), but is also the case in well-studied estuaries like San Francisco Bay, California (Cohen and Carlton 1995).

1.5 Vectors as Drivers of Marine Invasions

Analyses of marine invasions have frequently been conducted to assess human-mediated transport mechanisms (vectors) responsible for marine invasions, based upon life history characteristics, the time of detection, and the operation of vectors in the relevant geographic regions and temporal context. This approach has been used to assess vector strength, or the relative contribution of different vectors to the number of observed invasions, over time in specific locations (Cohen and Carlton 1995; Ruiz and Carlton 2003; Hewitt et al. 2004).

Where available, analyses of vector strength indicate that most marine invasions are attributed to the unintentional transfer of organisms by vessels (Reise et al. 1999; Ruiz et al. 2000; Fofonoff et al. 2003; Hewitt et al. 2004). While vessels have been a dominant vector on a global scale, other transfer mechanisms can also be important sources for marine invasions in some locations. Among these, the movement of live organisms for food, bait, aquaculture, or aquaria has been a common source of invasions (Cohen and Carlton 1995; Chapman et al. 2003; Weigle et al. 2005; Hewitt et al. 2007; Ruiz et al.

2011a). This intentional movement of organisms is often referred to as “live trade.” Marine invasions and spread of non-native species are also known to result from (a) movement of in-water structures, such as docks, (b) transfer of construction or restoration materials, such as sand and rock, and (c) construction of canals that connect water bodies, such as the Suez Canal and Kiel Canal (Gollasch et al. 2006).

Below, we provide a further description about movement of organisms by vessels and live trade. We highlight these two categories because they are dominant vectors for marine invasions, contributing strongly to the total number of documented invasions on regional and global scales (as above; see also Hewitt and Campbell 2010). However, we note that invasions from other vectors may have high ecological or economic impact, even if the total number of species invasions attributed to a particular vector is not great.

1.5.1 Introductions by Vessels

There are two dominant modes of transfer for marine species by vessels, excluding organisms shipped as cargo. Organisms commonly occur in the ballast materials of vessels and on hulls (and other underwater surfaces). A significant body of literature documents the occurrence of many taxonomic groups in ballast tanks and on hulls, across a wide variety of vessel types, underscoring the enormous potential for species transfer over great distances. For both ballast tanks and vessel hulls, the transfer of organisms is an unintended consequence of normal vessel operations, as discussed below. It is also evident that both modes of ship-mediated transfer have contributed strongly to invasions observed around the globe.

1.5.1.1 Ballast Water

Ballast is used by ships to maintain stability and trim. It is generally taken on in port before a ship’s departure. Prior to the 1900s, vessels used solid ballast (rocks and sand), but this has been replaced with ballast water, which may also contain sediments (Carlton 1985). A diverse array of marine organisms, from crabs and fish to bacteria and viruses, have waterborne life stages such as larvae (often microscopic) that are taken up in ballast in one region and discharged at subsequent ports of call, creating an efficient transfer mechanism for marine organisms (National Research Council 1996; 2011). For example, a single vessel can discharge > 50,000 metric tons of ballast water upon arrival, and recent estimates indicate vessels arriving from overseas to the continental U.S. alone discharge approximately 60 million metric tons of ballast water per year (Miller et al. 2011a). While there is considerable variation among vessels in the quantity of ballast discharge and its associated biota (National Research Council 2011), the cumulative effect of global ship traffic transfers large numbers of marine organisms throughout the world in ballast water, overcoming historical barriers to natural dispersal and allowing invasions to occur.

1.5.1.2 Biofouling.

Many marine organisms colonize hard substrata during part of their life cycle, including rock, coral, wood, metal, and many other materials. Vessels and maritime structures provide such substrata, which are utilized by a wide diversity of micro- and macro-organisms (Visscher 1927; Woods Hole Oceanographic Institution 1952; Haderlie 1984).

Many of these organisms live attached to the underwater surfaces of structures; these sessile species can include algae, barnacles, protists, oysters, mussels, coral, sponges, tunicates, bryozoans, and tube-building worms. In addition, mobile fauna such as snails, crabs, and fish can occupy (a) the structure created by attached species as well as (b) “niche areas” of the vessel (such as intakes and areas around propellers, rudders, and other in-water structures) that provide protection from high flow environments on the exposed hull surfaces. Some organisms, such as shipworms and particular isopods, burrow into wooden structures when available. Throughout this document, we refer to species associated with the underwater surfaces of vessels, whether mobile or sessile (fixed to a particular location) as “biofouling organisms.”

Movement of any in-water structure creates a potential opportunity to transfer associated biofouling organisms. Attached organisms can release gametes, larvae, or various types of spores upon arrival; some organisms may be able to spread via fragmentation; and mobile animals can simply crawl or swim away.

Despite existing hull husbandry practices to reduce undesirable effects of biofouling on vessel speed and performance (as described in Chapter 2), it is evident that extensive numbers of organisms are still transferred on vessels’ hulls, resulting in new invasions (Skerman 1960; Godwin 2004; Sylvester et al. 2011). Among vessel types there is a high degree of variation in the magnitude and diversity of associated biofouling organisms (Carlton and Hodder 1995; Ferreira et al. 2006; Davidson et al. 2008; Davidson et al. 2010). However, in contrast to ballast water usage, which is restricted to particular types of vessels, biofouling organisms can occur on any type of surface vessel (commercial, fishing, military, recreational, barge; see above), submarine (Voight et al 2012), or in-water structure. Another important distinction is that vessels are exposed continuously to colonization and release of biofouling organisms at each port of call, cumulatively through time between dry-dock and thorough cleaning, whereas ballast water uptake and discharge is much more episodic and limited in space and time (Miller et al. 2011a).

1.5.2 Introductions Resulting From Live Trade

The trade in live marine organisms and their release into the environment has historically been one of the top pathways for the introduction and establishment of non-native marine species. Live organisms are often moved intentionally among biogeographic regions for use as aquaculture species, bait, food, scientific research, and pets (aquaria). Importantly, live organisms are also moved unintentionally by humans, as a type of accidental “by-catch.” Such unintentional transfers can result when biota are associated with (a) target species that are moved for commercial purpose (as above) or (b) packing materials or processes used in transfer of live species and other goods (e.g. ice chests). These unintentional transfers include a remarkably diverse range of taxonomic groups, from free-living organisms (such as macro-invertebrates and fishes) to those that occur attached or within organisms (such as microorganisms, including parasites and pathogens).

It is evident that live trade has been a potent source of invasions in some regions (e.g. Cohen and Carlton 1995), but it also has received less attention than vessels as a source of marine invasions, especially in terms of the current magnitude and geographic variation in such species transfers. Moreover, while the transfer of species poses some risk of release

and establishment, not all transfers result in release. For example, many organisms moved for consumption or for pets (aquaria) may not be released to the wild, although a subset of these are released or escape. Despite some uncertainty about various dimensions of live trade, past invasions have resulted from such species transfers, regardless of whether release is intended or not. Below, we provide further background information for selected components of live trade.

1.5.2.1 Aquaculture.

Among the unwanted consequences of importation of aquaculture species is the establishment of exotic pests, pathogens and predators (Culver and Kuris 2004; Moreno et al. 2006; McKindsey et al. 2007; Naylor et al. 2010) that become problematic for cultured and native species. Eldredge (1994) reviewed species introduced both intentionally and unintentionally to the Pacific Islands via aquaculture. From giant clam aquaculture alone, seven bacteria and bacterial diseases, four parasites, and three protozoans and protozoan diseases are known to have been introduced to various locations in Asia and the Pacific (Humphrey 1988). One of the best-known examples of an accidentally imported disease is shrimp virus IHNV (infectious hypodermal and hematopoietic necrosis virus), which was accidentally introduced to Tahiti, Guam, and Hawai'i and causes stunted growth and mortality in shrimp. Aquaculture species themselves can become problematic if they escape from pens, tanks, and marine cages, or in the case of organisms planted directly into the environment, when they reproduce or spread out of control. For example, several algal species (including *Kappaphycus striatum*, *Gracilaria salicornia*, and *Hypnea musciformis*) were introduced to Hawai'ian waters for aquaculture purposes and have since become pest species, overgrowing coral, outcompeting native algae and ruining beaches for human enjoyment by washing up in huge drift piles (Preskitt et al. 2001; Smith et al. 2004; Nelson et al. 2009; Vermeij 2009).

Although many of the species transferred for marine culture are actively managed in pens or selected areas, stocking also occurs. This has been most common with fishes in low salinity habitats (see Cohen et al. 2005). For example, tilapia (*Oreochromis mossambicus*, *Oreochromis* hybrids, and *Tilapia zilli*, native to Africa,) were brought into the Micronesia region for aquaculture and mosquito-control purposes, have become established in the region, and have been the target of eradication efforts on Palau and Nauru (Nelson and Eldredge 1991; Nico and Walsh 2011). However, there are also examples of stocking to create marine invertebrate fisheries, such as the king crab introduction in Russia; this has created a large population of the introduced crab that is spreading in Scandinavia, creating some concerns about ecological and fisheries impacts (Jørgensen and Nilssen 2011). In the Pacific, there have been introductions of hatchery-raised giant clams (tridacnids) to many overharvested and non-native localities. These seeding efforts have sometimes been associated with the introductions of some diseases, parasites, and gastropod predators, most notably the predatory snail *Cymatium muricinum* (reviewed in Eldredge 1994). Since the 1920s, *Trochus niloticus* has also been brought in to many localities outside its native range (including the Marianas, Chuuk, Kosrae, Pohnpei) in order to create new fisheries for trochus shell (Eldredge 1994). More recently, the sandfish (*Holothuria scabra*) has been introduced to Kiribati from Fiji and to New Caledonia from Wallis.

1.5.2.2 Live Food Trade.

Marine organisms imported live for food can become established if they a) accidentally escape from holding tanks or pens or b) are “planted” in the environment, either for short-term use or to establish local populations. This is perhaps best illustrated by the massive transfer of oysters to California in the late 19th and early 20th centuries, from eastern North America and Asia (Carlton 1979; Miller et al. 2007). This resulted in the unintentional transfer of many other associated organisms, including a diverse range of taxonomic groups (e.g., bacteria, protists, crustaceans, gastropods, and bryozoans) that were present in and on the oysters, and over 80 non-native species established in California may have arrived by oyster importation (Ruiz et al. 2011b). Other examples of established non-native species associated with live food trade on the U.S. West Coast include several brackish water species (that use both freshwater and marine environments): the Chinese mitten crab (*Eriocheir sinensis*), the crayfish *Procambarus clarkii*, and the clam *Corbicula fluminea* (Cohen and Carlton 1995).

Transfers of organisms for food have resulted in introductions in other parts of the U.S. and globally. This has been documented for some transfers of shellfish, including oysters, mussels, lobsters, and crabs (Wolff and Reise 2002; Chapman et al. 2003, Jørstad et al. 2007; Miller et al. 2007; Fofonoff et al. 2009). In addition, the recent arrival of the northern snakehead (*Channa argus*) to eastern North America is attributed to its importation for food and subsequent release (Orrel and Weigt 2005). It is noteworthy that snakehead fishes and mitten crabs, both attributed to live food trade as a mechanism of introduction, are now listed as “injurious wildlife” in the U.S. under the federal Lacey Act, prohibiting future importation and interstate movement (Thomas et al. 2009; Miller 2011).

1.5.2.3. Pet/Aquarium Trade.

The release of species associated with the aquarium trade represents a significant vector for introductions of non-native aquatic and marine organisms (Ruiz et al. 1997). In the mainland U.S., 150 species that have invaded natural ecosystems have been transferred via aquarium and ornamental culture trade (Padilla and Williams 2004). In some cases, release from aquaria is accidental (through public aquarium outflows, escapes from tanks/pens during storms, etc.), but in others, pets and plants are released into local waters by aquarists who no longer want them. In contrast to transfer via shipping in which organisms are released into only a few locations (mainly ports), aquarium plants and animals are widely distributed into homes and businesses, and thus potentially may be released into a wider distribution of natural habitats, including coral reef habitats (e.g., Semmens et al. 2004). Non-native species linked to the aquarium trade include intentionally traded species and species transported accidentally with these and aquarium components such as live rock (Bolton and Graham 2006; Minchin 2007; Duggan 2010). Generally speaking, organisms imported intentionally for the aquarium trade are often hardy species (i.e., able to withstand stress of transport and a relatively wide range of environmental conditions), and those that survive transport are hardy individuals, increasing the potential for survival upon release.

Two high-profile examples of marine invasions associated with the aquarium and pet trade are the alga *Caulerpa taxifolia* and the Indo-Pacific lionfish (*Pterois* spp.). The alga, which now carpets vast swaths of the Mediterranean Sea, outcompetes native algae and sea grasses, apparently causing major changes in habitat and food sources for many native

organisms (Meinesz and Hesse 1991; Bellan-Santini et al. 1996). This species was also detected in California and was the focus of an intensive and successful eradication effort (Anderson 2005). *Caulerpa taxifolia* is also invasive in New South Wales, Australia, where control and eradication efforts are ongoing (Creese et al. 2004). The lionfish, a popular aquarium fish, is now established in the Caribbean and Western Atlantic, where it appears to be altering reef fish community structure through predation (Whitfield et al. 2002; Albins and Hixon. 2009).

1.5.2.4. Bait.

Imported bait, including algal packing materials and associated organisms, is often discarded into the environment, providing another transfer mechanism for marine introductions (Weigle et al. 2005). Available studies indicate a large volume (number) of bait shipments occur in some regions, and these shipments can include a diverse assemblage of associated non-target species (Passarelli et al. 2010; Haska et al. 2011). As with live food imports, associated organisms found in bait shipments range from macrofauna to microorganisms, including parasites and pathogens (Pernet et al. 2008; Haska et al. 2011). Moreover, several recent invasions may have resulted from bait transfers, such as colonization of western North America by the knotted wrack (*Ascophyllum nodosum*), the common periwinkle (*Littorina littorea*), and the green crab (*Carcinus maenas*), which originated from the North Atlantic coast (Miller et al. 2004).

1.5.2.5. Scientific Research.

Some marine organisms are imported for research and teaching purposes, presenting a potential opportunity for release of non-native species to local environments. While this can occur, relatively few invasions have been attributed to this mechanism in existing analyses for multiple global regions (Cohen and Carlton 1995; Hewitt et al. 1999; Fofonoff et al. 2009; Minchin and Gollasch 2002; Siguan 2002).

1.6 Distribution of Marine Invasions across Habitat Types

In marine ecosystems, most known invasions are reported from within protected bays and estuaries, with relatively few non-native species documented along exposed coasts or in deep water (Carlton 1979; Ruiz et al. 1997; Wasson et al. 2005; Preisler et al. 2009). While this does not imply that offshore waters are immune to invasions, the observed pattern indicates that bays are hotspots for invasion. This is likely driven, at least in part, by (a) the relatively high concentration of shipping and other activities that deliver organisms to port systems as centers of human commerce and (b) the relatively prolonged time periods that vessels spend stationary in ports.

Within bays and estuaries, a large proportion of non-native species is associated with artificial hard substrata, such as pilings, docks, and seawalls (Cohen and Carlton 1995; Wasson et al. 2005; Glasby et al. 2007; Ruiz et al. 2009). It is not clear what factors generate this pattern. It is thought that the presence of artificial substrata may facilitate establishment of non-native populations, providing a beachhead for colonization and possible spread to surrounding areas. One implication of this is that construction in ports and harbors (which usually include use or creation of man-made structures such as pilings

and walls) may increase the probability of invasions, independent of propagule supply.

Despite this general pattern of association with artificial substrata and protected waters, marine invasions do indeed occur on natural substrata (e.g., rock, cobble, and reefs) and in outer coastal waters. This is illustrated by *Didemnum vexillum*, a colonial tunicate that has covered extensive offshore areas of seafloor in the Georges Bank of eastern North America (Bullard et al. 2007; Valentine et al. 2007). Additional examples are also documented in tropical ecosystems such as Hawai'i (see Section 1.7.1). Thus, it is not surprising to see that outer coastal waters are susceptible to invasions, even at considerable depths, given a supply of non-native organisms with suitable characteristics.

1.7 Geographical Patterns of Marine Invasions

Invasions have occurred commonly in coastal marine habitats during recent time. Hundreds of non-native marine species are known to be established in many well-studied regions throughout the world, such as Australia (Hewitt and Campbell 2010), the Mediterranean Sea (Galil 2009), the continental U.S. (Ruiz et al. 2000; 2011a), and Hawai'i (Carlton and Eldredge 2009). It is clear that some non-native marine species are having significant ecological, economic, and human-health impacts (Carlton 2001). Importantly, a comprehensive estimate of marine invasion impacts is not available for any global region, because (a) many invasions are undetected (Carlton 1996; Ruiz et al. 2000) and (b) effects of most invasions have not been studied and remain difficult to predict (Ruiz et al. 1999; 2011b).

For marine ecosystems, most of the invasions to date have been detected in temperate latitudes, compared to polar or tropical regions (Hewitt 2002; Ruiz and Hewitt 2009; Ruiz et al. 2009). A similar pattern has been reported for some taxonomic groups in terrestrial habitats, where the number of established non-native species increases from high to subtropical latitudes followed by a precipitous decline in the tropics (Sax 2001). This pattern may reflect historical differences across latitudes in (a) the amount of research on biological invasions, (b) understanding of species biogeography and (c) the level of organism transfer, or propagule supply. Although not well quantified, the level of research and economic activity (trade and transportation which transfers organisms) is concentrated at mid-latitudes. In addition, it is also possible that tropical and polar regions are relatively more resistant to invasions, due to either environmental or biological conditions.

Despite the dominance of information about temperate invasions, it is evident that marine invasions do occur in tropical marine systems. This is illustrated by the introduction and rapid spread of the lionfish in the Caribbean basin (Guerrero et al. 2008; United States Geological Survey 2011). Lionfish, native to the Indo-Pacific, have invaded the U.S. coast from Florida to Rhode Island, and several Caribbean locations. These aggressive predators have reduced the abundance of native fishes on coral reefs (Albins and Hixon 2009) and mangrove habitats (Barbour et al. 2010) and are the target of management efforts. Yet, to date, few studies have begun to explore the extent to which tropical marine invasions are occurring relative to those in mid-latitudes. Hawai'i is exceptional in this regard, and some background data also exist in Guam, as outlined below.

1.7.1 Marine Invasions in Hawai'i

Carlton and Eldredge (2009) compiled a comprehensive monograph of introduced and cryptogenic marine species from the Hawai'ian Islands, which includes species of protists, fungi, invertebrates, fish, algae, and flowering plants. They reviewed 490 species, including (a) 301 species considered to be established non-natives and (b) 117 species classified as established cryptogenic species (of uncertain biogeographic origin). The remaining 72 species were non-native but either not established or not known to be established.

Crustaceans, insects, mollusks, and ascidians were among the most speciose taxonomic groups in this analysis. Indo-Pacific species comprised the largest portion at 46%; Western Atlantic species represented 22% and species from the Eastern Pacific made up 7%. The origin of 34% was unknown, but most likely was Indo-West Pacific or Western Atlantic.

For these documented invasions in Hawai'i, 70% were classified as introductions attributable to shipping (including either ballast water or biofouling, or both), and 15% were attributed to intentional and accidental releases. Only 11 species were considered introduced prior to 1900. Over 290 species are thought to have been introduced in the early 20th century, although many may have been transported earlier. Intentional releases occurred during two phases: (a) between 1895 and 1939, when 10 species were introduced, and (b) between 1950 and 1974, when 17 species were released. Intentional introductions appear to have ceased after 1974. Overall, the greatest number of introductions was detected in the mid-20th century and more recently, through numerous harbor and shoreline surveys and collections.

Remarkably, of the 301 introduced species considered, only six have been studied for impacts at the community or ecosystem level. Some of the major studies have been carried out on the snapper *Lutjanus kasmira* (ta'ape), the sponge *Mycale grandis*, the barnacle *Chthamalus proteus*, the octocoral *Carijoa riisei* (snowflake coral), and the algae *Kappaphycus* sp. and *Acanthophora spicifera*. The Caribbean mangrove *Rhizophora mangle* has become a particularly conspicuous species that is undergoing rapid spread in Hawai'i.

Among reported impacts in Hawai'i, several non-native species of marine algae, introduced for aquaculture purposes, are now overgrowing coral reefs and crowding out native algae (e.g., Smith et al. 2004; Vermeij et al. 2009; Carlton and Eldredge 2009); the non-native octocoral *Carijoa riisei* threatens the black coral fishery down to depths of 120 m (Grigg 2003); an Australian sponge, *Mycale grandis*, overgrows and kills corals (Coles and Bolick 2007); community structure of native reef fishes is likely affected by *Cephalopholis argus*, an introduced piscivorous grouper (Dierking et al. 2009); competition for shelter with the introduced snapper *Lutjanus kasmira* may make native goatfish more vulnerable to predation (Shumacher and Parrish 2005); and non-native tilapia are considered a serious threat to native aquatic plants (K. Peyton, University of Hawai'i, personal communication 2009).

A handful of these species have become the target of management efforts, including hand removal by volunteers, a massive pier wrapping project in a Maui harbor, the use of a "super sucker" which can be used to vacuum algae off the reef (The Nature Conservancy

2012), and experimental-scale biological control, but eradication has not yet been successful. Costs for marine invasive-species management in Hawai'i exceed millions of U.S. dollars (A. Montgomery, Hawai'i Department of Land and Natural Resources, personal communication).

1.7.2 Marine Invasions in Guam and Micronesia

Humans have transported many marine organisms to Guam and other parts of Micronesia over time. Some non-native species have successfully colonized and are documented for the region, but the full extent of marine invasions is much more difficult to determine as no comprehensive study of the marine invasive species of Micronesia currently exists.

Micronesia as a whole lies within the planet's greatest region of marine biodiversity, the coral reef region of the Indo-West Pacific (Vermeij 1978; Paulay 2003; Kingsford et al. 2009). The natural marine habitats of Micronesia are extremely diverse, ranging from the rocky shores of volcanic islands to coral reefs, mangroves, estuaries of small rivers, the lagoons of atolls, and many other habitats. In addition, many new habitats have been created by human activities, especially with the addition of artificial structures to create ports and harbors.

For Micronesia, the biota associated with many of these habitats has not been well characterized, especially given the high diversity and areal extent of the region. A recent series of surveys documented 5,640 species from the Mariana Islands, including some non-indigenous species (Paulay et al. 2002; Paulay 2003). However, even where surveys exist, recognizing introduced species is a major challenge in the face of this high native diversity and the relatively recent onset of marine biological studies in relation to the long history of human activity in the region.

A variety of criteria are used for recognition of non-native species including: (1) lack of previous known occurrence in a region, (2) recent range expansion, (3) association with likely vectors of introduction, (4) association with known invaders, (5) strong association with artificial substrata or human-disturbed habitats, (6) restricted local distribution, (7) disjunctive global distribution, (8) poor adaptation for long-range natural dispersal, and (9) exotic evolutionary origin (Chapman and Carlton 1994). The high diversity of the region means that many native species remain to be discovered, so that criteria 1 and 2 are difficult to apply. Micronesia is close enough to a major region of biodiversity that Criterion 7 is more difficult to apply than in such isolated island regions as Hawai'i or New Zealand.

Many marine organisms known to occur in Guam and other islands are widely distributed in both the Atlantic and Pacific oceans, but have not previously been treated as introductions anywhere. Some of these are probably undiscovered introductions, others represent species complexes, and others may be organisms which have not diverged enough to become distinct species since the closure of the ocean basins (Vermeij 1978; Lambert 2002; Lessios 2008). Criterion 5 may be a stronger indicator of native status, but native species may also show similar traits, for example some native species with fossil records on Guam are restricted to Apra Harbor, and frequently occur on artificial substrata.

Using a combination of the above criteria, Paulay et al. (2002) identified 21 non-native marine species as established in Guam waters and an additional 21 non-native species as recorded for the area but not known to have established populations. In a review of available recent literature, using similar methods, 33 non-native marine species that are considered to be established in Micronesia as a whole can be readily identified, including nine species in Palau, 25 in Guam, five in the Commonwealth of the Northern Marianas Islands (CNMI), five in the Federated States of Micronesia (FSM), one in Kiribati, and six in the Republic of the Marshall Islands (RMI). An additional 23 non-native marine species have been reported for the region, but to date it is not known whether or not these species have established populations. A more recent and comprehensive analysis is presented in Chapter 5, reporting the occurrence of additional non-native species in Micronesia.

These documented non-native species occurrences represent gross underestimates of the number of invasions in Micronesia, for several reasons. First, many important groups of organisms, including copepods, amphipods, isopods, mysids, marine insects, and bryozoans have not been well studied in Micronesia. In the Hawai'ian Islands, where these taxa have been better-studied, these five groups alone contained 68 non-native species (Carlton and Eldredge 2009). Second, the biota for many regions of Micronesia has simply not been sampled. Third, where surveys exist for particular groups and locations, these are not comprehensive inventories of all species present but instead an analysis of a subset of the total species pool. The combination of high biodiversity and limited taxonomic effort means that much of the biota in the region is unidentified. Moreover, the difficult taxonomy and biogeography of many of the identified species means that a large fraction of the biota deserves cryptogenic status, and can neither be designated as native or introduced (Carlton 1996; Paulay et al. 2002).

The known established marine invaders in Guam and elsewhere in Micronesia are dominated by sessile organisms that occur on hard substrata (18 of 25 species for Guam and 25 of 33 for all of Micronesia). Cnidarians (six hydrozoans, one anemone) and tunicates (nine species) are the most numerous non-native taxa in Micronesia. Motile taxa are represented by the crab *Metopograpsus oceanicus*, two gastropods (*Trochus niloticus* and *Tathirella iredalei*), and five fish species. All of the fishes identified in the present review are capable of inhabiting freshwater and marine (or at least brackish) habitats (this, however, does not include three species of non-native marine fishes reported from Apra Harbor by Smith et al. 2009). The majority of non-native marine species in Micronesia (18 of 33) are species of uncertain geographic origin, but very broad ranges in multiple oceans, with cryptogenic ranges in the Atlantic, Indian, and Pacific Oceans. At least 20 of the 33 species introduced to Micronesia have also been introduced to the Hawai'ian Islands (Carlton and Eldredge 2009).

Most of the detected non-native species for Micronesia (16 of 33 species) are attributed to ship biofouling as a possible vector, but seven of these species (including hydrozoans and barnacles) have planktonic life stages and could have been transported either by fouling or ballast water. One notable fouling introduction was the hydroid *Eudendrium carneum*, native to the Western Atlantic, and introduced to Palau in July 1997 when a floating bridge was brought to Palau from Guangzhou City, China (Shine et al. 2003). Three species were introduced by fisheries activities -- the mother-of-pearl snail (*Trochus niloticus*, also referred to in the region as the topsnail) and the peacock bass (*Cichla ocellaris*) were

deliberately stocked (Maciolek 1984; Smith 1987; Eldredge 1994; Lever 1996), while the parasitic snail *Tathrella iredalei* was introduced with giant clams (*Tridacna* sp.) via aquaculture (Eldredge 1994). The western mosquitofish (*Gambusia affinis*) was widely stocked in freshwater and brackish water for mosquito control on many islands (Krumholz 1948; Maciolek 1984; Lever 1996). The tilapias *Oreochromis mossambicus* (Mozambique tilapia and hybrids) and redbelly tilapia (*Tilapia zilli*) were both stocked in Guam reservoirs for control of aquatic weeds, but *O. mossambicus* was also widely introduced to many islands for aquaculture and as bait for tuna (Maciolek 1980; Lever 1996). It is unclear how the sailfin molly (*Poecilia latipinna*) was introduced to Guam; it may have been an aquarium release, intended for insect biocontrol, or as a baitfish (Maciolek 1984; Lever 1996).

The 23 additional non-native species that are documented without established populations add to our knowledge of the vectors which are active in the region. Perhaps most instructive is analysis of a floating dry-dock, the *Machinist*, which was towed from Hawai'i to Guam, having been positioned in the Philippines prior to its existence in Hawai'i. At the start of its voyage, 113 species were identified on its hull, and at least 42 species were identified soon after arrival in Apra Harbor. At least 12 species were considered definite introductions to Guam. However, many of these organisms survived the voyage in poor condition, so their ability to colonize Guam waters is uncertain (Paulay et al. 2002). At least two species of fishes (*Neopomacentrus violascens* and *Omobranchus elongatus*), each represented by single specimens, were found associated with ship hulls in Apra Harbor (Eldredge 1994; Paulay et al. 2002). These could have been transported in ballast water, in sea-chests (openings on the outer hulls of vessels for water intake), or on slow-moving structures such as dry-docks.

At least 12 marine species have been introduced for aquaculture, of which 10 have failed to survive or reproduce, or are apparently confined to aquaculture facilities. Four species of shrimp are, or have been cultured on Guam, starting in 1978. One of these, the catadromous *Macrobrachium rosenbergii*, escaped into rivers on Guam when dams burst during a typhoon in 1992, but its establishment in the wild is unknown and does not appear to have been studied (Eldredge 1994). Three species of edible oysters (the Pacific oyster, *Crassostrea gigas*; the spiny rock oyster, *Saccostrea echinata*; and the Philippines rock oyster, *Saccostrea mordax*) have been stocked in Guam and Palau, but failed to reproduce (Eldredge 1994). In the 1930s, Japanese pearl companies stocked waters in the Marshall Islands, Palau, and Christmas Island, Kiribati, with the non-native pearl oysters *Pinctada fucata martensi* and *P. maxima*, but these operations were abandoned during World War II, and the oysters are not known to have become established (Eldredge 1994). A notable freshwater introduction, the chevron snakehead (*Channa striata*), escaped from fish farms in the 1970s, and is established in the Ajayan River drainage on Guam. Attempts at eradication are underway (Nico and Walsh 2011).

In summary, the available data demonstrate that marine invasions are occurring in Micronesia associated with the known transport mechanisms that are driving invasions throughout the world. Most invasions reported for Micronesia to date are known from Guam and have been associated with shipping. However, it is critically important to recognize that the extent of marine invasions to the region (a) has not been estimated formally or quantitatively and (b) is certain to far exceed the documented number of non-

native species to date, as with many other regions (Cohen and Carlton 1995; Carlton and Eldredge 2009). The ecological, economic, and social impacts of marine invasions are not well-known in Micronesia, in part because so few invaders have been identified, and in part because the known non-native species have not been carefully studied (for further discussion see Shine et al. 2003; Marino et al. 2008; Appendix A).

Chapter 2: Overview of Current Regulations, Guidelines, and Practices Related to Ship-Mediated Marine Bioinvasions

By Chela.J. Zabin, Gregory M. Ruiz, Gail V. Ashton, and Ian C. Davidson

2.1 Introduction

Historically, ships have played a dominant role in the transfer of non-native marine species, leading to biological invasions throughout the world, as outlined in Chapter 1. Although the issue of marine invasions has received significant attention in recent time, the rate of reported invasions has increased in the past few decades, and this increase has been driven largely by shipping (Cohen and Carlton 1998; Hewitt et al. 2004; Ruiz et al. 2000; 2011b). In response, numerous regulations, agreements, and guidelines have emerged to reduce the likelihood of species invasions at national, regional and international levels (see recent review by Hewitt et al. 2009a). It is important to also note that these existing frameworks are undergoing rapid changes, which aim to further limit the transfer of organisms.

In general, and within the specific context of the Buildup, U.S. Executive Order 13112 on Invasive Species (signed by President Clinton in 1999) directs U.S. federal agencies to: "... not authorize, fund, or carry out actions that it believes are likely to cause or promote the introduction or spread of invasive species in the United States or elsewhere unless, pursuant to guidelines that it has prescribed, the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species; and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions."

The Executive Order applies to all activities of federal agencies and also establishes the U.S. National Invasive Species Council (NISC), to coordinate actions to prevent and control non-native species throughout the U.S. federal government. Toward this end, NISC has developed a National Invasive Species Management Plan and implemented a formal framework of interagency and advisory meetings to limit the extent and impact of biological invasions.

In addition to the overarching framework outlined in Executive Order 13112 for the U.S., there are also some specific regulations and guidelines to limit species transfers by ships (including ballast water and hull biofouling) , but to date these guidelines are either not comprehensive or are not currently established (such as the IMO hull fouling guidelines). These guidelines exist primarily at national and international levels. It is also noteworthy that different requirements and practices exist for commercial versus military vessels.

This chapter provides a review of current regulations, guidelines, and practices for management of ballast water and hull biofouling. We focus on commercial and military vessels, examining differences in the way in which ballast water and biofouling are managed for these vessel types. Throughout, we consider these management practices in the explicit context of Guam, the Commonwealth of the Northern Mariana Islands, Palau, the Federated States of Micronesia, and the Republic of the Marshall Islands.

2.2 Ballast Water

2.2.1 Regulations and Guidelines

2.2.1.1 Commercial Vessels.

At a national level, U.S. federal regulations exist currently for ballast water management and discharge by commercial vessels arriving to U.S. ports. The federal regulations governing ballast discharge in the U.S. were issued by the USCG (United States Coast Guard 2004), and more recently by the EPA (United States Environmental Protection Agency 2008; see National Research Council 2011 for review). At the present time, the regulations by these two agencies are similar. Both require commercial vessels arriving to U.S. ports from beyond the exclusive economic zone (EEZ) to treat ballast water of coastal origin (i.e., taken up within 200 nautical miles (nmi) of shore) prior to discharge in U.S. waters. In general, discharging vessels arriving from overseas are required to treat their ballast water by (a) use of open ocean ballast water exchange (i.e., flushing out tanks in open ocean, > 200 nmi from shore) or (b) an alternative technology that is approved for use (of which there currently are none). In addition, the EPA regulations also apply to some coastwise (domestic) vessel traffic along the western U.S.

Under the USCG regulations, commercial vessels (whether arriving from a foreign or a domestic port) are also required to submit a detailed report to the USCG on the origin, treatment, and volume of discharges. These reports are submitted for each arrival event to evaluate compliance and changes in ballast water management over time. Vessels out of compliance with regulations are subject to criminal prosecution and financial penalty (United States Coast Guard 2004).

The aim of current U.S. federal regulations is to reduce the concentration of coastal organisms delivered in discharged ballast water that pose a risk of invasion to subsequent ports of call and coastal waters of the U.S. During ballast water exchange, coastal organisms are replaced with oceanic organisms. In general, it is considered unlikely for coastal organisms to survive in the open ocean (or to reach coastal habitats if discharged at sea), or for oceanic organisms to colonize coastal regions, due to their respective habitat requirements. While ballast water exchange provides a significant reduction of coastal organisms delivered in ballast water (Minton et al. 2005; Ruiz and Reid 2009; Bailey et al. 2011), some residual coastal organisms are still present following this treatment, and, critically, there are logistical constraints that prohibit its application for some routes and conditions (Miller et al. 2011a). For these reasons, there is significant momentum to replace ballast water exchange with treatment technologies, which (a) can be used on most vessels and routes and (b) achieve lower concentrations of organisms in ballast discharge than possible with ballast water exchange (National Research Council 2011).

New regulations are now being advanced by U.S. federal agencies for ballast water to meet specific discharge standards which are lower than organism concentrations often achieved by ballast water exchange. This is reflected in a Notice of Proposed Rulemaking (United States Coast Guard 2009) issued by USCG, which is required to regulate ballast water under the Nonindigenous Aquatic Nuisance Species Prevention and Control Act of 1990

(updated by the National Invasive Species Act of 1996). This rule has just cleared administrative review, and a Final Rule is scheduled for publication in March 2012; this is expected to result in new requirements (regulations), but the specific details and timetable are not yet available publicly. Similar regulations to require specific discharge standards are also under consideration at the EPA (United States Environmental Protection Agency 2011), which is required to regulate ballast water discharge under the Clean Water Act of 1972 (see National Research Council 2011 for review of recent requirement to regulate ballast water under this law).

Requirements for ballast water treatment are also being advanced at the international level by the International Maritime Organization (IMO). The International Convention for the Control and Management of Ships' Ballast Water and Sediments was adopted in 2004, establishing ballast water management requirements for commercial shipping on a global scale. The IMO convention will slowly phase out ballast water exchange, replacing it with treatment technologies to achieve specific discharge standards (International Maritime Organization 2004). The IMO discharge standards are the same ones that have recently¹ been proposed by USCG¹ and the EPA.

The IMO Convention is awaiting ratification and is not yet in force. The Convention requires ratification by at least 30 countries accounting for 35% of the world's merchant shipping. As of February 2012, it had been approved by 33 countries that represent 26% of the global fleet (International Maritime Organization 2012).

Although not directly relevant to Micronesia, it is also perhaps useful to note that several individual state regulations exist for ballast water discharge in the U.S. (e.g. California, Oregon, Washington and Michigan; see National Research Council 2011 for

¹ The Final Rule was issued by USCG and published in the Federal Register after completion of this report. For specific details see: Standards for living organisms in ships' ballast water discharged into U.S. waters, Federal Register, Volume 77, Number 57, March 23, 2012¹

discussion). These state regulations do not replace federal regulations, but instead impose additional requirements on commercial vessels. In some cases, the state regulations result in more stringent discharge standards and have created additional requirements for treatment of coastwise vessel traffic among U.S. ports. Some of these state requirements are also written into (included) in current, existing federal regulations from the EPA.

In considering the geographic scope of this report, USCG and EPA regulations apply to commercial vessels arriving to Guam, Commonwealth of Northern Mariana Islands (CNMI), and Hawai'i. Thus, vessels arriving to each of these jurisdictions are presently required to either (a) retain ballast water, (b) undergo open ocean ballast exchange (at 200 nmi from shore), or (c) use an alternative ballast water treatment technology that is approved by USCG. As noted above, the requirements for ballast water treatment are likely to change to concentration-based discharge standards, which are pending at both the U.S. federal and international levels.

For the rest of Micronesia, there are no other countrywide or regional regulations that specifically address ballast water management and discharge by commercial operators. On a local scale, ballast water discharge is not allowed within 12 nmi of the Port of Saipan, per port regulations (Commonwealth Ports Authority Regulations Private Use of Harbor Property and Facilities 3.26b). In Palau, although there are no regulations specifically addressing ballast water, it is thought that discharges can be regulated as non-point discharge under the Environmental Protection Act 24 PNC. In several other parts of Micronesia, officials suggested that agencies regulating water quality already may have the legal authority to control deballasting. Moreover, it was widely recognized throughout Micronesia that the pending IMO standards would apply to arriving vessels, when they come into force. Palau, the FSM and the RMI each have pending biosecurity bills that would, among many other topics, address ballast water management.

One aspect not currently being considered in the management of ballast water in the region is the proximity of the Mariana Islands to the West Mariana Ridge (WMR). While none of the volcanic peaks of the WMR quite reach sea level, 11 summits have depths of less than 500 m, of which three seamounts (including Stingray Shoal) are 16 m or less in depth (Gardner 2010). The WMR is well within the 200 nmi allowable zone for ballast water exchange. Of equally great concern are a number of shallow banks west of Guam and the Marianas that are only about ~22 nmi or less from the main island chain. These shoals are potential landing sites for invasive species flushed from ballast. As such, "open ocean" ballast water discharge is not the ideal solution for the Marianas, and alternative technologies should be explored.

2.2.1.2 U.S. Navy Vessels

Although military vessels are exempted from the above regulations, there are separate requirements that exist for the U.S. Navy. Specifically, when U.S. Navy ships take on ballast water within 3 nmi of shore (or in areas that are potentially polluted), they are instructed to exchange ballast water outside the 12 nmi zone from shore before next entry (Section 22-10.3.1, Environmental and Natural Resources Manual 2007; OPNAVINST 5090.1C, updated July 18 2011). U.S. Navy ships are instructed to pump out and twice fill tanks with clean seawater outside the 12 nmi mark, and to do this exchange even when

deballasting has happened before exiting the 3 nmi mark (or polluted waters) to remove any contaminated residual ballast water. The ships' engineers are instructed to record in ships' engineering logs such ballasting and ballast exchange, including the location and amount of water taken on (Section 22-10.3.2, Environmental and Natural Resources Manual 2007).

Based on current policy, two key differences exist in regulations for U.S. Navy vessels compared to commercial vessels. First, for U.S. Navy vessels, the required distance from shore for source of ballast water (3 nmi) or ballast water exchange (12 nmi) is much less than that for commercial ships (200 nmi). Second, we are not aware of a reporting requirement or analysis for U.S. Navy vessels, in which compliance with these requirements has been evaluated (see Section 2.2.2). In addition, we note that regulations for commercial vessels are rapidly moving toward a requirement for alternative treatment technologies with specific discharge standards, and we are not aware of similar efforts to develop such requirements for U.S. Navy vessels.

By having ballast water sources (including ballast water exchange) closer to shore, the likelihood of transfer of coastal organisms by U.S. Navy vessels to a suitable habitat is increased per unit ballast water volume relative to commercial vessels that conduct exchange in the open ocean (see Chapter 3 for comparison of traffic and ballast discharge between these vessel types). With increasing proximity to any particular shore, the concentration of coastal organisms is expected to increase, and the probability that organisms can reach coastal habitats by currents should also increase. For both attributes, the specific decay functions with distance from shore will vary geographically and temporally. Nonetheless, it is certain that coastal organisms occur in many regions at 3- 12 nmi from shore. It is partly for this reason that greater distances were required for ballast water exchange by commercial vessels (Brickman 2006; Miller et al. 2011a). Moreover, there is evidence that ballast water exchange closer to shore does entrain coastal organisms, which can be discharged at subsequent ports of call (Endresen et al. 2004; Cordell et al. 2009; Simkanin et al. 2009).

It is worth reiterating that the 12 nmi stipulated by the U.S. Navy for ballast water exchange may lead to ballast water being flushed in close proximity to shallow shoals only 22 nmi from the main island arc of the Marianas, as well as to the West Marianas Ridge approximately 100 nmi from the islands. These shoals and seamounts could become areas for alien coastal species to settle and invade.

A recent study aboard U.S. Navy supply vessels (oilers) along the eastern U.S. found a high efficacy for ballast water exchange, when conducted properly (Ruiz and Smith 2011). Experimental tests found that double ballast water exchange removed 99% of the original water and up to 99% of selected coastal organisms, compared to untreated control tanks on the same vessels. While comparable or better than similar tests on commercial vessels (Ruiz et al. 2005; Bailey et al. 2011), it also appears that concomitant entrainment of new coastal organisms occurred with this nearshore ballast water exchange, as perhaps expected (see above discussion). Thus, ships that undergo nearshore ballast water exchange can have residual coastal organisms from a previous source (albeit with severely reduced concentrations compared to pre-exchange conditions) as well as additional coastal organisms that are entrained during the nearshore exchange process.

Based on available information for both commercial and U.S. Navy vessels (Minton et al. 2005; Holm et al. 2005; Levings et al. 2004; Cordell et al. 2009; Ruiz and Smith 2011), it is apparent that the current ballast water management practices on the Navy vessels will often not allow them to meet the concentration-based discharge standards for zooplankton that are being advanced for commercial vessels by the U.S. and IMO (see above). These new standards are more stringent than ballast water exchange, at least for zooplankton concentrations (Minton et al. 2005), requiring fewer than 10 organisms (≥ 50 microns in size) per cubic meter. Importantly, this standard applies to total concentrations and does not distinguish between coastal and oceanic organisms. Thus, even if all coastal organisms could be replaced by the process of ballast water exchange (which does not occur), the entrainment of new organisms from nearshore or oceanic waters would frequently cause exchanged ballast water to exceed discharge standards.

Although the U.S. Navy is exempted from the discharge standards now being proposed for commercial vessels by the USCG, EPA, and IMO, all military vessels do fall under the jurisdiction for Section 312(n) of the Clean Water Act, which requires establishment of Uniform National Discharge Standards (UNDS). More specifically, Section 312(n) of the Clean Water Act requires the DoD and EPA to determine which discharges from military vessels require control and to set standards for environmental protection. While ballast water was identified previously as a discharge that required control by UNDS (United States Environmental Protection Agency 1999), no specific guidance or standard has been provided to date for this discharge.

Another area of concern is the risk of invasive species being transported to Micronesia and Hawai'i by foreign military vessels of partnering countries (e.g., Singapore, Philippines, Japan, Australia, etc.) that will arrive in the area to partake of training and joint exercises with the U.S. military. The routes and anticipated frequency of such foreign military vessel visits, as well as the ballast water guidelines these vessels are expected to follow, will need to be clarified.

2.2.1.3 Military Sealift Command Vessels

Supply vessels for the U.S. Navy operate under the Military Sealift Command (MSC). Some supply vessels are owned and operated by the MSC, representing a subset of U.S. Navy-owned vessels. However, additional supply vessels are privately owned or operated, under contract to the MSC. This latter group is distinctly different from other commercial vessels, which may transport cargo but are not under MSC orders.

Vessels that are owned or operated by the MSC are governed by the same environmental instruction as U.S. Navy vessels. However, ships that are operated by civilians under contract to the MSC are not subject to the Navy's regulations and are thus not obligated to carry out any of the Navy guidelines for environmental stewardship. It appears regulations for commercial vessels would apply in the latter case, but it is not clear (a) the extent to which these vessels operate with this understanding and (b) what management practices are used routinely on these vessels (see below for additional details).

2.2.1.4 Other Military Vessels

Vessels operated by the U.S. military (including Army, Navy, Marine Corps, Air Force, MSC, and USCG) are all exempt from U.S. regulations that exist for commercial vessels, as outlined above. While ballast water on all military vessels falls under the jurisdiction of UNDS, no ballast discharge standards have been advanced under UNDS to date for these vessels (United States Environmental Protection Agency 1999). Aside from the ballast management requirements in place for U.S. Navy vessels (above), we were unable to identify similar policies or requirements for other branches of the military or for military vessels of other countries when operating in U.S. waters.

2.2.2 Current Practices, Operating Procedures and Compliance

2.2.2.1 Commercial Vessels

A considerable amount of information is available on ballast water management for commercial vessels arriving to U.S. ports, because the USCG has established a reporting and analysis mechanism through the National Ballast Information Clearinghouse (NBIC). As noted above, commercial vessels are required to submit a report on ballast water management and discharge upon arrival to U.S. ports, and these data are used by NBIC to characterize status and trends in ballast water compliance and management (for more detail see <http://invasions.si.edu/nbic/>).

For the two-year period 2006-2007, NBIC received over 200,000 ballast water reporting forms that were submitted by ships' personnel or agents for arriving vessels (Miller et al. 2011b). Using an independent data set, it was estimated that 83.5% of overseas arrivals and 77.8% of coastwise arrivals (from another domestic port in the contiguous U.S.) were in compliance with the reporting requirements that exist. Most (76.9%) of these commercial arrivals reported no ballast water discharge. The remainder reported a cumulative discharge of >390 million metric tons of ballast water over the two-year period, including 111 million tons from overseas sources and 280 million tons from domestic sources. For the overseas ballast water, 81.7% of the total volume had reportedly undergone some type of treatment (ballast water exchange) prior to discharge, whereas 18.3% was not treated before release into U.S. waters. Under current USCG regulations, a similar requirement for treatment of ballast water from domestic sources (by coastwise traffic) does not exist; however, recent regulations by the EPA, and also those for a subset of States, do require ballast water treatment for some domestic sources (United States Environmental Protection Agency 2008; National Research Council 2011).

Miller et al. (2011b) estimated that ballast water reports were submitted by 62.6% of overseas arrivals to Guam and 73.7% to Hawai'i for 2006-2007. These compliance rates were below the national average (83.5%). A recent examination of NBIC reporting data, for the five-year period of 2005-2009, suggested that reporting compliance for arrivals to Guam and Hawai'i remains at approximately this level (<http://invasions.si.edu/nbic/>). For this five-year period, overseas arrivals reported discharge of 358,496 metric tons of ballast water to Guam, and an estimated 15.5% of this volume was reported to be untreated (i.e., did not undergo ballast water exchange). This represents a minimum estimate, given the low reporting compliance for Guam, which does not include roughly one third of the commercial vessel arrivals (see Chapter 3 for additional information on ballast water movement within Micronesia, and between Micronesia and Hawai'i).

Overall, Guam and Hawai'i have a relatively low number of vessel arrivals, representing 0.9% and 2.5% of the total vessel traffic reported for the entire U.S. in 2005-2006 (Miller et al. 2011b). Moreover, these regions accounted for an even lower percentage of the total reported volume of ballast discharge, reflecting the fact that these regions are net importers, with the exception of some transshipping operations. Commercial ships tend to arrive loaded with cargo and leave with less than they came with. Thus, the need for deballasting is likely to be lower in the region than in many other port locations; instead, Hawai'i and Micronesia are likely net exporters of ballast water (Godwin and Eldredge 2001). Despite the low relative volumes, ballast water discharges into these regions create opportunities for species transfer, and ballast uptake in these regions increases the probability of spread both within and outside of each region.

Much less information is available about ballast water management in other parts of Micronesia. In most locations in the region, management officials told us they depended on ships and shipping agents to be aware of existing regulations and to follow them. However, we note that few regulations exist currently. In the FSM, legal code allows for the inspection of ballast by agricultural quarantine inspectors (FSM Code, Title 22, 410); in most locations, it appears that environmental protection or environmental quality agencies also have the authority to regulate ballast water. As far as we were able to determine, none of the jurisdictions in the region check the records of arriving vessels to evaluate the extent of ballast water management and discharge.

While IMO discharge standards appear likely to come into force in the near future, requiring ballast water management throughout Micronesia, understanding the current and future ballast water practices will require increased capacity. Outside of the ballast- water reporting program described above for the U.S. jurisdictions, based on extensive interviews and correspondence with port officials throughout Micronesia, it appears there are no programs with such a focus in the region. Thus, evaluating ballast management in Micronesia would require personnel and training, which are not currently available. Further, it is noteworthy that existing programs throughout the world have primarily served to compile self-reported data from ships' personnel, with little effort to implement tests that verify whether ballast water exchange was conducted properly (but see Noble et al. 2010), which would require some additional development and training.

2.2.2.2 Military Vessels

In contrast to commercial vessels operating in Guam and other U.S. waters, relatively little information is accessible to evaluate current practices for U.S. military vessels, which are not required to submit reports to the USCG. While the U.S. Navy has a specific requirement to conduct ballast water exchange and record ballast water management in the ships' engineering logs, as noted above (Section 22-10.3.1, Environmental and Natural Resources Manual 2007; OPNAVINST 5090.1C), we are unaware of any effort to synthesize, analyze, or evaluate data on implementation of the Navy's ballast water management program. Instead, it is our understanding that existing data remain distributed across individual ships' logs and are not readily accessible. As a result, it appears there are no summary statistics available to characterize (a) the extent of compliance with OPNAVINST 5090.1C, (b) locations of ballast water sources, exchange and discharge, or

(c) volumes of ballast water discharged to Micronesia, Hawai'i, or other locations.

A small amount of information is available on supply vessels that operate under the MSC; because some of these vessels submitted ballast water data to the USCG through NBIC (see above for description). From 2005 to 2009, 77 MSC arrivals to Guam reported to NBIC, representing < 20% of the total estimated arrivals to Guam for this period (for commercial and MSC vessels combined; see Chapter 3). These MSC vessels reported

7,408 metric tons of ballast water discharged in Guam, and 15.2% of the total volume had not been treated by ballast water exchange. This accounts for 2% of the cumulative ballast water discharge reported to NBIC for Guam during this time period, and the percentage of untreated discharge is similar to that reported for commercial vessels to Guam (15.5%). However, with such a low proportion of the MSC arrivals included, it is premature to draw any conclusions about the relative contribution or nature of ballast water management by MSC vessels. Equally important, the volume of ballast discharge is not a good proxy for concentration of organisms or the probability of invasion (see National Research Council 2011 for discussion of this issue).

Beyond such records for MSC vessels, no other information was available to us to evaluate ballast water management and discharge of other Navy or other military vessels arriving to Micronesia or Hawai'i.

Some U.S. Navy vessels, such as surface combatants, have compensated fuel stowage systems, which are also subject to Navy regulation (Section 22-10.3.3, Environmental and Natural Resources Manual 2007). These regulations require vessels to record seawater intake occurring in potentially polluted areas or within 3 nmi of shore during routine internal fuel transfer for propulsion plant operation (but do not require ballast water exchange). Most fuel operations are reported to occur away from ports, possibly restricting uptake and transfer of coastal organisms. However, we have no access to information on the location of operations, volumes of water involved, or biota (types and concentrations) associated with this water arriving to Guam or any other region.

In addition, amphibious vessels are instructed to wash down any amphibious vehicles they are recovering (as well as anchors, anchor chains, and other shipboard equipment) and to dispose of wash water 12 nmi outside of the next operating area. This is outlined in Section 22-10.3.4 of the Environmental and Natural Resources Manual (2007). We have no information on the frequency or locations of this activity, or the biota that may be associated.

2.3 Biofouling

2.3.1 Regulations and Guidelines

2.3.1.1 Commercial Vessels

Biofouling is probably the most important vector of invasive species introductions. Biofoulers may account for up to 55% of marine pests globally, while in Australia over 60% of the known introduced species have most likely arrived as biofouling (Hewitt and

Campbell 2010). Despite this, the requirements surrounding biofouling on vessels are less advanced with respect to biosecurity than those for ballast water discharges. Existing requirements that apply to hull husbandry are motivated primarily by international vessel classification societies for insurance purposes (Takata et al. 2006), operational performance, and efficiency of the vessel, instead of prevention of species transfers and biological invasions. There are currently no international requirements that aim specifically to manage biofouling and associated invasion risks by commercial, military, or recreational vessels. Nor are there such requirements specific to Guam or the rest of Micronesia. However, the IMO has recently agreed to guidelines for biofouling with this goal (see below), and regulations are advancing for several specific regions around the globe.

For the U.S., existing requirements for hull husbandry focus on safety and operations. The USCG requires most large commercial vessels that operate in U.S. waters to be inspected at least 2 times every 5 years, with 3 years as the maximum interval between inspections. Newer vessels can qualify for underwater inspections under certain circumstances under the USCG regulations, and other vessel types are exempt. Although it appears that the USCG may have the authority to regulate the extent of biofouling as well (Hewitt et al. 2009a), this has not resulted in any specific regulations or requirements to date. None of the countries or states in the Micronesian region has additional regulations or guidelines for the management of biofouling.

In contrast, several regional or state regulations are emerging that seek to limit biofouling transfers and the likelihood of invasions. Strict regulations exist for vessels applying for permits to enter (as opposed to passing through) the Papahānaumokuākea National Monument, Northwestern Hawaiʻian Islands (Papahānaumokuākea Marine National Monument Best Management Practices No. 011, 2009), whereby the vessels must meet specific standards indicating clean hulls. However, these regulations do not apply to vessels transiting through the monument nor do they apply to other areas of Hawaiʻi. In addition, the State of California is in the process of enacting regulations for control of biofouling on commercial vessels arriving to ports within the state (http://www.slc.ca.gov/Spec_Pub/MFD/Ballast_Water/Laws_Regulations.html).

On a global basis, several countries already have voluntary guidelines for management and have developed very detailed recommended management practices. For example, New Zealand has released draft regulations requiring all vessels entering territorial water to be free of biofouling (Ministry of Agriculture and Forestry 2010).² Australia has released draft antifouling and in-water cleaning guidelines for all vessels and other moveable structures in aquatic environments (Department of Agriculture, Fisheries and Forestry 2011), and was, at the time of this report, accepting public comment on whether to adopt voluntary or mandatory regulations³. Most recently, the IMO has adopted guidelines for management practices to reduce invasion risk associated with biofouling of commercial vessels (International Marine Organization 2010).

2.3.1.2 Military Vessels

For U.S. Navy vessels, there is an established schedule for inspection, and the level (both type and extent) of biofouling is used to determine the need for cleaning, dry-docking and application of coatings (Naval Ships Technical Manual (NSTM) 2006). The NSTM Chapter 081 lists criteria for frequency of hull inspection and in-water cleaning (i.e., removal of biofouling organisms), including a fouling rating system on which to base maintenance, information on tools to clean hulls underwater, a decision tree for other actions based on coating condition and rust, and limited information on underwater paint systems for U.S. Navy ships.

² New Zealand was slated to release mandatory regulations for commercial and recreational vessels in 2012, but had not done so at press time. Further information on these regulations and enforcement is available at <http://www.biosecurity.govt.nz/enter/ships>.

³ Further information on Australia's biofouling regulations is available at <http://www.daff.gov.au/animal-plant-health/pests-diseases-weeds/marine-pests/biofouling>

As specified in NSTM 081, cleanings of ablative coatings (paints that work by slowly eroding, exposing new layers of anti-fouling compounds at the surface) are not done until 24 to 36 months after application, as the anti-fouling paint is expected to work well until then. Underwater paintings and coatings are expected to require no cleaning during the first year or two of service. Following this initial high-performing period, hulls may be cleaned as often as required to maintain fouling below acceptable levels. Acceptable is defined as: not above a one-knot speed penalty at shaft revolutions per minute (rpm) for standard sea-speed, not over a fuel usage penalty of 5% to attain standard sea-speed, or not to exceed fouling rating limits outlined in NSTM 081. Though heavy fouling and hard calcareous fouling in particular is to be avoided, full hull in-water cleanings are not expected to occur more frequently than every six months, even with tired coatings in high fouling bioregions. At present, dry-dock intervals for U.S. Navy ships range between five and twelve years, the upper limit far exceeding that for commercial vessels.

Beyond the hull itself, specific underwater fixtures require the use of specialized husbandry protocols, as outlined in NSTM 081. Vessels intended for “silence” (submarines) have specialized hull husbandry protocols intended to maintain that feature. This may include sheathing of certain features while in port. On all ships, sonar equipment, propulsion equipment in general (including bow-thrusters and emergency propulsion units), and the bow area receive priority attention, and may be cleaned much more frequently than the entire hull. Propellers, which are not painted with anti-fouling paints, foul more quickly than painted areas. In general, these are expected to be cleaned quarterly, although practices vary depending on operations. The NSTM also mentions that sea-chests commonly require hand tools for cleaning.

The UNDS, established under the Clean Water Act of 1996, has identified hull coating leachate and underwater ship (hull) husbandry as discharges requiring control for DoD vessels (United States Environmental Protection Agency 1999). Reports that characterize the nature of these discharges indicate that there is the potential for transport of non-native species associated with the hulls of vessels and also vessel cleaning, but the reports did not identify analyses that characterized the transfer of organisms on DoD vessels or the associated biosecurity risks (<http://unds.bah.com/Nod/uwshphub.pdf>).

The U.S. Navy has sustained a long-term program that records data and maintains information on the extent and type of biofouling organisms present on Navy vessels, following protocols outlined in NSTM 081. Based on interviews with U.S. Navy personnel, it is our understanding that a routine schedule of in-water inspections and associated data (for biofouling) are maintained for all Navy-owned vessels. Existing analyses of these data to examine the potential for non-native species transfers with the U.S. Navy vessels could not be found.

Vessels that are privately owned and operated under the MSC appear to not be subject to similar requirements for inspections, records, and maintenance as outlined above for U.S. Navy-owned vessels. Navy personnel indicated that most such vessels under contract to MSC do not follow the U.S. Navy protocols for biofouling and operate instead under guidelines for commercial vessels, as discussed above.

Aside from the Navy, it is not clear if any specific regulations, requirements, or policies

may exist for biofouling associated with other types of U.S. military vessels. Inquiries to DoD and associated research did not identify any existing policy in this regard.

2.3.1.3 Other Vessels and In-Water Structures

Any in-water structure or platform such as a floating dry-dock that is allowed to accumulate marine organisms has the potential to transfer non-native species when moved to another location. Although most recent efforts to evaluate and prevent marine invasion outcomes have focused on large vessels, small recreational craft and other in-water structures (such as drilling rigs and dry-docks; see below) can be potent sources of invasions. Indeed, even if these represent low frequency arrivals to a region, they can be sources of high-density inocula, especially because they may have high port residence times, slow travel speeds, and highly variable maintenance practices (see Section 2.3.2 for discussion).

For example, transportation of a decommissioned vessel (e.g., for scrap metal breaking or an artificial reef) may transfer large biofouling assemblages because the vessels have often been laid-up in port for long periods of time with little to no hull husbandry and are then towed slowly to another destination. These two attributes allow for extensive colonization of the outer hull by organisms and facilitate transfer and survival under low shear forces (Davidson et al. 2008). A similar situation exists for floating dry-docks, mobile drilling platforms, floating docks, pontoons, navigation buoys, and fish aggregating devices (FADs), which operate often with high residence times and slow transport speeds. Indeed, although the literature on stochastic and high-density biofouling transfer events is limited, there are examples of such vessels and structures arriving to Hawai'i and Guam (Doty 1961; Brock et al. 1999; deFelice 1999; Godwin and Eldredge 2001). Floating FADs have also occasionally arrived at Saipan and Tinian waters within the past decade, concomitant with the increased use of that fishing technology in the Central and Western Pacific region.

Considering this more broadly, the transfer of any in-water material has some probability of transferring associated organisms, if present. Although this section focuses attention on vessels as a transfer mechanism for biofouling organisms, the same concept applies to the transfer of other materials as well, including port infrastructure (caissons, seawalls, rip-rap materials, sand), construction equipment (dredges and barges), scuba diving gear, and other equipment. This broader range of transfer mechanisms is outside the scope of the current chapter but will be revisited in the Biosecurity Plan (Chapter 6).

To our knowledge, there are currently no regulations or guidelines in Micronesia that address biofouling and invasion risks associated with the movement of these types of vessels, structures, and platforms, however both the FSM and RMI are in the process of developing biosecurity bills that will address these issues. Inquiries to DoD and review of available documents did not identify any such regulations or guidelines.

2.3.2 Current Practices, Operating Procedures and Compliance

2.3.2.1 Commercial Vessels

There are strong incentives to reduce biofouling on vessels, as it reduces streamlining of vessels and thus increases the drag, resulting in higher fuel consumption and longer transit times. Fouling on propellers, rudders and intake pipes can also interfere with functionality. To reduce biofouling, vessels are cleaned in dry-dock, often at set time intervals, and antifouling or foul-release coatings (paints) are applied to prevent the settlement or accumulation of marine organisms on boat hulls. Painted surfaces are also cleaned in water to remove biofouling organisms that accumulate between dry-docking intervals.

Several factors are known to influence the extent and species richness of fouling communities on underwater surfaces of ships, including age and type of coatings, route, speed, and frequency of operation (including port residence times). New vessels tend to have relatively low biofouling levels, due to several attributes, such as (a) complete coating of underwater surfaces with intact paint surfaces, (b) relatively high performance of new coatings, and (c) a paint type that is selected to be appropriate for the intended function (route and tempo) of the vessel, which can change over the approximate 30-year lifespan of the vessel. In general, the performance of coatings to prevent biofouling deteriorates with age, requiring routine cleaning and reapplication (Visscher 1927; Haderlie 1984; Schultz et al. 2011).

Controlling for other factors, short residence times in port and fast traveling speeds reduce the likelihood of an extensive fouling community on the exposed hull surfaces (Coutts and Taylor 2004; Davidson et al. 2009; Floerl and Coutts 2009; Sylvester and MacIsaac 2009). Floerl and Coutts (2009) also noted the “potential ramifications on the human-mediated spread of non-native marine species from commercial vessels being moored stationary for extended period of time due to the economic crisis. Vessels which visit a diverse or extreme range of environments (e.g., freshwater of the Panama Canal, warm water tropical ports, freshwater and cold water high-latitude ports), exceeding environmental tolerances of many biofouling organisms, are likely to be less prone to biofouling accumulation than vessels which remain within a narrow environmental range (Visscher 1927; Skerman 1960; Coutts and Taylor 2004, Davidson et al 2006). In addition, “niche” areas, or those protected from laminar flow (i.e., crevices), appear to be more susceptible to hull fouling (Coutts and Taylor 2004; Davidson et al. 2009). Thus, a vessel with low surface complexity will likely be cleaner than a vessel with complex and numerous niche areas, independent of other influences on hull fouling.

Many, if not most, anti-fouling coatings (which operate to reduce settlement of organisms) and foul-release coatings (which operate to prevent permanent adhesion, and therefore accumulation of organisms, under shear forces) are engineered to work best when vessels are underway (Lewis 2002b). Thus, vessels that are seldom used, slow moving or poorly maintained are at high risk of being fouled. In general, vessels that are laid-up or spend long residence times in port can accumulate extensive biofouling, relative to vessels that are in continuous service or operate with shorter port residence times. Moreover, increased residence time in ports also causes niche areas, such as intakes and rudders (which are protected from shear forces while the vessel is underway), to be highly vulnerable to

fouling, even on otherwise well-maintained vessels.

Since most existing guidelines and practices to reduce biofouling are aimed at maintaining the operational safety and cost efficiency of vessels, and are not driven by reducing invasion risk, there has been little incentive to address biofouling for (a) niche areas that do not increase drag, (b) slow-moving vessels, and (c) vessels that remain stationary for long periods of time. Yet, from a biosecurity perspective, high biofouling levels in niche areas (even though a small overall proportion of underwater surface area of a ship) are thought to pose significant invasion risks. For similar reasons, the transfer of biofouling communities on vessels that are slow-moving or that have had long residence times, even if rare events, is of considerable concern.

These gaps in current biofouling management practices are now the focus of guidelines and requirements, which are still taking shape around the world. Some programs are including (a) requirements for in-water hull inspections and consistently maintained reports (logs) on hull biofouling, and, (b) specific standards on permissible levels of biofouling for operations (California State Lands Commission 2011; Department of Agriculture, Fisheries and Forestry 2011; Ministry of Agriculture and Forestry 2010).

At the current time, there are no specific requirements to manage or report biofouling associated with commercial vessels operating in Micronesia, beyond those discussed in Section 2.3.1.1 (however, regulations should be forthcoming for FSM and RMI, upon approval of their biosecurity bills). While there is considerable literature on biofouling on vessels operating throughout the world (as above), relatively little information applies to Micronesia specifically. However, Section 2.3.3 provides new data on biofouling surveys conducted during this project.

2.3.2.2 Military Vessels

All U.S. Navy vessels operating in Micronesia and elsewhere in the world are expected to have regular in-water inspections for extent and type of biofouling coverage, as specified in the NSTM 2006 and discussed previously (see Section 2.3.1.2). According to U.S. Navy personnel, most of the records (including data and photographs collected during inspections) are maintained by the U.S. Navy, and these can be especially useful for analysis of biofouling associated with these vessels (see Bendick et al. 2010; Schultz et al. 2011). Based on interviews with U.S. Navy personnel and literature searches, we were unable to identify such analysis to examine biosecurity issues associated with these vessels (see also Section 2.3.1.2).

We were not given access to these records and therefore were unable to assess either (a) the hull maintenance and cleaning schedules for U.S. Navy vessels arriving to the Micronesia region or Hawai'i or (b) the extent and diversity of biofouling organisms associated with such Navy vessels. There are at least three steps that would be needed to examine these records. First, we would need to know the name (or other unique identifier) of Navy vessels arriving to or visiting Micronesia or Hawai'i, in order to examine the associated inspections records. This request was denied, due to concerns about national security. Second, we would need to access the records themselves. While this can clearly be done (see Bendick et al. 2010), it is also our understanding that many records are not readily available or in

electronic format, requiring considerable effort (the third step).

In-water cleaning occurs in Apra Harbor, as outlined in NSTM 081 protocols, according to U.S. Navy personnel. A commercial dry-dock on Guam services MSC vessels, and U.S. Navy vessels are also sometimes dry-docked here for emergency repairs. Further details on the frequency or particular methods surrounding each aspect above were not available to us.

While existing protocols and schedules for hull biofouling management clearly apply to the surface combatants, there is some uncertainty about their application to supply vessels, barges, floating dry-docks, lighters, small craft or auxiliaries associated with U.S. Navy activities. We have discussed earlier this issue with respect to those MSC vessels that are privately owned and under contract. Other vessels with limited (local) operating distances also may not receive the same attention as surface combatants, with respect to biofouling inspection and maintenance, however we have no data on this to evaluate implementation or performance of existing protocols.

2.3.3 Survey of Biofouling on Commercial and MSC Vessels in Guam

We surveyed six MSC vessels and eight commercial vessels that were docked in Apra Harbor in summer and fall 2010. For each vessel, information concerning the hull maintenance history and voyage characteristics was collected using a questionnaire that was completed by a member of the crew. Questions included date of last dry-dock or delivery of the vessel, regular service route/destinations visited in the previous year, average speed of the vessel, and average in-port duration.

In-water surveys were conducted using SCUBA to access biofouling communities on hull surfaces and niche areas on one side (non-dock side) of each vessel. The following areas were targeted during the surveys: bulbous bow, bow thruster, bow hull surface areas, bilge keel, mid-ship hull surface areas, rudder, propeller, propeller-strut, and stern hull surface areas. In-water survey duration was approximately 60 minutes. This time was divided between the target areas described and other niche areas were sampled as encountered during the survey

Digital photographs were taken of all fouling communities encountered to assess the extent of fouling. Where fouling was present, the total abundance of attached macro-invertebrates was estimated to the nearest order of magnitude for each of the targeted survey areas; as only a portion of each vessel was surveyed, this represented a minimum estimate of abundance and also provided a standard measure for comparison across vessels. In addition, samples of invertebrates were collected and examined to assess the diversity (composition) of the biofouling community. Samples of the attached invertebrates were dislodged carefully and collected in zipped bags. A sample of each organism that appeared morphologically distinct was collected to provide an estimate of species diversity (richness) on the vessel. On return to the lab, each sample was inspected under a microscope and described using taxonomic characteristics (dead specimens were not included in this assessment).

As a coarse measure, morpho-taxa (or organisms that appeared to be different species based on morphology) were used as a conservative estimate of the total number of species.

Many species are cryptic and difficult to differentiate without in-depth (morphological and molecular) analyses and taxonomic expertise, which exceeded the scope of the current project. Furthermore, the analysis focused only on large (>1mm) invertebrates and did not include smaller organisms and algae that were present. Thus, pragmatically, morpho-taxa were used to provide a quick, first assessment for our analysis and data presentation here. Although algae are an important component for biofouling communities, these were excluded from this initial assessment, because none of the biologists involved had sufficient taxonomic expertise for this group.

2.3.3.1 Vessel Histories.

All vessels sampled had been either delivered new or dry-docked within the past four years (Table 2.1). Three of the MSC vessels were nearing the end of this dry-docking period, which suggests that they could go into dry-dock in the very near future; according to interviews, most were planning to maximize the five-year window before going into dry-dock again. Five of the commercial vessels sampled were also towards the end of this expected service window, however these vessels were all new builds (generally subsequent antifouling paint applications deteriorate more quickly) and were recently inspected by underwater survey.

Based on interviews, a stark contrast existed between MSC and commercial vessels in terms of both in-port duration and average speed (Table 2.1). Commercial vessels spent minimum time in port (less than one day) and moved quickly between locations (14-21 knots, with the exception of Comm 8 which is a locally-operating vessel on a slower schedule). However, MSC vessels spent up to and sometimes over four weeks in a single location, and did not move quickly between locations (<14 knots). Several of the MSC vessels spent >60% of their time in one location (Guam for these vessels) and tended to stay within the central Pacific region, with occasional trips further afield (Table 2.1). Commercial vessels operated on a regular route, either between the East-Central and West-Pacific (Comm 1-4), Central and West-Pacific (Comm 5-7) or in a very small area around Guam (Comm 8).

Table 2.1 Vessel characteristics from questionnaires of vessel crew. Characters considered indicative of potential for heavy fouling are highlighted in grey.

Vessel	Dry-dock (DD)/ New build (NB)	Duration in Port	Average Speed (knots)	MSC Program/ typical round-trip duration	Destinations in past 12 months/ regular route for commercial vessels
MSC 1	DD 2007	2 wks	8-14	NFAF	Pacific: SW-NW-Central
MSC 2	DD 2007	65%	14	NFAF	North Pacific: Central-West, 65% time in Guam
MSC 3*	DD 2008	3-4 wks	10-14	NFAF	Pacific: SW-NW-Central, 70% time stationary
MSC 4	DD 2010	3-4 wks	12-14	PP	Gulf of Mexico-Panama-California-Central Pacific [normally stay within 7 th Fleet]
MSC 5	DD 2007	1 wk	13	NFAF	Pacific: SW-NW-Central
MSC 6	DD 2009	3-4 wks	12	PP	Gulf of Mexico-Panama-California-Central Pacific [normally stay within 7 th Fleet]
Comm 1	NB 2007	6-12 hrs	21	35 days	North Pacific: East-Central-West
Comm 2	NB 2007	6-12 hrs	21	35 days	North Pacific: East-Central-West
Comm 3	NB 2007	6-12 hrs	21	35 days	North Pacific: East-Central-West
Comm 4	NB 2007	6-12 hrs	21	35 days	North Pacific: East-Central-West
Comm 5	NB 2007	6-12 hrs	14	21 days	North Pacific: Central-West
Comm 6	DD 2008	6-12 hrs	15	21 days	North Pacific: Central-West
Comm 7	DD 2009	6-12 hrs	14	28 days	North Pacific: Central-West
Comm 8	DD 2008	2-3 days	unknown	7 days	Local vessel, stays within 150 miles of Guam

NFAF- Naval Fleet Auxiliary Force

PP- Prepositioning Program

7th Fleet encompasses the Asia-Pacific region from the Kuril Islands to the north to Antarctica to the south, from the International Date Line to the 68th meridian.

*-MSC 3 was scheduled to be taken out of service in December 2010 and thus may not have been maintained to 'normal' standards.

2.3.3.2 Extent of biofouling.

Biofouling was detected on all 14 vessels sampled in Guam. Twelve of the vessels had greater than 10,000 organisms across various submerged locations, indicating dense aggregations of biofouling (Figures 2.1 and 2.2). The remaining two vessels had abundances of invertebrates on the order of 1,000s of organisms (Comm 1 and Comm 2). There was a distinction between MSC ships and commercial ships: MSC vessels tended to have biofouling that was at least one order of magnitude higher than commercial vessels.

Figure 2.1. Biofouling organisms on vessels arriving to Guam. Left: High percent cover of fouling organisms below the rudder. Right: Sessile species such as sponges, tunicates and hydroids, growing on a grate provide habitat for mobile species.

For hull surfaces, biofouling tended to be most abundant at stern areas compared to bow and mid-ship areas among all vessels, and hull biofouling was far more extensive on MSC ships compared to commercial vessels (Figure 2.2). The higher biofouling at stern areas of most ships is a general feature of vessel biofouling because stern hull surfaces tend to have greater protection from laminar water movement which allows greater retention of biofouling organisms. The higher levels of fouling on MSC vessels was probably due (at least in part) to operational differences among the two ship types, especially port durations (time spent stationary) and average speeds, which are expected to increase biofouling accumulation (see Section 2.3.2 for discussion).

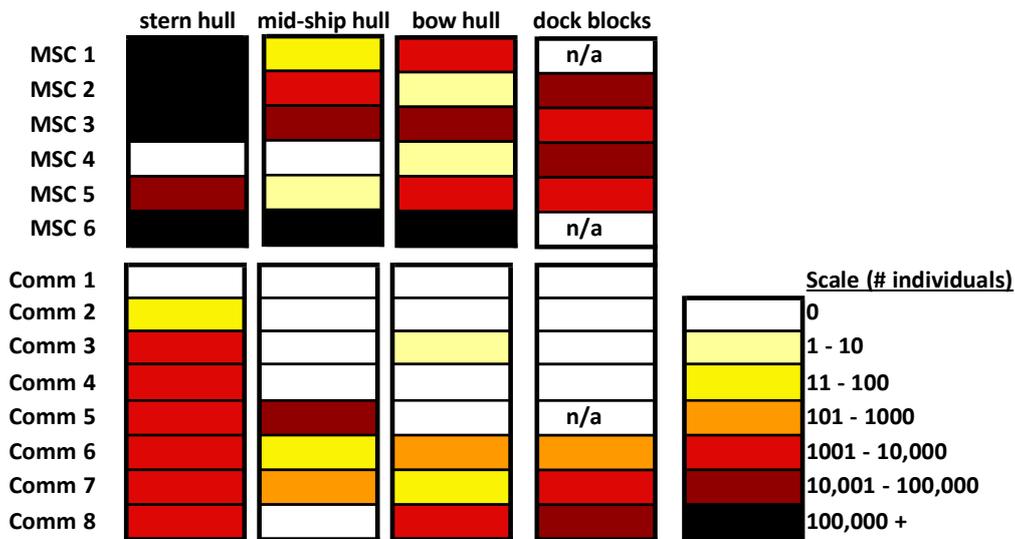

Figure 2.2. Biofouling extent on hull surfaces of 14 ships sampled in Guam. The scale of biofouling extent is color-coded to correspond with orders-of-magnitude abundances of macro-invertebrates detected for the portion of each vessel surveyed (see text). Biofouling was generally higher on stern surfaces than bow surfaces across all vessels and higher on MSC vessels (darker boxes) compared to commercial vessels.

The vessel with most fouling on hull surfaces (MSC 6) had hundreds of thousands of invertebrates at stern, midship and bow areas. This was a preposition ship, with long port residence times, but it was transient, moving among regions as distant as the Gulf of Mexico, California, and Micronesia (Table 2.1).

Four commercial vessels (Comm 1, 2, 3, and 4) had little or no biofouling on bow, midship and dock block surfaces. The major operational difference between these commercial vessels and others was that their voyage routes include trans-oceanic trips to the U.S. Pacific coast. All other commercial vessels had voyage routes within the Central- NW Pacific region.

Biofouling abundance on non-hull surfaces (vessel appendages and grates) was highly variable (Figure 2.3). The pattern of higher biofouling on MSC compared to commercial ships was most notable on propeller surfaces; most commercial vessels had zero or <10 organisms while all military ships had an order-of-magnitude higher abundance. One MSC vessel had more than 10,000 organisms on its propeller, which is unusually high for an in-service vessel. By contrast, bow thruster areas had similar high levels of fouling for both types of ship (commercial and military). Moreover, bow thrusters had the highest extent of fouling compared to other niche areas, and a majority of ships had tens to hundreds of thousands of invertebrates on thruster grates and within the thruster tube. Rudders also tended to have substantial numbers of fouling invertebrates associated with their surfaces, edges and articulations. The abundance of organisms detected on rudders was of a similar

range between commercial and military vessels.

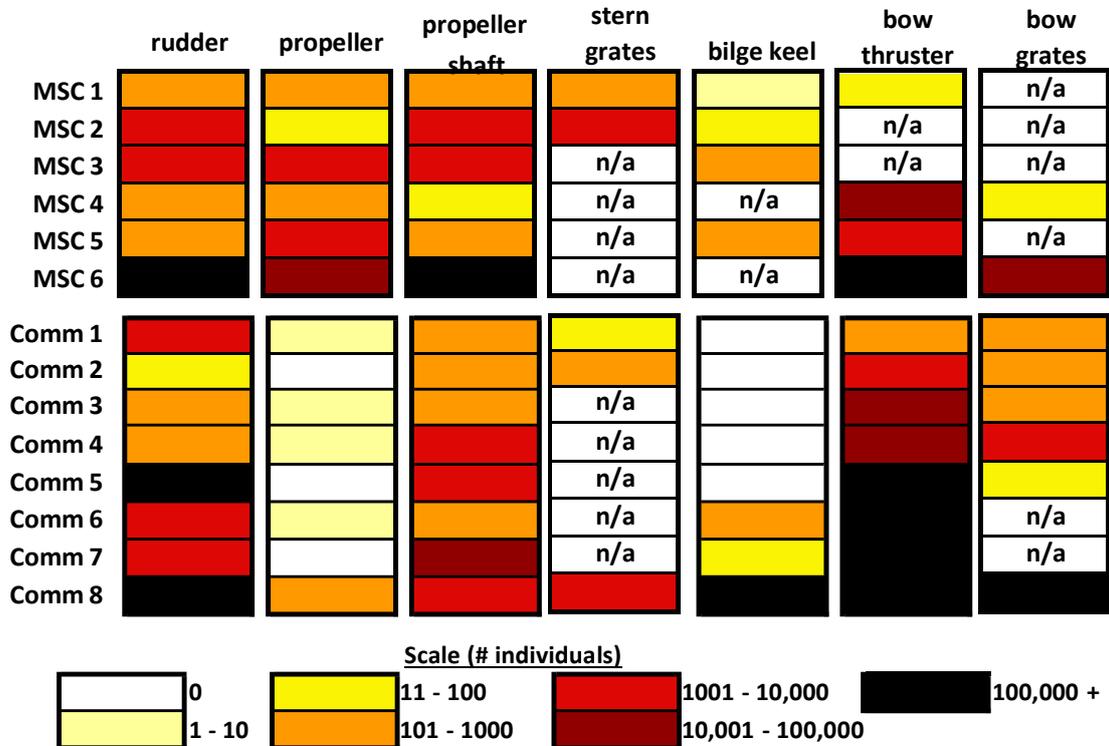

Figure 2.3. Biofouling extent on hull appendages or niche areas of 14 ships sampled in Guam. The scale of biofouling extent is the same as Figure 2.2, with white and black corresponding to zero and hundreds of thousands of organisms, respectively. Ships are listed down the side while niche area locations are listed across the top.

2.3.3.3 Biofouling composition.

The diversity of fouling organisms on both commercial and MSC vessels was high compared to previous studies (e.g., Davidson et al. 2009; Figure 2.4). Bryozoans, bivalves, tunicates and tubeworms were the most diverse groups on MSC vessels, while barnacles and bivalves were richest on commercial vessels. Various forms of algae were also encountered on all vessels, but the taxonomic diversities were not analyzed (as noted above).

The average number of morpho-taxa of invertebrates collected from MSC vessels (30) was slightly higher than for commercial vessels (27). It is noteworthy that this estimated species number was higher on both vessel types than that found in previous studies, using similar methods, on the west coast of North America (Davidson et al. 2009). MSC vessels 3, 4 and 6 each had above-average taxonomic diversities: these were the vessels which spend the most time in-port (3-4 weeks at a time). MSC vessels 4 and 6 were also both in the Prepositioning Program and generally stayed within a closer range of Guam than vessels in the Naval Fleet Auxiliary Force. Of the commercial vessels, vessels 5 and 8 had the highest numbers of morpho-taxa, which can be explained by the long duration since dry-docking for vessel 5 and narrow operating range and longer in-port duration for vessel 8.

The results also show that there was a wide variability in species diversity even when vessel histories were very similar. Commercial vessels 1-4 were operated by the same company and had very similar histories, yet the number of sessile morpho-taxa varied between 17 and 28 for these four vessels. Although not included in estimates of biofouling cover (Figures 2.2 and 2.3), which focused on sessile and sedentary invertebrates, a number of mobile species were found on the vessels, including crustaceans and mollusks (Figure 2.4), despite most of them being sampled soon after the vessel docked.

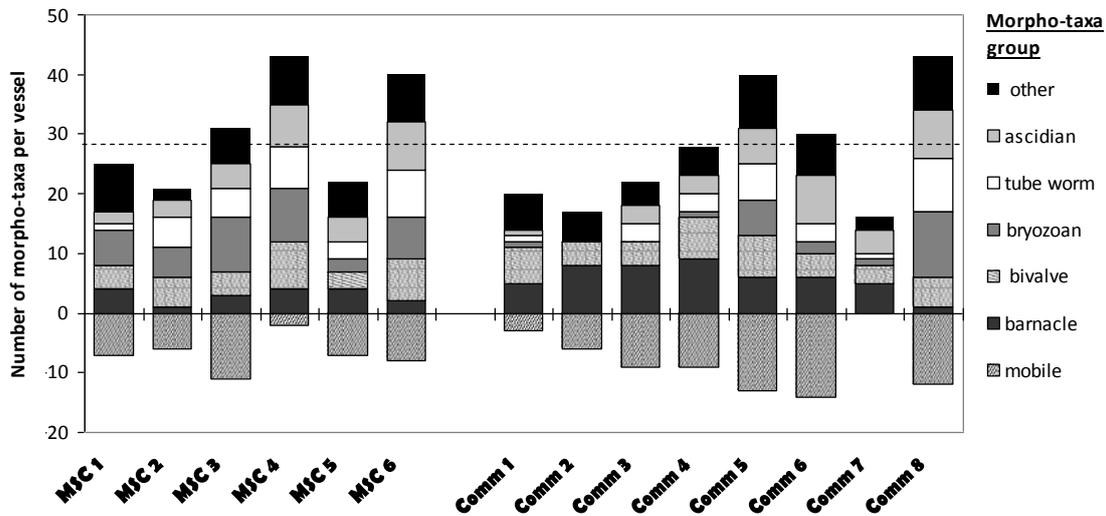

Figure 2.4. Diversity of morpho-taxa found on all surfaces of each vessel sampled during 2010. Vessels on the left are MSC and vessels on the right in the shaded portion are commercial vessels. Sessile species are accumulated above the x-axis (with the dashed line showing the mean value of 28.42 across all vessels) with mobile species shown separately below the x-axis.

2.3.3.4 Inferences for Hull-Mediated Transfers of Organisms to Guam, Hawai'i, and Micronesia.

It is evident that substantial numbers of organisms are currently associated with MSC and commercial vessels that arrive to Guam. Despite a relatively small sample size of vessels, the 2010 surveys indicated that both abundance and diversity (species number) on these Guam arrivals was often high relative to similar analyses of commercial vessels in other regions (Coutts and Taylor 2004; Davidson et al. 2009; Sylvester and MacIsaac 2009). It is also important to emphasize that these were minimum estimates for abundance and diversity, because (a) only a portion of each vessel was surveyed, (b) the analysis focused only on macro-invertebrates, excluding algae and other smaller organisms that were present, and (c) the use of morpho-taxa can only detect species with conspicuously different morphological characteristics. Further study of existing samples would certainly reveal higher taxonomic diversity (species number). Nonetheless, the current coarse-grained analysis provides a clear indication that transport of biofouling organisms to and from Guam is relatively high for these vessels on a per-capita basis.

While multiple factors may contribute to the accumulation of biofouling communities on vessels, vessel speed and port residence time probably explain (at least in part) why such dense and diverse communities occurred on many Guam arrivals (see Section 2.3.2 for discussion of mechanisms). Vessel speeds were slower for these arrivals, and port residence times longer, compared to many biofouling studies on vessels in other regions (e.g. Gollasch 2002; Davidson et al. 2009; Sylvester et al. 2011). In addition, it is also the case that most studies of vessel biofouling have occurred in temperate latitudes (Pyefinch 1950; Skerman 1960; Gollasch 2002; Sylvester et al. 2011; Godwin 2004 is an exception), and it is possible that the rates of biofouling accumulation or survival (persistence) are greater for either tropical systems or the specific routes represented. Perhaps important in this regard is that many of the surveyed vessels operate within tropical waters, and sometimes within a narrow range of ports, providing stable environmental conditions (i.e., temperatures and salinities) compared to some routes. The available data are presently insufficient to test the relative contribution of these (and other mechanisms) to the observed patterns.

While the identity and biogeography of the organisms has not yet been determined in the current analysis, it is unlikely that all fouling species encountered are native to Guam. Instead, simply based on voyage histories, the assemblages may include species that are non-native to Guam and other regions of Micronesia, and some of these species may not yet be present (established as self-sustaining populations or invasions) in the region. Further evaluation is required for these particular ship-biofouling samples, but also for the background communities in ports and harbors of Micronesia (see Chapter 6), in order to obtain robust estimates of non-native species richness on vessels and the proportion of novel species that have not yet colonized Guam or Micronesia.

2.4 Conclusions

2.4.1 Ballast Water

While ballast water management practices are advancing on a global scale to limit non-native species transfers by this vector, there are some conspicuous gaps for Micronesia and Hawai'i, including the following:

- On a broad scale, management requirements do not exist at the present time for ballast water discharged in many ports and coastal areas throughout Micronesia.
- While this will change if and when the IMO international regulations eventually come into force, most countries in Micronesia do not currently have a program or specific plan to assess compliance with these requirements.
- While the U.S. Navy has established requirements for ballast water exchange, there is uncertainty about whether these requirements apply to vessels operated under MSC; if not, and these are considered commercial vessels, a large fraction of MSC vessels that arrive to Guam appear currently to be out of compliance with USCG federal regulations.
- It is not evident whether any policies or requirements exist for DoD vessels operated by other branches of the military. Although these vessels fall under the

UNDS process, no ballast water guidelines or discharge standards have been issued under this program to date.

The U.S. Navy was quick to adopt requirements for ballast water management, which were contemporary with those implemented for commercial vessels, but there are some substantive differences between these programs. First, U.S. Navy vessels are allowed to conduct ballast water exchange much nearer to shore (3-12 nmi versus 200 nmi), which increases the likelihood of non-native coastal species transfers. Second, we are unaware of any program by the U.S. Navy to evaluate compliance with this requirement in Guam, Hawai'i, or elsewhere in the world. Third, it appears that ballast management of the commercial fleet is poised now to transition from ballast water exchange to more stringent, concentration-based discharge standards, but we are unaware of a similar transition plan for U.S. Navy vessels.

We recognize that ballast discharge volumes in Guam and Hawai'i by U.S. Navy vessels are likely to be relatively small, whether considering cumulative or per-capita volumes, but the current treatment requirements may be less protective than those for commercial vessels. As discussed above, treatment efficacy will depend on location of ballast management and other factors. Importantly, the data required for this assessment were not available to us, and it appears such an assessment has not been made.

2.4.2 Biofouling

The available data suggest that per-capita transport of biofouling organisms to Guam by commercial and MSC vessels is relatively high, creating significant opportunities to transfer species. While the current analysis has focused on arrivals to Guam, it is critical to recognize that all of these vessels have visited other regions. Thus, they may simultaneously be a source of new introductions to Guam and other ports of call, including those in Hawai'i and elsewhere in Micronesia. Moreover, native and non-native species present in Guam (a regional hub) can colonize vessels and be transferred sequentially to other ports, in a hub-and-spoke model of dispersal (see Carlton 1995). Chapter 3 further illustrates the degree of connectivity between Guam and other ports in Micronesia and Hawai'i.

It is also apparent that the management practices outlined in NSTM 081 for hull husbandry (see Section 2.3.1) are not applied to all MSC vessels, given the extent of biofouling observed on several vessels. This is perhaps not unexpected for vessels that are relatively stationary (such as preposition ships) or slow-moving supply ships, where the penalty in time and fuel are not major considerations for additional maintenance.

Obviously, the current data cannot be extrapolated to other types of U.S. Navy vessels (e.g., surface combatants), where the frequency of operations and speed differ substantially. Although the Navy conducts routine in-water surveys, as discussed previously, these data were not available for us to evaluate the extent and composition of biofouling for vessels visiting Guam. Importantly, the surveys are used primarily to sustain vessel performance, and we are unaware of an analysis of these data by the U.S. Navy to assess the opportunity for non-native species transfers to Guam or elsewhere.

Although the window of opportunity is open for hull-mediated transfers of non-native species by MSC and commercial vessels that visit Guam, it should be noted that these vessels may not be out of compliance with current regulations. It is presently unclear whether those outlined in NSTM 081 are intended to apply to all MSC vessels (i.e., privately owned or operated vessels under contract to the U.S. Navy), and husbandry requirements for commercial vessels are still largely undeveloped with respect to biosecurity (see Section 2.3.1). In addition, we are unaware of any requirements for husbandry of vessels and equipment used by DoD contractors, or for movement of decommissioned vessels by DoD; barges may be of particular concern in this regard for Micronesia, because of (a) their long residency periods and slow speeds, as discussed previously, and (b) a likely increase in barge traffic during the Buildup on Guam (see Chapter 3). Thus, the lack of a well-defined, consistent, and effective approach to hull husbandry (to limit species transfers) represents a clear gap in biosecurity, given the importance and dominant role of hull biofouling as a vector for introductions of marine species throughout the world (Chapter 1).

Chapter 3: Current and Predicted Vessel Flux and Related Activities

By Gregory M. Ruiz, Chela J. Zabin, and Mark Minton

While Chapter 2 reviewed current management practices for vessels operating in the region of interest for this report (Micronesia and Hawai'i), Chapter 3 summarizes what is known about the magnitude of vessel movements (flux) and vessel-related activities for these areas. The predominant focus is on military and commercial vessels, examining (a) the number of arrivals and (b) the direct linkage to other geographic regions. This approach provides one measure of connectivity among port systems, and the potential for movement of organisms associated with vessels. In addition to consideration of military and commercial vessels, this chapter also summarizes information for other types of vessels and vessel-related activities with relevance to species introductions.

Some of the same data presented here are used for a more detailed analysis and risk assessment for biofouling organisms, which combines vessel movement and non-native species information, in Chapter 5. The current chapter is intended to provide a broad overview of vessel movement patterns, describing both sources and constraints of available information. In this sense, Chapter 3 provides important background information and sets the stage for the subsequent analyses.

While this report attempts to consider both past activities and possible future shifts across vessel-related vectors, associated with the Buildup (construction) phase and post-Buildup phase in Guam, it is important to recognize that the latter are extrapolations as provided in previous reports. For example, projections of increased vessel traffic (arrivals) exist for Guam, both during and after Buildup. While such an increase appears inevitable for both military and commercial traffic, there is some uncertainty about the rate and magnitude of increase. Moreover, there is likely to be high uncertainty about geographic source(s) of vessel traffic for both military and commercial vessels, which will respond to dynamic strategic and financial interests respectively.

Finally, while a distinction is made throughout this chapter between military and commercial activities, it is also recognized that the magnitude of commercial activities (during and after Buildup on Guam) will be affected by the increased military activity and associated personnel. This indirect effect or feedback is inevitable, given the significant size of the military presence in Guam.

3.1 U.S. Military Vessels

There are many different types of U.S. military vessels that currently visit Guam. The following vessel types are home ported or regularly visit the DoD port in Inner Apra Harbor (Department of Defense 2009, 2010):

<u>U.S. Navy (COMNAVMARIANAS)</u>	<u>USCG</u>
SSNs/Sub Tender	225' Buoy Tender (responsible for Guam,
Logistics Prepositioned Ships	most of the Marianas, and Kwajalein)
MSC Combat Stores Ships	110' Patrol Boat
Maritime Prepositioning Ships	25' Response Boat
MSC Ammo Ships	
H60s	

Several additional U.S. Navy vessels will be home ported in Guam following the Buildup. These include: High Speed Vessels (HSVs) and a Littoral Combat Ship (LCS).

In addition to the home-ported vessels, the DoD port in Guam serves 12-14 ammunitions ships in the region, with 275 total days per year of use at its Kilo Wharf. Kilo Wharf appears to be near capacity, as Fleet and MSC vessels have been turned away due to lack of space at the wharf (Department of Defense 2009; see Volume 2).

Military vessel arrivals to Guam occur generally at the DoD port, or Naval Base Guam, which is distinct from the commercial Port of Guam. Although adjacent to each other in Apra Harbor, the military and commercial ports function largely as separate entities from the operations and record-keeping perspective.

The U.S. Navy reported 143 ship arrivals into the DoD port in 2008; 268 were reported in 2009, and 271 in the first 10 months of 2010 (Table 3.1). For 2009, the only year for which we were able to obtain data, the DoD port in Okinawa reported 175 visits of MSC traffic, and 85 days of warship traffic.

Additional vessel traffic data were provided for MSC vessels (and are presented in Section 3.3), but for the all other vessel types we have no further information on (a) the frequency with which vessels have visited Naval Base Guam, (b) their residence time in port, or (c) their specific transit histories (routes and ports of call). Although such data exist for U.S. Navy surface combatants and other vessels, these data were considered sensitive information and were not available to us.

The DoD provided lists of typical last ports of call for some of the vessel types arriving to Guam (Table 3.2). It is clear that military vessels arriving to Guam visit many ports throughout Asia and the Pacific Islands region as well as some ports in the Middle East (the latter not shown in Table 3.2). However, it is important to note that this is not a full list of vessel histories and ports visited; also excluded are any data on the frequency of port visits. Without such comprehensive data, it was not possible to evaluate the relative importance (weighting) of different ports, or the degree of connectivity to Guam for the U.S. Navy ships. Such data were only available for vessels operated under MSC, allowing for an analysis of a portion of the military ship traffic, the military supply ships.

Table 3.1 Number of ship arrivals by type reported by Naval Base Guam for Inner Apra Harbor.

Ship type	2008	2009	2010 (10 months)
CVN (aircraft carrier)	3	0	0
SSGN (nuclear-powered cruise missile submarine)	0	16	7
SSN (nuclear-powered fast attack submarine)	12	51	41
AS (submarine tender)	1	4	0
CG (guided missile cruiser)	5	3	1
DDG (guided missile destroyer)	14	23	12
FFG (guided missile frigate)	0	3	7
LCC (amphibious command ship)	0	1	7
Amphibious craft	3	5	4
Foreign	11	9	0
Research	0	7	8
NOAA	0	1	5
MSC	40	80	87
Commercial tankers	0	8	13
USCG	54	57	79
Totals	143	268	271

Military ship traffic and personnel are expected to increase as a result of the Buildup, which will also affect commercial traffic (see later sections). Based on recent interviews, the U.S. Navy projects only a modest increase in military ship traffic in Guam post- Buildup. The Navy estimates that approximately (a) 600 vessel movements per year (which includes arrivals, departures, and berth changes) are expected post-Buildup and (b) 65% of these vessel movements are expected to be transient vessels, for which Naval Base Guam is not the home port.

The U.S. Navy is proposing changes to Apra Harbor which would provide berthing capacity for an aircraft carrier. The carrier is expected to visit Guam three to four times a year, staying approximately three weeks each visit, up to a maximum of 63 cumulative days each year (Department of Defense 2010). Munitions operations that involve vessels are also projected to increase by 40 visit days to 315 per year (Department of Defense 2010).

Table 3.2 Typical last ports of call for vessels arriving to Naval Base Guam by vessel type. These are examples of ports visited but are not comprehensive, and vessels do visit additional ports.

Vessel type	Last ports of call
ACT	Philippines, Korea
ACTL (Assault troop carrier)	Kwajalein
AGOR (Oceanographic research)	Taiwan
AOR (Replenishment)	Philippines, Korea, Wake Island
ARS (salvage ship)	Saipan
AS (sub tender)	Saipan, Philippines, Hong Kong
CG (guided missile cruiser)	Japan, Philippines, Hawai'i, Korea, Malaysia
CV/CVN (aircraft carrier)	Japan, Philippines, Korea
DD/DDG (destroyers)	Australia, Japan, Philippines, Hawai'i, Korea, Thailand, Singapore
FFG (guided missile frigate)	Australia, Japan, Philippines, Hawai'i, Singapore, Palau
SSN (nuclear-powered fast attack submarine)	Saipan, Japan, Philippines

Plans for the Buildup include (a) relocation of Marine Corps assets and troops from Okinawa and (b) training exercises on the island of Tinian that involve the deployment of amphibious vehicles from Guam. Aside from what is outlined generally in the DEIS (Department of Defense 2009), we were not able to determine which, if any, specific in-water assets and vessels will be relocated from Okinawa.

With respect to training exercises on Tinian, amphibious task force visits, typically three weeks in duration, are expected to increase from two to four a year. The composition of the amphibious fleet varies with the mission, but may be up to 15 total vessels, typically including three ships carrying personnel, equipment, and the amphibious vehicles, and an escort of four surface combatant ships. Anti-submarine and strike force surface and subsurface vessels may also be included. In addition to these transient ships, the expanded harbor would house 12 AAVs (amphibious assault vehicles), two rigid hull inflatable boats and eight combat rubber raiding craft.

Of the transient ships associated with the amphibious task force, according to the FEIS (Department of Defense 2010), this fleet might travel to Guam from either Okinawa or California before deployment to Tinian, or travel directly to Tinian. More detailed information is not available for the future traffic patterns associated with the additional aircraft carrier, amphibious group, or other vessels associated with Naval Base Guam.

Aside from routine supply and training operations based in Guam and Tinian, such forecasts are undoubtedly difficult (if not impossible), given the shifting background of geopolitical and strategic interests.

3.2 Commercial Cargo Vessels

Guam and Hawai'i are major shipping hubs for commercial vessel traffic in Micronesia (Figure 3.1). Most commercial cargo entering Micronesia from the east or west goes to Guam (see also Section 3.3). Commercial cargo comes to Guam via three major trade routes: U.S. West Coast, Asia, and other foreign ports, and via transshipments within Micronesia.

Most trade routes from the U.S. Mainland to Guam also include Hawai'i. As indicated in Figure 3.1, all regular U.S. West Coast shipping lines to Micronesia stop in Hawai'i before continuing to Guam and west to Asia, returning directly back to the U.S. Mainland. In addition to these major shipping lines, Hawai'i also receives some commercial vessel traffic directly from Micronesia and the surrounding region (Godwin and Eldredge 2001).

Although most commercial vessels arriving to the region come to Guam, movement of cargo by vessels also creates connectivity throughout Micronesia, making it possible for species that occur (or colonize) in Guam to be transferred to other locations. Commercial inter-regional shipping currently follows various routes, and examples include:

1. Guam, Ebeye (RMI), Kwajalein (RMI), Majuro (RMI), Kosrae, Pohnpei (FSM), Chuuk (FSM), Guam
2. Guam, Saipan (CNMI), Yap (FSM), Koror (Palau)
3. Guam, Chuuk, Pohnpei, Kosrae, Guam
4. Guam, Saipan, Rota/Tinian (CNMI)

Although the magnitude of intra-regional transport is not great for commercial vessels, it is highly regular, as indicated here for 2009-2010. Kosrae, Pohnpei and Chuuk received usually two visits a month from Matson vessels traveling on a circuit between FSM and Guam. Port times appear to be extremely short, just a few hours in each location. Kosrae is also connected to Guam via (a) Kyowa Lines, which arrived on about a one-month interval, with some overnight stays, and (b) a fuel tanker, which arrives on a two-month interval. Regular commercial ship traffic to Chuuk also comes from Asian ports: the state received Kyowa vessels, at a rate of about two per month, from the Far East, and a fuel tanker once a month from variable locations including Guam, Majuro, Singapore, and the Solomon Islands. Yap was less directly connected to Guam, with Matson vessels coming from Palau two times a month, and one to two visits per month from Kyowa Lines coming from Hong Kong and Japan. FSM states are further connected by a government run passenger and cargo vessel based in Pohnpei (four to five times per year to Kosrae from Pohnpei) and by federal patrol boats.

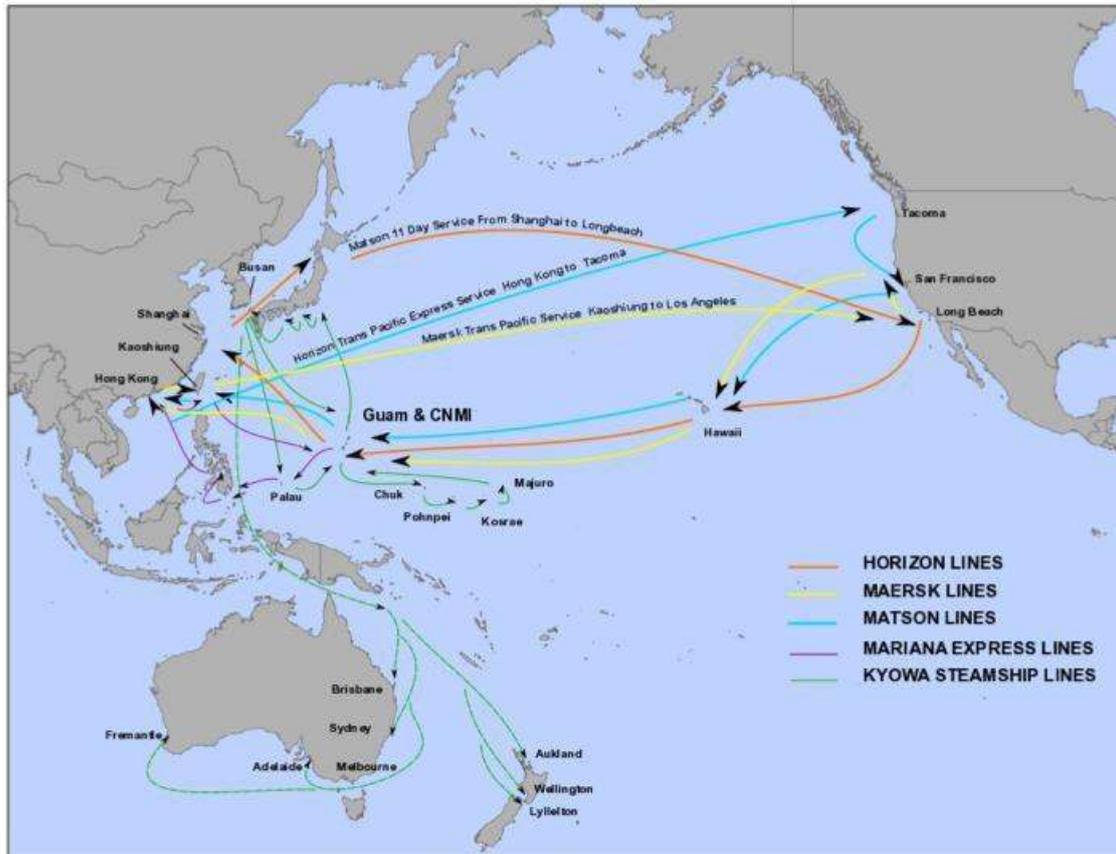

Figure 3.1. Recent commercial ship traffic routes in the region (from FEIS, Chapter 2, Figure 14.1-2; Department of Defense 2010). It is worth noting that not all jurisdictions nor ship routes appear in this image.

From a relative perspective, commercial traffic to most regions of Micronesia includes a strong linkage to Guam. For example, about 80% of the commercial ships arriving in Palau have stopped in Guam during 2009-2010. Palau also receives ships coming directly from Australia and various Asian ports, including oil tankers arriving once a month from Indonesia and the Philippines. A barge travels regularly between Palau and Yap, indicating a further level of intra-regional connectedness, independent of Guam.

The relative magnitude of commercial vessel traffic and connectivity is examined in greater detail in the next section (Section 3.3), based on past data, but future changes in traffic patterns are challenging to predict. In recent years, the number of commercial ships of all types calling at the Port of Guam has declined (PB International 2008). Commercial cargo ships (container ships and break-bulk/roll-on, roll-off (RoRo)/bulk) declined from 445 visits in FY 2003 to 353 in FY 2009 (Figure 3.2). However, the volume and nature of commercial ship traffic and perhaps routes will be affected by the Guam Buildup, and these effects are likely to differ during the Buildup and post-Buildup phases.

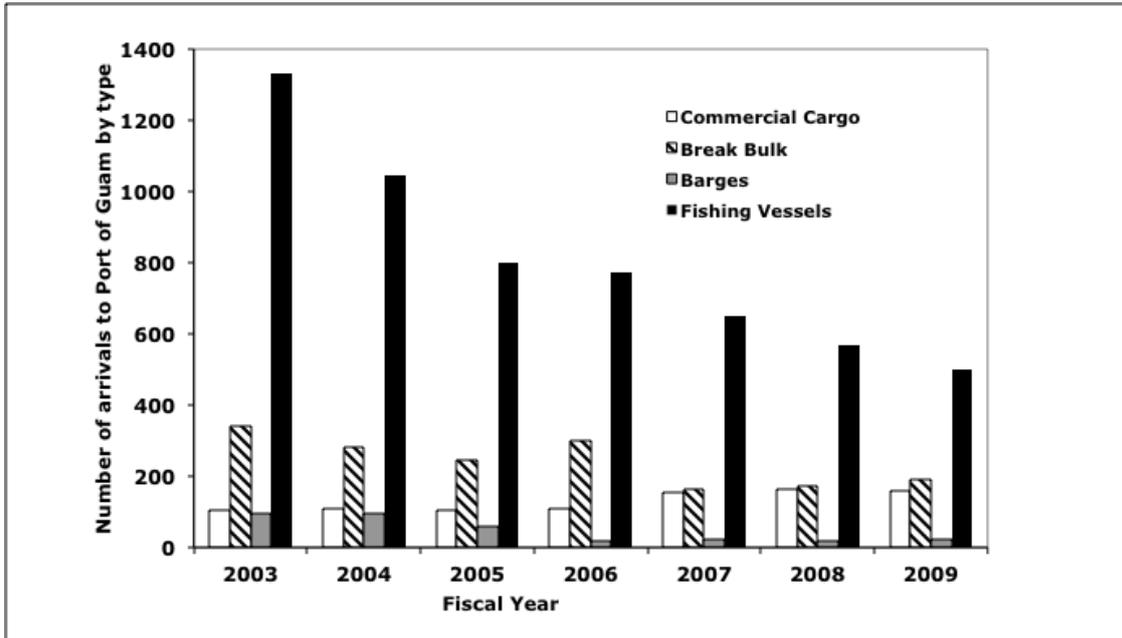

Figure 3.2. Number of commercial ship visits by vessel type to the Port of Guam per fiscal year. Data provided by the Port of Guam.

Guam cannot supply sufficient materials or labor for the construction phase. Thus, imports of construction materials, equipment, and supplies are expected to increase rapidly as the Buildup proceeds. Although information about the source of construction materials was not available, approximately 50% of the materials are expected to come from Asia (PB International 2008), but the sources are also likely to be strongly affected by market prices and other forces, which are dynamic. Thus, shipping imports associated with construction are likely to differ (both in geographic source and quantity) from historical patterns.

In addition to construction materials, the Buildup phase will require a significant and temporary increase in civilian workforce. Imports of household goods, food, and other commodities will increase to support those working on the Buildup. The source(s) of the temporary workforce will affect the geographic origin of shipped goods. While household goods may move along established shipping routes, demand for particular types of goods may shift according to geographic origins and customs of the workforce, having potential consequences for the trade of live organisms associated with food and pets (see Chapter 4 for further discussion).

Published projections for commercial shipping through 2018 predict a peak in the number of commercial container ship arrivals at 269 visits to Guam in 2015 (Table 3.3), during peak construction, slightly more than double the average number for 2003-2009 (see Department of Defense, 2009, Volume 4). An estimated 532 arrivals for break-bulk and RoRo ships are predicted during peak construction, slightly less than double the average annual number for 2003-2009. An additional 150 vessel trips by tugboats (tugs) and scows are anticipated over an eight to 18 month period during peak construction, compared to previous baseline traffic.

Across these vessel types, total additional commercial ship visits could increase by as much as 537 in a peak year, driven by the large pulse in construction materials and equipment delivered by break-bulk and RoRo vessels.

In the post-Buildup phase, following the pulse of construction and associated personnel, the number of commercial ship arrivals is expected to form a new baseline that is above recent (2009-2010) pre-Buildup levels. This overall increase in shipping reflects an increase in demand for goods, related to a projected increase in population size.

Table 3.3. Projected changes in number of commercial ship arrivals to the Port of Guam by vessel type. Data from FEIS (Department of Defense 2010; Volume 2, Tables 14.2-2 and 14.2-3-3).

Year	Container ships	Break-bulk/RoRo Ships	Total
2011	211	450	661
2012	244	532	776
2013	252	519	771
2014	258	507	765
2015	269	262	531
2016	255	199	454
2017	215	204	419
2018	207	206	413

From 2006-2009, barge traffic has been relatively infrequent at the Port of Guam, with 20 or fewer barges calling at the port each year (Figure 3.2). As recently as 2004, however, barge traffic had been significantly higher, with more than 100 such vessels arriving in port. Projections for barge traffic are not available in port documents, but it is reasonable to assume that the number of these vessels will increase along with other commercial ships during the Buildup.

Outside of Guam, with the possible exception of Saipan, it appears that other locations in Micronesia are not anticipating an increase in commercial shipping as a direct result of the Buildup, based on meetings and discussions with local management agency personnel. In Saipan, port officials have been approached by shipping concerns inquiring whether the port could accommodate vessels, should there be a back-up in unloading cargo to Guam during the Buildup. While it appears that Majuro hopes to increase its transshipping business in the near future, making better use of an underutilized container yard, we were unable to identify a specific plan for this activity in association with the Buildup.

3.3 Regional Comparison of Vessel Traffic and Geographic Connectivity

While previous documents on the Guam Buildup have focused some attention on the possible effects of shipping traffic to individual locations, and especially Guam (as above), it is of particular importance from a biosecurity perspective to also consider overall regional traffic patterns and connectivity. The first two sections (Sections 3.1 and 3.2) describe some of the linkages that exist among ports, in terms of vessels that move from one port to another, creating opportunities for species transfers to occur. Here, we expand upon this treatment and formally evaluate (a) the number of vessel arrivals to ports in Micronesia by vessel type, (b) the number of vessel visits to each country in Micronesia, (c) the last port of call (LPOC) and next port of call (NPOC) for vessels arriving to Micronesia, (d) the flux (number) of vessels that move among paired ports in Micronesia (and in both directions between Micronesia and Hawai'i) and (e) the reported ballast water discharge volumes for vessels arriving to Guam and also those moving from Guam to other regions of the U.S.

This regional analysis focuses primarily on commercial and MSC vessels, for which sufficient data could be obtained; the necessary data for similar analysis of other U.S. Navy ships (e.g., combatants) were not made available, as noted previously (see Chapter 1, Section 1.2). Throughout this section, only the direct links among ports and regions were evaluated, including LPOC and NPOC. Because vessels can often visit many ports with the potential to accumulate organisms, both on the hulls and in ballast tanks, indirect links among ports can also be important sources for invasions and are considered further in Chapter 5.

3.3.1 Sources of Data and Methods for Analyses

To characterize regional vessel traffic, data were collected and compared from multiple sources, as follows:

1. Data were obtained from Lloyds List Intelligence for commercial vessel arrivals to Micronesia over a 10-year period (1999-2009). For each unique vessel arriving to the region in Lloyds' database, an extensive synthesis of information concerning vessels and

maritime traffic on a global scale, we requested a complete history of all ports of call (globally) within this time period, including dates of arrival and departure.

2. Similar data were requested and obtained for MSC vessels arriving to Guam during the same time period.

3. For vessels that reported ballast water information to the National Ballast Information Clearinghouse (NBIC) (see Chapter 2 for description), we obtained (a) records of arrivals to Guam and CNMI, (b) records of ballast water discharge to Guam, and (c) records of ballast water discharge to U.S. ports for water aboard vessels that originated in Guam.

4. For vessels arriving to Guam and the Northern Marianas Islands, we obtained arrivals data reported to USCG National Vessel Movement Center (NVMC).

Each of these data sources provided individual vessel identification numbers, which could be used to identify unique vessels and subsequent vessel movements. These datasets were used to create a single synthetic dataset of unique vessel arrivals to Guam and other jurisdictions of Micronesia, and their voyage histories (ports of call) both before and after calling on Micronesia. This dataset provided the basis for analysis presented here for arrivals and direct linkages (LPOC and NPOC) of vessels calling on Micronesia; the scope of this analysis is expanded in Chapter 5 to also consider indirect linkages, based on these voyage histories over a multi-year time horizon.

Additional information was available for fishing vessels, which were excluded from this analysis. In particular, the Lloyds dataset contained some data on fishing vessels. This was combined with data from multiple ports throughout Micronesia, to estimate flux (number of arrivals) for fishing vessels that is presented below in Section 3.5. In many cases, LPOC and NPOC data were not available for fishing vessels, limiting the extent of analysis to flux measures (i.e., arrivals to a port) and preventing a broader consideration of geographic linkages such as the one presented for commercial and MSC vessels.

3.3.2 Unique Vessels Visiting Micronesia

Based on a synthesis of available datasets, 461 unique commercial vessels and 123 unique MSC vessels were identified with a record of arrival to Micronesia during the 11- year time period (Figure 3.3). As noted previously, the U.S. Navy would not provide unique vessel identifications (or voyage histories) for vessels other than MSC due to security restrictions, so it is not possible for us to provide a comparable estimate for the number of unique surface combatants or other U.S. military vessels visiting Micronesia.

Figure 3.3 also indicates the number of unique vessels found in each of the four respective datasets, which were compared to create a synthetic dataset for further analyses. As illustrated for commercial vessels (top panel), no single dataset had a comprehensive record of arrivals, so a combination of the four datasets provided a more complete record than any individual dataset. In contrast, the MSC dataset is thought to provide nearly a complete record of MSC vessel arrivals to Micronesia, and the other sources listed in Section 3.3.1 were used to fill in some gaps in voyage histories for these vessels.

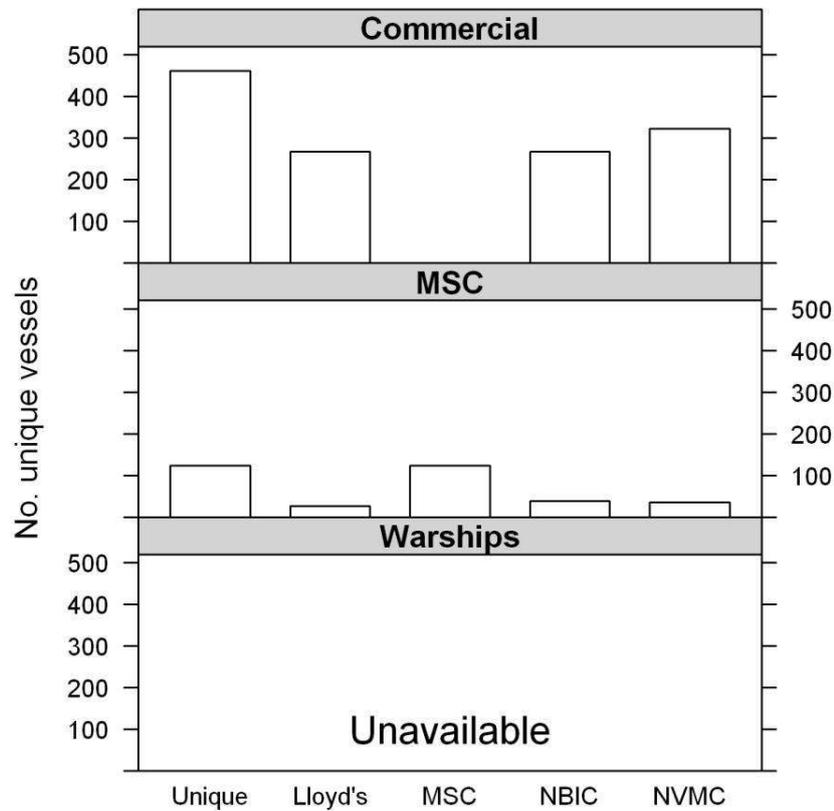

Figure 3.3. Number of unique vessels reported to have visited Micronesia from 1999-2009, according to data source. On the x-axis, “Unique” indicates the total number of unique vessels, based on synthesis and comparison across data sources (Lloyds, MSC, NBIC, NVMC; see text). Also shown for each data source is the number of unique vessels reported. Comparable data were not provided by DoD for warships (Navy vessels other than MSC).

We emphasize that neither synthetic dataset for commercial or MSC vessels is likely to be comprehensive, in terms of unique vessels, arrivals, or voyage histories. There is no clear way to verify or assess the percentage of all vessels included. Moreover, it is evident that vessel arrivals were missing from each dataset, suggesting the synthetic datasets are also likely to include omissions. For this reason, the information presented here and throughout should be considered a minimum estimate of vessel arrivals and connectivity among ports.

3.3.3 Vessel Flux for the Micronesian Region

The number of unique vessels is a useful measure to consider from a management and policy perspective, especially considering any possible future efforts to implement management actions or outreach, but the vessel arrival events are the operative measures from an invasion perspective. Each arrival event presents a potential opportunity for species transfer, and each arrival has a unique set of environmental and biological conditions that affect whether species can survive and spread. Even the same individual vessel arriving at different points in time will have a unique history of recent port visits and voyage conditions, husbandry or management conditions, and therefore a unique set of potential associated biota.

Figure 3.4 shows the mean number of arrivals per year to ports in Micronesia for each of three vessel types, based on available data (see Section 3.3.1). Commercial vessels accounted for 70% of reported arrivals to Micronesia, whereas the remaining 30% were attributed to MSC vessels (20%) and additional U.S. Navy and other military vessels (10%). This estimate includes each arrival to a port in Micronesia, regardless of LPOC; intra-regional flux (or traffic among ports within Micronesia) is addressed separately below (see Section 3.3.5).

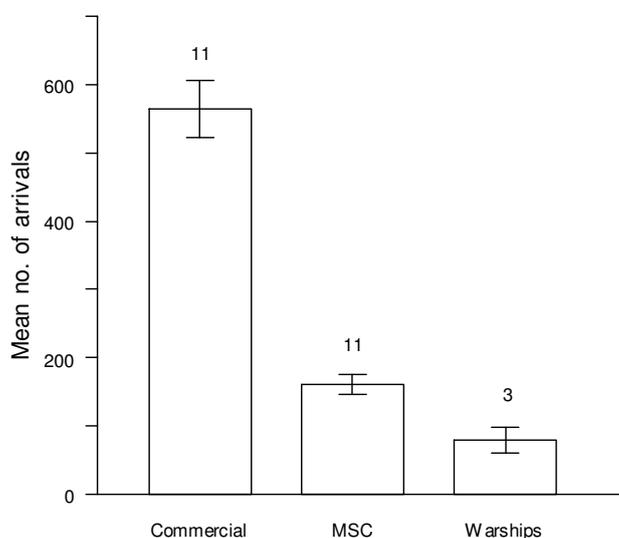

Figure 3.4. Annual mean (\pm standard error) for number of arrivals to Micronesia by vessel population. The number of years of data is indicated above each bar; commercial ships and MSC data are from 1999-2009, while the warships are from 2008-2010.

3.3.4 Vessel Flux into the Separate Countries within Micronesia

For commercial vessels, Guam had the largest number of arrivals for ports in Micronesia, with an average of 374 arrivals/year reported from 1999-2009 (Figure 3.5A), including vessels arriving from LPOCs both within and outside of Micronesia. This accounted for 66% of the commercial arrivals that we were able to document for the region during this time period. The second largest number of commercial arrivals was to CMNI (Figure 3.5A), with 26% of the average annual traffic for the region. Thus, Guam and CNMI account for > 90% of commercial vessel arrivals recorded in our dataset (see Section 3.3.1).

A similar pattern was observed for MSC vessel traffic, with over 90% of average annual arrivals in Micronesia recorded in Guam and CNMI over the same time period (Figure 3.5B). The relative contribution of arrivals to CNMI (~34% of total annual flux for MSC in the region) was slightly higher than that for commercial vessels (26%), during the same time period, as seen in comparison of Figure 3.5A and B.

A comparable analysis of vessel flux was not possible for other types of U.S. Navy vessels (or other military vessels), since we did not have access to data on arrivals or transit histories. Thus, beyond vessels operated by MSC, military vessels are excluded here and from subsequent analyses in this chapter, representing an information gap for vessel traffic associated with the Guam Buildup and Micronesia overall.

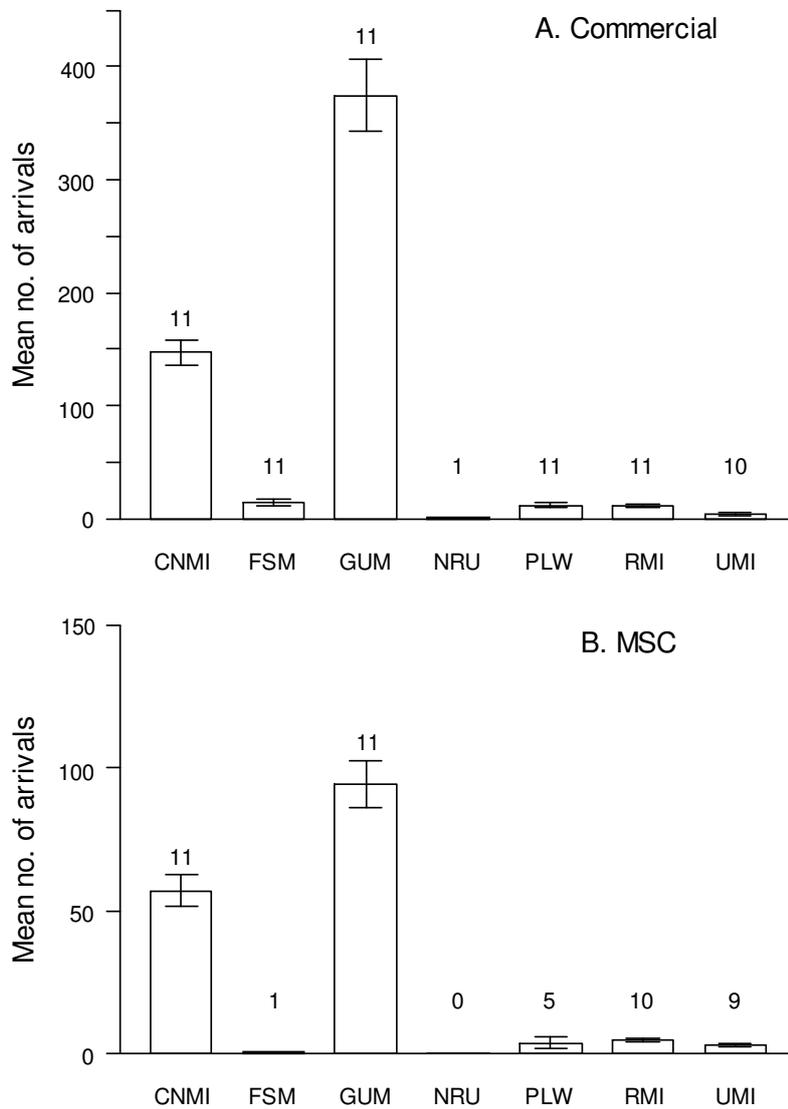

Figure 3.5. Annual mean (\pm standard error) number of arrivals for different regions of Micronesia for (A) commercial vessels and (B) MSC vessels. Shown are: Commonwealth of Northern Mariana Islands (CNMI), Federated States of Micronesia (FSM), Guam (GUM), Republic of the Marshall Islands (RMI), Nauru (NRU), Republic of Palau (PLW), and the U.S. Minor Outlying Islands (UMI). The number of years of data is indicated above each bar [Note: Only years for which arrivals were reported are included in the mean estimates for each country. Thus, overall mean arrivals for the entire 11-year period would be lower for those countries with fewer years of reported arrivals.]

3.3.5 Vessel Transit Histories

Across the entire 11-year time period, we documented 7,973 vessel arrivals to ports in Micronesia, including commercial and MSC vessels. MSC vessels represented 22% of the total arrivals. The distribution of these arrivals among countries is shown in Figure 3.6 (top panel). As expected from the previous section, the majority of arrivals for each commercial and MSC vessels occurred in Guam and CNMI.

We were able to document some portion of the previous voyage histories for most MSC and commercial vessel arrivals (see Section 3.3.1 for sources). Figure 3.6 (bottom panel) shows the percentage of arrivals to each country for which voyage history was available, according to type (extent) of historical data. Across all countries: (a) LPOC was available for $\geq 99\%$ of arrivals of each vessel type; (b) NPOC was available for a smaller subset of MSC arrivals (94%) and commercial arrivals (84%); and (c) data on additional ports of call, or transit history, were available for 74% of commercial vessels and 97% of MSC vessels.

The sections below present an analysis to examine connectivity among ports, using these data for LPOC and NPOC. Although some additional transit information was obtained for most vessel arrivals, it is difficult to evaluate its completeness. One measure of completeness may be the temporal extent of records, which is < 100 days for 10-20% of arrivals. Analysis in Chapter 5 evaluates this extended transit history information, considering indirect connections (i.e., those ports visited beyond simply LPOC and NPOC). Characterizations of connectivity presented here and in Chapter 5 should be considered minimum estimates, because data on direct and indirect linkages are not available for all vessels that arrived in Micronesia.

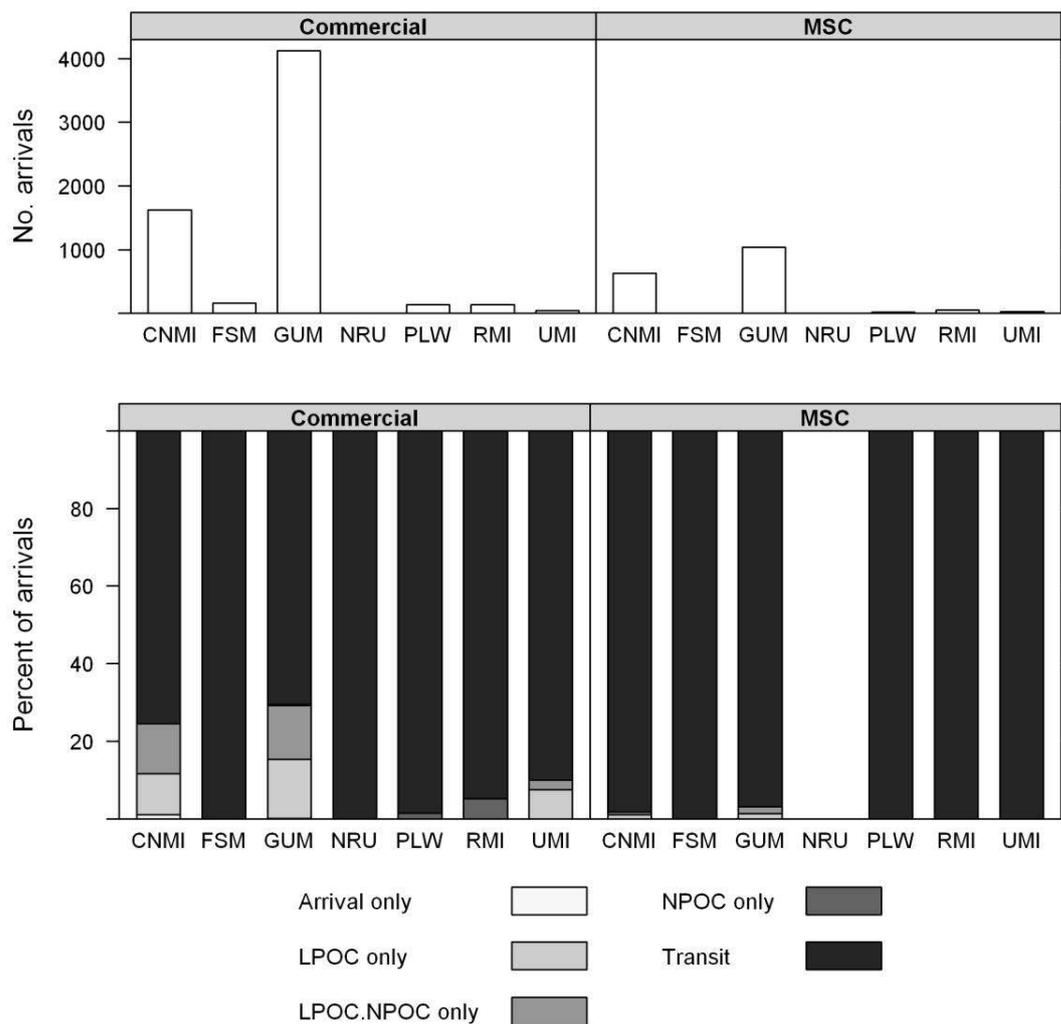

Figure 3.6. Data used in connectivity analyses of Micronesia and Hawai'i. Shown for each commercial and MSC vessel arrivals to Micronesia are (A) total number of arrivals by the country and (B) percentage of arrivals to each country with associated data on vessel transit history. Categories of vessel history types are: arrival record only; last port of call (LPOC) only; next port of call (NPOC) only; LPOC and NPOC only; extended transit history that includes additional ports beyond LPOC and NPOC.

3.3.6 Last and Next Ports of Call for Vessel Arrivals to Micronesia

Figures 3.7-3.10 show the geographic distribution of LPOC and NPOC of arrivals to Micronesia for each commercial and MSC vessel, from 1999-2009, indicating the connectivity that exists with specific geographic regions or countries around the globe. Overall, most connections for both vessel types were with Asia and the western U.S. As expected from above, Guam had the largest number of arrivals. For both MSC and commercial vessels, Guam was also connected to the largest number of ports (for both LPOC and NPOC). Finally, the extent of vessel traffic that connects Guam to other parts of Micronesia, as well as Hawai'i, is evident for both MSC and commercial vessels.

A more detailed view of connectivity for vessel traffic within Micronesia, and between Micronesia and Hawai'i, is presented in Figures 3.11 and 3.12 (for commercial and MSC vessels, respectively). As expected from previous maps, Figures 3.11 and 3.12 illustrate the strongest connections (in terms of vessel arrivals) were between Guam-Hawai'i and Guam-CNMI, for traffic moving in both directions between these locations. This pattern existed for both the commercial and MSC vessel traffic. In addition, commercial vessels exhibited relatively strong linkages between Guam-Palau, Guam-FSM, and Hawai'i-UMI (Figure 3.11).

Thus, both commercial and MSC vessels showed strong linkage between Guam-Hawai'i, with connectivity throughout Micronesia, illustrating the magnitude of vessel flux and the potential opportunity for ship-mediated species transfers to occur associated with biofouling (of hulls) or ballast water from these vessels. It should be noted that the scale differs between the two figures, and there is more commercial than MSC traffic overall.

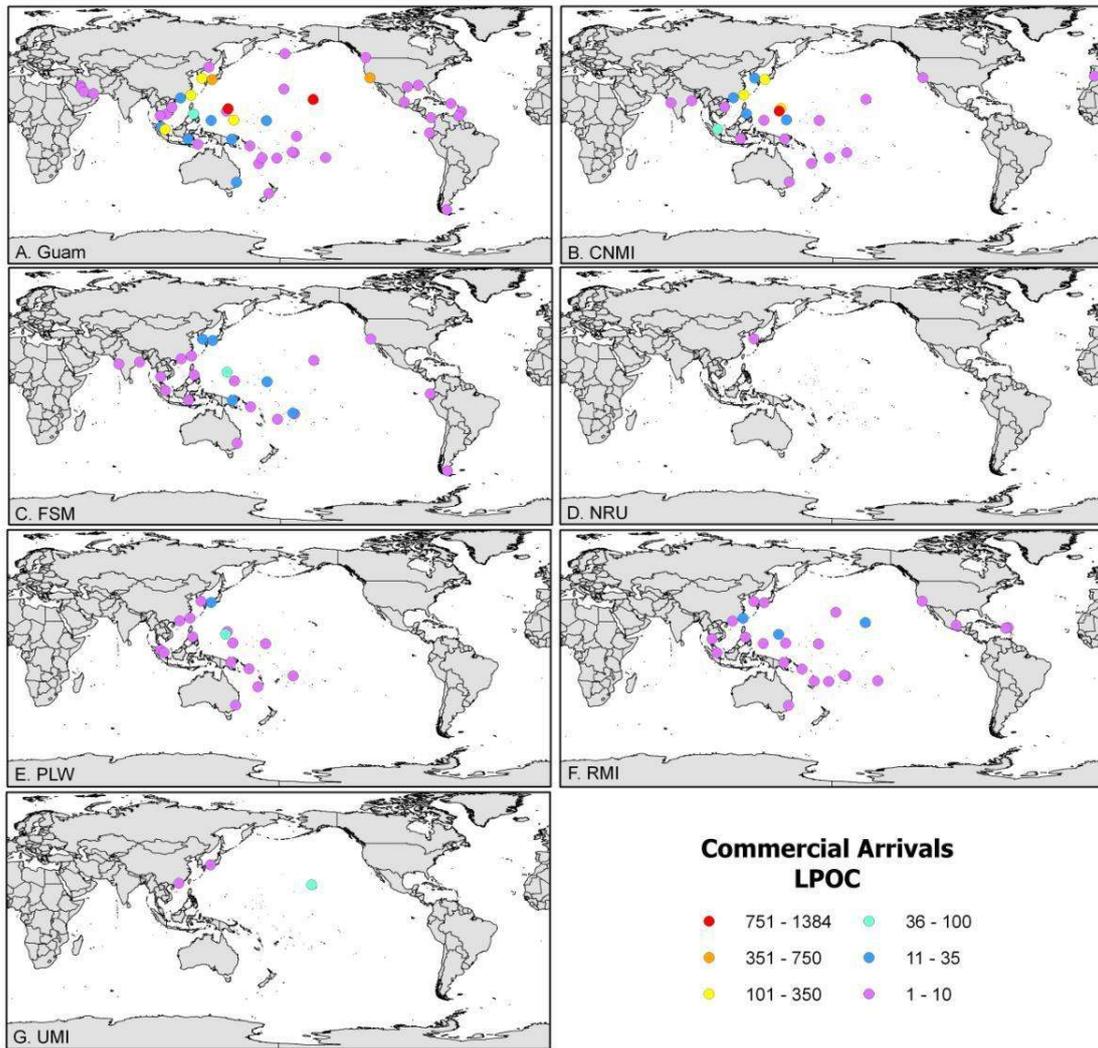

Figure 3.7. Last port of call (LPOC) of commercial vessel arrivals between 1999-2009 to different countries and states in Micronesia. Shown are: A. Guam, B. Commonwealth of Northern Mariana Islands (CNMI), C. Federated States of Micronesia (FSM), D. Nauru (NRU), E. Republic of Palau (PLW), F. Republic of the Marshall Islands (RMI), and G. U.S. Minor Outlying Islands (UMI).

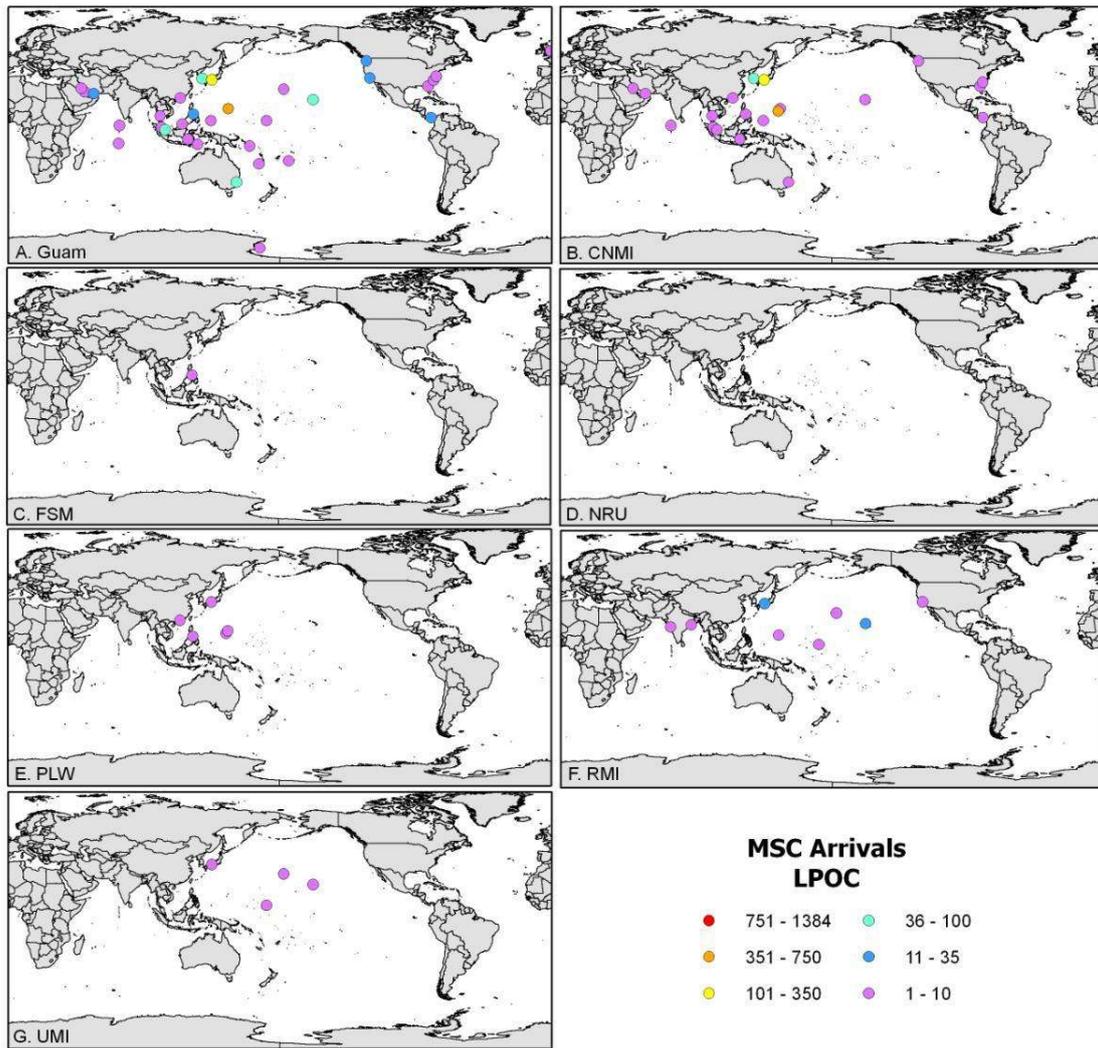

Figure 3.8. Last port of call (LPOC) of MSC vessel arrivals between 1999-2009 to different countries and states in Micronesia. Shown are: A. Guam, B. Commonwealth of Northern Mariana Islands (CNMI), C. Federated States of Micronesia (FSM), D. Nauru (NRU), E. Republic of Palau (PLW), F. Republic of the Marshall Islands (RMI), and G. U.S. Minor Outlying Islands (UMI).

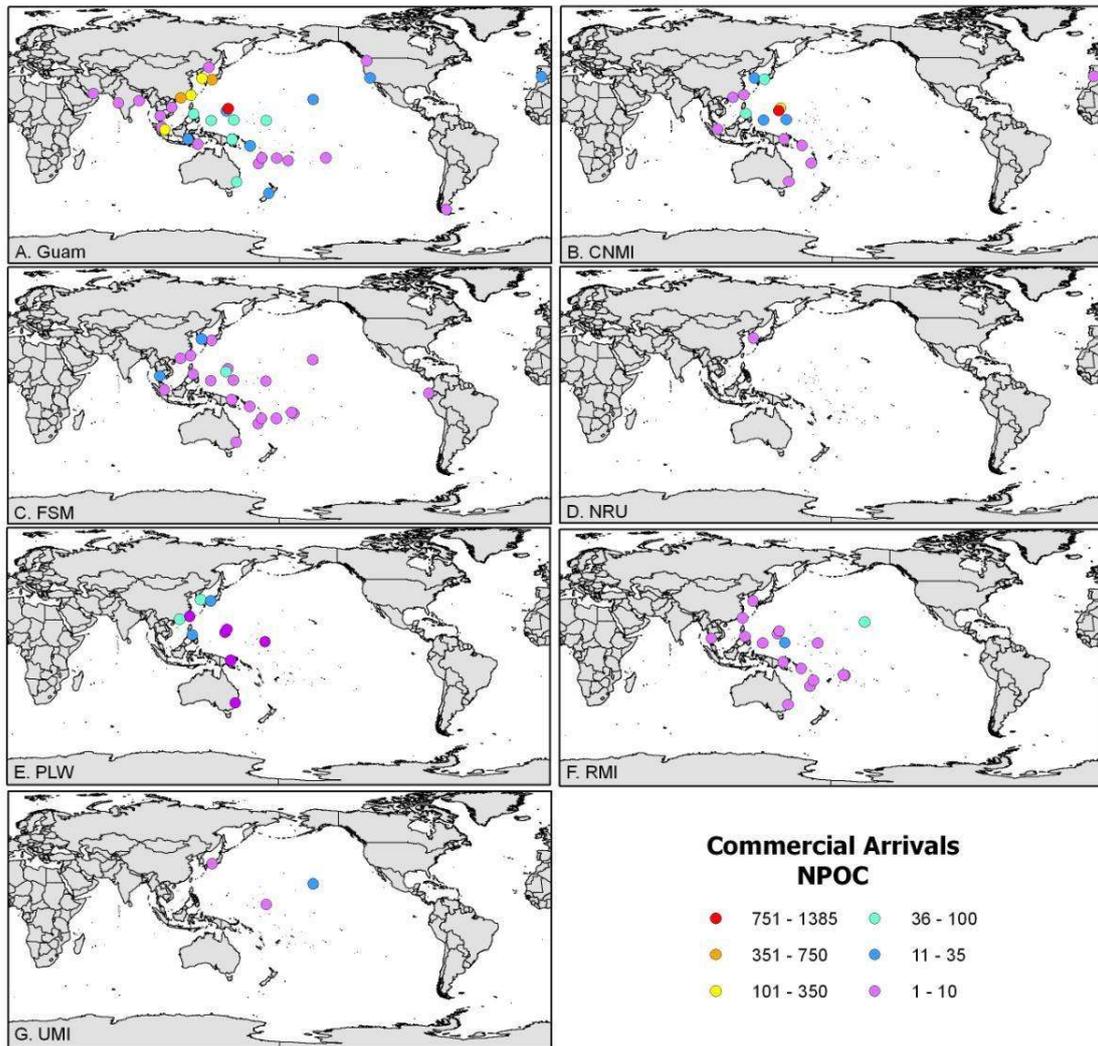

Figure 3.9. Next port of call (NPOC) of commercial vessel arrivals between 1999-2009 to different countries and states in Micronesia. Shown are: A. Guam, B. Commonwealth of Northern Mariana Islands (CNMI), C. Federated States of Micronesia (FSM), D. Nauru (NRU), E. Republic of Palau (PLW), F. Republic of the Marshall Islands (RMI), and G. U.S. Minor Outlying Islands (UMI).

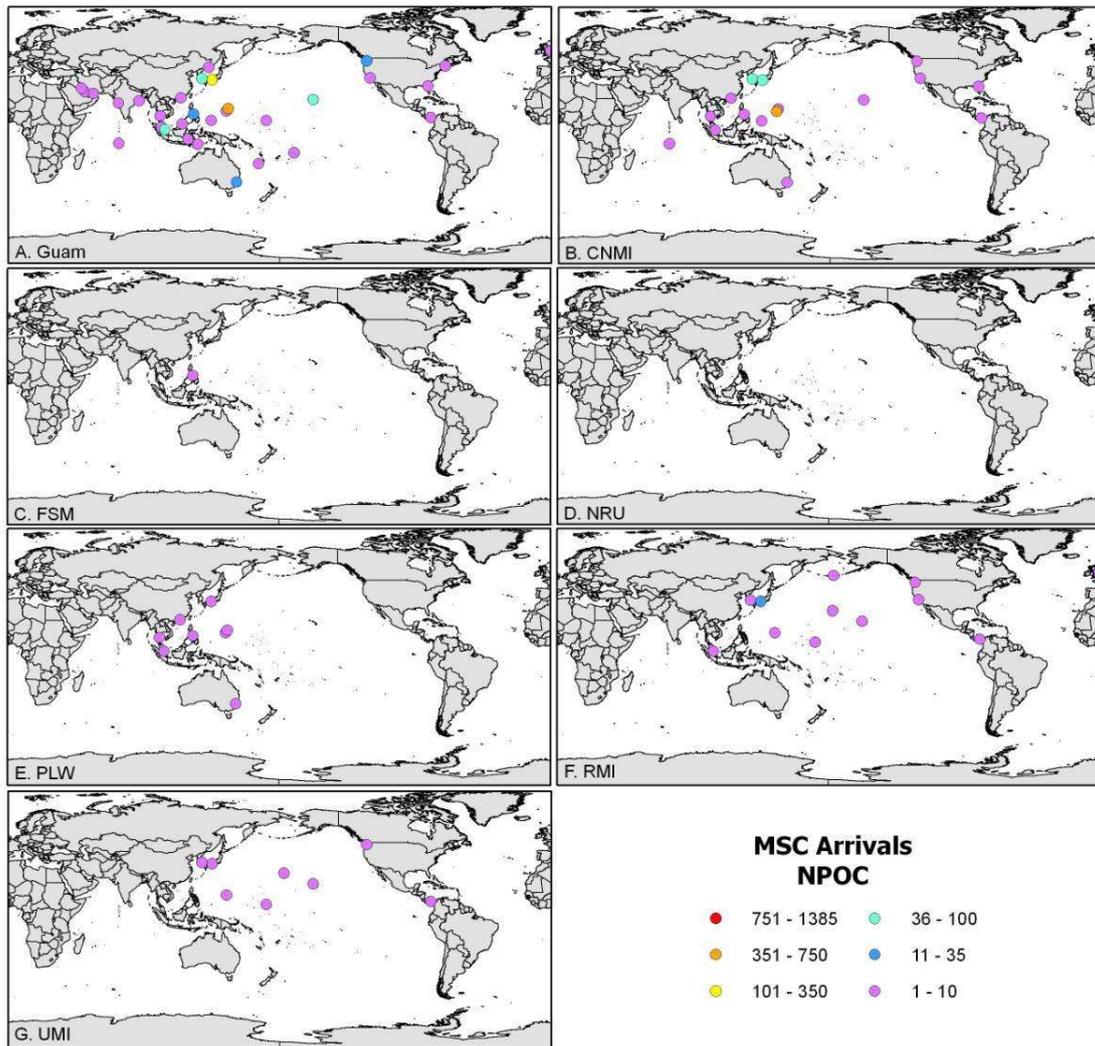

Figure 3.10. Next port of call (NPOC) of MSC vessel arrivals between 1999-2009 to different countries and states in Micronesia. Shown are: A. Guam, B. Commonwealth of Northern Mariana Islands (CNMI), C. Federated States of Micronesia (FSM), D. Nauru (NRU), E. Republic of Palau (PLW), F. Republic of the Marshall Islands (RMI), and G. U.S. Minor Outlying Islands (UMI).

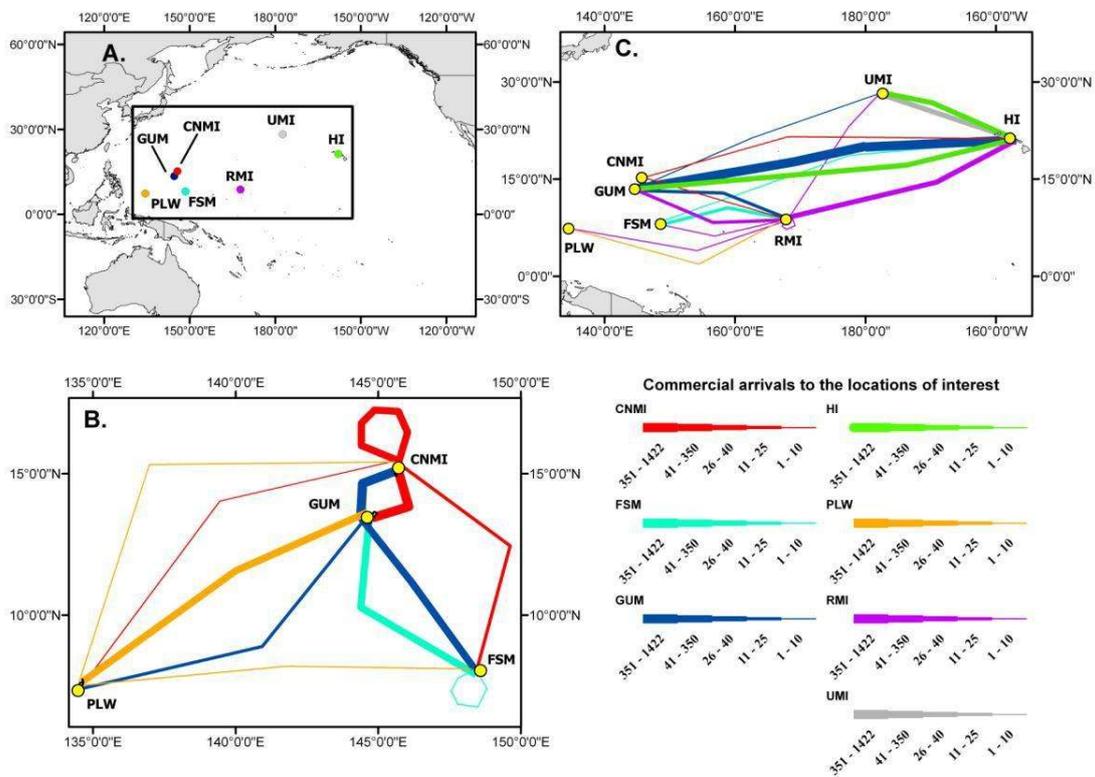

Figure 3.11. Maps showing the connectivity (number of arrivals) of Micronesia, Guam and Hawai'i resulting from commercial ship traffic. A) Color coding associated with the ports of arrival. B) Connectivity between Guam (GUM), the Federated States of Micronesia (FSM), the Commonwealth of the Northern Mariana Island (CNMI), and Palau (PLW). C) All arrivals to and from Hawai'i (HI), the Republic of the Marshall Islands (RMI), and the U.S. Minor Outlying Islands (UMI). In these figures, color denotes the destination port (as shown in panel A), and the width of line is scaled to the number of arrivals from the connected port. For example, the dark blue line between CNMI and Guam indicates the number of vessel arrivals to Guam from the Northern Marinas Islands (as LPOC). In contrast, the red line connecting these locations indicates traffic that originates in Guam and arrives to CNMI.

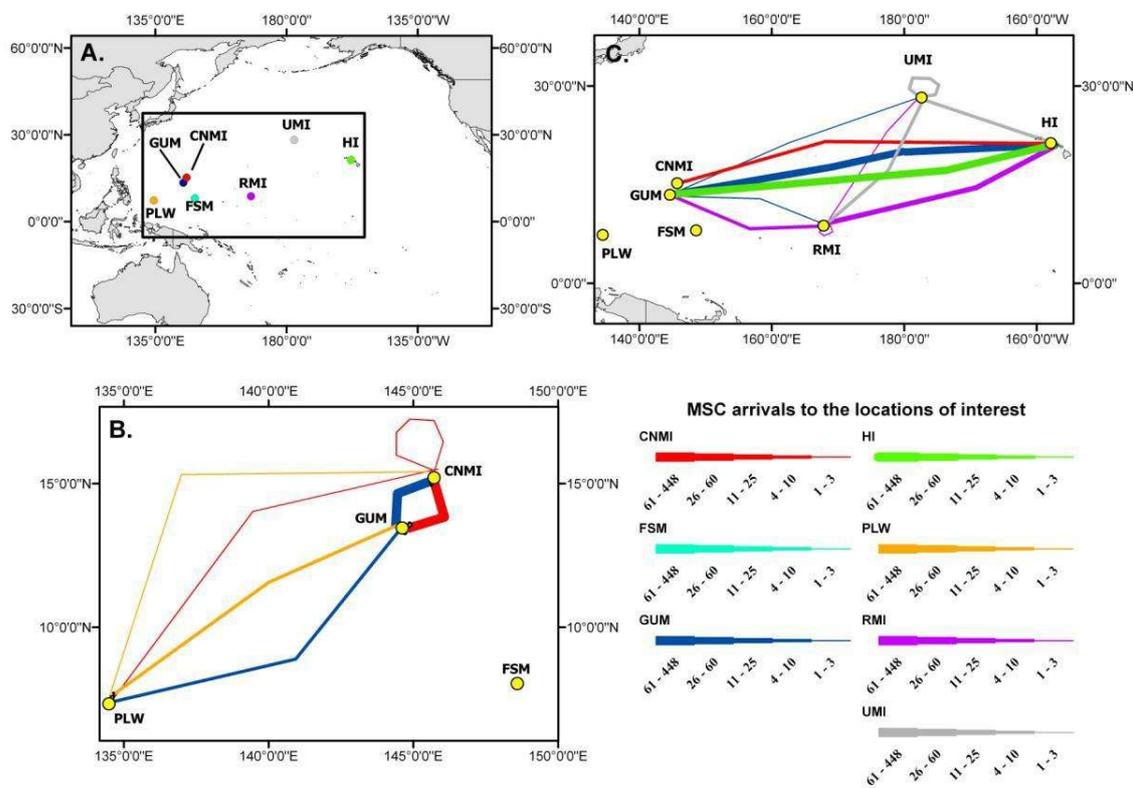

Figure 3.12. Maps showing the connectivity (number of arrivals) of Micronesia, Guam and Hawai'i resulting from MSC ship traffic. A) Color coding associated with the ports of arrival. B) Connectivity between Guam (GUM), the Federated States of Micronesia (FSM), the Commonwealth of the Northern Mariana Island (CNMI), and Palau (PLW). C) All arrivals to and from Hawai'i (HI), the Republic of the Marshall Islands (RMI), and the U.S. Minor Outlying Islands (UMI). In these figures, color denotes the destination port (as shown in panel A), and the width of line is scaled to the number of arrivals from the connected port. For example, the dark blue line between CNMI and Guam indicates the number of vessel arrivals to Guam from the Northern Marinas Islands (as LPOC). In contrast, the red line connecting these locations indicates traffic that originates in Guam and arrives to CNMI.

3.3.7 Ballast Water Flux Associated with Guam and the Northern Mariana Islands

Records exist for the discharge of 365,904 metric tons of ballast water to Guam between 2005-2009 for commercial and MSC vessels. Figure 3.13 shows the volume of this ballast water as a function of vessel type, geographic source region, and whether it was reportedly managed (treated by ballast water exchange) prior to discharge. As discussed in Chapter 2, most vessels do not discharge ballast water upon arrival, and information is available for only a subset of arrivals. The available data provide a minimum estimate for ballast volume discharged to Guam from various source regions and illustrate that some of this water was reported to be untreated.

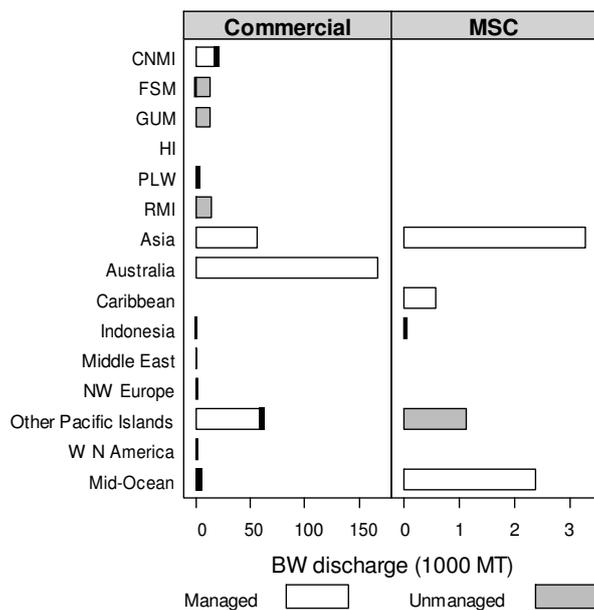

Figure 3.13. Source regions and volume of ballast water reported to USCG as discharged in Guam by commercial and MSC vessels, 2005-2009. Total volumes are shown in thousands of metric tons (MT) as a function of source and management (i.e., whether water was reported to be treated with ballast water exchange or not). The specific source regions of interest include the Commonwealth of Northern Mariana Islands (CNMI), Federated States of Micronesia (FSM), Guam (GUM), Hawai'i (HI), Republic of the Marshall Islands (RMI), and the Republic of Palau (PLW).

In similar fashion, Figure 3.14 shows data available for ballast water discharge to CNMI. Although many ships did not report information, the available data suggest a relatively small volume is discharged in this country. It is noteworthy that the small volume of ballast that originated in Guam was untreated, indicating that an occasional transfer of coastal organisms entrained in ballast tanks from Guam to CNMI may occur without any management to reduce concentrations (see Chapter 2 for discussion).

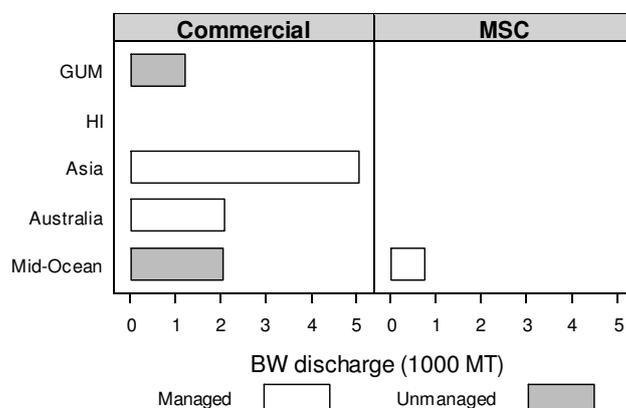

Figure 3.14. Source regions and volume of ballast water reported to USCG as discharged in the Commonwealth of the Northern Mariana Islands by commercial and MSC vessels, 2005-2009. Total volumes are shown in thousands of metric tons (MT) as a function of source and management (i.e., whether water was reported to be treated with ballast water exchange or not).

Figure 3.15 summarizes the data reported to USCG on ballast water discharged in the U.S. that originated in Guam and the Northern Mariana Islands. The largest reported volume is from MSC vessels, which reported discharge from Guam to Hawai'i and Puget Sound, Washington. All reported discharge was treated, although treated water may still contain coastal organisms (see Chapter 2 for further detail). Also, as noted throughout, this represents a minimum estimate, as only a fraction of MSC vessels appear to submit reports to USCG (as discussed in Chapter 2).

3.4 Barges

Barge traffic in Guam and Micronesia appears to be highly dynamic, making it particularly difficult to project traffic for future planning purposes. At the same time, barges may pose unique and relatively high risks with respect to transfers of non-native species, both as novel introductions into Micronesia and spreading non-native species within the region, due to the nature of their operation. Here, some of the key issues and uncertainties are highlighted for marine biosecurity associated with barges.

While included in the above analysis of regional traffic patterns, it is evident that fewer barge arrivals to Guam were reported or recorded in the broad-scale datasets used in this analysis (see Section 3.3.1) than were reported by the Port of Guam, suggesting that we have underestimated the magnitude of this traffic. In addition, barge traffic has been low in recent years, with as many as 100 barge arrivals reported to the Port of Guam in 2004 (as noted earlier; see Figure 3.2). We should expect barge traffic to Guam to increase, due to increased importation of materials and increased local activity (e.g., dredging, construction) surrounding the Buildup. The source(s) of these barges are not presently known, nor are the associated husbandry practices. Based upon interviews with DoD personnel, it appears

likely that the geographic source of barges, their movement, and any associated biosecurity measures will be determined by contractors.

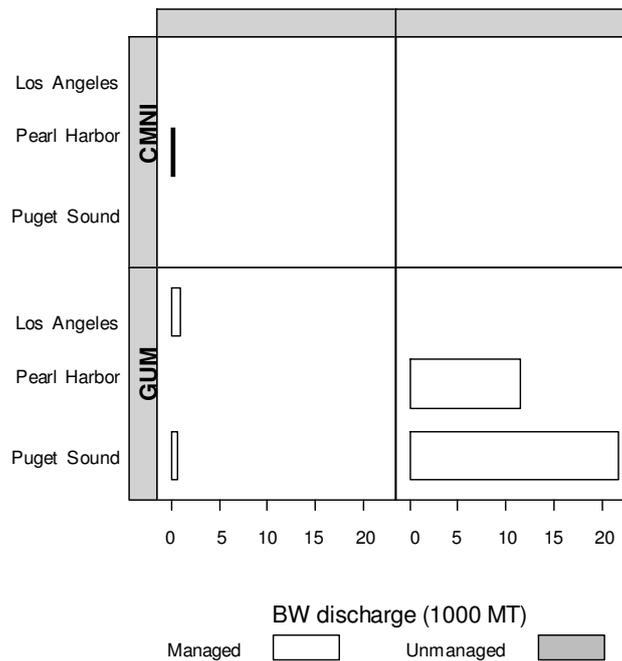

Figure 3.15. Ballast water discharge reported to USCG that originated in the Commonwealth of the Northern Mariana Islands (CNMI) and Guam (GUM) to other ports of the U.S., 2005-2009. Total volumes are shown in thousands of metric tons (MT) as a function of vessel type (commercial versus MSC), geographic recipient, and management (i.e., whether water was reported to be treated with ballast water exchange or not).

In general, barges can have a relatively high potential for transfer of marine species, because of their mode and tempo of operation. These vessels often have long residence times in a particular port or region, residing in shallow and productive waters, compared to a commercial vessel that is in transit and has shorter residence times in port. When barges are moved to new locations, the travel speed is relatively slow. As outlined in Chapter 2, the extent of biofouling is expected to increase with long residence times in port and slow vessel speeds when underway, when controlling for other factors (e.g., husbandry practices). Moreover, long residence time after arrival at a new location can increase the probability that the associated fouling organisms reproduce and colonize the recipient region.

There are several examples of extensive biofouling communities and non-native organisms associated with such slow-moving vessels (Coutts 2002; Coutts et al. 2010a; Hopkins and Forrest 2010), underscoring the biosecurity risks for barges brought into Guam. In an example from the region, a barge from China was brought in as a temporary bridge between Babeldaob and Koror in Palau. The barge did not have antifouling paint and apparently introduced at least one species, a hydroid, to Palau (Colin 2009).

Of additional concern is the potential use of these particular barges and associated construction equipment in other jurisdictions of Micronesia. Once in the region, there may be economic incentives to use such vessels and equipment for projects (e.g., dredging or construction) in other parts of Micronesia, creating the potential for intra-regional transfers of any associated organisms.

Beyond the Guam Buildup, several locations are or have been recently engaged in major construction projects such as roadway expansions/repairs (Chuuk, Yap and Palau) and airport expansions (Pohnpei and Majuro). Pohnpei anticipates that a foreign vessel will be used for its planned harbor dredging. If countries in the region responded to the increased population on Guam with increases in these types of projects, risk associated with this vector could also increase.

Another area of potential concern is a proposed plan to use Pagan Island in the Northern Marianas as a dumping site for debris from the March 2011 Japan tsunami. The proposal put forth by Japanese investors would involve bringing in vessels with tons of tsunami debris to Pagan, and bringing out mined volcanic ash (pozzolan) from the island for use in cement industry. Presumably, slow moving barges would be used for the transport of debris and pozzolan to and from Pagan. Implementation of the plan would furthermore require the construction of a seaport for docking vessels. All these activities could facilitate the establishment of invasive biofoulers originating from Japan. The Pagan dumpsite proposal first made the news in the second quarter of 2012 (Eugenio, 2012). There seem to be no recent updates on the status of the proposed plan, nor of the likelihood that the plan will push through.

While we provided recommendations to DoD in early 2011 to include biosecurity guidelines for barges associated with contracts and construction in Guam, to minimize the probability of marine invasions, it is also evident that barges pose significant risks in other parts of Micronesia, independent of DoD activities. Aggregate, loaded on barges, typically comes to Micronesia from China, Taiwan, and the Philippines. Rather than unloading in port, it appears to be common practice for barges to sit in harbors for long periods, with aggregate removed as needed (Figure 3.16).

Figure 3.16. A barge from the Philippines loaded with aggregate sits in Yap's harbor.

3.5 Fishing Vessels

Historically, Guam and Palau have had the most commercial fishing vessel arrivals in the region. Figure 3.17 shows the average number of arrivals per year for various parts of Micronesia, as provided by the respective regions, Lloyds, NVMC, and NBIC. However, based on discussions with local ports and resource managers, it appears that additional vessels arrive that do (a) come into port and (b) report arrivals to local authorities. Thus, as with commercial cargo vessels, the data presented represent a minimum estimate of actual arrivals.

The number of fishing vessels reported to visit Guam has declined significantly over the past several years. According to port statistics, visits by commercial fishing vessels have declined steadily from 1,332 in 2004 to 499 in 2009 (see Figure 3.3). This decline may be due at least in part to the Shark Finning Act of 2000, which prohibits vessels from countries engaged in shark finning from transshipping through Guam. In addition, there appears to have been a major shift in tuna fishing activities, moving away from Guam. Most other locations in Micronesia have also experienced a downturn in recorded fishing vessel visitation.

Although owned by foreign concerns, most fishing vessels in the region tend to fish within state or territory waters and return to local home ports, and thus represent little risk of non-

native species transfer. However, in Palau, many vessels in the “local” fleet return home to Taiwan or the Philippines for New Year celebrations, staying away for a month or longer. These vessels are likely to be colonized by fouling organisms while abroad, especially given the relatively long residence times, having the potential to transport non- native species to Palau upon return. Fishing vessels based in foreign ports including Taiwan, China, Japan, Korea and Papua New Guinea also arrive to all Micronesian ports, including large “mother ships,” which take off-loaded catch from the locally based fleet (Figure 3.18). To our knowledge, the extent or composition of biofouling on fishing vessels arriving from outside of Micronesia has not been characterized, so the magnitude of any associated species transfers is unknown at the present time.

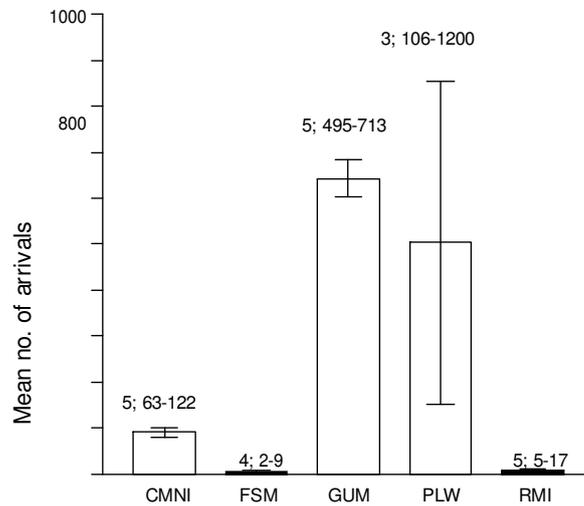

Figure 3.17. Annual mean (\pm standard error) for number of fishing vessel arrivals to countries in Micronesia. Shown are arrivals for Commonwealth of Northern Mariana Islands (CNMI), Federated States of Micronesia (FSM), Guam (GUM), Republic of the Marshall Islands (RMI), and the Republic of Palau (PLW). Above each bar the number of years of available data is indicated, followed by the range (minimum-maximum) in total number of annual arrivals reported per year.

Figure 3.18. A large fishing vessel at mooring in Pohnpei.

Despite a lack of available data, there is certainly a perception within Micronesia that many foreign fishing vessels may be significant sources of both marine and terrestrial non-native species. Scientists from USDA were told by Pohnpeian officials that Japanese long line vessels “are dirty and exchange commodities between ships”. On Kosrae, a new saltwater catfish reportedly first appeared in the area where Chinese vessels anchor, and locals associate this fish with those vessels. On Yap, invasive species managers suggest that the Norway rat may have been introduced to the islands from Chinese fishing vessels. The concern over the perceived and in some cases demonstrated dirtiness of some fishing vessels in regards to potential invasive species is well known throughout the region.

In addition to vessel arrivals themselves, fishing vessels seized on suspicion of illegal fishing are another potential source of non-native species transfers, which may be unintentionally facilitated (enhanced) by increased residence times in port due to impoundment. Illegal fishing is a problem in most locations in Micronesia. Typically, following apprehension by marine patrols, these vessels are seized and brought into the nearest harbor, where they may sit for long periods as cases progress through the courts. Most locations report one to three such cases per year. Palau, the only locality for which we were able to obtain records, had 45 cases between 1994 and 2010. Vessels included steel and wooden hulled boats of various sizes and types, mostly from the Philippines, Indonesia, China and Taiwan.

There is no clear link between the population on Guam and the volume of fishing-vessel traffic; however, if new species become established in the region as a result of the Buildup, these vessels could provide a vector for the spread of non-native species within the region.

3.6 Cruise Ships

Cruise ship traffic to Guam is relatively minor, with six to eight calls on average each year in recent years. Cruise ships visiting Guam have ranged from 400 to 800 feet in length and tend to stay for only part of a day in port (PB International 2008).

Worldwide, cruising is expected to increase 4.5% to 5.5% from 2007-2017, then by 3.5% to 4.5% by 2017-2020, according to information collected from the International Cruise Line Association for the Guam's Port Master Plan (PB International 2008). However, cruise traffic to Guam may increase more rapidly. Several cruise lines have expressed interest in coming to Guam, with some projections of 20 to 30 vessel visits per year, if port improvements are made.

Cruise ships appear to be a minor part of shipping traffic to other locations in the region; most locations reported one to three ship arrivals per year with short (one day or less) stays. Palau receives about five to 10 ships a year, which typically stay three to four days, and arrive from Japan, the Philippines, and Australia. Few locations have sufficient harbor depth and dock capacity for large ships; those that do arrive tend to anchor outside the harbor, with smaller boats bringing passengers ashore. Pohnpei is intending to dredge its harbor channel with the goal of providing appropriate anchorage for cruise ships; cruise ships arriving in Pohnpei tend to have stopped previously in Guam and Papua New Guinea.

3.7 Private Yachts/Other Recreational Vessels

There are three marinas under control of the Port Authority of Guam, as well as a privately run marina and a private yacht club on Guam. The Gregorio D. Perez Marina near downtown (also known as Agana Boat Basin or Hagatna Marina) provides berthing and mooring space for approximately 165 recreational, charting, fishing and public agency boats. The Agat Marina, on Guam's west coast, has capacity for 150 boats. Both the Perez and Agat marinas have launch ramps for trailered boats. The Port of Guam also controls the Harbor of Refuge, at the eastern end of Piti Channel, which is primarily used as shelter for boats during typhoons and for long-term storage for boat owners. Aqua World Marina, which leases land adjacent to the Harbor of Refuge, also has a small number of berths as well as commercial marine-based businesses. The nearby Marianas Yacht Club has moorings for members, which are also used by visitors.

We were unable to determine the volume of recreational boating in the region. The yacht club currently has 90 members. There are several races each year, including one from Guam to Rota, and an annual fishing derby on Saipan, which attracts upwards of 70 boaters from different parts of Micronesia and farther abroad. The number of participants coming from afar is at least partially dependent on weather conditions and fuel costs in a given year. The Marianas Yacht Club hosts only four to five visiting yachts each year. Many of these boats come from Southeast Asian and long stays are fairly typical. Although we could not find any projections for recreational boating traffic during the Buildup and post-

Buildup, it is reasonable to assume that the number of recreational boaters will increase to some extent with the influx of new island residents. Membership at the yacht club was higher before the recent decline in military personnel on the island, so it is likely to rise again when greater numbers of troops move to Guam.

The master plan for the port calls for expansion of Gregorio D. Perez marina, where there is a waiting list for slips (PB International 2008). At Agat, the master plan recommends the replacement of slips and piers and potentially the extension of a breakwater. General repairs to anchorages are proposed for the Harbor of Refuge, along with maintenance and repair facility and a haul out facility.

Yacht arrivals to many parts of Micronesia appear to be a minor component of boating traffic. A few details from visits to some locations throughout the region serve to illustrate this:

- Chuuk reported between two and 11 yacht arrivals a year over the past four years, and some of these stayed a week or longer. Previous ports of call included many locations in Japan, Australia, Solomon Islands, and elsewhere in Micronesia. About 1/3 of these vessels were headed to Guam from Chuuk, and nearly all were planning to stop elsewhere in Micronesia.
- Palau receives about two yachts a month, and many of these travel to Guam and have stopped previously in the Philippines.
- Kosrae receives about eight to 10 yachts a month from numerous locations including Panama, U.S., Netherlands, and elsewhere in Europe. Most of these have stopped in either Fiji or Pohnpei before arriving to Kosrae.
- Yap reports about six yacht arrivals a year. Data on LPOC were not available, but in 2005 and 2007, Koror was the next port of call for over half of the yachts calling on Yap. Other vessels went to Rota, Cebu and Kosrae from Yap.
- Pohnpei also has small vessel traffic (Figure 3.19) from Australia, New Zealand, and possibly the Philippines; these rarely travel to Guam or CNMI, but more regularly visit Palau, other states of the FSM, and RMI.

Figure 3.19. Recreational vessels in Pohnpei's Harbor.

3.8 Miscellaneous Small Vessels

This group includes any small craft, including research vessels, training or educational vessels ("semester at sea" type vessels), missionary boats, traditional voyaging canoes, etc. that fall outside of the normal vessel traffic. Research vessels occasionally visit Guam and Saipan, sometimes without having made prior contacts with the port, management agencies, and/or educational organizations. Saipan has also hosted a Japanese "school afloat" vessel, and Palau has been visited by a heavily fouled missionary boat from Korea. Traditional voyaging canoes also sometimes visit Guam; in the past these have come from the Carolines and Hawai'i.

For these vessels in Micronesia, as well as for recreational vessels discussed in the previous section, there was no information available about the marine biota (biofouling) that may be associated with them.

There are also various passenger/cargo vessels that run between islands within and between some of the Micronesia jurisdictions. These would include vessels which go from the main islands in most jurisdictions such as Majuro, Chuuk, Pohnpei, Yap, and Palau to smaller islands within the jurisdictional boundaries of these island groups, but some vessels also cross between jurisdictions, especially within the FSM where vessels travel between the four states and the various islands within each of the states. For these types of vessels as well as private yachts, there is typically little to no biosecurity mechanisms currently in

place when arriving at an outer island group port of call.

3.9 Grounded and Abandoned Vessels

Shipwrecks, vessel groundings on the reef, and abandoned vessels are not uncommon on Guam or elsewhere in Micronesia (Figure 3.20). While the Buildup is not expected to directly result in more groundings, there is a higher likelihood of such incidents as vessel traffic of all kinds increases. In Guam, previous cases of grounded vessels that were reportedly abandoned by owners remained on the reef for months, while agencies attempted to determine who was responsible for cleanup. Although jurisdictions in Micronesia appear to often have the legal authority to collect damages and payment for cleanup from ship owners, logistical difficulties of removal or prosecution appear to hinder actions, especially when vessels have been abandoned by the owners. Again, no information is available on biofouling associated with these vessels, but long residence times can facilitate species transfer (as discussed above), and vessels on reefs can potentially release species directly into highly valued natural habitats (versus harbors).

Figure 3.20. Abandoned vessels are a problem in all locations in Micronesia.

3.10 Laid-up Vessels

Worldwide, shipping is down due to the economic downturn, and commercial vessels are sitting in ports while shipping agencies wait for shipping to pick up (Floerl and Coutts, 2009). We are unaware of any plans in Guam to allow such laid-up vessels to reside locally, but such a plan was being discussed in Palau, and it is possible that this may come under consideration for Guam or elsewhere in Micronesia in the future. Palau was approached by a group that wished to explore moving 30 vessels laid up in Davao, Philippines to the Palau harbor, where mooring spaces are less costly; any action on this proposal had been deferred at the time of this report.

Pearl Harbor in Hawai'i has recently received decommissioned U.S. Navy vessels from the West Coast of the U.S. Additional decommissioned vessels are expected to be moved to Pearl Harbor, but information was not available on how many of these vessels are expected or what the ultimate plans are for them. While these vessels are expected to adhere to U.S. Navy protocols with regards to ballast water (see Chapter 2), we were unable to determine if and how hull fouling is addressed for these and other inactive Navy vessels surrounding movements. Given that the existing protocols for hull maintenance are motivated by the need to maintain operational readiness (see Chapter 2), it is not clear whether these also apply to (and are implemented for) decommissioned vessels, which can have extensive biofouling communities and may be transferred to other locations (Davidson et al. 2008, deFelice and Godwin 1999), presenting a risk of non-native species transfer.

3.11 Ship Breaking

There are no current plans in Guam for breaking of decommissioned vessels for scrap metal, but this is being discussed for a location just south of the port in Saipan. If this plan goes forward in Saipan, it could lead to increased species introductions (for the same reasons outlined above), depending on the extent and nature of biosecurity protocols that could be used.

3.12 Fish Aggregating Devices

On Guam, the Department of Aquatic and Wildlife Resources (DAWR) uses old U.S. Navy buoys from Portland, Oregon as fish aggregating devices (FADs). These arrive clean and dry and are assembled on Guam. There are 14 designated locations for FAD deployment at depths between 500 and 3,000 fathoms. FADs are monitored by aerial survey twice a year. On Yap, FADs are constructed on island using coconut fronds and other local materials; these are fished regularly by the local fleet with the Yap Fishing Authority in control of deployment and maintenance.

While these particular practices appear to be extremely low risk for non-native species introductions and spread, elsewhere in Micronesia abandoned boats and other floating objects are sometimes deployed as FADs and are not well-monitored. We are aware of several that have been deployed around Saipan and Palau. One of the Palauan FADs, an abandoned vessel, ran aground and had to be broken up and sunk. In such cases, the source(s) and relocation of floating objects is of paramount concern in minimizing the potential translocation of non-native species; it is often not clear what policies or practices

may exist for use of vessels or other floating materials throughout the region.

3.13 Dry-docks

Guam has two floating dry-docks, owned and operated by the Guam Shipyard. Both dry-docks were towed to Guam from other locations: the Adept, from Subic Bay, Philippines and the Machinist (“Big Blue”) from Pearl Harbor, Hawai’i. Based on interviews with U.S. Navy and Port of Guam personnel, there are currently no plans to bring in additional dry-docks to Guam associated with the Buildup.

There is a proposed transfer of a dry-dock from Guam to Saipan by a ship maintenance company. A new dry-dock has been proposed for Majuro to service the purse seiner fleet, and permits have been approved, but problems with the site are holding up development; the proposed dry-dock, Ching Fu, would come from Taiwan. There have been some discussions about bringing a dry-dock to Pohnpei in the future. Small non-floating dry-docks (slipways) also exist on Yap and Kosrae (Figure 3.21), but no plans for changes to these facilities were reported.

Figure 3.21. A slipway in Yap servicing a small vessel.

In addition to concerns about biofouling on floating dry-docks that may be moved from one location to another, as observed with the transfer of the Machinist to Guam (Paulay et al. 2002), biofouling organisms removed from ships in the dry-dock and released to local

waters may affect invasion probability. There are currently no management practices in place addressing biofouling organisms released by dry-docks. In Guam, Hawai'i and Saipan, the EPA regulates dry-dock activities under the Clean Water Act, specifically focusing on the prevention of water pollution from rinse water and from dry materials removed from ships in dry-dock. These regulations do not specifically address the risks of non-native species transfers. Resource managers and officials throughout Micronesia expressed concerns with such issues and unregulated boat maintenance associated with dry-docks.

The DoD runs a dry-dock on Kwajalein Atoll. Information was not available to determine how frequently this dry-dock is used and what environmental regulations the DoD might have in place to prevent non-native species transfers from dry-dock activities.

3.14 Floating Docks/Pontoons and Other Structures

The docks at Perez and Agat marinas on Guam are floating structures, moored to fixed structures. Many of these are in disrepair. The Port Master Plan (DB International 2008) calls for replacing and expanding the floating docks and slips in these two marinas. Floating security barriers are planned for the DoD side of Apra Harbor.

The Port Master Plan for Guam proposes the construction of an additional 2,250 feet of refurbished and new wharf structures on the commercial side of the harbor. At the Agat Marina, the plan proposes extending the existing breakwater and general repairs and expansions at both Perez and Agat marinas which include the placement of concrete and/or metal fixed piers and pilings.

Significant additions to the DoD side of Apra Harbor are planned and/or are in progress, including dredging to create a new deep-draft channel, construction of a new wharf at Polaris Point to accommodate an aircraft carrier, a rip-rapped revetment, and an extension of Kilo Wharf using concrete caissons. The concrete caissons brought to Guam for Kilo Wharf construction were built in Japan and towed to Guam, after several months of sitting in the water. It is not clear what biofouling organisms were associated and transferred to Guam on these structures, which were cleaned only after being sunk in Apra Harbor.

The source of materials for the proposed structures on Guam was not known at the time of this report, and the development or application of any biosecurity protocols to minimize associated species transfers is also uncertain.

No other ports in the region except Guam report current plans for construction or replacement of existing floating or other structures. Most port agencies indicated that they were under capacity in terms of operations, with the exception of being able to accommodate cruise ships, and did not believe the Guam Buildup would require port expansions. Only Pohnpei was considering dredging and construction for cruise ships; this idea is still in an initial phase and is not yet part of any written plan.

3.15 Oil Drilling Platforms, Oil Production, and Exploration Vessels

Exploratory drilling for oil is being proposed in Palau. As with barges, drilling platforms

can reside in one location for long periods and develop extensive biofouling communities and are transferred (under slow speed) to other locations, posing a high risk of species introductions. There are currently no regulations on Palau for biofouling on drilling rigs and platforms.

As far as we could determine, there are no drilling or underwater exploration plans elsewhere in Micronesia. Nonetheless, given the shipping connection between Palau and Guam, activities in Guam could affect regional spread of species, should an invasion occur in Palau.

3.16 Buoys and Channel Markers

Navigation aids, such as buoys and channel markers, are maintained in Guam and CNMI by harbor staff, the USCG, and (in the case of CNMI channel markers) by the Division of Fish and Wildlife. Elsewhere in the region, navigation aids are maintained by harbors and marine resources agencies. As with other floating artificial substrata, these navigation aids become covered with biofouling. As long as they remain in place (and are generally not moved to other locations for relocation or cleaning), they do not present a high risk of non-native species transfer.

3.17 Dive and Recreational Fishing Gear

Scuba diving and recreational fishing are popular activities on Guam for military personnel, locals, and tourists alike. Scuba gear is also used for work activities for military and research personnel. If wet gear is moved between locations, there is a possibility of transferring organisms. Although we have not seen any official estimates of predicted growth in participation in these activities, we expect that an increase in population will result in an increase in recreational/charter fishing activities and snorkeling and scuba both on Guam and within the region in general.

Palau, Chuuk, and Yap are considered world-class dive destinations, with many divers visiting each of these islands in turn. Currently about 40,000 visitors come to Palau annually; about 80% of these are divers. Chuuk receives 3,000 visitors a year, nearly all of whom come to dive; Yap receives 4,000-5,000 a year, with 80-90% coming to dive. Tourism increases are also anticipated on Pohnpei, which, along with Palau, is expanding its airport to accommodate more visitors. Palau has officially invited the U.S. military for R&R (rest and relaxation); the Chuuk Visitor's Bureau was planning to attend a tourism trade show to court military visitors, and is working to get direct flights to Chuuk from the Philippines (and/or Taiwan).

To our knowledge, there are no management practices in place in the U.S. military, Guam or elsewhere in Micronesia to reduce the risk of transfer of non-native species through recreational fishing or diving activities. In the Papahānaumokuākea Marine National Monument (Northwestern Hawai'ian Islands), strict protocols are in place to prevent transfer of organisms on scuba gear, clothing or research equipment (PMHM Best Management Practices 2009).

3.18 Kayaks, Outriggers, and Personal Watercraft

Water activities are popular on Guam and elsewhere in the region for military personnel, locals, and tourists. Although there are no official estimates of predicted growth in participation in these activities, it is likely that increases in the local population size will result in an increase in water activities of all sorts, including those that involve small boats and personal watercraft. Military personnel coming to Guam may also ship such vessels with their personal goods. We are unaware of any existing management practices in Micronesia to reduce the transfer of marine organisms on or in small watercraft.

3.19 Summary

The goal of this chapter was to review current and projected future activities surrounding vessels, considering what is known about magnitude of these activities and existing practices from a marine biosecurity perspective. The treatment here summarizes available details compiled during the scope of the current project, but this is by no means a comprehensive or complete view of all relevant information. As noted at various points throughout this treatment, there are some gaps in the available data, such that the analysis presented here provides a minimum estimate of magnitude and geographic connectivity for some key mechanisms for species introduction and spread.

Conspicuous gaps in the current analysis exist for traffic patterns and ballast water delivery patterns associated with U.S. Navy ships and other military vessels. While estimates were made available for the number of arrivals for these vessels to Guam, but the following limitations exist:

- LPOC and voyage histories were not made available for U.S. Navy vessels, or other military vessels, except for those provided by MSC for supply vessels.
- While voyage histories were available for many MSC vessels, these were often limited to a short time horizon and appear to be incomplete records.
- Most vessels that operated under MSC did not report ballast water discharge or management data to USCG, so there is a major gap in information about the volume, geographic source(s), and management for water discharged in Guam and CNMI.
- No information was provided from DoD on ballast water discharge and management for any U.S. Navy, MSC, or other military vessels arriving to Micronesia or Hawai'i.

For non-military vessels, some additional information gaps are also apparent for Micronesia, as follows:

- Except for Guam and CNMI, commercial ships arriving to ports in Micronesia do not report ballast water discharge and management information, as there are no existing requirements or programs for this purpose.
- Information on voyage histories (and even LPOC) is only available for a small

fraction of fishing vessels and barges arriving in Guam and other jurisdictions of Micronesia.

- The numbers of barge arrivals in Micronesia appear to be underestimated in many of the existing datasets.

Despite these limitations, the current analysis provides an estimate of current vector activity in Micronesia and illustrates the connectivity that exists, both within the region and globally, especially for vessels. This information, along with that presented in other chapters, provides an important background for developing the biosecurity plan and recommendations outlined in the final chapter. Toward that end, we have included above some activities that are not currently prevalent, or even now in operation, within Micronesia but may become relevant in the near future; in nearly all cases, these activities are at least under consideration, even if they are not now operating in the region. This approach was intended to be as comprehensive as possible, in order to advance a biosecurity plan that captures as many future activities as possible that are relevant to the region.

Chapter 4: Live Marine Organism Importation and Trade

By Chela J. Zabin, Lucius G. Eldredge, and Gregory M. Ruiz

4.1 Importation Regulations and Enforcement

Trade in certain live organisms is regulated at the international level by CITES, to which the U.S. and Palau are signatories, and whose conventions are followed by the FSM and RMI. With the goal of protecting endangered or threatened species, CITES restricts the trade of organisms appearing in its three appendices. Of relevance to the region, giant clams (those in the Family Tridacnidae) and many coral species are CITES species, and are thus subject to specific restrictions. However, there are no international conventions prohibiting trade of marine organisms considered to be non-native, invasive⁴ or nuisance species.

In the U.S., some non-native species are specifically listed and prohibited from importation by the Lacey Act 1900 (for animals) and the Plant Protection Act 2000 (for plants and plant pests). Few marine and estuarine organisms are prohibited under these statutes. Exceptions under the Lacey Act include mitten crabs (crabs in the genus *Eriocheir*) and snakehead fishes (in the family Channidae, largely restricted to freshwater), which are listed as “injurious wildlife,” prohibiting any foreign export or interstate movement of live organisms without a federal permit. To similar purpose, the marine alga *Caulerpa taxifolia* (aquarium strain) is listed as a “noxious weed” under the Plant Protection Act, which prohibits importation into the U.S. or transportation across state boundaries without federal permit.

Current regulations for the importation and movement of live marine organisms in Micronesia are summarized in Table 4.1 and are reviewed in more detail below.

⁴ Note: in this section, the term “invasive” is used to describe non-native species that are perceived to be or perceived to have the potential to be problematic, as opposed to those being imported purposely. Worldwide, most aquaculture species and other live trade (pets, live food) species are non-native to the regions to which they are imported.

4.1.1 Importation Regulations

4.1.1.1 Guam.

DAWR maintains an informal “white list” of marine and aquatic organisms that can be imported live, including aquarium species and food species, such as New England lobster (*Homarus americanus*) and Pacific oysters (*Crassostrea gigas*). The white list mainly includes species already present on Guam (native or already established non-natives) and those that have a long history of importation into Guam with no known negative impacts. A few organisms are allowed for import only for Underwater World, Guam’s aquarium, as the biosecurity and sanitation procedures at the aquarium presumably meet high standards.

Permits must be obtained to bring in species on the white list, even small numbers of individuals for personal use. Importers can submit requests for permits to import organisms not on the list; these are reviewed and approved on a case-by-case basis, with the onus on the importer to prove an organism is not harmful. Importers must have a certificate of health from the point of origin for organisms being brought to Guam.

4.1.1.2 Hawai’i.

Hawai’i’s Department of Agriculture maintains a list of organisms that cannot be brought into the state, including many marine fishes and some species of crabs, octopus and jellyfish (scyphozoans), as well as a list of conditionally approved and restricted organisms, both of which contain numbers of marine species. An importer must have a permit to import anything on the list of conditionally approved organisms. Businesses wishing to import organisms on the restricted list must, as a condition of obtaining a permit, undergo a site inspection. Although terrestrial plants, microorganisms and pathogens appear on the various lists, we could find no lists for macroalgae. The state’s rules and lists are available on the state Department of Agriculture’s website <http://Hawai’i.gov/hdoa/pi/pq/import>.

4.1.1.3 Commonwealth of the Northern Marianas Islands (CNMI).

Imports to CNMI are regulated by USFWS and the Commonwealth’s Department of Fish and Wildlife (DFW) and Department of Agriculture. The DFW website (<http://www.dfw.gov.mp/Enforcement/Fishing%20Regulations.html>) lists species that are allowed for importation; these include several species of birds and mammals. No amphibians or reptiles are permitted. For invertebrates, including marine invertebrates, only those that can be demonstrated to be “not harmful” are permitted. Marine invertebrate importations tend not to be closely regulated. Giant clam spat have been provided to the CNMI from Palau on several occasions over the past 25 years. The only requirements were health certificates from Palau that stated that the clams were not harmful for human consumption. No fish or algae are listed on the DFW website, although enforcement officers are using an unofficial “white list” of freshwater fish species from Australia to make determinations for import permits to CNMI. These rules apply regardless of the number of individuals or purpose of the importation.

4.1.1.4 Republic of the Marshall Islands.

Republic of the Marshall Islands (RMI) does not maintain a list of either prohibited or allowed marine species. Requests for importation permits are decided on a case-by-case basis by Marine Resources and Agricultural Quarantine. For a permit to be approved, an importer must make the case that a proposed species does not pose an environmental threat. A health certificate from an independent veterinarian must accompany live imports. RMI is in the process of reviewing its quarantine regulations. A draft biosecurity bill is also now in progress, which may revise import and export regulations and practices.

4.1.1.5 Federated States of Micronesia.

By federal law, Federated States of Micronesia (FSM) prohibits the importation of exotic plants or animals, except under permit by the Director of Resources and Development (FSM Code, Title 23, Resource Conservation, Section 315). The code also states that no CITES species can be imported (FSM Code, Title 23, Section 8). All import permits must be approved by federal quarantine and undergo a pest risk analysis before a permit is approved. Under Kosrae State Code, if a plant or animal is not already found in the state, an importer must apply to the Department of Agriculture, Land and Fisheries for permission (KSC Title 14 Section 14.204), but it appears that review of permit applications happens at the federal level. Importers must have a certificate of health from the point of origin. Elsewhere in FSM, there do not appear to be any additional regulations at the state level regarding the importation of live marine species. All these regulations will be reviewed and updated after the approval of the new biosecurity bill.

4.1.1.6 Palau.

Palau's Plant and Animal Quarantines and Regulations (1999) contain schedules of prohibited plants and animals. These schedules were updated in 2002 to include any species or hybrid of tilapia (*Oreochromis* spp.), which is currently the only listed marine or aquatic species; however, the government is currently considering removing tilapia from the prohibited list, to promote its use in agriculture (see Section 4.2.1).

In 2006, the regulations were again amended, giving the Palau National Invasive Species Council (Palau NISC) the responsibility of reviewing an application for the importation of any species not already present on Palau. The Palau NISC has 30 days to carry out its review, but may request longer if further study (at the importer's expense) is required. This amendment also gives the Palau NISC the responsibility of advising the Palau Department of Agriculture on species that should be added or removed from the prohibited species schedules.

At ports of entry, including the post office, inspectors from the Palau Department of Agriculture are charged with carrying out inspections of cargo, mail, baggage, passengers, ships and airplanes. All live imports must have a permit issued by the Palau Department of Agriculture and live organisms must have received a certificate of health from their country of origin. Imported organisms can be placed in quarantine for further observation and treatment at the importer's cost if necessary. Although we were told that no live organisms could be imported for food, we did not find this restriction in the regulations.

In Palau, species intended for aquaculture must be approved by the Bureau of Aquaculture,

and are to be held in quarantine for seven days for observation by the Marine Resources Bureau. Nonetheless, there appears to be little capacity to do more than qualitative, visual screening to make a judgment about whether organisms “look healthy” and to sort out obvious non-target species accidentally included in shipments before release. Quarantine officials have the legal authority to inspect an importer’s facilities after organisms have passed through quarantine and can order organisms back into quarantine and/or destroy them after release, but it is not clear how frequently, if ever, this has been done.

4.1.3 Effectiveness of Port Inspections.

Details on interceptions of non-native marine and aquatic species were not available from local agencies, but anecdotal information suggests that smuggling of these organisms certainly occurs at some locations:

- The golden apple snail (*Pomacea canaliculata*) was discovered in Guam in 1984 in Agana Spring and 1986 in Laguas River, where it was being collected for food by local residents (Smith 1992). As the two water bodies are not connected, it is likely that the snail was moved by humans (See Section 4.2.2).
- Saipan has a large population of workers from countries that prize live food, especially fish and other seafood. Officials from management agencies there report having seen Chinese mitten crabs (*Erocheir sinensis*), non-native snails, non-native groupers, (subfamily Epinephelinae) and live swamp eel (probably *Monopterus albus*), for sale at local markets three to four years ago. None of these species can be legally imported.
- On Palau, it is assumed there is a large amount of unregulated trade between the southwestern islands, the Philippines and Indonesia.
- On Majuro, a crocodile apparently smuggled in as a pet was later released on the island and had to be captured by management agencies.

4.2. Aquaculture

4.2.1 Regulations and Industry Standards

Import regulations provide one level of biosecurity, providing pre-border protection from introductions of unwanted species. Another level of protection can result from post-border regulations or practices, which limit potential movement of organisms (and any associated biota) through various means. In many regions of the world, aquaculture species are typically non-native to the areas where they are raised. Even with permitted use, regulations or guidelines are sometimes used to prevent escape of the target organisms or associated species, especially parasites and pathogens, into natural habitats (e.g., National Research Council 2003, European Union 2007, Padilla et al. 2011).

Currently, there are no international conventions that address aquaculture practices to reduce the risk of invasive species. Despite the lack of binding instruments, there are several voluntary guidelines regarding the introduction and transfer of aquatic organisms.

The Convention on Biological Diversity, acknowledging the risk of invasive species transfer via this vector, strongly urges the consideration of native species for aquaculture and requests signatory countries to conduct scientific risk assessments for introductions before allowing the importation of new species (COP 7 Decision VII/5 45: <http://www.cbd.int/decision/cop/?id=7742>). Guidelines for the prevention of invasive-species transfers from aquaculture have been developed by the Food and Agriculture Organization (Food and Agriculture Organization 1995, 1996, 1997; Arthur et al. 2008; Bondad-Reantaso et al. 2008), the International Council for the Exploration of the Sea (International Council for the Exploration of the Sea 2005), and the World Conservation Union (IUCN) (Hewitt et al 2006) These guidelines have not been adopted by the U.S. or any of the countries in Micronesia. Recommendations for quarantine procedures for the region were made by the Secretariat of the Pacific Community (Humphries 1995), but most of the localities in Micronesia do not presently follow these recommendations, likely due to lack of capacity. SPC is currently working on an Aquatic Biosecurity Regional Strategy, as it has been identified as one of the main priorities at the SPC Head of Fisheries meeting held in Noumea in 2011. This regional strategy will have several components, one of which will be exclusively focused on aquatic species introductions. This component will include technical guidelines for import risk analysis, minimum requirements for pre and post-border quarantine methods, species lists, countries/competent authorities' lists, diseases list, among others.

The U.S. Department of Commerce is developing a national aquaculture policy that would provide a uniform set of regulations for all open ocean aquaculture in federal waters (<http://aquaculture.noaa.gov/>). However, at this time in the U.S., there is no single body that regulates aquaculture; a number of federal, state and local agencies may have jurisdiction, and oversight has been characterized as inadequate for dealing with invasive species (Naylor et al. 2010).

Despite a long history of aquaculture, and significant current official investment and interest, the Micronesian region has not had a uniform aquaculture policy and little attention appears to be focused on the issue of marine invasions. As an example, the alga *Kappaphycus alvarezii* has been brought to numerous Pacific Island countries and territories, beginning in the 1970s. A review of these introductions (Sulu et al. 2004) found only a single case in which a documented quarantine effort was made. Within individual countries, permits and approvals for aquaculture ventures are needed from multiple agencies, most of which deal with issues such as water pollution, earthmoving and construction, but none specifically address non-native species transfer. However, recently there have been several examples of introductions of aquatic species for aquaculture purposes within the Pacific where a risk analysis prior the introduction was carried out, and proper pre- and post-border quarantine measures were implemented. These include introduction of seaweeds from Indonesia to FSM, introduction of sandfish (holothurians) from Fiji into Kiribati, introduction of seaweed (improved variety) from Indonesia to Fiji, introduction of red tilapia from American Samoa to Samoa, introduction of GIFT tilapia from Malaysia to Solomon Islands, introduction of freshwater prawn from Thailand to Fiji, introduction of seaweeds from Malaysia to Papua New Guinea (PNG), and introduction of blue shrimp from Brunei to Fiji.

Other than import regulations, we were not able to find regulations that dealt with

preventing escapes (or movement) of non-native species or genetic material (although the new biosecurity bills being developed for Palau, FSM and RMI have specific sections dealing with the introduction and transfer of live organisms, including pre- and post-border quarantine measures, required certificates, and health certificates). On the whole, aquaculture policies and practices generally do not seem to be integrated with biosecurity plans or concerns. For example, the government of Palau is now considering the removal of tilapia from its list of prohibited species, and promotion of its use in aquaculture, despite many years of effort on the part of conservation agencies and community volunteers to eradicate tilapia there. The new plan, however, is an improvement over earlier tilapia introductions into Palau because it involves the introduction of GIFT Nile tilapia, which is a good option for aquaculture development and income generation. Previous introductions of tilapia in Palau involved the mossambicus tilapia (*O. mossambicus*), which is not only less suited for aquaculture, but also has a high invasiveness potential.

Biosecurity issues, both in terms of aquaculture disease and non-native species that might escape into the wild, are addressed in a draft version of CNMI's Aquaculture Development Plan. The policy is being developed by the Northern Marianas College Cooperative Research Extension and Education Service (NMC-CREES); its overarching goal is to increase aquaculture over the next five years. The plan specifically identifies the need to (a) establish a quarantine facility, (b) improve the capacity to diagnose aquaculture diseases, (c) carry out a risk assessment for any aquaculture species proposed for import into CNMI and (d) develop a list of potentially invasive species for CNMI. The draft plan lays out the need for funding for additional personnel with technical expertise in several areas. However, there also was no specific request that would increase local capacity to carry out risk assessments for proposed non-native species introductions, to monitor for escapes, or to carry out a rapid response if such escapes are detected; it is not clear what resources would be available to implement this plan.

A draft Guam Aquaculture Plan is currently being reviewed by the SPC and the University of Guam, but the plan does not directly address biosecurity issues.

In the FSM, the National Aquaculture Plan will be developed through a national consultation which will be held in 2013. A profile of aquaculture on Pohnpei (Pohnpei Marine Development 2004) outlines opportunities and constraints for further development of the industry. Non-native species are addressed only briefly. The report acknowledges the lack of regulation on the importation of aquaculture species and on the industry itself, as well as the lack of ability to enforce any existing permit requirements.

The aquaculture policy for RMI is currently under revision. We were unable to obtain a copy of the current plan but were told that issues of non-native species would be addressed in the revised version.

4.2.2 Compliance with Regulations and Practices

We were unable to determine the degree of compliance with existing regulations for import and use of aquaculture species, or the ability of agencies to enforce them. Data collected by relevant agencies are sparse; most available information was anecdotal, being limited to observations and incidents with little or no documentation.

Within Micronesia, as elsewhere, there is likely some amount of unofficial or unapproved aquaculture using non-native species. We were told of such attempts that were started without the approval of relevant agencies, including the following:

- In 2009, an algal species (*Gracilaria* sp.) from the Philippines and approximately 5,000 Japanese abalone (*Haliotis asinina*) were reportedly set out in pens near the Tinian port without an environmental review. We were told that the algae were hand-carried on an airplane to Tinian in coolers, which were not inspected by quarantine officers. The operation has since been shut down by management agencies, but approximately 1,700 abalones are apparently still present on the island.
- In 1989, the introduced golden apple snail (*Pomacea canaliculata*) was discovered growing in tilapia aquaculture ponds on Guam. The snail was being harvested and sold by the farmer, who told government officials that it had arrived accidentally with the tilapia fry imported from Taiwan (Smith 1992). In 1990, officials ordered the farmer to destroy the snails and subsequent surveys of his ponds and nearby stream indicated that he had complied. However, a dense population of the snail was found one year later in a Mangilao wetland, some 20 miles from the aquaculture facility, where it was being collected by local people.
- A student at the University of Guam reportedly planted two non-native oyster species from the Solomon Islands and Palau in Sasa Bay (Apra Harbor), Guam, in 1978 and 1979 as an aquaculture experiment. At least one of these two non-native species successfully spawned and recruited (Braley 1984); oysters were stolen from one of the student's study sites. The outcome of this intended transplant is unknown.
- On Kosrae, there are reports of a non-native, salt-water catfish species that first appeared around the harbor area where Chinese fishing vessels anchor, according to officials there. It is unclear whether this species was intentionally brought or might have been an accidental release.

In addition, poaching is reported to be a problem for aquaculture on Chuuk, and could potentially compromise any biosecurity measures in place. We were told that a Korean operation brought coral perch (family Scorpaenidae) from Korea to Chuuk Lagoon, where they were kept in pens to be raised to market size. In the first year, someone cut the pen net, releasing approximately 1,000 individuals. It is believed that all of the fish were caught, as they tend to school and are unafraid of humans. Poaching of smaller-scale local operations is apparently also not uncommon. Enforcement agencies apparently lack the capacity to deal with this problem.

Table 4.1 Summary of current regulations, standards, enforcement and compliance for the imports of live organisms.

	U.S. Military	Guam	Hawai'i	CNMI	RMI	FSM	Palau
Regulations	Abides by local regulations	No restrictions for 8 or fewer individuals; unofficial white list for >8; additional permits decided case-by- case	Lists of conditional, restricted and prohibited species. Permits for restricted species require site inspection.	“Harmful” invertebrates disallowed; other permits on case-by- case basis; unofficial white list used for freshwater fish	Permits on case-by- case basis	No CITES organisms; organisms not already in FSM, case-by- case basis	Tilapia only prohibited marine/aquatic species; organisms not already in FSM, case-by- case basis with NISC review; aquaculture imports held in quarantine 7 days for observation, sort out non-target species
Enforcement at ports of entry	Civilian enforcement at ports	Seaports/airports: cargo inspected based on bills of lading, baggage based on declarations; no mail inspection without probable cause					
Post-entry enforcement	Same as civilian	Not illegal to possess import- restricted organisms	N/A	No capacity	No capacity	No capacity	Quarantine can seize illegally imported organisms

	U.S. Military	Guam	Hawai'i	CNMI	RMI	FSM	Palau
% cargo, baggage, passengers screened	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown
Effectiveness of screening	Unknown	Unknown	Unknown	Unknown; reports of illegal organisms in food markets; one case of high-profile illegal aquaculture	Unknown; little anecdotal evidence of smuggling	Unknown; little anecdotal evidence of smuggling	Unknown; suspected smuggling and illegal trade especially in the southwestern islands
Export screenings	Prior to moving personnel, all personal effects screened in-home	Brown tree snake only.	Ag X-ray screening on departure for U.S. Mainland	None			Ag can inspect

4.3 Current and Anticipated Live-organism Trade

4.3.1 Aquaculture

Hawai'i and Micronesia have a long history of moving organisms into and within the region for aquaculture and for restocking declining wild populations. Some of these efforts have ceased, such as the introduction of the topshell (*Trochus niloticus*), which now has protected status on some islands where it has become established; others, such as the intra-regional movement of giant clams (family Tridacnidae), continue to this day. This history of marine species transfers is detailed by Eldredge (1994) and includes fish, crustaceans, mollusks and algae from both temperate and tropical locations. In addition, the spread of diseases and pests of aquaculture species in the Pacific is reviewed by Humphries (1995). Currently, there are a number of aquaculture facilities in the region.

Nearly all countries and island groups in Micronesia promote aquaculture as a way to increase local food supply and income. Below, we outline briefly some of the current activities by location.

4.3.1.1 Guam

On Guam there are three commercial facilities and a facility run by the University of Guam. The main species being imported are tilapia (*Oreochromis* spp.), white-legged shrimp (*Litopenaeus vannamei*), walking catfish (*Clarias batrachus*), and milkfish (*Chanos chanos*); the first three species are raised for food, and the latter is used for bait by tuna longliners. These organisms are generally imported from Taiwan, Malaysia and the Philippines. Some trials are also currently underway for red snapper and humpback grouper imported from Palau. The one facility we visited on Guam is located on a cliff and drains water from its tanks onto a limestone pond above the reef flat. Stock of the diatom *Chaetoceros gracilis* culture for this facility is occasionally imported from Hawai'i, and brine shrimp (*Artemia* sp.) is ordered from various off-island businesses; neither food source is included on Guam's white list.

Other marine species that have been imported for the aquaculture trade include giant clams, the Australian oyster (*Crassostrea echinata*), the Pacific oyster (*Crassostrea gigas*), the Australian rock oyster (*Saccostrea commercialis*), the Solomon Island mangrove oyster (*Saccostrea cucullata tuberculata*), the topshell (*Trochus niloticus*), the limpet (*Cellana mazatlandica*), the penaeid shrimps (*Penaeus monodon* and *P. stylirostris*), the mangrove crab (*Scylla serrata*), and the mullet (*Mugil cephalus*) (reviewed in Eldredge 1994).

The draft Development Plan for Aquaculture on Guam includes a section evaluating high-potential species for aquaculture development. For several of the candidate aquaculture products (e.g., grouper, mangrove crabs, freshwater prawn), the fry will probably need to be imported from overseas.

4.3.1.2 Commonwealth of Northern Mariana Islands.

On Saipan, NMC-CREES is active in promoting aquaculture, including tank-reared white-legged shrimp (*Litopenaeus vannamei*), various tilapia, wild-caught rabbitfish (*Siganus*

sp.), and mullets (*Mugil* spp.). NMC-CREES was also involved in a venture on Tinian that involved placing Japanese abalone (*Haliotis asisina*) and algae (*Gracilaria bailinae*) from the Philippines in cages near the seaport (as noted previously). The latter operation was shut down following questions about whether it had received appropriate environmental review. NMC-CREES has recently sponsored a conference on open ocean cage culture, which it is promoting as easy to do and harmless to the environment, and is the lead agency in charge of developing an aquaculture plan for CNMI.

The history of aquaculture on Saipan includes (a) the rearing of shrimp imported from Guam and the Philippines in a flow-through system, (b) giant clams brought from an aquaculture center on Palau and placed in the lagoon (these efforts failed due to poaching), and (c) the importation of the topshell (*Trochus niloticus*) in 1938, during the Japanese period. The last is now a protected species. Currently, a private venture, Saipan Aquaculture, raises white-legged shrimp which it sells locally and exports to Guam for food and to Asia for broodstock. There are eight tilapia growers in CNMI raising three strains of the fish.

4.3.1.3 Republic of the Marshall Islands.

On Majuro, current aquaculture ventures include giant clams (broodstock from various locations in the Marshall Islands), corals raised for the aquarium trade and black pearl oysters (*Pinctada margaritifera*). Microalgae are brought in from Australia, Hawai'i and Florida and used as food for these ventures. A barramundi (*Lates calcarifer*) and cobia (*Rachycentron canadum*) aquaculture project, which brought stock from a hatchery in Australia, failed about two years ago for economic reasons. Marine Resources officials had raised concerns about whether cobia, which are a highly migratory species, were appropriate for aquaculture, but the project was ultimately approved. It appears that all animals were removed when the facility closed. *Trochus niloticus* was also brought to the Marshalls by the Japanese and is still present there.

4.3.1.4 Kosrae.

Giant clams (with broodstock from various locations within Micronesia) and corals are now being raised on Kosrae. A state-funded project to raise local mud crabs (*Scylla serrata*) is also in operation, with crabs cultured in a state-run hatchery and out planted to grow-out tanks. The topshell (*T. niloticus*) from Pohnpei and the green snail (*Turbo marmoratus*) were brought to the island in the 1940s or 1950s, with *T. niloticus* having become established; *T. marmoratus* was an unsuccessful introduction. Kosraean officials report that *T. niloticus* were protected from fishing until they established populations.

4.3.1.5 Federated States of Micronesia.

The development and promotion of aquaculture is one of the major program areas under development for the College of Micronesia, which has campuses in all the FSM states. Among the targeted organisms are pearl oysters, sea cucumbers and rabbit fish (College of Micronesia 2009). The pearl-oyster program is the most developed of these programs, and is underway on Pohnpei. The Pohnpei Agricultural and Trade School previously cultured pearl oysters, sponges, corals, and marine ornamental, but closed in 2005. Other species

recently proposed or tried for aquaculture there include the alga *Kappaphycus* (introduced in the late 1980s from the Philippines, and slated for re-introduction from Indonesia in the near future), white-banded sea perch and milkfish (the latter having been brought in 2004-2005, probably from the Philippines). A successful private sponge culture in Pohnpei Lagoon was established in the 1980s and exported quality sponges. We were unable to determine whether these operations are still in existence. A proposal to farm tilapia was recently turned down by Marine Resources, however these fish have recently become established in the island's streams and are thought to be an escaped or intentional illegal aquaculture species.

The red alga *Euchema spinosum* and one additional *Euchema* species were also attempted for aquaculture on Pohnpei, but low yields due to grazing by rabbit fishes made this economically unfeasible, and the project was abandoned in the early 1980s. However, these algae species were also brought from Pohnpei to Kosrae, Majuro, Mili and Likiep. While it does not seem that the algae survive well on the reef, they were reported growing on aquaculture structures in Likiep (Eldredge 1994). The topshell (*T. niloticus*) was brought to Pohnpei from Chuuk and Palau in the 1930s, resulting in a fishery peaking in 1951 (Eldredge 1994).

On Chuuk, known established non-native species are the result of aquaculture introductions. These include *T. niloticus*, established in the 1930s, and one or two species of sea cucumbers. A more recent attempt at largescale aquaculture by a Korean firm was foiled by poachers (see Section 4.22). The company has an ongoing Memorandum of Understanding with the Chuukese government to continue aquaculture research, but no new activity has occurred for two to three years. A government hatchery raises pearl oysters, but these are derived from local stock. There are about 20 giant clam farms on Chuuk, with seed material coming from Pohnpei. Poaching is reported to be a problem for these smaller local farmers as well.

On Yap, native sea cucumbers, coral and fish are raised in aquaculture, as well as giant clams from Palau. Non-native tilapia have invaded mangrove system and are perceived to be bothering native fishes.

4.3.1.6 Palau.

The Micronesian Aquaculture Demonstration facility on Palau produces giant clams for outplanting and export for aquariums and is involved in pilot projects for the rearing of other local organisms. Other aquaculture species include groupers (*Epinephelus fuscoguttatus*), shrimp, milkfish and mangrove crabs from the Philippines and Taiwan. Species that have also been tried in Palau include the Pacific oyster (*Crassostrea gigas*), rabbit fish (*Siganus* sp.), coral trout (*Plectropomus leopardus* and *P. aerolatus*), and Napoleon wrasse (*Cheilinus undulatus*).

4.3.2 Pet/Aquarium Trade

Because detailed records are not kept in the various jurisdictions of Micronesia on pet trade of aquatic organisms, we were unable to obtain much information on the types and numbers of marine species imported to Micronesia for home and commercial aquaria. Overall, the

region is likely a net exporter of marine aquarium species. However, an estimated 149,650 fish for aquaria (reported only as “tropical fish”) were imported to Guam from foreign sources between 2007-2009 (Walsh et al. 2010). It is unknown how many additional fish may have arrived from domestic sources or how many of the total were marine species. Additional unrecorded sources of marine species for aquaria include species ordered online and arriving to the region via domestic postal mail or courier services. It is expected that most aquarium species are shipped via air (Cole et al. 1999). Inspections are challenging because these shipments tend to not be well-labeled and inspectors have insufficient training to identify species. There is also little self-regulation within the industry to screen for potential invasive species (Gertzen et al. 2008).

There are relatively few retail outlets in Micronesia for aquarium fish, invertebrates and algae. For example, we are aware of two commercial outlets on Guam. Freshwater aquarium plants and animals are also sold at the local farmer’s market and at a store located on one of the U.S. military bases on Guam (the Navy exchange). DAWR receives about 15 import requests a year from pet trade importers, with organisms coming mostly from Taiwan, Malaysia, Philippines, Korea, and the U.S. mainland.

4.3.3 Live Food Imports

On Guam, some 30 importers currently bring in about 50 live-food imports a year. These include live lobster, clams, abalone, mangrove crabs, and coconut crabs. These live-food items are imported from a variety of locations, which include the FSM, Philippines, U.S. mainland and New Zealand. Biologists from the USGS and the Smithsonian Institution visited seafood markets that carried live fish and shrimp on Guam in Feb 2010. Customers had the option of taking home live seafood (Walsh et al. 2010). We also observed live fish, coconut crabs (*Birgus latro*) and shrimp for sale at the Farmers Market in Dededo, Guam.

While it is possible that fishing vessels may also carry live seafood (see Section 4.2.2), we have no data on the frequency or extent to which this occurs or the possible species involved.

4.3.4 Live Bait and Other Vectors

Milkfish, imported from outside the region, are raised commercially for bait. Other than this, there does not seem to be a market in the region for imported live bait. We did not find any evidence of the importation into the region of live marine species for other uses, such as biological control or scientific research.

4.3.5 Expected Increase in Live Organism Importation

Currently, legal importation of live marine organisms appears to be fairly limited in the region; however, this may shift with an increase in population on Guam.

Globally, aquaculture production has more than doubled both in value and volume in the past decade, becoming one of the fastest-growing sectors in the world food economy (Naylor et al. 2010). This trend is likely to increase as pressure increases on dwindling wild populations of fish and other seafood. In the region, aquaculture is expected to increase

(Ponia 2010), and local aquaculture projects will likely continue to be encouraged as the population grows. In addition to increasing the risk of importing pest species (including disease organisms), aquaculture-related activities, such as the movement of stock animals and aquaculture equipment and structures into and within the region may also increase the risk of non-native species transfer.

It is also likely that the number of aquarium enthusiasts and the demand for salt water aquarium species will rise along with the general increase in population related to the Guam buildup.

Relevant to the Buildup, demand for live food could rise with increase in population and prosperity. The species and number of individuals being imported both legally and illegally is likely to be tied to the ethnic makeup of workers and military personnel coming to the region. For example, seizures of illegally imported animals and animal products on Saipan increased with the increase in Chinese nationals who came to work at the island's garment factories (see Section 4.1.3). Among the risks of live-food imports are accidental or intentional releases by individuals hoping to start populations they can harvest. With the closure of the garment factories on Saipan, the grow-out of non-native species for use as a food resource by alien workers is reported to have declined, and will likely continue to decline (barring the growth of similar new industries on the island).

While numbers of organisms and sources are unknown, it is certain that the amount of goods and personnel moving into and within the region will increase. It appears that such an increase could strain the available capacity to inspect and control the flow of these organisms, since there are reported to already be limitations in this regard at the present time.

4.3.5.2 Other Micronesian Countries.

Officials we spoke with at nearly every jurisdiction in the region felt they were understaffed, underequipped, and undertrained to carry out thorough inspections of the current amount of cargo, baggage and passengers, much less handle any potential future increase or carry out any post-border enforcement. Other barriers to effective detection and enforcement include social and cultural factors. For example, one agriculture inspector in FSM indicated that he was embarrassed to search the suitcases of female passengers. Other possible hurdles to biosecurity measures mentioned by inspectors and managers in the region included nepotism, favoritism, public distrust of the government, and land-ownership regulations that hamper government agencies from carrying out management/eradication programs that require access to privately-held lands.

4.4 Conclusions

4.4.1 Pre-border Biosecurity

Trade in live marine organisms is a major vector for the transfer of non-native species around the globe. However, there are no international conventions prohibiting or regulating trade that focus explicitly on non-native species. U.S. federal law prohibits the importation of a few non-native species under the Lacey Act (1900) and the Plant Protection Act (2000), however only a few marine or estuarine species are listed.

Within the Micronesian region, most jurisdictions maintain either “white lists” of allowed species, or lists of prohibited or restricted species. With the exception of Hawai’i, Guam, and Saipan, few lists or regulations address marine species, having been developed primarily to protect agriculture. Several other gaps exist in terms of pre-border biosecurity for movement of live marine organisms:

None of the states or countries in the region appears to have the capacity to carry out thorough inspections of luggage and cargo in terms of trained personnel. Many lack equipment such as X-ray machines and computers that could make enforcement more efficient and effective. Anecdotal information indicates that smuggling of live species is occurring throughout the region, including estuarine and marine organisms.

None have the capacity to carry out investigations or effective enforcement beyond ports of entry. In some cases, this is due to discrepancies between import regulations and other laws, as in Guam, where it is not illegal to possess certain species prohibited for import. Domestic mail is not routinely inspected, providing a potentially important (but poorly documented) pathway for trade in non-native species between the continental U.S. and Hawai’i, Guam and CNMI.

Even for declared or permitted live imports, species-level identifications, labels and any certification (of disease-free status or absence of associated organisms) are often poor, making any assessment and pre-screening difficult at best. Little to no screening of outgoing cargo occurs in the region.

4.4.2 Post-border Biosecurity

While it is clear that live marine species are currently imported into the region and also transferred between island groups for food, bait, pets/aquaria and aquaculture, there are few regulations, guidelines, and plans to minimize potential invasion risks. This is perhaps most relevant for aquaculture, because (a) the Micronesian region has a long history of aquaculture and (b) most countries and island groups are actively encouraging the expansion of aquaculture.

Few countries or island groups in the region have an articulated plan for aquaculture development and practices (such plans are being developed for Saipan and the RMI). We did not encounter any regulations that dealt with preventing escapes of non-native species or genetic material. Many of the species used for aquaculture are non-native and potentially carry a high risk of invasion, relative to accidental introductions, having been selected explicitly for traits including hardiness, rapid growth, and large body sizes, and for the ability to do well in the salinity and temperature regimes in the region.

Aquaculture species also present a risk of introducing plant pests, animal parasites, pathogens, and other hitchhikers that could impact the aquaculture species, native communities, or natural resources.

We found several gaps in biosecurity related to aquaculture, including:

- The decision process for permitting use of selected species for aquaculture, in terms

of assessing possible risks of invasion, is often not well defined.

- While many of the countries and states in the region have regulations aiming at insuring that such imports arrive disease- and pest-free, there appears to be little capacity (including quarantine facilities and technical staff) to ensure that this is the case.
- Measures to prevent the escape of non-native aquaculture species have not been entirely successful. Breakage of pens, poaching, natural disasters (e.g. typhoons, floods), and other incidents have resulted in the release of non-native species.

Illegal aquaculture using non-native species also appears to be occurring to some extent in the region, in the form of small scale backyard aquaculture setups. On the whole, aquaculture policies and practices generally do not seem to be integrated with biosecurity plans or concerns, either on a regional basis or even within individual countries.

4.4.3 Live Trade and the Buildup

It is likely that the Buildup will result indirectly in some increased trade in live marine organisms for the following reasons:

- An increased demand for live seafood. Construction workers and other workers moving to the region to provide services for the increased number of service personnel and their families are expected to come from Asian countries in which fresh food, including live seafood, is highly prized. An increase in the island's population due to the Buildup is also likely generally to result in a greater number of people who can afford to purchase fresh, imported seafood.
- An increased demand for pets and aquarium species due to the expected increase in population and income.
- An increase in aquaculture ventures. As the population of Guam increases, aquaculture may be increasingly promoted as a way to provide local food and to replenish or replace dwindling wild-caught stocks.

It is not clear how management agencies will respond to minimize risks of invasions associated with any such increase in live organism trade. The enforcement of border and post-border regulations on trade in live organisms is the responsibility of civilian governments and outside of the jurisdiction of the U.S. military. Management agencies throughout the region appear to be operating at or beyond capacity at the present time, and are likely to be further taxed by any increases in activity unless systems across the board are enhanced and improved in step with any increases.

PART II.
Risk Assessment

Chapter 5: Assessment of Marine Invasion Risks Associated With Relocation of U.S. Marine Corps Forces to Guam

By Chad L. Hewitt, Marnie Campbell, Paul W. Fofonoff, and Mark Minton

5.1 Introduction

Global marine biosecurity efforts for the last several decades have focused on ballast water (and sediment) mediated species transfers, with several nations developing independent management arrangements while the international community moved towards a binding agreement (e.g., Gollasch et al. 2007; Hewitt et al. 2009a). Ballast water had been implicated as the most likely vector responsible for several high profile marine species invasions (e.g., Carlton 1985; 2001; Carlton and Geller 1993). Examples include:

- the global increase in toxic dinoflagellate blooms (Hallegraeff 1993);
- the introduction of the comb-jelly (*Mnemiopsis leidyi*) into the Black, Azov and Caspian Seas contributing to the collapse of the anchovy fishery (e.g., Kideys 2002);
- the dominance of the Asian clam (*Corbula (Potamocorbula) amurensis*) in San Francisco Bay, California (Nichols et al. 1990); and
- the invasion of the northern Pacific seastar (*Asterias amurensis*) into Hobart, Tasmania and Port Phillip Bay, Victoria (Ross et al. 2003).

The finalization of a ballast water convention by the IMO (International Maritime Organization 2005; see also Chapter 2 for discussion), following more than fourteen years of negotiations (Gollasch et al. 2007; Hewitt et al. 2009b, b), has resulted in a refocus on the potential for biofouling to transport species (e.g., Hewitt et al. 2009c, d). Biofouling has long been recognized as an introduction mechanism (e.g., Carlton 1979; Carlton and Hodder 1995) and has been increasingly identified as an equal if not greater risk than ballast water during the last decade (e.g., Hewitt et al. 1999, 2004; Thresher 2000; Gollasch 2002; Hewitt 2002, 2003; Lewis et al. 2003, 2004; Minchin 2006, 2007; Schaffelke et al. 2006; Schaffelke and Hewitt 2007; Hewitt and Campbell 2008, 2010; Lewis and Coutts 2010).

Despite increasing awareness of these transport mechanisms, our knowledge base is limited, resulting in the need for decision support tools that provide consistency and transparency during decision making in the face of uncertainty. Risk based decision frameworks for the management of ballast water mediated introductions have been under development since the mid-1990s. The implementation of these Decision Support Systems (DSS) has demonstrated the utility of risk analysis in the field of marine biosecurity.

Application to biofouling however has been slow.

Risk analysis is commonly used for management of such issues because pragmatic decisions can be made that provide a balance between competing environmental and socio-economic interests, despite limited availability of information (e.g., Hayes and Hewitt 1998; Campbell 2005, 2006, 2008, 2009; Hayes et al. 2004a; Hewitt et al. 2006; Barry et al. 2008; Campbell and Hewitt 2008, 2011).

In a marine biosecurity context, conventional risk assessment methodology consists of five steps:

1. Identifying endpoints (within biosecurity common endpoints are a breach in quarantine or a subsequent impact)
2. Identifying hazards
3. Determining likelihood
4. Determining consequences and
5. Calculating risk

This process is similar (following the five step process) to the risk management standard used in Australia and New Zealand (Standards Australia 2000, 2004) and the risk framework agreed by U.S. Aquatic Nuisance Species Task Force and National Invasive Species Council (2007). Marine biosecurity risk endpoints are typically (a) inoculation (breaking the quarantine barrier), (b) establishment, and (c) spread (Figure 5.1).

This chapter concentrates on developing an understanding of the hazards (i.e., potential non-native species which could be transported to Micronesia) and the relative likelihoods of their arrival, based on records of shipping over an 11-year period, resulting in an assessment of the most likely species to arrive in Guam which would break the quarantine barrier (inoculation endpoint) and spread subsequently to other jurisdictions of Micronesia and Hawai'i. Based on information collected from USCG ballast water reporting forms (see Chapter 4), the majority of vessels arrive fully laden and do not discharge ballast in Guam. The situation is less clear for the rest of Micronesia and for vessels transiting from Micronesia to Hawaii. Where vessels arriving to Guam do arrive in ballast, or need to undertake ballast management for trim during off-loading, the discharges are generally small. As a consequence of these low ballast discharge volumes, and also limited data availability for many parts of Micronesia, this risk evaluation concentrated on biofouling related transport alone.

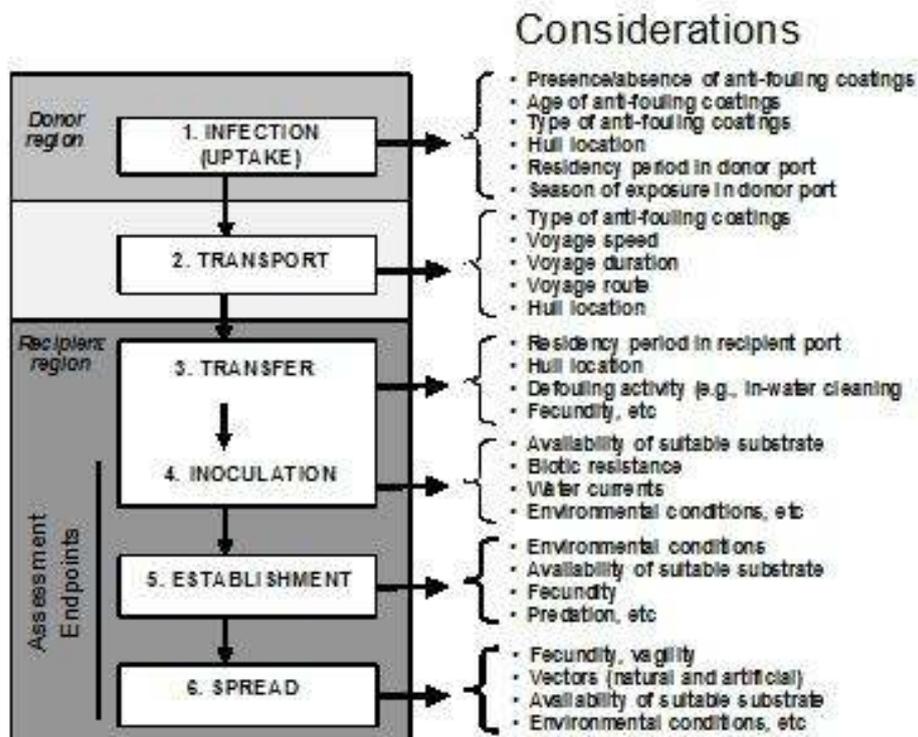

Figure 5.1. Conceptual model of the invasion process, with explicit identification of assessment endpoints in the recipient region and considerations in the risk analysis (adapted from Lewis and Coutts 2010).

5.2 Methods

This risk assessment followed the previously described five step process: identify endpoints; identify hazards; determine consequences; determine likelihood; and calculating risk (*sensu* Standards Australia 2000, 2004). For this assessment, consequence was deemed to be high for any species that was capable of “breaking” the quarantine barrier. Therefore, it evaluates risk across two identified endpoints, inoculation and spread (Figure 5.1), including the initial likelihood of inoculation to Guam was subsequently evaluated for spread to other jurisdictions of Micronesia and Hawai’i (Figure 5.2). This risk assessment focused on two elements: (a) the likelihood of a species’ arrival to Guam, and to Micronesia as a whole and Hawai’i, and (b) evaluating the arrival likelihood independently for each Micronesian State and Hawai’i and via Guam. Likelihood was determined based on analysis of international vessel voyages prior to entry into Micronesia between 1999 and 2009, and Hawai’i between 2006 and 2011, to determine the exposure to global bioregions and using information on the global distribution of known non-native marine species to

determine the likelihood of transport. This data range was the most recently available at the time that the analysis was undertaken and the period for which information on the majority of vessel types was available. Earlier records were not used due to data inconsistencies and cost constraints.

Global non-native marine and estuarine species data derived from Hewitt and Campbell (2008, 2010) were used as a starting point to identify hazards (i.e., marine and estuarine species with known invasion history), with significant effort by the current team to update the known information on global marine and estuarine invasions through literature and web-based reviews of species reports for known invaders and collection of reports of new invaders.

Global non-native marine and estuarine species were categorized as hazards based upon their potential to breach the Micronesian quarantine border, as demonstrated by a history of invasions in other regions.

Based on information collected from ballast water reporting forms, the majority of vessels arrive fully laden and do not discharge ballast in Guam (see Chapter 3). Where these vessels do arrive in ballast, or need to undertake ballast management for trim during off-loading, the discharges are generally small. However, as outlined in Chapter 3, the data for ballast water discharges is incomplete for Guam, especially for U.S. Navy vessels, and also for all ships in other countries throughout Micronesia.

This risk evaluation concentrated exclusively on biofouling related transport alone. The movement of vessel's hulls themselves (instead of ballast water) is the mode of transport for organisms which is analyzed here, and extensive information on geographic origins and traffic history for commercial and MSC vessels was obtained for this analysis. Data on vessel traffic was not available for U.S. Navy combatants, due to concerns about national security (see Chapter 1), and were therefore excluded entirely from this analysis. Hull biofouling is a key vector for marine introductions, as summarized below (see also Chapter 1), and biofouling by ships may provide a useful model for evaluating marine invasion risks.

5.2.1 Identifying Endpoints

The endpoint of the risk analysis is a critical stage in scoping the context of the assessment and determines the detail of consequence analysis to be used (e.g., Campbell 2006, 2008). For example, unintentional introductions of non-native marine species associated with the movements of species, feed stocks, and movement of equipment would typically consider quarantine endpoints – that is any un-permitted breach of the border (e.g., Hewitt and Hayes 2001, 2002; Hayes 2002; Campbell 2006, 2009). Marine biosecurity risk can be evaluated across three endpoints, inoculation (or entry), establishment, and spread.

This risk assessment focuses primarily on the international entry of vessels (inoculation endpoint) into Guam and the subsequent assessment of spread to other jurisdictions of Micronesia and Hawai'i, with less extensive evaluations of establishment. It is worthwhile to note that while the role of Guam as a shipping hub for the Micronesia region and as a primary departure point for shipping heading from Micronesia to Hawaii is important, there

are other potential direct and indirect routes for shipping in the region, all of which may assist in the spread of non-native species to both individual jurisdictions as well as the region as a whole. For example, there is shipping from various Asian ports directly and indirectly to a variety of the jurisdictions of Micronesia as well as ship movement between various islands of Micronesia that may or may not include stops in Guam.

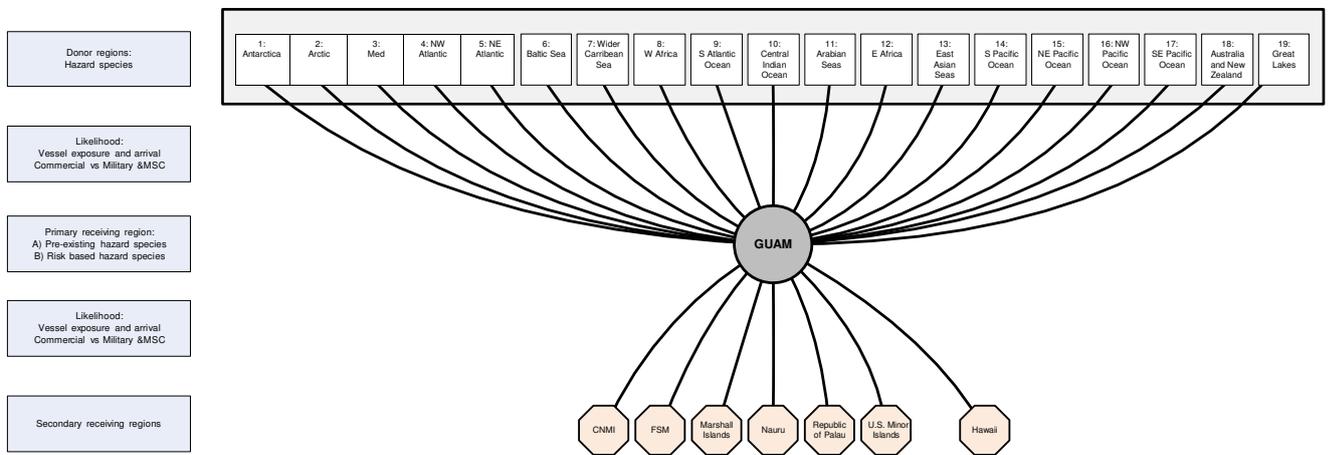

Figure 5.2. Conceptual model of this risk assessment.

5.2.2 Identifying Hazards

Hazards have been defined in this context as non-native marine and estuarine species that:

- have the potential to transcend the Micronesian quarantine border and
- have demonstrated or inferred potential to cause impact.

A comprehensive assessment of the recognized marine and estuarine invasions from throughout the globe was conducted building upon the work undertaken by Hewitt and Campbell (2008) and Hayes et al. (2004a). This provided the basis for identifying species level hazards. This report has compiled information from over 1,000 data sources including primary (peer reviewed journals and books) and secondary ('grey' literature such as websites, policy documents, online databases, reports; typically not peer-reviewed) literature, and information derived from a number of researchers.

Data for global species distribution was recorded using the 18 large scale IUCN marine bioregions (Kelleher et al. 1995) identified in Hewitt and Campbell (2008) (Figure 5.3). These are considered close representatives of widely accepted biological provinces rather than the finer scale ecoregions of Spalding et al. (2007) or the Large Scale Marine Ecosystems (Watling and Gerken 2004). The designation and use of biogeographic boundaries has engendered significant debate in the literature, however the use of provinces with recognition of overlapping boundaries provides the basis for the Kelleher et al. (1995) designation. This system creates a sequence of 'core' and 'transitional' areas which are roughly equivalent to the Spalding et al. (2007) 'ecoregions' used by Molnar et al. (2008). Hayes et al. (2004a) used these 'core' and 'transitional' areas described by Kelleher et al. (1995) in their identification of 'next pests.' However, these finer scale regions do not represent provincial boundaries and therefore do not offer a conservative approach to estimating species distributions.

By recording species at the bioregion level it is assumed that the species is present in all ports in the bioregion. Due to limitations on the data available from many parts of the world, and the rapidity with which species can be transported and spread within a region, this assumption avoids an overly restrictive data collection exercise. Also, pragmatically, data are simply not available on occurrence for a finer-grain spatial scale for many marine species.

The database of global marine and estuarine introductions developed here now includes 2,365 species. Over 98% of the 2,365 species were allocated to possible transport vectors. This followed the criteria and methods proposed by Hewitt and Campbell (2008, 2010) and was based on:

- examination of life history characteristics (at the species level where available);
- morphological characteristics and
- habitat distribution.

Where species-level information was not readily available, genus-level characteristics were used to classify morphological characteristics and habitat associations.

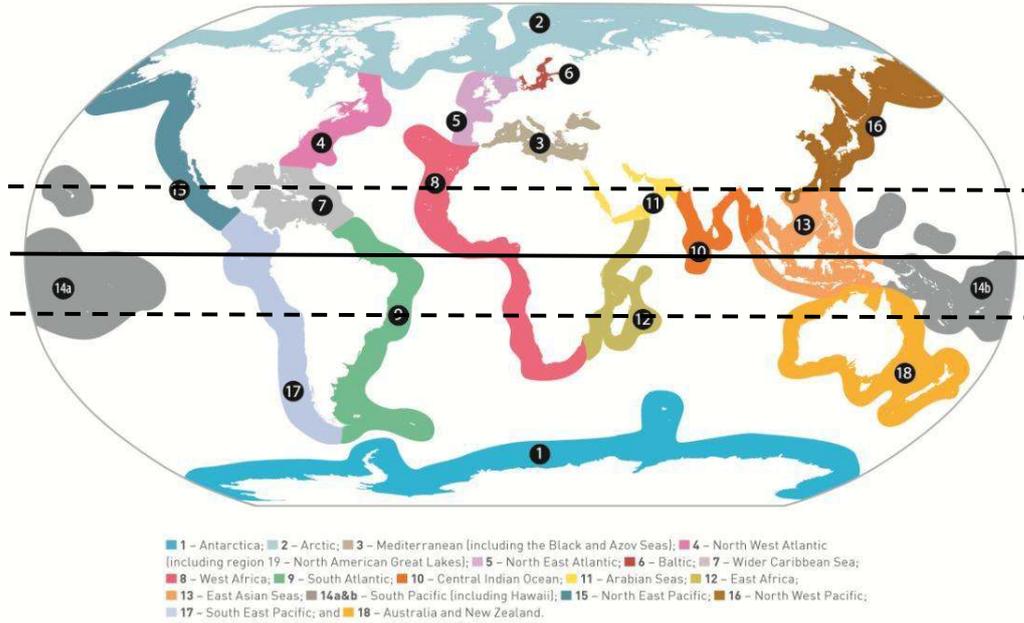

Figure 5.3. IUCN Bioregions as defined by Kelleher et al. (1995) and modified following Hewitt and Hayes (2002). Solid line represents the equator (0°) and dashed lines represent the tropics ($\pm 23.5^\circ$) [Figure from Hewitt et al. 2011; provided with permission from Australian Department of Agriculture, Fisheries, and Forestry (DAFF)]

The global dataset indicates that more species have life history characteristics associated with vessel traffic (ballast water and biofouling combined) than any other vector (Figure 5.4).

This species dataset was restricted further on the basis of records of species in each of the jurisdictions of Micronesia. Within the global dataset, 136 species are recognized as native to Micronesia resulting in a reduction to 2,229 species that have a known history of invasions and are not naturally present in jurisdictions of Micronesia. An additional 109 species are recognized as non-native or cryptogenic in Guam, restricting the hazards to Guam to 2,120 species. A total of 1,358 species were identified as being associated with vessel biofouling in the global dataset, and 1,241 of these species were not known to be present in Guam. Of the 109 non-native or cryptogenic species to Guam, 84 are associated with biofouling. Not all species currently introduced to Guam are present at other Micronesian locations resulting in a latent risk to the various jurisdictions of Micronesia (except Guam) and Hawai'i from Guam identified in Table 5.1.

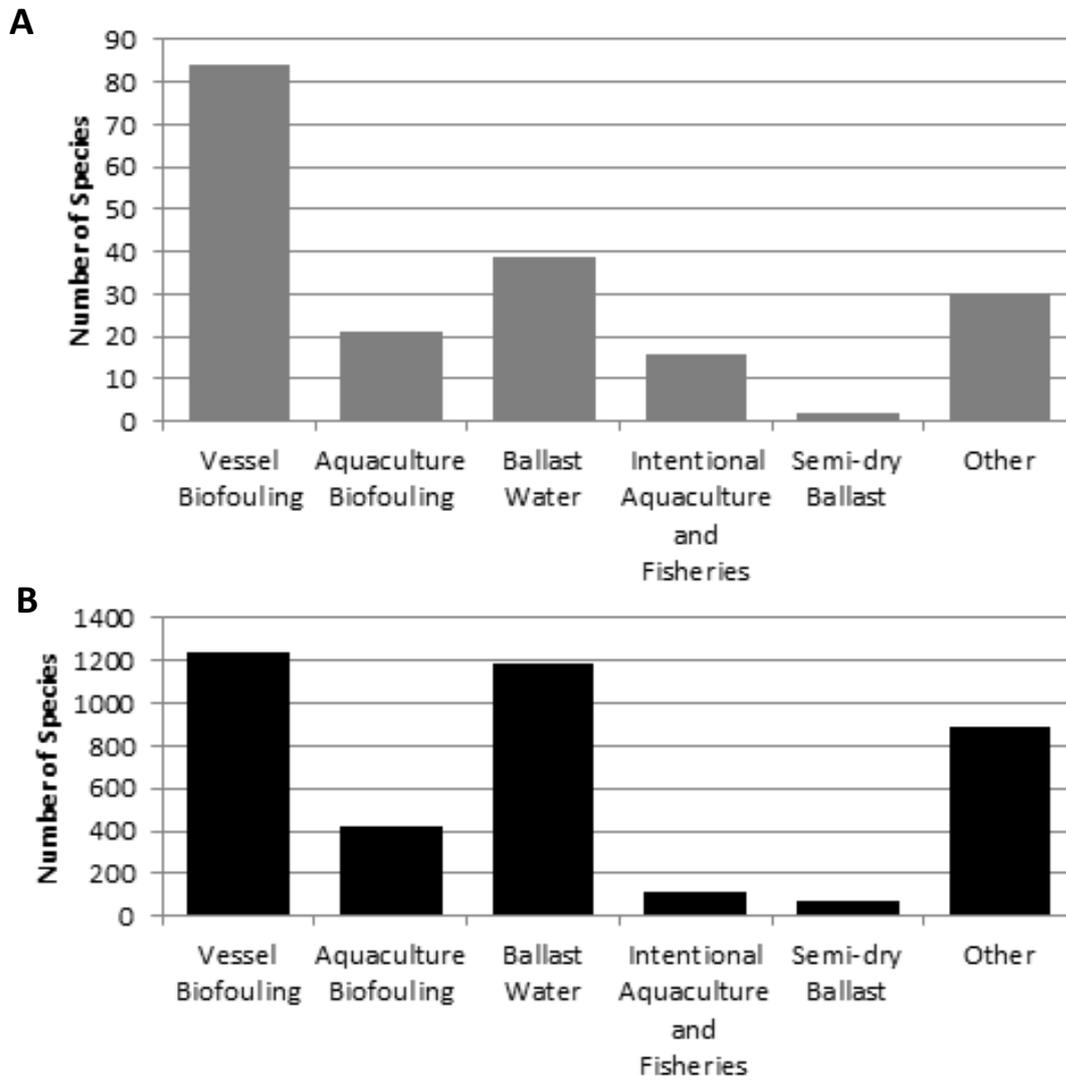

Figure 5.4. Number of non-native and cryptogenic species identified in the global dataset as present in Guam (A) or absent from Guam (B), which are likely to be transported by different vectors.

Table 5.1. Potential exposure to non-native and cryptogenic species already present in Guam (109) or globally (2,365) that are not known to be present in the various jurisdictions of Micronesia (except Guam) or Hawai'i, for A) all transport vectors and B) restricted to species inferred to be transported by biofouling. FSM = Federated States of Micronesia; RMI = Marshall Islands; CNMI = Commonwealth of the Northern Mariana Islands; Palau = Republic of Palau; UMI = United States Minor Islands; HI = U.S. State of Hawai'i

A) All Transport Vectors

<i>Potential Exposure</i>	<i>Guam</i>	<i>FSM</i>	<i>RMI</i>	<i>CNMI</i>	<i>Palau</i>	<i>UMI</i>	<i>HI</i>
Guam (109)		83	79	91	82	100	30
Global (2365)	2,120	2,226	2,238	2,256	2,242	2,297	1,898

B) Biofouling Transport

<i>Potential Exposure</i>	<i>Guam</i>	<i>FSM</i>	<i>RMI</i>	<i>CNMI</i>	<i>Palau</i>	<i>UMI</i>	<i>HI</i>
Guam (84)		65	61	74	66	77	20
Global (1358)	1,241	1,293	1,297	1,333	1,324	1,341	1,018

5.2.3 Determination of Likelihood

The likelihood (or probability) of an event occurring was categorized using a likelihood matrix (Table 5.2). In this risk assessment the likelihood of a biofouling species not currently present in Guam was assessed as a function of the proportion of vessel arrivals in Guam that were likely to transport a species based on the voyage histories of vessels and the global distribution of species. For example, if more than 75% of the vessel arrivals in Guam had visited bioregions with Species X during a voyage duration of 365 days, then Species X would be categorized as having a “high” likelihood of inoculation for the 365 day window: this is an expansion (to include probabilities) on the standard likelihood matrix that has been used in marine biosecurity assessments in New Zealand

(Campbell 2005, 2008; Campbell et al. in review), Australia (Campbell and Hewitt 2011) and the Mediterranean (Campbell 2006). Two significant likelihood endpoints were identified for evaluation of international biofouling species:

- inoculation of species to Guam
- spread from Guam to other jurisdictions of Micronesia.

Table 5.2. Likelihood measures for marine biosecurity risk analysis (modified from Campbell and Gallagher 2007). An event is defined as an activity that may lead to an undesirable outcome.

Descriptor	Description	Probability of event occurring
Negligible (N)	The event is unlikely to occur	<1%
Extremely Low (EL)	The event will only occur in exceptional circumstances	1-10%
Very Low (VL)	The event could occur but not expected	10-25%
Low (L)	The event could occur	26-50%
Moderate (M)	The event will occur in many circumstances	51-75%
High (H)	The event will occur in most circumstances	76-100%

5.3 Inoculation to Guam

The likelihood of species inoculation to Guam was evaluated as transport pressure for each species (ranked negligible to high). Transport pressure can be derived from:

- the species uptake/settlement opportunity to colonize the vessel based on connection with overseas ports,
- the number of vessels arriving from regions where the species is present based on extended voyage characteristics (ranging from 30 days to 5 years) and
- species transport survival based on physical and physiological stress during the voyage.

Several assumptions were made in this analysis:

1. Species were assumed to be able to infect a vessel (via biofouling settlement) at any time throughout the year (equivalent to assuming reproductive activity throughout the year).
2. Species detected in a bioregion and reported in the literature were assumed to have established in the bioregion.
3. Species detected in one location within a bioregion were assumed to be present in all areas (ports) of a bioregion.
4. Vessels were assumed to have some areas without fully active antifouling coatings, such that they were vulnerable to colonization by biofouling organisms;
5. Vessels were assumed to have some areas protected from the hydrodynamic (sheer) forces created by vessel speed.
6. Inoculum pressure was calculated for all of the target locations (jurisdictions of Micronesia or Hawai'i) rather than on a port by port basis.
7. All vessel categories were assumed to be equally able to transport all species.
8. All pathways from various bioregions to Micronesia are equally 'stressful' (e.g. no influence of trans-equatorial transits).
9. Only species listed in the invasive species database are considered a threat, or can be introduced.
10. The invasive species database has complete distribution records for all species.
11. Cryptic diversity, while known to be common in marine organisms, is ignored.

5.3.1 Transport Pressure

Transport pressure was comprised of several elements including:

- the transport frequency (number of opportunities for transport),
- a measure of how readily a species can survive the transport process and
- the inoculation opportunity for a species to depart the vessel and settle in the receiving port.

Similar to the analysis by Hayes et al. (2004a), this assessment assumes that the opportunity for organisms to be transported is directly correlated with the number of ship visits from a region. In keeping with previous assessments (Hayes and Hewitt 1998, 2000; Hayes and Sliwa 2003; Hayes et al. 2004a; Barry et al. 2008), it also assumes that a species record in a bioregion is considered a demonstration of establishment throughout the bioregion, and that all ports in that bioregion are infected.

For the purposes of transport pressure the element of assessment is the vessel, therefore the demonstration of a species likely presence in/on a vessel is the focus, rather than the abundance of a species in/on any individual vessel.

Analysis of vessel activity was initially based on the Lloyds Maritime Intelligence Unit dataset (hereafter Lloyds MIU dataset) representing commercial vessels, petroleum vessels, non-trading vessels, naval vessels, commercial fishing vessels and recreational vessels (>25

m) entering Micronesia from 1999 – 2009 and including all ports of call during this period (this of course does not include items such as the numerous smaller yacht which enter and depart the various jurisdictions of Micronesia and Hawaii). The Lloyds MIU dataset allowed a further differentiation of vessel categories, including separating petroleum vessels from commercial (merchant) vessels, and identifying sub-categories of non-trading vessels.

The Lloyds MIU dataset represents an accumulation of Port State reports and does not represent a complete set for a number of vessel categories. Vessels not able to be self-propelled (barges) are rarely recorded by Port State control. Similarly vessels under 25m length, such as recreational vessels and fishing vessels, are rarely recorded. Military vessels frequently claim sovereign immunity and do not report to Port State control but are hosted by local military. As a consequence, the DoD was requested to provide entry and voyage information on Military vessels, specifically MSC and Warships. Entry information was provided for MSC vessels with limited voyage history; however Warship entry information was only provided for a three year period (2008-2010) and did not include voyage history (see Chapter 3). As a consequence, warships (combatants) could not be assessed herein.

The Lloyds MIU dataset required significant error checking for overlapping voyage statistics. To reduce the overlapping voyage statistics in which individual vessels are represented in multiple records (i.e., locations) at the same time, records from earlier than 1999 were removed as consistency of reporting could not be verified. Poor spatial resolution such as designation of ports as ‘Pacific Ocean,’ ‘Australasia,’ and ‘Southeast Asia’ were assigned to IUCN bioregions where unequivocal, or removed from the dataset. These changes resulted in <5% removal rate for the Lloyds MIU dataset.

Vessels are not of a consistent size, nor do they ‘behave’ in an identical fashion (e.g., Carlton 1985, 1996, 2001; Hewitt et al. 1999, 2004; Ruiz et al. 2000; Gollasch 2002; Fofonoff et al. 2003; Minchin 2006). As a consequence, vessels were divided into a number of categories (and further into subcategories where appropriate) to reflect the various management regimes and previously recognized differences in vessel activity (e.g., Ribera and Bouderesque 1995; Ruiz et al. 2000; Carlton 2001; Lewis et al. 2004; Floerl and Inglis 2005; Floerl et al. 2005; Minchin 2006; Hulme 2009). These are assumed to approximately correspond to vessel behaviors (e.g., maintenance history, voyage characteristics, speed [see Section 5.3.1.3]) however; it has been assumed here that no particular vessel characteristic is more or less likely to transport a species.

Vessel categories identified in the Lloyds MIU dataset include (see glossary also):

- **commercial vessels** including merchant vessels and cruise ships,
- **petroleum production and exploratory industry vessels** including offshore anchor handling/support/supply, pipe laying vessels, drilling platforms/ships and floating production, storage and offloading (FPSO) given they are solely employed within the sector,
- **naval vessels** (both foreign and domestic) including primarily naval auxiliary tankers and MSC vessels,

- **non-trading vessels** which encompass a wide variety of vessel types including the sub-categories of tugs, research vessels, dredges, barges and yachts > 25 m or super yachts (differentiated based on differing behaviors including speed, duration in port, and voyage characteristics) and
- **fishing vessels** including commercial vessels engaged in the industry of capturing wild stocks of living marine resources: fishing (general); trawler (all types); whaler; fish carrier; and fish factory.

As stated above, petroleum industry vessels represent a significant class of commercial (merchant) vessel with widely varying characteristics including long residence times and slow speeds for some vessel types.

Elements of transport pressure are further analyzed below.

5.3.1.1 Opportunity to Infect the Vessel in the Donor Port.

The opportunity for a species to infect (e.g., be taken up in ballast water, settle on or recruit to) a vessel is a combination of the location of operations, the timing of the opportunity being coincident with a reproductively active period for sessile and sedentary species, maintenance history (including antifouling paint condition), and the amount of time available for a species to settle or colonize the vessel.

Biofouling community development begins as soon as materials are placed in the water (e.g., Sutherland and Karlson 1977; Floerl 2002; Prendergast 2010). As a consequence, shortly after being cleaned (in dry-dock or in the water), the settlement of marine organisms and development of a biofouling community begins (see Hayes et al. 2004b; Lewis et al. 2004; Jenkins and Martins 2010). The rate of this development can be reset or delayed through various means, including in-water cleaning and appropriate application of antifouling paints. However, when the vessel is taken as a whole, the 'niche' biofouling areas including sea-chests, bow and stern thrusters, propellers, propeller shafts and rudder areas are likely to have established biofouling communities shortly (3 – 6 months) after cleaning or antifouling paint application (e.g., James and Hayden 2000; Floerl 2002; Hayes 2002; Coutts et al. 2003; Coutts and Taylor 2004; Hayes et al. 2004b; Lewis et al. 2004; Piola et al. 2009). Therefore, few limitations to settlement exist for any individual species when considering the vessel as a whole, hence, all vessels can be colonized.

Settlement opportunity for some species also involves an element of timing. Mobile species associated with biofouling have the ability to swim to the vessel hull or into niche areas; therefore no restriction on the timing of settlement occurs. For species that are sessile or sedentary, typical means of establishing in a new location are either by accidentally getting 'swept' to another location by hydrodynamic forces (e.g., waves, propeller wash, currents), or by reproduction. Many sessile or sedentary marine species spawn gametes (reproductive elements) into the water column where fertilization and development occurs, or hatch larvae directly into the water column – these species are known as meroplankton since they spend a portion of their life-cycle in the water column. Once development has progressed sufficiently (ranging from minutes to months for different species), the larval form is able

to settle onto hard substrate by metamorphosing into an adult.

In order for a meroplanktonic species to be taken into the ballast of a vessel or to settle on a vessel, it is necessary that the species' timing of reproduction (reproductive phenology), and settlement viability for biofouling species, is coincident with the duration in port. Assessing settlement opportunity directly requires a significant increase in our current state of knowledge – there is limited data on the timing or triggers (cues) of reproduction for many non-native marine and estuarine species, particularly in non-native regions. This is particularly important as non-native species expanded on their realized niche to utilize their fundamental niche and hence they often behave in ways that are not recorded within the literature. For example, *Mytilopsis sallei* (black striped mussel) in Darwin harbor, Northern Territory, Australia, produced two, potentially three cohorts in a seven-month period (Campbell and Hewitt unpubl. manuscript). In Hong Kong Harbor, where it is also introduced, it produces two cohorts per 12 months (Morton 2009). In its native environment, *M. sallei* reproduces once every 12-18 months (e.g., Kalyanasundaram 1975). Similarly, the larval durations and metamorphosis requirements have yet to be determined for many non-native species.

Given that settlement opportunity acts to reduce risk, it is more conservative to assume that all species reproduce year-round and therefore have the ability to inoculate any vessel that comes to port, regardless of port stay duration. As more information comes to light, or when the focus is reduced to a smaller subset of species, better life-history information can be obtained and applied to refine predictions in a management context.

5.3.1.2 Transport Frequency.

The number of vessel entries arriving from each bioregion (LPOC) over the period from 1999 to 2009 was calculated as a total across all vessel categories and for MSC. For each of the 1,241 biofouling species not currently established in Guam, the number of vessels arriving from bioregions in which the species was known to be present, either as a native, cryptogenic or a non-native marine species based upon the revised species database from Hewitt and Campbell (2008; 2010), was calculated to represent the raw transport frequency of each species. This number represents the number of potential opportunities for the species to have been transported into Guam waters over the 11-year period based on voyage histories.

In contrast to ballast water transported species, biofouling species accumulate since the last cleaning (including in-water cleaning, dry-docking or antifouling paint application); however this data is infrequently available for evaluation. Most commercial vessels have dry-docking rotations of greater than three years and up to five years (Lewis 2002a; Davidson et al. 2009). In order to capture the likely accumulation of species, the influence of voyage duration on species exposure was assessed by creating voyages into classes of 30 days, 60 days, 90 days, 183 days, 365 days (1 year), 730 days (2 years), 1,095 days (3 years), 1,460 days (4 years), and 1,825 days (5 years) prior to entry into Guam.

The commercial and MSC fleet entering Guam traded with all global bioregions within voyage durations of 365 days (1 year) for either commercial or MSC vessels (Figure 5.5). In other words, the vessels entering Guam had visited all 18 global bioregions within 365

days prior to arrival.

Transport patterns differed between bioregions (Figure 5.6). The increase in transport frequency from bioregions (i.e., number of vessels that had previously visited a particular bioregion) as voyage durations are increased from 30 days to 365 days can be seen with the addition of lighter shades of grey. As would be expected, more distant bioregions such as the North West and North East Atlantic, Wider Caribbean, and the Arabian Seas are largely represented in voyage lengths greater than 183 days.

Commercial vessels (Figure 5.7A) are unevenly distributed across bioregions (Simpsons Evenness = 0.518), with a higher connection (>800 vessel entries) to the East Asian Seas and South Pacific Ocean and a second tier of association (>400 vessel entries) to NE Atlantic and Central Indian Ocean. In contrast, MSC vessels (Figure 5.7B) are more even in their biogeographic spread (Simpsons Evenness = 0.658) with high connectedness (>800 vessel entries) to the Wider Caribbean, NW Atlantic, NW Pacific East Asian Seas and Arabian Seas, and a second tier of association (>400 vessel entries) to the South Pacific, NE Pacific, SE Pacific and Australasia.

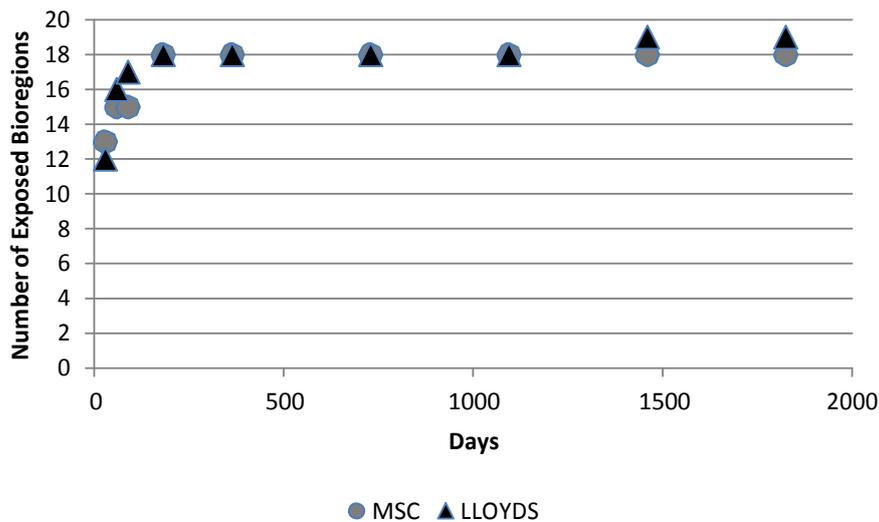

Figure 5.5. Number of bioregions visited by vessels entering Guam between 1999 and 2009 with increasing voyage duration (data from Lloyds MIU and DoD datasets).

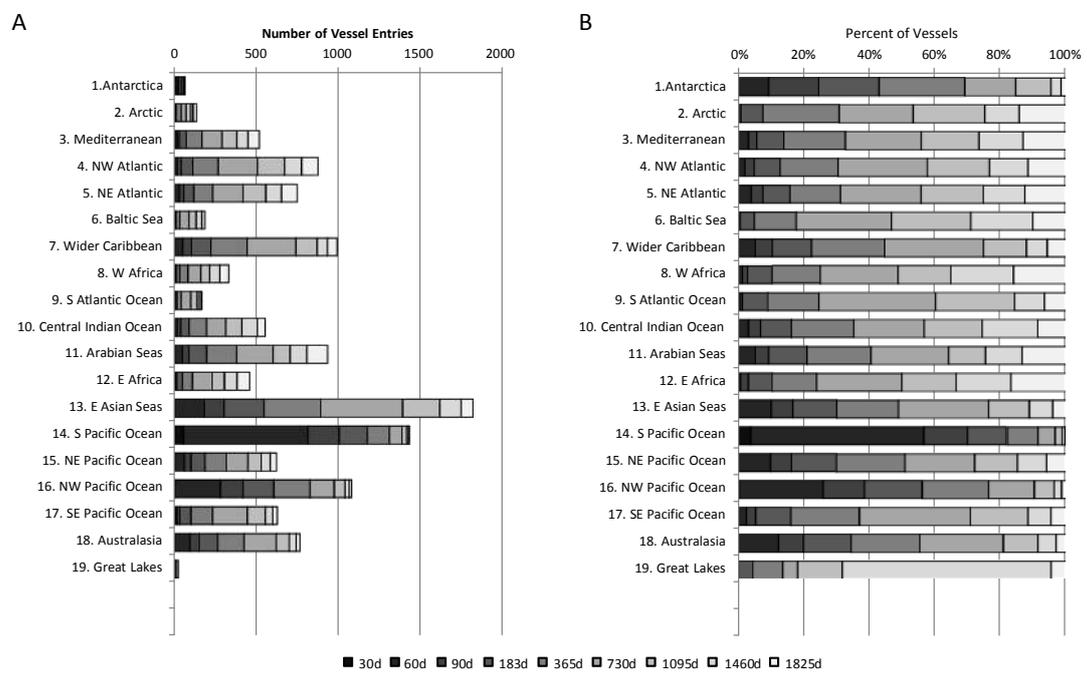

Figure 5.6. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to Guam from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU dataset and DoD dataset).

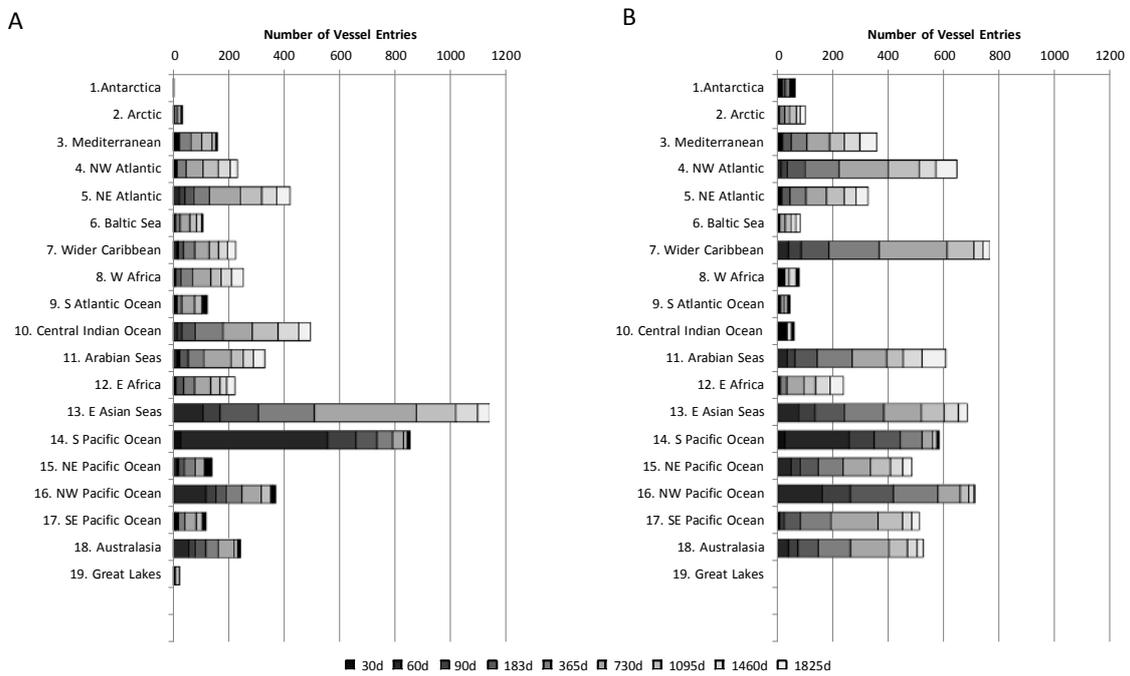

Figure 5.7. Number of A) commercial vessels (all categories) and B) MSC vessel (all categories) entries to Guam from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period (Lloyds MIU and DoD datasets).

5.3.1.3 Transport Survival.

The transport process can create significant physical and physiological stresses on species that influences the ability of a species to survive a voyage.

Physical stress on species is primarily associated with vessel speed, with several studies demonstrating the relationship between speed and shear stress on species survival (e.g. Coutts 1999; Davidson et al. 2009; Coutts et al. 2010a, b). Analyzing the Lloyds MIU dataset for vessel speeds across vessel categories (Figure 5.8) revealed no significant differences across the broad vessel categories, despite significant differences between individual vessels within categories. Vessels in the categories commercial, petroleum, non-trading (specifically tugs, barges, and dredges), illegal foreign fishing vessels (IFFVs) and recreational vessels are known to operate under slow speeds, which can support significantly increased survival (e.g., Floerl and Inglis 2005; Floerl et al 2005; Davidson et al. 2009; Coutts et al. 2010a, b).

Additionally, while vessel speed is correlated with species presence on exposed hull surfaces (e.g. Coutts et al. 2010a, b), numerous protected niche areas such as sea-chests (e.g., Coutts et al. 2003; Coutts and Taylor 2004; Coutts and Dodgshun 2007), bow and stern thrusters, propellers and propeller shafts, will act to provide species the opportunity to survive despite high vessel speeds (e.g., James and Hayden 2000; Hayes 2002; Coutts and Taylor 2004; Hayes et al. 2004b). As a consequence, speed may not provide differentiation between vessel types or significantly reduce risk.

Physiological stress can be created by the type and condition of antifouling paints (e.g., Piola and Johnston 2006) as well as the voyage route. Antifouling paints are explicitly designed to minimize and delay the settlement of epibenthic species on the hull surface. Exhaustive research accounts detail the efficacy and various failures of antifouling paints (e.g., Minchin 2006; Dafforn et al. 2008; see also various publications in the journal *Biofouling*). Most recently, the ban on organotin paints, specifically tri-butyltins (TBTs) has increased the investigations into viable alternatives and resurrected the concerns over biofouling mediated invasions. Note, that Navy and Coast Guard vessels are exempt from the ban on organotin paints. Antifouling paints differ significantly in their intrinsic effectiveness, but also vary according to the method and location of application (Lewis 2002; Lewis et al. 2004; Piola et al. 2009). From a management perspective, information on antifouling paint type, application procedures, efficacy and timing of application is difficult to obtain. As a consequence, the use of antifouling paint information was not considered in this risk assessment.

Physiological stress associated with exposure to changing environmental conditions is likely for biofouling species associated with the external hulls of vessels. Transport between high or mid-latitude regions on either side of the equator will expose species to the physiological stresses of increased water temperature during transit. Similarly, freshwater species in transit across oceanic barriers (e.g., between the North American Great Lakes and the inland waters of Europe) will experience fully marine waters during transit across the North Atlantic. Many trade routes to Micronesia include a significant change in latitude, or transits accompanied by a freshwater transit through the Panama Canal, or a high salinity transit of the Suez Canal. Quantifying the effect of these transits is difficult without specific laboratory analyses of physiological tolerance and exposure for individual species. As this factor only acts to **decrease** the likelihood of transit survival, leaving it out of the current assessment provides a conservative result until definitive information is available. Therefore we have assumed that all voyage pathways are equally stressful.

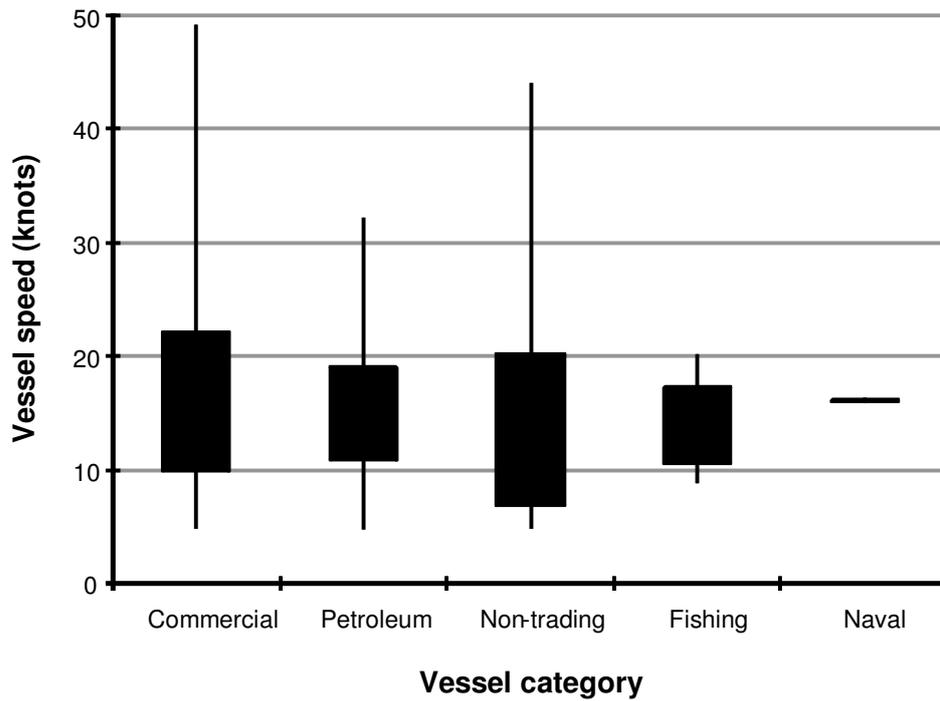

Figure 5.8. Reported speeds for vessels based on vessel categories (maximum/minimum reported range indicated by line, 90% confidence intervals around the mean represented by blocks). Slow moving drill rigs and drill ships have been estimated to have a vessel speed of 5 knots and are included in with petroleum vessels; recreational vessels >25 m are included in non-trading vessels. Vessel speeds for IFFVs and recreational vessels <25 m could not be obtained. Data from the Lloyds MIU dataset (Hewitt et al. 2009e).

5.3.1.4 Inoculation Opportunity.

Similar to the opportunity for species to settle in the donor port, attached biofouling species need to either reproduce (sexually or asexually) or be scraped off the hull to inoculate a receiving port. Any sedentary, infaunal and mobile fauna associated with biofouling assemblages (e.g., gastropods, crabs and other mobile crustaceans, small fishes such as blennies and gobies, seastars), including those occurring in sea-chests, will have increased opportunity to depart the vessel either by being dislodged or by swimming or dropping off the vessel. Inoculation opportunity is typically believed to be a function of port duration, and the reproductive maturity or vagility (ease of movement) of individual species.

As with the previous discussion, reproductive activity can be influenced by many factors including the intrinsic maturation rate of the individual, and extrinsic factors such as temperature and day length (e.g., Minchin and Gollasch 2003). These influences on reproduction are difficult to ascertain and expected to vary among ports. The action of being scraped off a hull is a stochastic process and depends on a number of elements including the species location on the hull, type of antifouling coating, its attachment mode, and the handling of the vessel in port. The vagility of sedentary and mobile fauna associated with biofouling is, by definition, high. These species are capable of moving and will therefore have the opportunity to leave the vessel at any time once in port. As a consequence, biofouling and biofouling associated species were assumed to have the ability to reproduce (sexually or asexually), escape and/or swim away or be scraped off, all year around.

5.3.2 Summary of Inoculation to Guam Likelihood

One approach to estimate likelihood is to determine the relative number of opportunities for a species arrival and entry into a new location as outlined previously. To reiterate the various assumptions used in this approach: species were assumed to be present in all areas (ports) of bioregions to which they had been introduced or were native; all vessels were deemed to have an equal opportunity of a species settling, regardless of time of year or of time since dry-docking, in-water cleaning or antifouling paint application; and all transport pathways were considered to be equally stressful. Note that this is a conservative estimate and it is not currently possible to refine further as data are not sufficient at the present time for this.

To determine likelihood of inoculation for an individual species, the number of vessels arriving from all bioregions where that species was present (as a native, cryptogenic or non-native population) was summed to provide a cumulative number of vessel opportunities for that species to be transported into Guam. This value was then divided by the number of vessels entering Guam to provide the percentage of total opportunities for entry as a relative measure. This relative probability was then categorized into Likelihood probabilities (Table 5.2) to provide a categorical rank for each of the nine voyage periods (30 days, 60 days, 90 days, 183 days, 365 days, 730 days, 1,095 days, 1,460 days, 1,825 days) as a function of percentage of total visits (Figures 5.9 & 5.10).

Twenty-one per cent (n=264) of the 1,241 biofouling associated non-native species not present in Guam were identified as having a negligible inoculation likelihood in the initial 30 day voyage period (Figure 5.9B), however the number of species categorized as “Negligible” reduced to 8% for 60 day voyages and subsequently to <1% for voyages greater than 365 days. In other words, as the assessment examined longer voyage durations, more bioregions were visited resulting in fewer species assessed as having less than 1% of vessels likely to transport the species.

In contrast, more than 18 per cent of the 1,241 biofouling associated non-native species not in

Guam were ranked as having Moderate or High inoculation likelihood across all voyage lengths and vessel types (ranging from 26.3% in 30 day voyages to 18.3% in 1,825 day voyages), with **72 biofouling species having a “High” likelihood** (>75% probability) and **155 biofouling species having a “Medium” likelihood** (>50% probability) of inoculation to Guam after 1,825 day voyages (5 years) (Table 5.3).

In evaluating the inoculation likelihoods, the relative contribution of MSC vessels to the number of “High” and “Medium” likelihood species were examined. Military vessels were found to increase the “High” likelihood of inoculations for voyages greater than 60 days (2 months), with a peak after voyages of 183 days (40 species), reducing to a shift of 10 species for 1,460 days (4 years) and 1,825 days (5 years) voyage lengths (Figures 5.9, 5.10 & 5.11). These shifts in additive inoculation likelihood attributed to military vessels is greater than their contribution to vessel numbers alone, particularly recognizing the significant limitations of data gaps and noting that MSC vessels are likely to spend a greater amount of time in port, thus increasing both the vessel infection and port infection likelihoods.

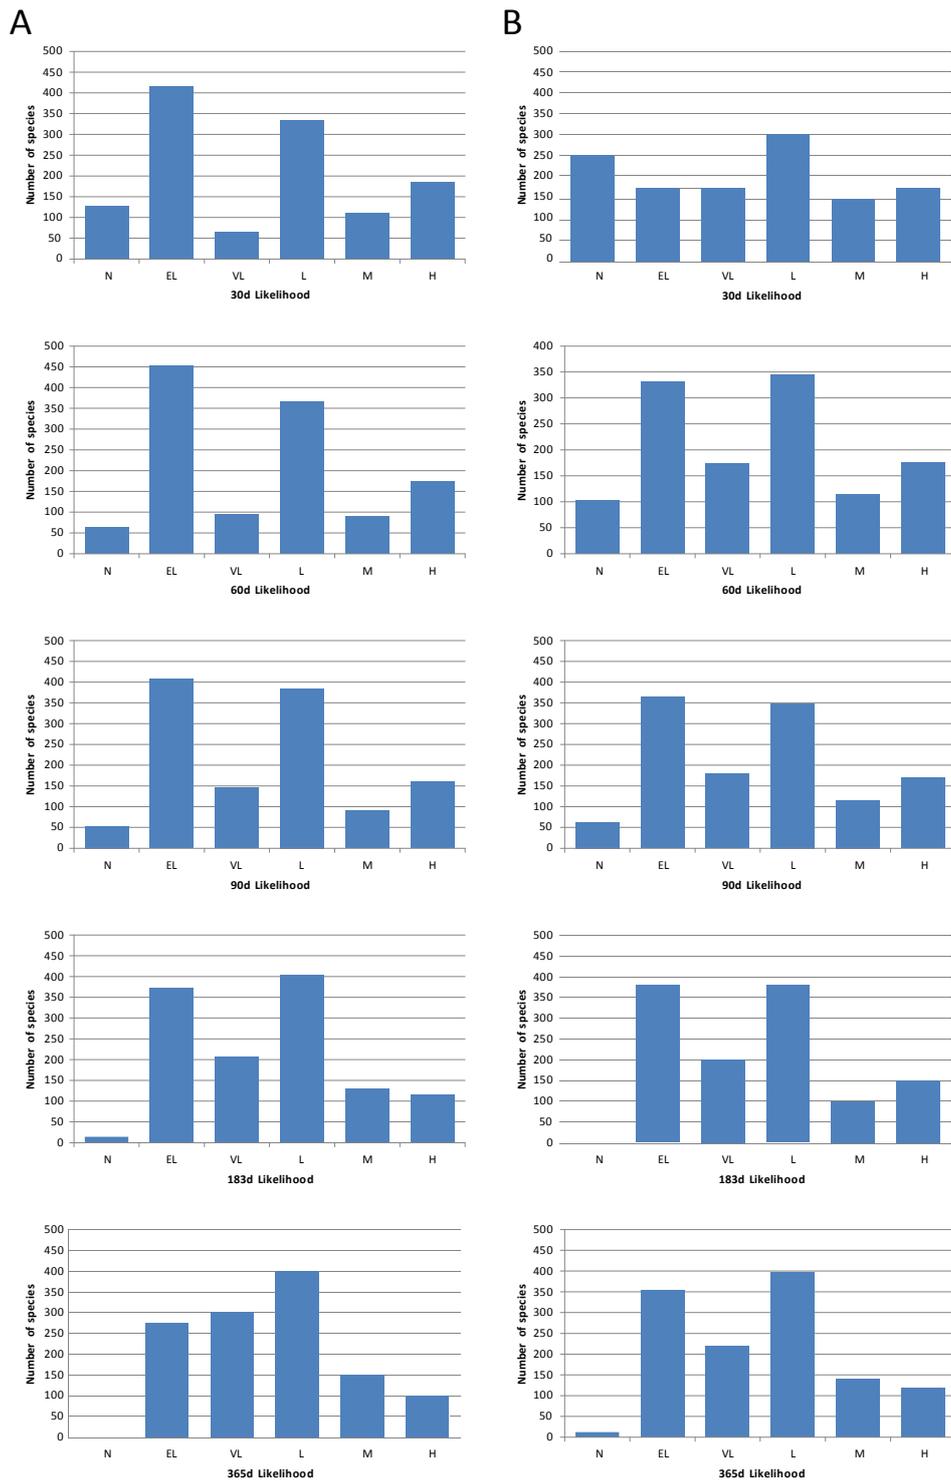

Figure 5.9. Number of species for Inoculation Likelihood Ranks to Guam for voyage durations less than 365 days (1 year). A) commercial vessels alone, B) commercial and MSC vessels. Where N = negligible, EL = extremely low; VL = very low, L = low, M = moderate, and H = high. Data from Lloyds MIU and DoD datasets.

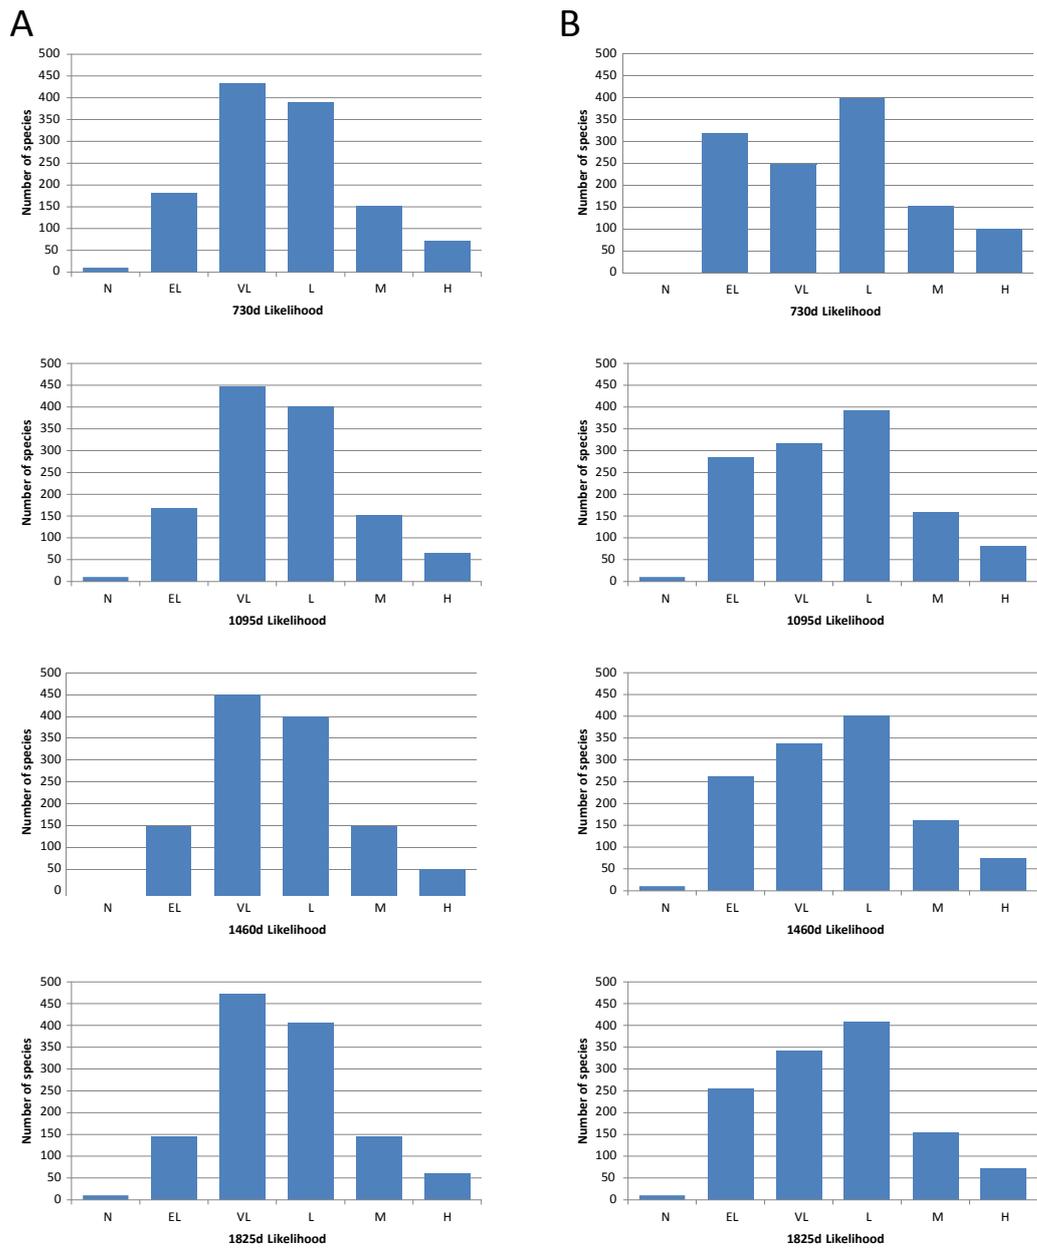

Figure 5.10. Number of species for Inoculation Likelihood Ranks to Guam for voyage durations greater than 365 days (1 year). A) commercial vessels alone, B) commercial and MSC vessels. Where N = negligible, EL = extremely low; VL = very low, L = low, M = moderate, and H = high. Data from Lloyds MIU and DoDdatasets.

Table 5.3. Biofouling species with a “High” (n=72) and “Medium” (n=155) likelihood of arrival in Guam associated with all vessel traffic.

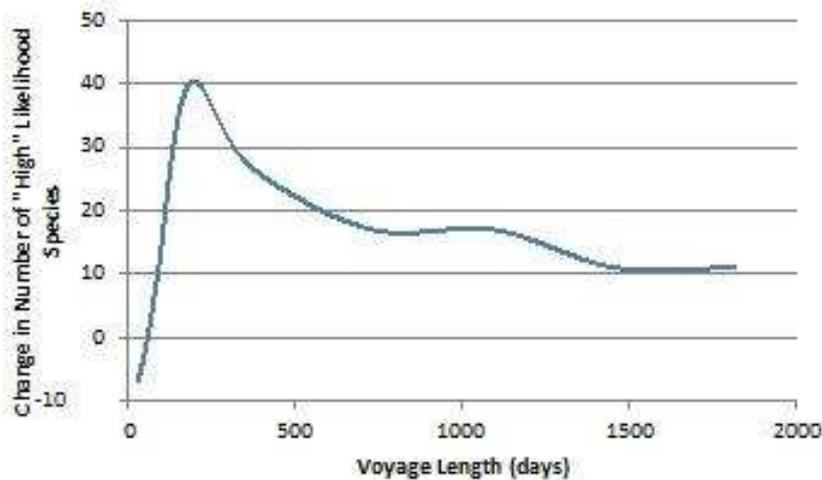

Figure 5.11: The estimated change in the number of “High” likelihood of inoculation species between analysis of commercial vessels alone and commercial and MSC vessels.

5.4 Spread from Guam to other jurisdictions of Micronesia

Spread is the progressive expansion and establishment in locations beyond the first site of establishment in the receiving region. This can be facilitated either by natural or human mediated means, however in this assessment the evaluation is restricted to human mediated spread. This assessment is interested in the increased likelihood of inoculation into a jurisdiction of Micronesia or Hawai’i as a consequence of trading activity in Guam. For this evaluation each jurisdiction of Micronesia (CNMI, FSM, RMI, Palau, and also the UMI) was evaluated for species arrival likelihoods based on direct entry (following the methods described in Section 5.2), with comparison between commercial vessel entries and the additive effect of MSC vessels.

Ultimately, once a species has become established in a high traffic port, or ‘transport hub’, there is some probability that domestic vessels will be colonized by non-native species and translocated to more locations across a region. As successive hubs are colonized, the number of populations from which natural spread can occur increases via natural dispersal (Floerl 2002). This pattern of spread, termed the ‘hub and spoke’ dispersal (*sensu* Carlton 1996) is typical of marine non-native species (Carlton 1996, Cranfield et al. 1998). Recent modeling analysis indicates that spread of non-native organisms can not only occur from hubs, but also from seemingly unimportant transport nodes (Floerl et al. 2009). Nonetheless, transport hubs were consistently more likely to become infested by an invader and to accelerate spread to secondary locations faster when compared with low traffic nodes (Floerl et al. 2009).

The role of Guam as an entry port to Micronesia and Hawai'i using a "hub and spoke" model was assessed, where the likelihood species already present in Guam or deemed to have a high likelihood of inoculation in Guam (Section 5.2, above) was compared with the species with high likelihoods of direct entry to determine the extent to which increased likelihood of transfer and arrival to a jurisdiction of Micronesia other than Guam. The likelihood of arrival of species to each jurisdiction of Micronesia (other than Guam) and Hawai'i for commercial, MSC and all (commercial and MSC) vessels across the nine voyage durations was assessed.

5.4.1 Commonwealth of the Northern Mariana Islands (CNMI)

The CNMI received 3,312 commercial and 4,769 MSC vessel entries during the assessed period (Figures 5.12 and 5.13). Approximately 19% of these vessels arrived directly from Guam. Commercial vessels had strong affinities with the NE Atlantic (5) and the East Asian Seas (13) bioregions, with a decreased trade across a wide number of bioregions. The NE Atlantic and East Asian Seas bioregions represent more than 20% of commercial vessel trade. In contrast, Military vessels exhibit a much broader exposure to bioregions, particularly Indian Ocean and Pacific Basin bioregions and therefore broader exposure to a wider suite of species. The trading activities of vessels visiting CNMI are broad with the 30 day voyages sampling nine bioregions, rapidly reaching 18 bioregions with voyages of 365 days (Figure 5.14).

The inoculation likelihoods of species increase with the addition of MSC vessels (Figures 5.15, 5.16). No species were categorized as having "High" likelihood of inoculation when assessed for commercial vessels alone, with the addition of MSC vessels increasing the "High" risk species to 15 species for voyages of 1,825 days (5 years) (Table 5.4).

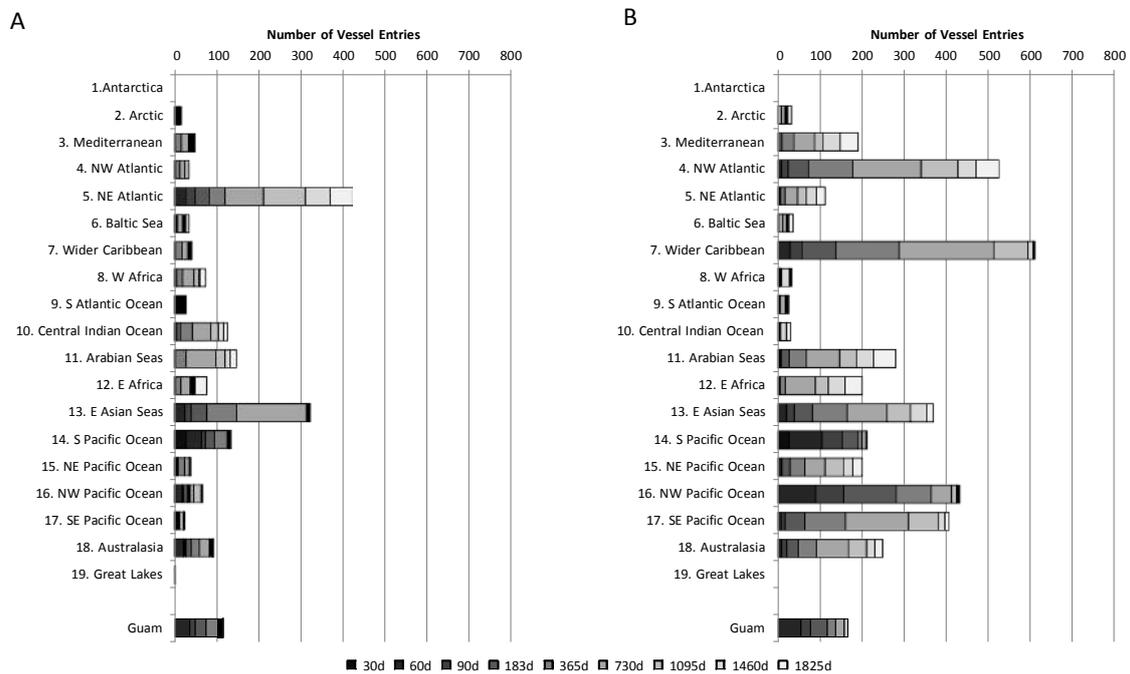

Figure 5.12. Number of A) commercial vessel (all categories) and B) MSC vessel (all categories) entries to CNMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries vessels (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

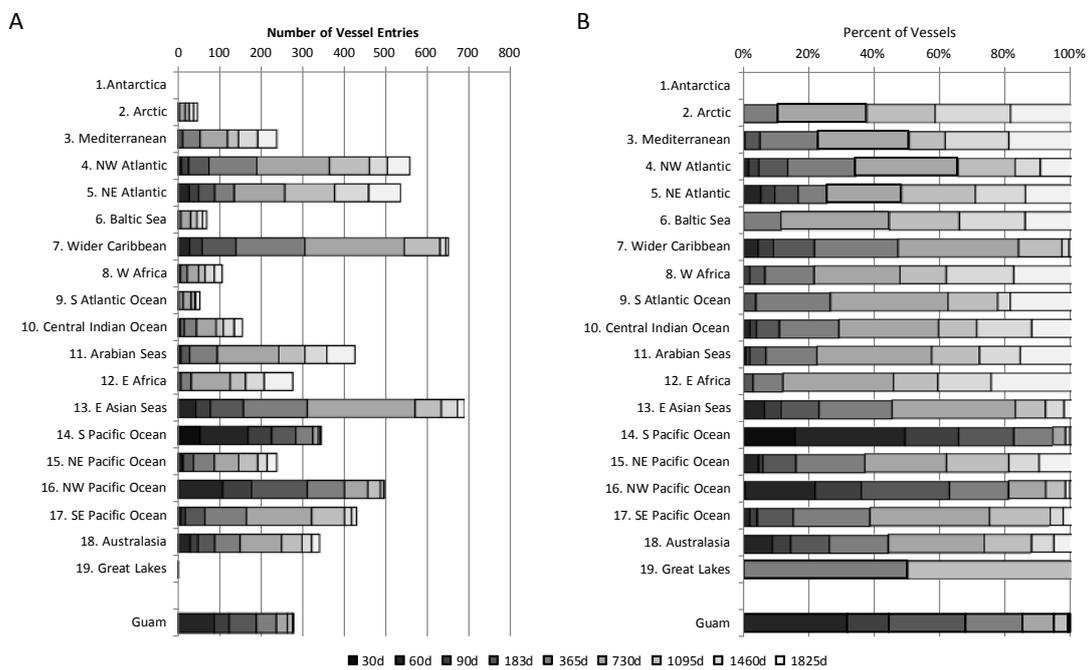

Figure 5.13. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to CNMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

5.4.2 Federated States of Micronesia

The Federated States of Micronesia (FSM) received 783 commercial vessels and 28 MSC vessel entries during the assessed period (Figures 5.17, 5.18). Approximately 15.5% of these vessels arrived directly from Guam. Commercial vessels had strong affinities with a restricted suite of Pacific bioregions (East Asian Seas-13, South Pacific-14, and Northwest Pacific-16), representing more than 62% of total trade. In contrast, few military vessels traded with FSM and were restricted to the South Pacific Ocean and NW Pacific. As a consequence, military vessels contribute little to the likelihood of species inoculations based on vessel entries alone. The trading activities are widespread initially, with 30 day voyages reaching seven bioregions, however only after 730 day voyages the maximum of 17 bioregions are reached (Figure 5.19).

The inoculation likelihoods of species do not change with the addition of military vessels (Figures 5.20 and 5.21) due to the limited number of military vessel entries. The overall result is 42 species identified as ‘High’ likelihood of inoculation for voyages of 1,825 days (5 years) (Table 5.5).

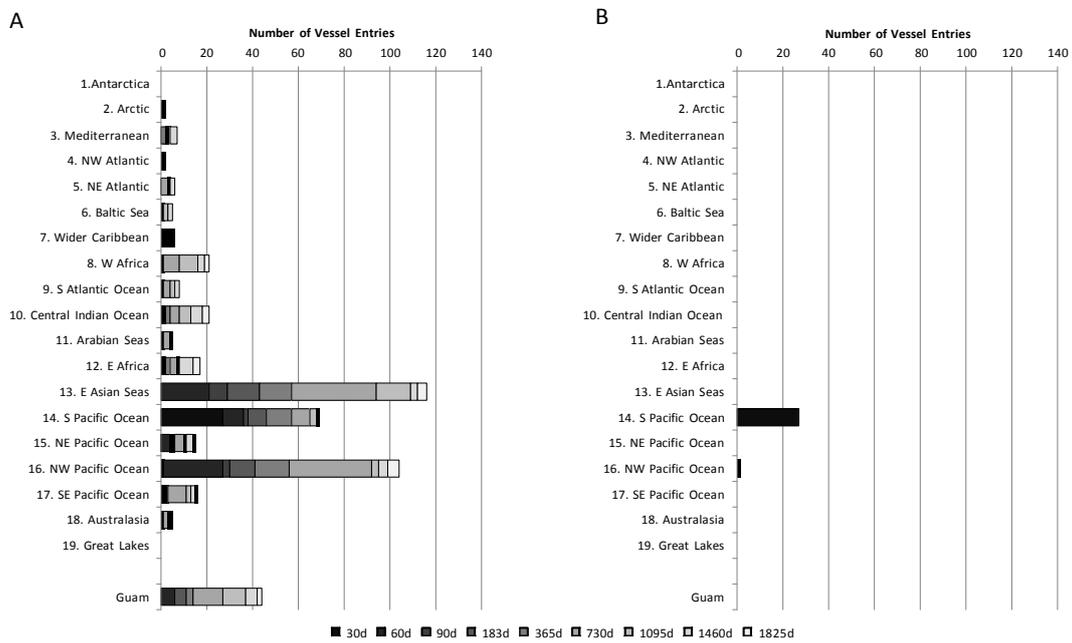

Figure 5.17. Number of A) commercial vessel (all categories) and B) MSC vessel (all categories) entries to the FSM from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

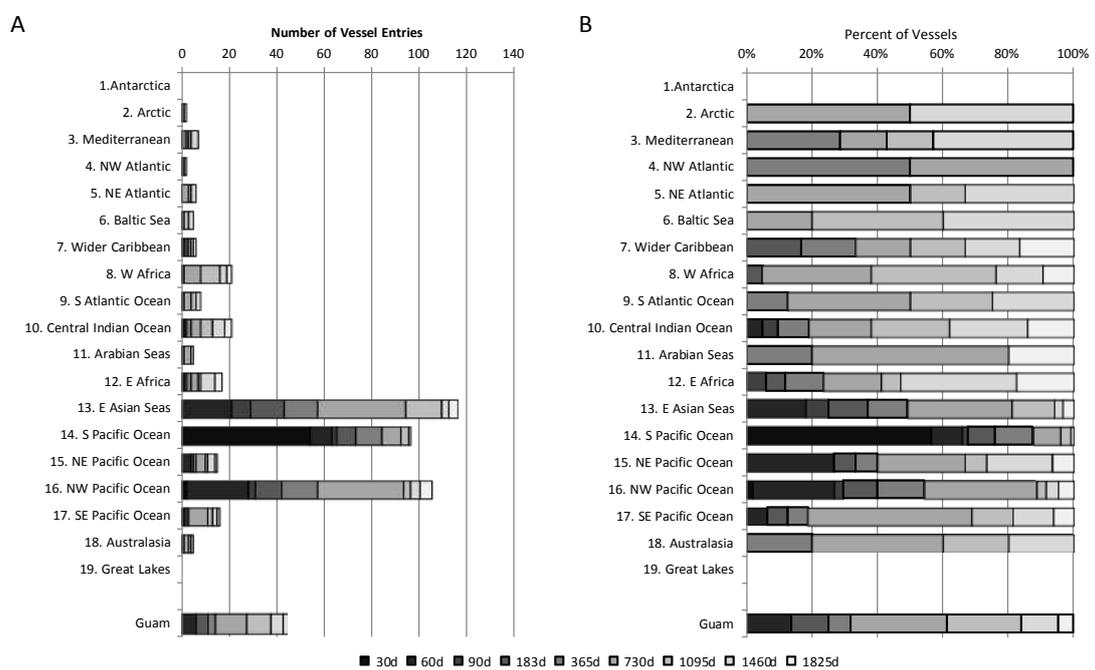

Figure 5.18. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to FSM from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

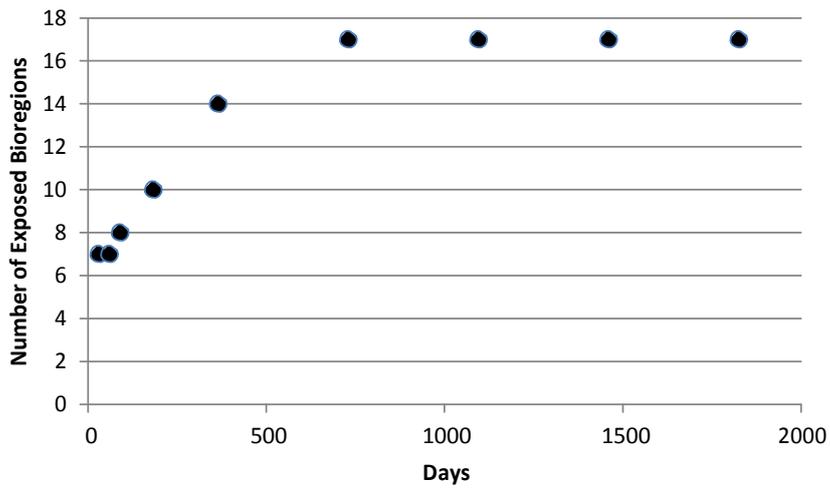

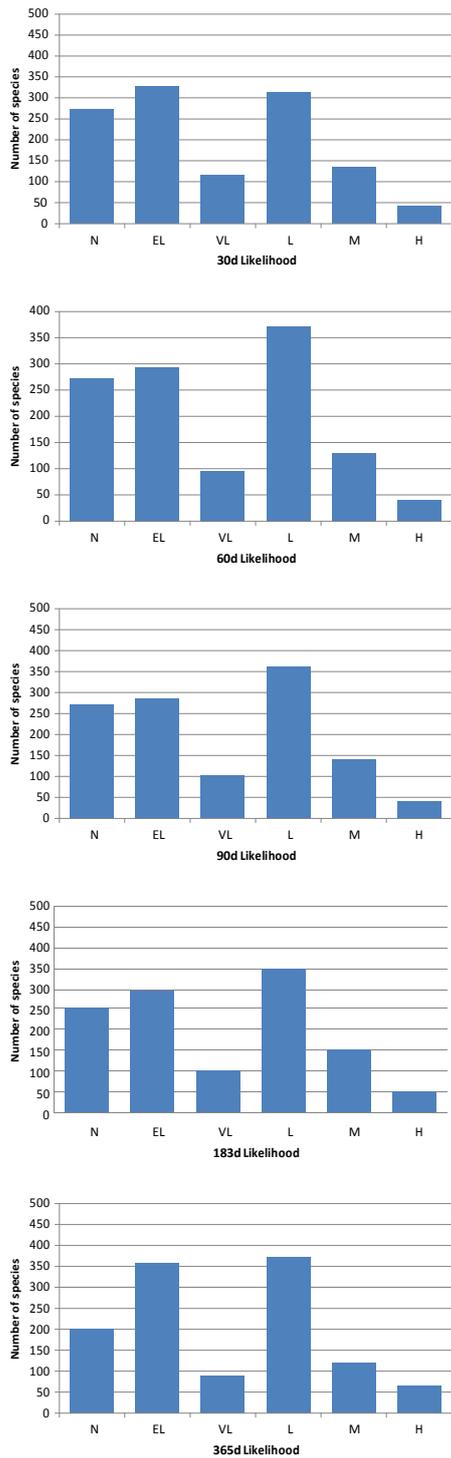

Figure 5.19: Number of bioregions visited by vessels entering FSM between 1999 and 2009 with increasing voyage duration (data from Lloyds MIU and DoD datasets).

5.4.3 Republic of the Marshall Islands

Republic of the Marshall Islands (RMI) received 540 commercial vessels and 630 MSC vessel entries during the assessed period (Figures 5.22 and 5.23). Approximately 6% of these vessels arrived directly from Guam. Commercial vessels had strong affinities with a restricted suite of Pacific Rim bioregions (East Asian Seas-13, South Pacific-14, Northeast Pacific-15, and Northwest Pacific-16), representing more than 47% of total trade. In contrast, military vessels exhibit a much broader exposure to bioregions, particularly Atlantic and Mediterranean bioregions, and therefore broader exposure to a wider suite of species. The trading activities rapidly sampled a wide variety of bioregions, with vessels arriving from 10 bioregions in 30 day voyages and reaching saturation (18 bioregions) with voyages of 365 days (Figure 5.24).

The inoculation likelihoods of species decrease with the addition of military vessels (Figures 5.25 and 5.26), in part due to the reduction of emphasis on Northeast and Northwest Pacific bioregions as trading partners. The combined result of commercial and military (MSC) traffic is 34 species identified as ‘High’ likelihood of inoculation for voyages of 1,825 days (5 years) (Table 5.6).

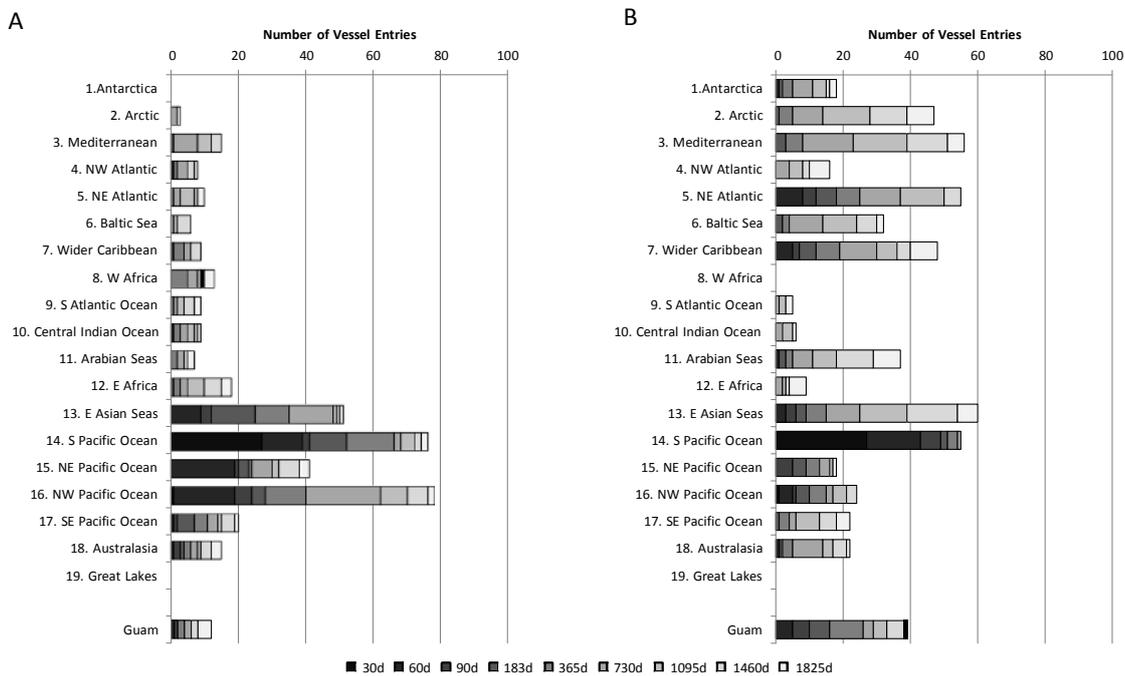

Figure 5.22. Number of A) commercial vessel (all categories) and B) MSC vessel (all categories) entries to RMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

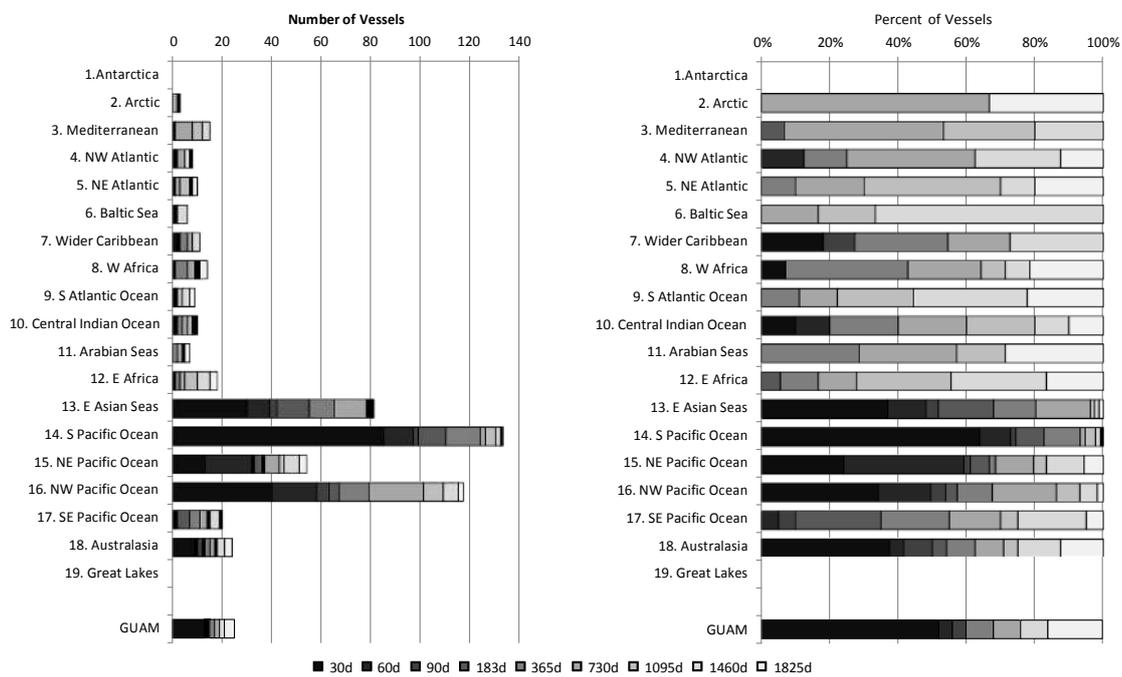

Figure 5.23. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to RMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

5.4.4 Republic of Palau

The Republic of Palau received 707 commercial vessels and 159 MSC vessel entries during the assessed period (Figures 5.27 and 5.28). Approximately 15% of these vessels arrived directly from Guam. Commercial vessels had strong affinities with a restricted suite of bioregions (East Asian Seas-13, Central Indian Ocean-10, South Pacific-14, and Arabian Seas-11), representing more than 46% of total trade. In contrast, military vessels exhibit a much broader, albeit minor, exposure to bioregions. The trading activities initially had a small sample of bioregions at short voyage durations (30 days = 5 bioregions, 90 days = 8 bioregions) but reached 17 bioregions with voyages of 365 days and saturation after 1,460 days (4 years) (Figure 5.29).

The inoculation likelihoods of species are not significantly affected with the addition of military vessels (Figures 5.30 and 5.31), largely due to the minor contribution military vessels make to the trading activities of Palau. The combined trading activities result in 31 species identified as ‘High’ likelihood of inoculation for voyages of 1,825 days (5 years) (Table 5.7).

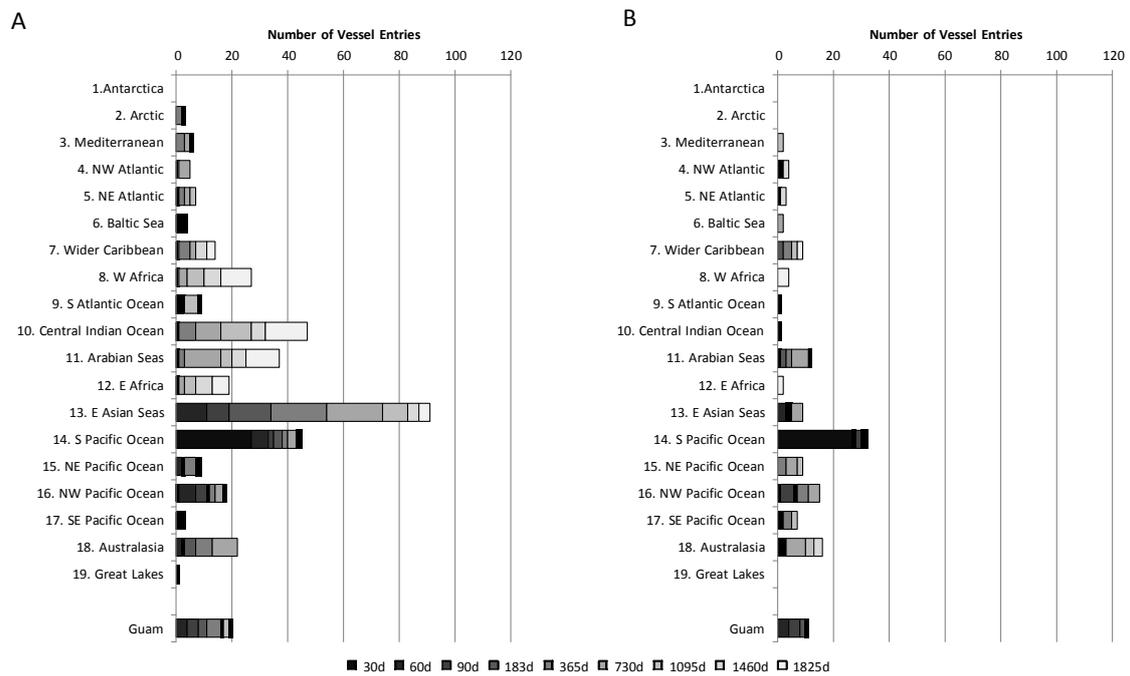

Figure 5.27. Number of A) commercial vessel (all categories) and B) MSC vessel (all categories) entries to the Republic of Palau from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

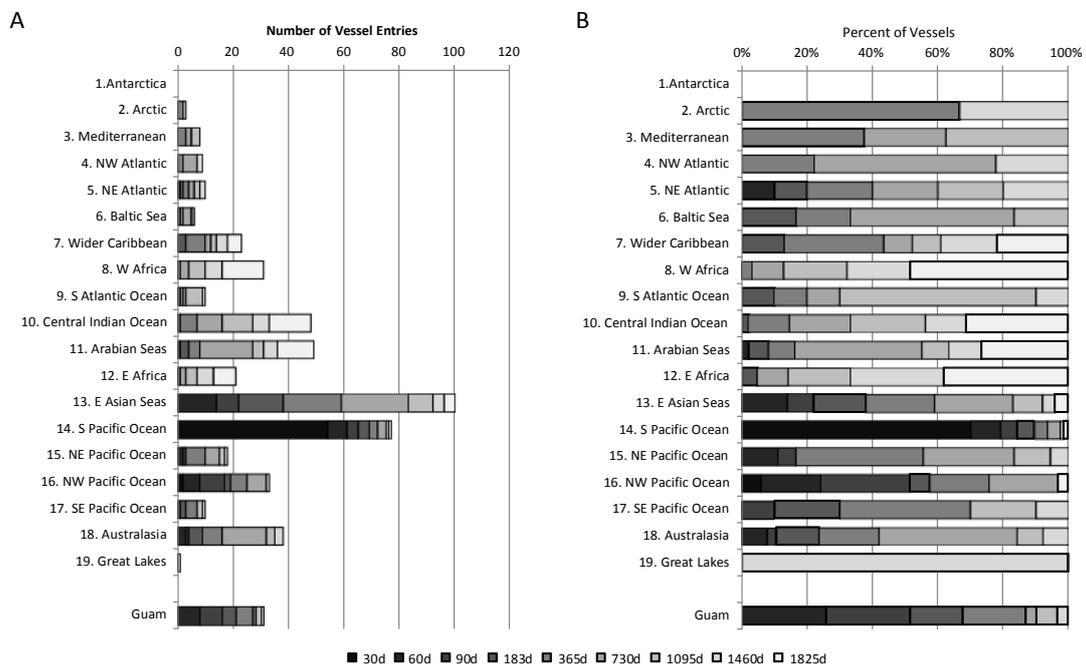

Figure 5.28. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to the Republic of Palau from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

5.4.5 United States Minor Islands

The United States Minor Islands (UMI) received 58 commercial vessels and 762 MSC vessel entries during the assessed period (Figures 5.32 and 5.33). Approximately 7% of these vessels arrived directly from Guam. Commercial vessels were of insufficient number to ascertain string trade affinities other than relationships within the South Pacific. In contrast, military vessels exhibit a much broader exposure to bioregions, particularly throughout the Atlantic, Mediterranean and Pacific basins, and therefore broader exposure to a wider suite of species. The trading activities slowly sampled bioregions, with only five bioregions being visited for 30 day voyage windows and only reaching saturation (18 bioregions) after 1,460 days (4 years) (Figure 5.34).

The inoculation likelihoods of species should only be considered for all vessels (commercial and military) due to the inability to assess on the basis of insufficient numbers of commercial vessel entries (Figures 5.35 and 5.36). Military vessels therefore significantly increase the risk of species entry. This results in 31 species identified as ‘High’ likelihood of inoculation for voyages of 1,825 days (5 years) (Table 5.8).

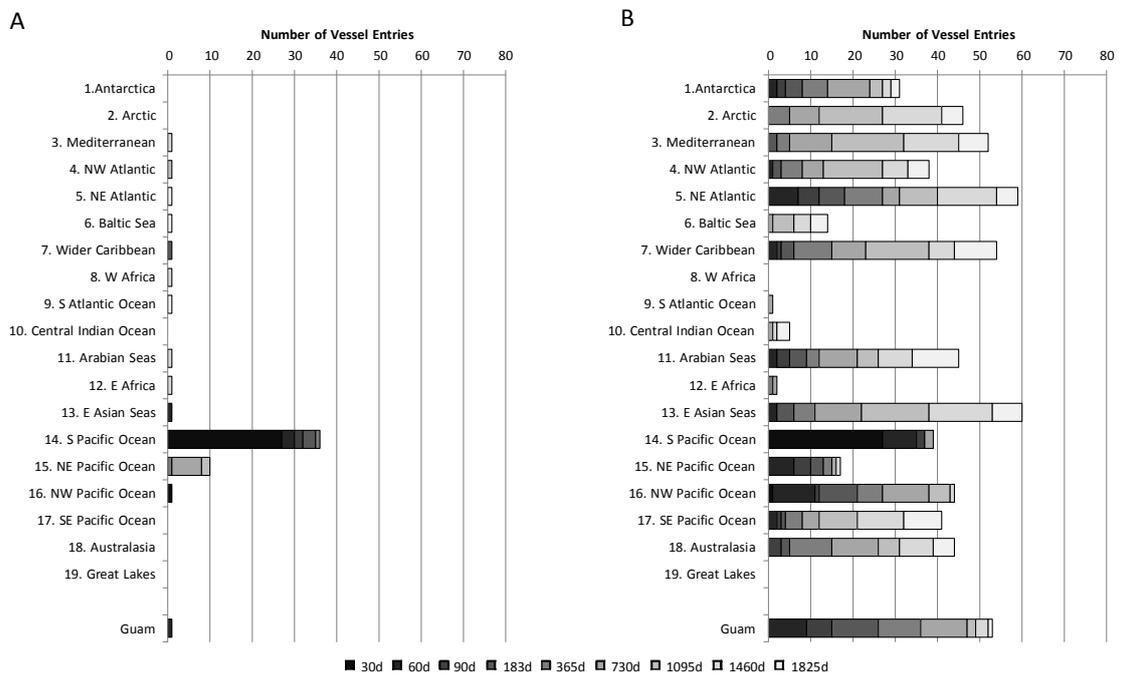

Figure 5.32. Number of A) commercial vessel (all categories) and B) MSC vessel (all categories) entries to UMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

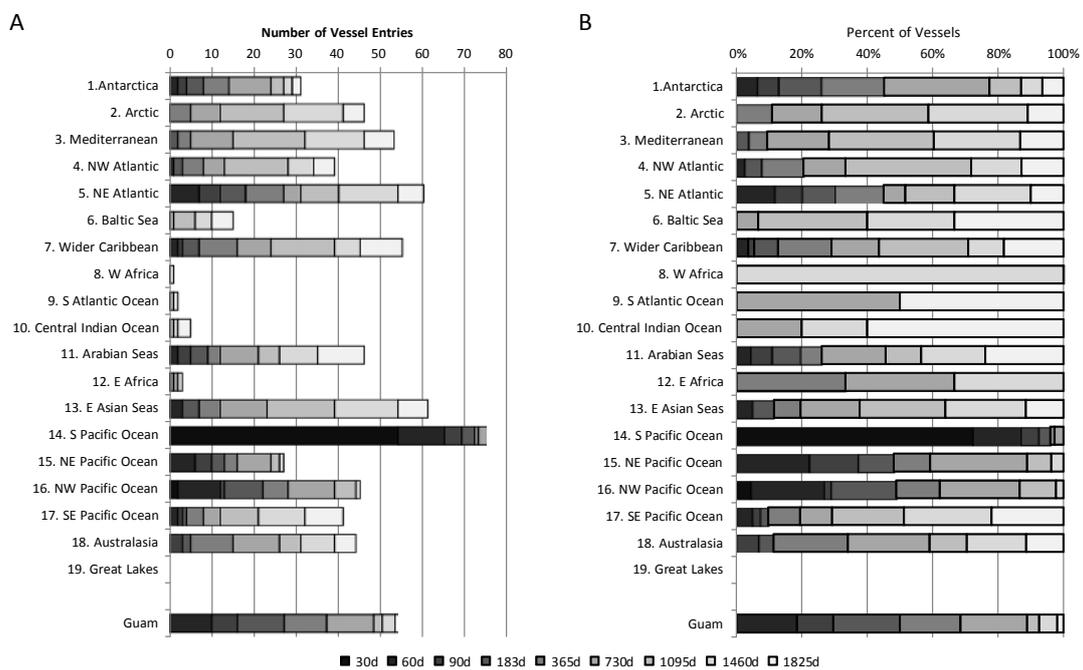

Figure 5.33. Number and percentage within a bioregion of all vessel (all categories of commercial and MSC vessels) entries to UMI from 1999 to 2009 which had traded with specific bioregions for voyages of 30d, 60d, 90d, 183d, 365d (1yr), 730d (2yrs), 1095d (3yrs), 1460d (4yrs), or 1825d (5yrs) during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels transiting Guam are also represented in Bioregion 14 South Pacific Ocean.

5.4.6 State of Hawai'i

Hawai'i received 6,380 vessel entries of which 6,030 were commercial vessel entries, 318 were fishing vessel entries, and 54 were MSC vessel entries during the five year period (Figures 5.37). It should be noted that this was only half of the 10-year period for which data were available for Micronesia. It should also be noted that data were only available LPOC, and data for cumulative voyage histories were not available unlike analyses for Micronesia, hence presentation of a single panel for HI (Figure 5.37). Slightly more than 1% of these vessels arrived directly from Guam. Commercial vessels had strong affinities the Northeastern Pacific (15) and the Northwestern Pacific (16) bioregions, with a decreased trade across a wider number of bioregions. The Northeastern Pacific and Northwestern Pacific bioregions represent more than 81% of commercial vessel trade. MSC vessels have a similar level of exposure to bioregions as commercial vessels, with 78% of vessel entries derived from the Northeastern Pacific and Northwestern Pacific bioregions. Fishing vessels primarily arrive from Northwestern Pacific and the South Pacific (14) bioregions, representing 88% of all fishing vessel entries.

LPOC arrivals to Hawai'i during the evaluation period arrived from 15 of the 18 bioregions, with commercial vessels trading across all 15 bioregions, Fishing vessels with 7 bioregions and MSC vessels with 8 bioregions.

The inoculation likelihoods of species only slightly increase with the addition of MSC vessels for biofouling related risk (Figure 5.38). More than 160 species were categorized as having "High" likelihood of inoculation by biofouling for all vessel categories. In total, 317 species are ranked as "High" (167) or "Medium" (150) likelihood of inoculation (Table 5.9), with MSC vessels having no effect in the likelihoods of inoculation.
