15 Because the increased risk of release of hazards into the Micronesia Region due to the military
16 relocation through the intentional movement of reptiles is low, the risk of exposure of livestock and
17 poultry is low, and the significance of consequences of livestock and poultry exposure to Guam, the rest
18 of the Micronesia Region, and the rest of the United States is low, we conclude that the military
19 relocation-associated overall risk from reptiles is low.

20 **A6.3.3.6 Humans**

21 In this pathway, we consider the effect of the military relocation on risk to livestock and poultry health
22 through the movement of people into the Micronesia Region. The number of people travelling into the
23 Region will increase as a result of the military relocation. Discussion of risk to human health is limited to
24 the livestock and poultry hazards associated with people.

25 In this section, we do not cover objects potentially carried by humans, such as animal products or
26 smuggled live birds. Those are covered in the animal products and poultry pathways, respectively.

27 **A6.3.3.6.1 Hazards Associated with the Humans Pathway**

28 People can transport hazards in three roles: they can be infected hosts, they can be contaminated with
29 disease agents and serve as fomites, or they can serve as hosts to tick vectors of disease agents. Baggage
30 or other personal belongings accompanying travelers can be contaminated with disease agents or
31 transport tick vectors. Animal products can also be carried in baggage or personal belongings; this
32 possibility is covered in the animal products pathway. Table A6-14 lists hazards that are associated with
33 people or their accompanying baggage through the roles associated with humans, including hazards for
34 which humans may serve as dead-end hosts or play a minor or theoretical role in transmission.

4

1 **A6.3.3.6.2 Release Assessment: Humans Pathway**

2 **Likelihood of Hazard Association**

3 Infected humans can serve as reservoirs for transmission of Leishmania parasites to other mammals.
4 Worldwide, the incidence of human leishmaniasis is widespread and increasing, with 1 to 2 million
5 estimated new cases each year according to the WHO. Spread of leishmaniasis is facilitated by
6 international travel, and cases have been identified among military personnel after their return to the
7 United States from deployment to the Middle East (Aronson et al. 2006).

8 Infected humans can potentially serve as sources of transmission of *Bacillus anthracis* (CFSPH 2007a),
9 *Brucella abortus* (CFSPH 2007d), *Burkholderia mallei* (CFSPH 2007f), *Mycobacterium bovis* (CFSPH
10 2009c), or Nipah (CFSPH 2007j), rabies (CFSPH 2009m), Rift Valley fever (CFSPH 2007k), Venezuelan
11 equine encephalomyelitis (CFSPH 2008a), and vesicular stomatitis viruses (CFSPH 2008g), though the
12 role of humans in transmission of these disease agents is either theoretical or rarely reported. Other
13 hosts are epidemiologically more important than humans for harboring *Campylobacter fetus* bacteria
14 and screwworms (CFSPH 2009o). Human infection with trypanosomes that cause African animal
15 trypanosomiasis is very rare (OIE 2008r). Humans are generally thought to be dead-end hosts for
16 *Echinococcus* parasites and Eastern and Western equine encephalomyelitis, Japanese encephalitis, and
17 WNV (CFSPH 2007h, 2008a, 2009h).

18 Human infection with END or HPAI viruses can occur, but people play a more important role as fomites,
19 particularly by carrying the disease agents on contaminated clothing, than as infected hosts. African
20 swine fever, classical swine fever, and foot and mouth disease viruses and *Salmonella* bacteria can be
21 mechanically spread by people, clothing, or other personal belongings, which have been in contact with
22 affected premises (Sellers 1971; Pharo 2001; Sanchez et al. 2002; CFSPH 2009d, 2010a).

23 Ticks, including heartwater vectors *Amblyomma variegatum* and *A. hebraeum*, have been intercepted
24 from international travelers and their baggage arriving in the United States (Burrige et al. 2002; USDA-
25 APHIS 2009a).

26 **Traffic Volume and Origin**

27 Population summary information for the Micronesia Region can be found elsewhere in this document,
28 including expected increases in population from off-island individuals. Details concerning traffic volume
29 and origin information in this section may be found elsewhere in this document unless specifically
30 referenced below.

31 Significant increases in traffic will occur for military personnel and their dependents, who will be
32 assigned a tour of duty on Guam, either directly from other areas of the United States, or by way of the
33 United States for those being reassigned from current overseas locations. Hence, the impact to Guam
34 from additional military personnel and dependents will be from exposures common to the entire United
35 States which is free of foot and mouth disease, African swine fever, classical swine fever, END,
36 screwworms, Venezuelan equine encephalomyelitis, and HPAI.

1 The construction process will bring significant foreign labor forces to Guam. Foreign temporary workers
2 will include mainly small numbers of H1 professional and larger numbers of H2-B non-agricultural
3 workers. Direct impacts will be from a temporal influx of as many as 23,000 foreign, non-immigrant
4 temporary workers to support the relocation. We are assuming that the majority will be coming from
5 the Philippines, based on past worker recruitment patterns for Guam. In the past, the military has
6 preferred to hire Filipino workers because they are conversant in English. Smaller numbers of
7 managerial (H1) positions will be expected to come from Japan and Korea, in addition to the continental
8 United States or Hawai'i.

9 In-migrant workers are those who enter Guam from the Freely Associated States, including FSM, Palau,
10 and RMI, and thus share similar work status to Guam residents and are considered distinct from foreign
11 workers. They would be expected to marginally increase in numbers; however, their impact would be
12 minimal since they share common exposures in the Micronesia Region to those presently on Guam.

13 In terms of temporary visitors, Guam accommodates over one million tourists every year, primarily from
14 Japan, Korea, Taiwan, Hong Kong, and the Philippines, but also from the rest of the United States.
15 However, we have no reason to expect a significant increase in temporary visitors, specifically related to
16 the relocation.

17 The majority of tourism originates from Asia and the rest of the United States. Travel between Guam
18 and areas known to pose a risk for disease-carrying ticks in baggage or attached to returning travelers,
19 including Africa and the Caribbean, is not common. This is not expected to change with the military
20 relocation.

21 Guam has been subject to waves of illegal immigration in past decades, primarily from Asia. However,
22 intense efforts on the part of the Immigration and Naturalization Service to crack down on those
23 attempting to enter the United States through Guam or CNMI were effective in reversing this trend and
24 there is no reason to believe illegal trafficking of humans will increase with the military relocation
25 (1999).

26 ***Mitigations***

27 All international flights are channeled to the international airport on Guam. GCQA has customs
28 jurisdiction, and passengers from flight arrivals go through GCQA inspections.

29 All flights from Guam to the mainland United States go through Hawai'i where all passengers and cargo
30 are treated as foreign arrivals by Honolulu PPQ inspectors. In Hawai'i, all passengers, officers, and crew
31 members arriving by commercial aircraft or vessel and carrying plants, animals, microbial cultures, or
32 soil must complete the mandatory agricultural declaration form and submit the imported items for
33 inspection.

34 Currently U.S. CBP declaration forms for arriving international passengers collect information that
35 enables customs officials to identify those travelers who have been in recent contact with livestock or
36 poultry and to require disinfection of shoes and clothing or other steps as necessary to prevent disease

1 spread. The effectiveness of this measure will depend on awareness of the animal disease outbreak
2 status in countries of origin or embarkation and the ability of GCQA staff to rapidly adapt procedures
3 accordingly.

4 ***Summary***

5 Traffic volume for temporary visitors is unlikely to increase as a result of the military relocation. Nor do
6 we expect a change in travel patterns to areas that would increase risk for hazard introduction from
7 returning travelers or their baggage.

8 Military personnel and dependents will arrive directly from other parts of the United States, or after
9 having spent time in the rest of the United States following previous overseas deployment (Jimenez et
10 al. 2009). We assume that the time spent in other areas of the United States between deployments
11 would be sufficient to allow for the development of symptoms from most infections acquired while
12 overseas and thus allow for diagnosis and treatment. Thus, the risks that they will bring to Guam will
13 largely reflect those present in the rest of the United States and are considered to be negligible.

14 We expect a significant increase in temporary workers, with the majority expected to come from the
15 Philippines. A number of livestock diseases of concern are present in this area. However, the likelihood
16 of introduction via humans as fomites is mitigated by the inspection processes in place.

17 Current customs procedures allow for identification of international passengers that report recent
18 contact with livestock or poultry or presence on farms. If, as we believe, procedures are in place to
19 identify passengers arriving from areas with ongoing outbreaks of foot and mouth disease, END, HPAI,
20 and similar hazards, and exposure to farms, the risk will be negligible.

21 ***Humans Pathway Release Assessment***

22 The increased risk of release of hazards into the Micronesia Region due to the military relocation
23 through the legal movement of people is negligible.

24 The increased risk of release of hazards into the Micronesia Region due to the military relocation
25 through the illegal movement of people is negligible.

26 ***Humans Pathway Risk Estimation***

27 Because the increased risk of release of hazards into the Micronesia Region due to the military
28 relocation through the movement of people is negligible, we conclude that the military relocation-
29 associated overall risk for the human pathway is negligible.

30 **A6.3.3.7 *Animal Products***

31 In this pathway, we consider the effect of the military relocation on the risk to livestock and poultry
32 health through the movement of animal products into the Micronesia Region. For the purpose of this
33 analysis, animal products are defined as products of animal origin, including meat and meat products,
34 milk and milk products, blood and blood products, skins, feathers, wool and hair, and animal feed

1 containing products of animal origin. Animal products may be moved through legal or illegal means. The
 2 volume of animal products moving into the Region will increase as a result of the military relocation, due
 3 to increased numbers of people travelling into Guam and demands for animal products by a larger
 4 population.

5 **A6.3.3.7.1 Hazards Associated with the Animal Products Pathway**

6 Animal products can transport hazards as fomites. Table A6-15 lists hazards that can be associated with
 7 animal products, including hazards for which animal products may serve as only a minor or theoretical
 8 source.

2 ^b See Table A6-6. Not all species of all genera are associated with animal products.

3

4 **A6.3.3.7.2 Release Assessment: Animal Products Pathway**

5 **Likelihood of Hazard Association**

6 A variety of animal products, including milk, eggs, meat, blood, and other tissues, can serve as disease
7 agent sources. The disease agents listed in Table A6-15 have been detected in animal products, and
8 could at least theoretically be transported to the Micronesia Region in animal products. Such products
9 can enter the Micronesia Region in cargo, mail, or passenger baggage.

10 However, many of these disease agents are spread to susceptible species primarily through routes other
11 than direct exposure to contaminated animal products. For example, African horse sickness virus,
12 Capripoxvirus, Eastern equine encephalomyelitis virus, Nairobi sheep disease virus, Rift valley fever
13 virus, WNV, and the etiologic agents of equine piroplasmiasis, surra, African animal trypanosomiasis, and
14 theileriosis are spread primarily by vectors (CFSPH 2006a, 2007k, 2008a, b, OIE 2008r, CFSPH 2009l, q, n,
15 OIE 2009f, o, s). Other disease agents are spread primarily through close contact with infected animals;
16 these agents include Brucella abortus, duck hepatitis virus, END virus, HPAI virus, sheep and goat pox
17 viruses, rinderpest virus, porcine reproductive and respiratory syndrome (PRRS) virus, and Salmonella
18 Abortusovis, Gallinarum, and Pullorum (CFSPH 2005b, 2008d, f, e; Kahn and Line 2008; CFSPH 2009b, j,
19 OIE 2009m; CFSPH 2010b). Rabies is usually transmitted in saliva through bites from an infected animal
20 (CFSPH 2009m).

21 *Bacillus anthracis* transmission in animals occurs by ingestion or inhalation of spores; in humans, spread
22 is primarily through cutaneous contact, such as with contaminated hides or skins, or through ingestion
23 of contaminated meat (CFSPH 2007a). *Mycobacterium bovis* is transmitted through ingestion or
24 inhalation, or through breaks in the skin (CFSPH 2009c). The most common route of human infection
25 with *M. bovis* is through aerosol inhalation, or ingestion of contaminated dairy products (CFSPH 2009c).
26 Contaminated milk or colostrum is a primary source of transmission of Maedi-visna virus and the
27 *Mycoplasma* spp. that cause contagious agalactia (CFSPH 2007i, 2009e).

28 *Echinococcus granulosus* and *E. multilocularis* are spread primarily through ingestion of contaminated
29 tissues. The bovine spongiform encephalopathy agent is spread primarily through ingestion of
30 contaminated tissues, or feed that contains ruminant-derived protein (Sejvar et al. 2008). The scrapie

1 agent is transmitted through ingestion of contaminated blood, tissues, or secretions including milk
2 (Sejvar et al. 2008, OIE 2009e).

3 African swine fever, classical swine fever, foot and mouth disease, and swine vesicular disease viruses
4 are readily spread to swine through ingestion of contaminated meat, typically through garbage feeding
5 (OIE 2009g, h, j, r). foot and mouth disease virus can also be spread through ingestion of contaminated
6 milk (OIE 2009j).

7 The duration that disease agents remain viable in animal products varies by agent and environmental
8 conditions. For example, African swine fever virus can remain viable in blood at 4°C for 18 months, in
9 meat at 4°C for 5 months, in salted dried ham for more than 4 months, and in frozen carcasses for years
10 (CFSPH 2010a). Similarly, classical swine fever virus can remain infectious for three months in
11 refrigerated meat, more than 4 years in frozen meat, and more than 6 months in cured and smoked
12 meats (CFSPH 2009d). Foot and mouth disease virus is inactivated in animal muscle as pH decreases to
13 less than 6.5 after death, but can survive in chilled lymph nodes and bone marrow (CFSPH 2007e). Foot
14 and mouth disease virus in milk can be inactivated by heating at 100°C for more than 20 minutes, but is
15 not inactivated by low-temperature pasteurization (72°C for 15 seconds) (CFSPH 2007e). Swine vesicular
16 disease virus can remain viable in ham for 6 months, dried sausage for more than 1 year, and processed
17 intestinal casings for more than 2 years (OIE 2009r). *Bacillus anthracis* spores can remain viable for
18 decades on processed animal products such as dried hides or wool, and for 10 years in milk (CFSPH
19 2007a).

20 Imported meat has been confirmed or strongly implicated as a disease agent source. For example,
21 classical swine fever virus was detected in frozen meat imported into Switzerland from China in 1993
22 and from Romania in 1994 (Krassnig et al. 1995). Imported meat was identified as the most likely disease
23 agent source in a foot and mouth disease outbreak in the United Kingdom in 2001 and classical swine
24 fever outbreaks in Germany and Switzerland in the 1990s (Hofmann and Bossy 1998; Fritzeimer et al.
25 2000; DEFRA 2002). Imported unpasteurized cheese has been identified as a source of *Mycobacterium*
26 *bovis* in the United States (Winters et al. 2005; Harris et al. 2007; Kinde et al. 2007).

27 Hides, skins, hair, or wool are animal products that are plausible as transport vehicles for ticks. Ticks
28 reside on the hide or skin of living animals; however, the host becomes unattractive once the animal is
29 slaughtered and the tick is no longer able to ingest blood. There is evidence that some partially fed
30 ixodid ticks will detach from a recently slaughtered animal to seek a living host (Ergönül 2007). The
31 USDA national tick survey and PPQ pest interception databases include records of nearly 100
32 interceptions of vector ticks on hides, skins, hair, or wool (James and Freier 2004; USDA-APHIS-VS CEAH
33 2006; USDA-APHIS-PPQ 2010a). The tick collection reports do not indicate whether the ticks were alive
34 or dead at the time of collection, or whether the hides were raw or processed. Exotic ticks of the genera
35 *Rhipicephalus* and *Hyalomma* were the ticks identified most commonly in association with hides and
36 skins.

37 Illegal imports, by their nature, are difficult to describe and quantify. However, immigrant workers have
38 been reported to carry prohibited animal products in their accompanying baggage. For example,

1 immigrant construction workers have reportedly carried eggs and animal products for medicinal
2 purposes (Sgambelluri et al. 2009). Studies conducted in Taiwan and the United Kingdom agreed that a
3 large percentage of illegally introduced meat and meat products were introduced by passengers coming
4 from Asian countries (Shih et al. 2005; Hartnett et al. 2007). We have no data on the amount of animal
5 products seized at the A.B. Won Pat International Airport. However, during our site visit, agents from
6 GCQA seized products containing meat, animal feed of foreign origin, and smuggled live animals during
7 inspections conducted at the airport. Passenger baggage inspections are targeted toward flights deemed
8 high risk, such as those from the Philippines (Jimenez et al. 2009). In our visit to A.B. Won Pat
9 International Airport, the level of staffing was adequate to handle the number of inspections conducted
10 given the volume of passenger traffic and passenger baggage inspections were supported with dog
11 teams. However, infrastructure needed for operational support was lacking. For example, none of the
12 four x-ray machines were operational, and not all passenger baggage could be screened. Since current
13 staffing levels are operating at maximum capacity for conducting inspections, additional passenger
14 traffic associated with the relocation will require additional resources.

15 Animal products are likely more frequently smuggled in passenger baggage than via maritime cargo
16 routes. In cargo routes, prohibited agricultural products are commonly smuggled by misidentification of
17 contraband on manifests, such as relabeling of prohibited items as permitted goods (Wyler and Sheikh
18 2009). Increases in cargo and passenger traffic volume and potential changes in the location of trading
19 partners related to the relocation may contribute to an increase in the rate of prohibited animal
20 products entering Guam. The risk associated with food is mainly limited to demand for specialty foods
21 since the major exporters of these products to the Micronesia Region are from countries free of major
22 livestock diseases of importance, such as the United States, Australia, and New Zealand as detailed
23 elsewhere in this document. In addition, there have been reports of animal products such as pet food
24 from prohibited sources being found in local stores on Guam (Jimenez et al. 2009). These products are
25 generally less expensive than similar products from the United States, Australia, or New Zealand, which
26 might contribute to their appeal, especially for lower paid military personnel or their dependents
27 (Jimenez et al. 2009).

28 Because the United States is free of many diseases of concern, such as foot and mouth disease and
29 classical swine fever, domestic mail does not pose a risk for introduction of these agents; however, mail
30 from foreign locations may pose such a risk. All mail originating in the United States and most
31 international packages destined for the Micronesia Region are processed in Honolulu, Hawai'i, before
32 being sent to Guam. However, it is unclear to what degree foreign mail destined for Guam is inspected
33 in Honolulu. While Guam postal officials seem to rely on Hawai'i Department of Agriculture inspectors to
34 inspect this mail (Ericksen 2010; Shimizu 2010a), postal officials in Hawai'i seem to believe that GCQA is
35 carrying out these inspections (Gonzalez 2010). During the first site visit, we were advised that all
36 foreign mail that had passed through the Hawai'i facility was considered domestic mail, and was not
37 inspected in Guam. Furthermore, because it was domestic mail, GCQA inspectors could not open any
38 first class mail, even if it obviously contained agricultural products. Postal Service employees may notify
39 GCQA when they suspect non-first class mail to contain illegal plants or animals, and GCQA may obtain a
40 search warrant (Jimenez et al. 2009).

1 Evidence of smuggling activities via domestic mail comes from pilot studies conducted by USDA showing
2 that a large number of packages leaving Hawai'i for the mainland United States contained undesirable
3 organisms (Miller et al. 1992). We do not have estimates on the volumes and types of seized
4 commodities but several models have assessed that the risk of introduction of meats via mail is
5 relatively small compared with the risk from other pathways such as passenger baggage. A study in
6 Great Britain estimated that less than 0.5% of the total weight of illegal meat imports entered via post or
7 courier (Hartnett et al. 2007).

8 The recent outbreaks of foot and mouth disease in Asia and Europe are a reminder of the vulnerability
9 of the Micronesia Region to exotic animal diseases. Factors such as proximity to regions with endemic
10 disease, large amounts of boat traffic, larger population, and a large influx of tourists elevate the risk for
11 the illegal introduction of pathogens in animal products into Guam and the Micronesia Region. The
12 illegal importation of animal products provides a pathway around biosecurity controls and may allow
13 contaminated animal products to enter Guam.

14 Risk of illegal introduction of pathogens in animal products will come primarily from Asian regions,
15 particularly from the Philippines, as the movement of people and products to Guam will increase as a
16 result of the military relocation (Jimenez et al. 2009). A clear example of the potential threat is classical
17 swine fever, which occurs in several countries in Asia, including the Philippines (OIE 2009h; 2010h).

18 ***Traffic Volume***

19 Summary data for military and civilian imports may be found elsewhere in this document.

20 We do not have data on the expected increase in the volume of foreign imports of animal products
21 resulting from the potential 45% expansion in Guam's population during the military relocation. As a
22 proxy, we reviewed the population increase and corresponding increase in food commodity imports
23 between 1990 and 2009. Over this period, the population increased 34% (U.S. Navy 2009f). This was
24 associated with a more than a 200% increase in the total volume of imports of commodities; total
25 imports of eggs remained stable, while imports of meat and dairy products increased 125 and 450%,
26 respectively (GTIS 2010).

27 Detailed information for human travel may be found in the human pathways section.

28 ***Traffic Origin***

29 According to data provided by the Guam Bureau of Statistics and Plans for 2009, the major import
30 partners for all imported commodities to Guam, as measured in terms of U.S. dollar value, were the rest
31 of the United States (50%), Japan (14%), Western Europe (France, Italy and Switzerland) (13%), and
32 other Asian countries or regions (16%) (including China, Korea, Taiwan, Hong Kong, Singapore, Thailand,
33 and the Philippines). Food commodities and non-alcoholic beverages represented the largest
34 commodity group, making up over 30% of all imports in 2009 (BSP 2009b).

35 However, most animal product imports to Guam originate in the continental United States and the
36 majority of foreign imports of animal products are from New Zealand and Australia (GovGuam 2002;

1 Campbell 2010c). In FY 2009, imports from the continental United States accounted for more than
2 85% of meat products, 98% of eggs and egg products, and 75% of dairy products. Data for imports of
3 animal products and byproducts from foreign sources over the period 2005 to 2009 were obtained from
4 the Global Trade Atlas (GTIS 2010). Limited veterinary services and lack of slaughter facilities throughout
5 the Micronesia Region limit commercial trade in locally produced animal products, including meat, eggs,
6 and milk.

7 Specialty egg products, such as salted eggs and balut (embryonated, salted eggs) for which imports are
8 not restricted, have been exclusively imported from Asia (Japan, the Philippines, Taiwan, and Thailand),
9 but overall import volumes are small and have remained constant over the last decade.

10 It is expected that during the military relocation there will be an increase in the Asian population,
11 primarily workers from the Philippines (U.S. Navy 2009f), and that some immigrant workers will remain
12 on Guam after the construction phase is completed (U.S. Navy 2009g). Hence, there may be an increase
13 in demand for animal products from Asian countries. However, we assume that increase in demand will
14 have minimal impact on the origin of animal products. It is also assumed that during the construction
15 phase food services will be provided by contractors to foreign employees and those products will be
16 sourced from U.S. suppliers. Additionally, while Filipinos constitute a large segment of the immigrant
17 population working abroad, which is true for all of the United States, including Guam, historically there
18 is no evidence that an associated demand for foreign animal products has contributed to the
19 introduction of animal disease.

20 The relocation will increase the number of pets, primarily cats and dogs, on Guam. Most commercial pet
21 food that is imported into Guam is produced in and imported from the continental United States, and
22 foreign imports must comply with federal regulations for the processing of commercial animal food.

23 The Defense Commissary Agency provides groceries to military personnel, retirees and their dependents
24 (Melton 2009). All perishable food products procured by the Defense Commissary Agency, including
25 meat, eggs, and fresh dairy products, come to Guam from elsewhere in the United States. All meat
26 products procured by the Defense Commissary Agency require USDA certification and are sourced from
27 Nebraska. The amount of locally sourced food items is limited and provided by less than 20 local
28 retailers or businesses. Most suppliers of locally procured food products are from CNMI (Saipan and
29 Rota) (DeCA 2009, Melton 2009).

30 Information on origin of human travelers can be found in the human pathways section.

31 ***Mitigations***

32 Federal rules and regulations for the import of animal products are included in the USDA-APHIS-PPQ
33 Animal Product Manual and 9 CFR (USDA-APHIS 2010a). Guam laws and regulations are contained in the
34 Guam Administrative Rules and Regulations and the Guam Code Annotated (Supreme Court of Guam,
35 Compiler of Laws, Guam Administrative Rules and Regulations
36 <http://www.justice.gov.gu/compileroflaws/gar.html>).

1 Various sections of 9 CFR regulate importation of meat, poultry meat and eggs, animal byproducts, milk
2 and milk products, hides, skins, wool, hair, animal feed, and garbage. Most regulations restrict
3 importation from countries known to be affected with specific diseases of concern, including African
4 swine fever, classical swine fever, swine vesicular disease, foot and mouth disease, rinderpest, bovine
5 spongiform encephalopathy, HPAI H5N1, and END. Animal products are also restricted for anthrax and
6 animal disease vectors, including ticks. Furthermore, the Animal Product Manual cites regulations
7 administered by APHIS as well as certain Food Safety and Inspection Service requirements that must be
8 met in order to import certain animal products and byproducts and makes reference to other agencies
9 such as the Food and Drug Administration, whose requirements must also be followed (9 CFR § 94,
10 USDA-APHIS 2010a). Like live animals, animal products must be imported into the United States through
11 an approved port (9 CFR § 92, 9 CFR § 93, 9 CFR § 94, 9 CFR § 95,).

12 In addition to federal regulations, several Guam territorial laws and regulations are applicable. These
13 may be found in the Government Code of Guam Public Law (1956) and the Guam Administrative Rules
14 and Regulations. Regulations covered by these two documents pertain primarily to issues of food safety,
15 including import regulations that require milk pasteurization and grade standards. Additionally, the
16 Guam Administrative Rules and Regulations provide rules for processing garbage used to feed any
17 livestock species (26 GARR 14).

18 Importation of animal skin to Guam is limited to inspected tanned and chromed leather hides, which, in
19 contrast to untreated skins from freshly slaughtered animals, would be unlikely to harbor ticks (Ergönül
20 2006).

21 In 2008, 8,985 cargo documents (cargo manifests) were reviewed and cleared, and 19,180 cargo
22 inspections were conducted by GCQA inspectors, representing more than 19% of incoming cargo. Data
23 provided by the Maritime port indicate that two shipments for the FY 2009 contained prohibited meat.
24 Also, officials from GCQA have reported the entry of high risk cargo including eggs from Japan, China
25 and Korea (Sgambelluri et al. 2009).

26 The U.S. Army and Air Force have veterinarians who provide food safety and inspection services. Food
27 purchased by the military comes to the warehouse in the military port where it is inspected by military
28 veterinarians prior to distribution.

29 International flights to Guam arrive at A.B. Won Pat International Airport. GCQA has customs jurisdiction
30 and passengers from arriving flights go through GCQA inspections. Passenger inspections are targeted
31 towards flights considered to be high risk for importation of prohibited animal products, including flights
32 originating from Korea, China, the Philippines, Palau, and CNMI (Sgambelluri et al. 2009; Taijeron 2009).
33 Approximately 9% of passengers from high risk flights have their baggage inspected. GCQA detector dog
34 teams trained to detect agricultural products conduct regular operations in arrival halls at the airport.
35 Four dogs work two shifts for morning and night flights. Detection of undeclared items may result in
36 flight delays and fines up to \$1,000.

1 All seized goods containing animal products are destroyed. In the past, the use of x-ray machines
2 permitted the rapid screening of 100% of passenger baggage. At the time of our visit in November 2009,
3 four x-ray machines were present at the airport, but they were not functioning. While the use of x-ray
4 machines is important for detecting prohibited agricultural products, use of dogs can increase detection
5 by as much as two-fold (Shih et al. 2005). Overall, studies have found that the combined use of detector
6 dogs with x-ray screening results in 85% of meat products being detected (Pharo 2001). It is not clear
7 that there are sufficient functional x-ray units and detector dogs on Guam to achieve this level of
8 efficacy, however.

9 All flights from Guam to the mainland United States go through Hawai'i where all passengers and cargo
10 are treated as foreign arrivals by Honolulu PPQ inspectors. In Hawai'i, all passengers and crew members
11 arriving by commercial aircraft or vessel who are carrying plants, animals, microbial cultures, or soil
12 must complete a mandatory agricultural declaration form and submit the items for inspection.
13 Movement of plant products between Guam and the rest of the United States is restricted; however,
14 movement of animal products from Guam to the rest of the United States is considered a domestic
15 movement and, therefore, is not restricted.

16 Most military personnel and their dependents will be relocated to Guam from the mainland United
17 States and therefore will not pose a risk for introduction of contaminated animal products. In addition,
18 the military has procedures in place to mitigate the risk of introduction of prohibited animal products
19 into Guam. According to personnel at Andersen AFB, no cargo has ever been rejected (Hicks 2010). If the
20 regulations are properly enforced and inspections are performed appropriately, the risk should be
21 adequately mitigated.

22 ***Summary***

23 The volume of imports of animal products, including food commodities, animal feed, and hides and
24 skins, will increase with the military relocation. Most animal product imports to Guam originate in the
25 continental United States, New Zealand, and Australia, areas free from most hazards considered in this
26 assessment that could be associated with animal products. Federal and territorial regulations and
27 inspection procedures provide further mitigation against hazards for legal imports. However,
28 interdiction of smuggled products is unlikely to be 100% and increased demand for such products is
29 likely.

30 Despite current inspection procedures and GCQA fines for violations, passengers continue to bring high-
31 risk animal products into Guam. The predicted large influx of immigrant workers and progressive
32 increase in the number of tourists originating from Asian countries is likely to increase the volume of
33 smuggled animal products and the likelihood of introduction of livestock or poultry disease agents
34 associated with animal products. Passenger baggage passenger may be an important pathway of
35 introduction of contaminated animal products. In addition, there may be gaps in inspection of
36 international mail destined for the Region and animal products may therefore enter the Micronesia
37 Region through the mail.

1 ***Animal Products Pathway Release Assessment***

2 The increased risk of release of hazards into the Micronesia Region due to the military relocation
3 through legal movement of animal products is negligible.

4 The increased risk of release of hazards into the Micronesia Region due to the military relocation
5 through illegal movement of animal products is low.

6 **A6.3.3.7.3 Exposure Assessment: Animal Products Pathway**

7 ***Biological Factors***

8 Contaminated meat and other animal products may readily serve as fomites for the spread of a number
9 of important viruses, including African swine fever, classical swine fever, foot and mouth disease, HPAI,
10 and END viruses (Thomas et al. 2008). Livestock and poultry on Guam could be infected with these
11 viruses through being fed uncooked contaminated meat or poultry products, such as in table scraps or
12 other garbage. Many of these same issues and factors will also apply to the garbage pathway, a
13 discussion of which follows; they will be discussed there in additional detail.

14 ***Regional Factors***

15 Throughout the Micronesia Region, pigs are often reared in backyards and fed meat scraps. Feral swine
16 and poultry are present throughout the Region. Contaminated animal products could end up in waste
17 that is intentionally fed to pigs or disposed of where feral swine and poultry can access it.

18 Feral animals and birds contribute to spread where there is access to garbage or landfills by dropping
19 scraps in proximity to other livestock or feral animals (Hartnett et al. 2007), which is discussed in greater
20 detail in the garbage pathway section that follows.

21 ***Commodity Factors***

22 Illegal introduction of specialty and culture-specific foods, including meat and eggs, may increase in
23 volume, with the influx of workers. The high cost of importing commercial feed may also serve as an
24 incentive for illegal importation of animal products.

25 ***Summary***

26 Livestock and poultry on Guam may be exposed to animal disease agents through the feeding of
27 contaminated meat or poultry products. The presence of backyard poultry and swine, feral poultry and
28 swine, and garbage-fed swine operations increases the opportunities for exposure and subsequent
29 spread.

30 ***Animal Products Exposure Assessment***

31 The risk of exposure of livestock or poultry to hazards released into the Micronesia Region through the
32 animal products pathway is medium.

1 **A6.3.3.7.4 Consequence Assessment: Animal Products Pathway**

2 **Biological Consequences**

3 Spread of HPAI and END can be enhanced by the presence of feral and backyard free-ranging chickens.
4 Morbidity may approach 100% and mortality may be as high as 90% for both diseases in susceptible
5 chickens (CFSPH 2008d, 2010b). A similar situation is present with respect to feral swine and the swine
6 diseases of concern. Spread by similar means could occur with exposure of swine, cattle, pigs, sheep,
7 goats, and carabaos to foot and mouth disease virus, resulting in significant morbidity (CFSPH 2007e).

8 Because these disease agents are exotic to the United States, their introduction into Guam would likely
9 result in severe restriction of movement of animals and animal products from Guam to the rest of the
10 United States.

11 **Environmental Consequences**

12 In the face of an outbreak of an exotic livestock or poultry disease, such as END, classical swine fever, or
13 foot and mouth disease, it is likely that steps would be implemented to control or eradicate the disease,
14 which may include depopulation of sick and exposed animals as well as feral animals in the area.
15 Disposal of large numbers of carcasses, as well as litter and manure, would adversely impact the
16 environment, e.g. by leaching contaminants into the soil.

17 **Economic Consequences**

18 Control of even limited outbreaks could be costly. For example, Arizona and Texas each had only one
19 premises on which END infection was detected in 2002-2003; 10 infected premises were identified in
20 Nevada. Approximately \$3.5 million were spent on eradication efforts in Arizona, \$4.2 million in Texas,
21 and \$6.2 million in Nevada (USDA-APHIS-VS 2005).

22 Even more significant may be the possibility of trade restrictions being imposed by other countries on
23 trade in animals or animal products from the rest of the United States. Restrictions on trade from
24 anywhere in the United States could remain in place until steps are taken to regionalize Guam, which
25 would likely involve restricting the current free movement of animals and animal products from Guam
26 to the rest of the United States and through the Micronesia Region.

27 While livestock are not economically important to inhabitants of Guam and the rest of the Micronesia
28 Region, as evidenced by the total value of agricultural sales, estimated at \$2.8 million, and the size of
29 the agricultural sector as compared to other sectors, approximately 0.52% of the total workforce (USDA-
30 NASS 2009a), they are culturally important. Cultural and societal impacts might be more significant than
31 the economic consequences; however, this assessment does not take into consideration these intrinsic
32 values.

33 **Summary**

34 We expect the illegal importation of meat or other animal products contaminated with exotic livestock
35 or poultry disease agents to be a rare occurrence; however, once present in the Micronesia Region,

1 there are opportunities for exposure of livestock and poultry. Consequences of an outbreak of a disease
2 exotic to the United States would be significant.

3 ***Animal Products Pathway Consequence Assessment***

4 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
5 the Micronesia Region through the animal products pathway is low.

6 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
7 exposure to hazards released into the Micronesia Region through the animal products pathway is low.

8 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
9 hazards released into the Micronesia Region through the animal products pathway is medium.

10 ***Animal Products Pathway Risk Estimation***

11 Because the increased risk of release of hazards into the Micronesia Region due to the military
12 relocation through the animal products pathway is low, the risk of exposure of livestock and poultry is
13 medium, and the significance of consequences of livestock and poultry exposure is low, we conclude
14 that the military relocation-associated overall risk for the animal products pathway is low.

15 **A6.3.3.8 *Garbage***

16 Imported garbage includes refuse generated during a voyage, rejected cargo, and prohibited items
17 removed from passenger baggage at ports of entry. The main potential sources of garbage arriving in
18 the Micronesia Region are military aircraft and maritime vessels, private yachts, commercial airlines, and
19 civilian maritime vessels engaged in fishing or carrying passengers and cargo. Imported garbage may
20 enter the Micronesia Region through legal or illegal channels.

21 The relocation is expected to bring additional people, aircraft, cargo and cargo ships, and military ships
22 from foreign countries (U.S. Navy 2010a). Therefore, we expect the military relocation to result in an
23 increased volume of imported garbage, including rejected cargo and seizures of prohibited items from
24 passenger baggage.

25 **A6.3.3.8.1 *Hazards Associated with the Garbage Pathway***

26 Garbage can transport hazards in two roles: it can be, or be contaminated with, a disease agent and
27 serve as a fomite; or it can harbor vectors of disease agents. In this analysis, we consider garbage to be a
28 potential source of all hazards (see Table A6-4 and Table A6-6), including hazards for which garbage may
29 serve as only a minor or theoretical source.

30 **A6.3.3.8.2 *Release Assessment: Garbage Pathway***

31 ***Likelihood of Hazard Association***

32 Any of the hazards listed in Tables A6-4 and A6-6 could at least theoretically be transported to the
33 Micronesia Region in or as garbage. For many of these hazards, garbage is not a major means of spread.
34 However others, in particular disease agents associated with animal products, are readily spread

1 through contact with garbage. For example, contaminated meat in garbage is a well known source of
2 transmission of African swine fever, classical swine fever, foot and mouth disease, and swine vesicular
3 disease viruses, typically through garbage feeding to swine (OIE 2009g, h, j, r).

4 Garbage, including imported garbage, has been confirmed or strongly implicated as a disease agent
5 source in several outbreaks of African swine fever, classical swine fever, and foot and mouth disease.
6 Feeding swine with imported garbage that contains uncooked pork is the most common means of
7 introduction of African swine fever virus into uninfected swine herds in African swine fever-free regions
8 outside of Africa (EFSA 2010). For example, an African swine fever outbreak in Portugal in 1957 was
9 attributed to feeding of swine with contaminated garbage from an international flight (EFSA 2010).
10 Ship's garbage fed to swine was identified as the most likely source of foot and mouth disease virus in
11 foot and mouth disease outbreaks in California in the 1920s (USDA-APHIS-VS CEAH 1994). Illegally
12 imported ship's garbage fed to swine was implicated as a source of classical swine fever virus in an
13 outbreak in New Zealand in 1933 (Davidson 2002). Discarded food scraps in garbage sourced from a
14 naval shore base were identified as the most likely source of classical swine fever virus in a classical
15 swine fever outbreak in New Zealand in 1953 (Watt and Wallace 1954). More recently, discarded meat
16 fed to swine was identified as the most likely disease agent source in classical swine fever outbreaks in
17 Germany in the 1990s and an foot and mouth disease outbreak in the United Kingdom in 2001
18 (Fritzemeier et al. 2000; DEFRA 2002).

19 The duration that disease agents remain infectious in the environment varies by agent and
20 environmental conditions. Garbage can provide a dark, moist environment rich in organic matter that is
21 conducive to survival of some disease agents. For example, AIVs can survive for weeks in cool, moist
22 environments that contain organic matter (OIE 2009m). *Echinococcus* species can remain viable for
23 weeks to months in dark, moist environments (CFSPH 2009h). END virus can survive for weeks in
24 contaminated litter or soil (CFSPH 2008d). As noted above, African swine fever, classical swine fever, and
25 swine vesicular disease viruses can remain viable in dried meats and other animal products for months
26 to years. In contrast, other disease agents, such as the etiologic agents of dourine, heartwater, and
27 Japanese encephalitis, are much less stable outside of living hosts (CFSPH 2007h; OIE 2009i, l).

28 Accumulated garbage and trash provides food and harborage for rodents and breeding grounds for
29 arthropod vectors, including *Culex* and *Aedes* species mosquitoes, thereby potentiating risk for Japanese
30 encephalitis and dengue outbreaks (Gratz 1999a; Gratz 1999b).

31 ***Traffic Volume***

32 We expect the volume of garbage arriving in Guam to increase as a result of the relocation-associated
33 increase in the volume of movement of people and conveyances to Guam. The current system for
34 disposal of garbage in Guam appears to be working at capacity, and likely will not be able to
35 accommodate an increase in demand for capacity.

1 ***Traffic Origin***

2 Garbage imported into the Micronesia Region can be derived from a wide variety of sources, including
3 animal and plant products from regions of origin, embarkation, or transit of people and conveyances
4 arriving in the Region. Additionally, according to data provided by the Guam Bureau of Statistics and
5 Plans for 2009, the major import partners for all imported animal products to Guam were the United
6 States (50%), Japan (14%), Western Europe (France, Italy and Switzerland) (13%) and other Asian
7 countries or regions (16%) (including China, Korea, Taiwan, Hong Kong, Singapore, Thailand, and the
8 Philippines). After these animal products are used, they would be discarded as garbage and represent
9 the potential sources of disease agents. Additionally, garbage generated during training and military
10 exercises in Tinian is transported back to Guam. This is problematic, since it may contribute to the
11 spread of both agricultural disease agents and invasive species. For this reason, current federal
12 regulations prohibit such movement.

13 ***Mitigations***

14 Details on the regulation of garbage and solid waste are presented elsewhere in this document.

15 For federal regulatory purposes, the term “garbage” refers to all waste material that is derived in whole
16 or in part from fruits, vegetables, meats, or other plant or animal (including poultry) material, and other
17 refuse that has been associated with any such material (9 CFR §94).

18 Importation of garbage from all foreign countries except Canada into the United States is prohibited and
19 movement of garbage from Hawai’i, Puerto Rico, American Samoa, CNMI, FSM, Guam, the U.S. Virgin
20 Islands, RMI, and Palau to any other State is prohibited with few exceptions. We note, however, that the
21 garbage generated during training and military exercises in Tinian is transported back to Guam.

22 Garbage is regulated if it is on or removed from a conveyance that has been in any port outside the
23 United States and Canada within the previous 2 years. Garbage generated during international or
24 interstate movements, including food scraps, table refuse, galley refuse, food wrappers or packaging
25 materials, and other waste material from stores, food preparation areas, passengers' or crews' quarters,
26 or dining rooms, is regulated; this also includes meals and other food that were available for
27 consumption by passengers and crew on an aircraft but were not consumed (9 CFR § 94).

28 While on board a conveyance, all regulated garbage must be contained in tight, covered, leak-proof
29 receptacles. For Guam and CNMI, this generally extends to territorial waters, 12 nautical miles offshore.
30 If unloaded, regulated garbage must be moved under the direction of an inspector to an approved
31 facility for incineration, sterilization, or grinding into an approved sewage system (9 CFR § 94). Within
32 the Micronesia Region, port demand for waste reception facilities is highest in Guam (Nawadra et al.
33 2002). Waste, including regulated garbage, from large merchant vessels is generally not accepted in
34 Guam, and the commercial port generally does not accept waste from international vessels. At the
35 commercial port, commercial marinas, and fisheries wharves in Guam, waste is collected by private
36 waste collection companies under compliance agreements with APHIS and is subject to Port Authority
37 and government policies and regulations. In general in the Micronesia Region, waste from international

1 vessels that contains food waste is treated as quarantine regulated garbage. In Guam, regulated garbage
2 and rejected cargo seized from international vessels are incinerated.

3 Solid waste generated on land can be broadly categorized as municipal, commercial, or industrial.
4 Domestic solid waste generated on Pacific islands, including islands of the Micronesia Region, has been
5 estimated to include large proportions of packaging waste, food waste, and garden waste (WHO 1996).
6 Municipal, commercial, and industrial waste in Guam is disposed of at Ordot Dump, an unlined,
7 uncapped landfill that is scheduled to be closed in 2011 (GSWRIC 2010). A new landfill is under
8 construction. Household food waste is fed to pigs and chickens, or used as fertilizer (Nawadra et al.
9 2002). Quarantine and hospital waste is incinerated (Nawadra et al. 2002).

10 DoD waste is disposed of at the Navy Sanitary Landfill located on the Navy base, or at a landfill located
11 at Andersen AFB (U.S. Navy 2010a). At both of these landfills, waste is buried daily. Wood, such as
12 crates, and other green waste at the Andersen AFB landfill is shredded; the shredded waste is used for
13 landscaping on and off base. Waste from Navy ships berthed at Apra Harbor is disposed of at the Navy
14 Sanitary Landfill.

15 ***Summary***

16 Garbage is a potential source of introduction and spread of several hazards. The volume of international
17 and domestic garbage arriving in Guam is expected to increase as a result of the military relocation. As
18 risk increases with additional volumes of animal products imported, so too will the risk from the garbage
19 created from illegal imports of animal products. Despite the strength of regulations that serve to
20 mitigate risk, we conclude that some residual additional risk of hazard release remains.

21 ***Garbage Pathway Release Assessment***

22 The increased risk of release of hazards into the Micronesia Region due to the military relocation
23 through legal movement of imported garbage is negligible.

24 The increased risk of release of hazards into the Micronesia Region due to the military relocation
25 through illegal movement of imported garbage is very low.

26 **A6.3.3.8.3 Exposure Assessment: Garbage Pathway**

27 ***Biological Factors***

28 Disease agents associated with animal products are readily spread through contact with garbage. Fomite
29 spread of African swine fever, classical swine fever, foot and mouth disease, and swine vesicular disease
30 viruses from contaminated meat in garbage is well known to occur, typically exposing livestock through
31 garbage feeding to swine (OIE 2009g, h, j, r). Similarly, feeding uncooked chicken or other fowl
32 contaminated with HPAI or END viruses to poultry can result in poultry infection with these viruses
33 (Thomas et al. 2008).

1 **Regional Factors**

2 The relocation is expected to bring additional people, airplanes, cargo and cargo ships, and potentially
3 additional military ships from foreign countries. Increased garbage, seizures from baggage, and rejected
4 commodities can reasonably be expected. This increase may overburden the system to the point where
5 it cannot adequately address the risk these items may pose to Guam.

6 Pigs and poultry are the two production animal species of importance on Guam and are most likely to be
7 fed uncooked food waste, given the high cost of importing commercial feed and limited space for
8 garbage disposal on the island. Other livestock exposure to food waste is generally considered to be
9 limited to accidental access to improperly disposed of waste.

10 The feeding of garbage (as defined above) to swine is regulated by USDA (9 CFR § 166). While feeding
11 personal household garbage is not restricted, any garbage collected from other premises, including
12 restaurants, must be cooked and handled as described in the regulations. These regulations are not
13 currently enforced for backyard swine on Guam, leaving this pathway open.

14 Feral animals may be exposed to contaminated garbage while foraging in landfills. Scavenger species can
15 frequent landfills, including primarily feral pigs, but also dogs, cats, and birds. Landfills are fenced to
16 inhibit wind dispersal and to exclude animals from accessing the landfill. However, fencing is not always
17 fully effective. Although the military landfills have a perimeter fence, they may need a redesign or
18 upgrading to ensure that they are feral pig proof. Certain birds, in particular gulls (the black-headed gull,
19 *Larus ridibundus*) are scavengers at landfills and may carry meat scraps offsite, increasing risk of
20 exposure of other animals, including livestock and other feral animals (Hartnett et al. 2007).

21 **Summary**

22 The expected increase in the volume of garbage imported into Guam may overburden the waste
23 disposal system in Guam to the point at which it cannot adequately mitigate the risk that imported
24 garbage poses to livestock and poultry health on Guam. We expect importation of garbage containing
25 meat or other animal products contaminated with livestock or poultry disease agents to be a rare
26 occurrence, generally as importation of prohibited garbage; however, once garbage is imported,
27 opportunities for exposure of livestock and poultry are present. In addition, items illegally moved into
28 Guam as passenger baggage may end up in garbage fed to swine. The Swine Health Protection
29 regulations are not enforced on Guam, providing a pathway for disease agents to enter the swine
30 population.

31 **Garbage Pathway Exposure Assessment**

32 The risk of exposure of livestock or poultry to hazards released into the Micronesia Region through the
33 garbage pathway is medium.

1 **A6.3.3.8.4 Consequence Assessment: Garbage Pathway**

2 **Biological Consequences**

3 While the biological consequences are dependent on disease agent exposure to poultry or livestock on
4 Guam, END, HPAI, or foot and mouth disease virus, if introduced, could be spread widely by fomites.
5 Chickens are very susceptible to END and HPAI, experiencing significant mortality as a consequence of
6 infection. The presence of feral and backyard free-ranging chickens would likely enhance spread. For
7 both diseases, morbidity and mortality rates vary according to the strain of virus, but morbidity may
8 approach 100% and mortality may approach 90% in susceptible chickens (CFSPH 2008d, 2010b). Spread
9 by similar means could occur with exposure of swine cattle, pigs, sheep, goats, and carabaos to foot and
10 mouth disease virus, resulting in significant morbidity though generally low mortality (CFSPH 2007e).

11 Because these disease agents are exotic to the United States, their introduction into Guam would likely
12 result in severe restriction of movement of animals and animal products from Guam to the rest of the
13 United States.

14 **Environmental Consequences**

15 The volume of international and domestic garbage arriving in Guam is expected to increase as a result of
16 the military relocation. Such an increase would tax existing resources for disposal. In the face of an
17 outbreak of an exotic disease, such as END, classical swine fever, or foot and mouth disease, it is likely
18 that steps would be implemented to control or eradicate the disease, which may include depopulation
19 of sick and exposed animals as well as feral animals in the area. Disposal of large numbers of carcasses,
20 as well as litter and manure, would adversely impact the environment, e.g. by leaching contaminants
21 into the soil.

22 **Economic Consequences**

23 Control of even limited outbreaks would be costly. For example, Arizona and Texas each had only one
24 premise on which END infection was detected in 2002-2003; 10 infected premises were identified in
25 Nevada. Approximately \$3.5 million were spent on eradication efforts in Arizona, \$4.2 million in Texas,
26 and \$6.2 million in Nevada (USDA-APHIS-VS 2005).

27 Even more significant may be the possibility of trade restrictions being imposed by other countries on
28 trade in animals or animal products from the rest of the United States. Restrictions on trade from
29 anywhere in the United States could remain in place until steps are taken to regionalize Guam, which
30 would likely involve restricting the current free movement of animals and animal products from Guam
31 to the rest of the United States and through the Micronesia Region.

32 While livestock are not economically important to inhabitants of Guam and the rest of the Micronesia
33 Region, as evidenced by the total value of agricultural sales, estimated at \$2.8 million, and the size of
34 the agricultural sector as compared to other sectors, approximately 0.52% of the total workforce (USDA-
35 NASS 2009a), they are culturally important. Cultural and societal impacts might be more significant than
36 the economic consequences; however, this assessment does not take into consideration these intrinsic
37 values.

1 **Summary**

2 In a worst case scenario, an outbreak of a foreign animal disease such as END, HPAI, or foot and mouth
3 disease in the Micronesia Region poses a threat of introduction into Hawai'i or the continental United
4 States, given the interconnections between the islands of the Micronesia Region to each other, Hawai'i,
5 and the continental United States by air and sea. The economic impact of trade bans due to a poultry or
6 livestock disease outbreak in the Micronesia Region is likely to be insignificant to Guam and rest of the
7 Region, which lacks commercial livestock and poultry industries, as evidenced by the limited value of
8 agricultural sales and size of the agricultural workforce, but significant to the rest of the United States
9 (USDA-NASS 2009a). Regionalization policies would likely reduce the trade consequences at the national
10 level.

11 **Garbage Pathway Consequence Assessment**

12 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
13 the Micronesia Region through the garbage pathway is low.

14 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
15 exposure to hazards released into the Micronesia Region through the garbage pathway is low.

16 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
17 hazards released into the Micronesia Region through the garbage pathway is medium.

18 **Garbage Pathway Risk Estimation**

19 Because the increased risk of release of hazards into the Micronesia Region due to the military
20 relocation through the garbage pathway is very low, the risk of exposure of livestock and poultry is
21 medium, and the significance of consequences of livestock and poultry exposure is low, we conclude
22 that the military relocation-associated overall risk for the garbage pathway is low.

23 **A6.3.3.9 Other Cargo**

24 In this pathway, we consider the effect of the military relocation on the risk to livestock and poultry
25 health through the movement of cargo other than live animals, animal products, or garbage into the
26 Micronesia Region. Mail is considered within this pathway. We expect that pathway traffic volume in
27 cargo moved through legal or illegal means will increase as a result of the military relocation, due to
28 demands for consumer goods by a larger population.

29 **A6.3.3.9.1 Hazards Associated with the Other Cargo Pathway**

30 Cargo can transport hazards in two roles: it can be, or be contaminated with, a disease agent and serve
31 as a fomite; or it can harbor vectors of disease agents. In this analysis, we consider cargo to be a
32 potential source of all hazards (Table A6-4 and Table A6-6), including hazards for which other cargo may
33 serve as only a minor or theoretical source.

1 **A6.3.3.9.2 Release Assessment: Other Cargo**

2 ***Likelihood of Hazard Association***

3 Although ticks have a biotic requirement for living hosts, they are only intermittent parasites. Most tick
4 species spend the majority of their lifecycle free within the environment, and ticks at all lifecycle stages
5 have been reported to survive off the host for long periods of time, sometimes for months or years
6 (Randolph 2004). Ticks have been found on a wide variety of other inanimate articles offered for
7 importation. The USDA national tick survey database and PPQ pest interception database include
8 records of approximately 50 tick interceptions on various articles, ranging from construction materials to
9 pottery to wood packing materials (USDA-APHIS 2009a). The PPQ pest interception database includes
10 records of more than 80 instances of ticks having been transported to the United States on a wide
11 variety of imported live plants and plant material such as cut flowers, dried herbs, or handicrafts. There
12 is no distinguishable pattern in these interceptions. Most of the interceptions were of *R. sanguineus*, a
13 cosmopolitan tick species already present in the Micronesia Region, but exotic ticks of the genera
14 *Amblyomma*, *Dermacentor*, *Haemaphysalis*, and *Hyalomma* were also found. In general, it is possible for
15 ticks to be associated with almost any article, but considering the large number of articles that enter the
16 United States each day, relatively few interceptions have been recorded. Ticks have occasionally been
17 intercepted from the hides and skins of recently slaughtered animals.

18 In the 1990s, the majority of interceptions of non-indigenous mosquito species occurred around seaport
19 areas. Multiple studies have identified such interceptions (Whelan 1998; Whelan et al. 2001; Derraik
20 2004; Frampton 2005). Past and current data show that cargo containers are a pathway for the
21 successful introduction of non-indigenous mosquitoes at seaports (Lounibos 2002). Lounibos noted that
22 most successful mosquito invaders arrived by ship as larvae in containers or cargo (Lounibos 2002). It
23 takes approximately five to 15 days for a ship to travel to Guam from an Asian (China, Korea, Japan,
24 Indonesia, Malaysia, Philippines, Singapore), Oceanic (Australia and New Zealand), or American seaport.
25 It is likely that any adult mosquitoes aboard will die or disperse before the ship reaches Guam. However,
26 modern vessels can transport containers and cargo, which can carry a large number of propagules
27 (Frampton 2005).

28 Container shipping and the global used tire industry have contributed to the increased geographic
29 distribution of selected mosquito species (Frampton 2005). Approximately 75% of mosquitoes
30 intercepted on board cargo vessels were found in used machinery or used tires on board ships (Derraik
31 2004). Live mosquito larvae have also been found in tires and other salvage equipment brought back
32 from combat areas in the Pacific (Frampton 2005). Examples of recent introductions of non-indigenous
33 mosquitoes associated with the transport of used tires have occurred in Europe (Romi et al. 1997;
34 Schaffner 2004; Roiz et al. 2007). There are numerous reports of the importation of exotic mosquito
35 species to Australia (Whelan 1991, 1995; Whelan 1998; Lamche et al. 2004; Nguyen and Whelan 2007),
36 and sea containers have been proposed as a potential pathway for the introduction of mosquitoes into
37 Australia and New Zealand (Derraik and Calisher 2004). On a global scale, many insect vector invasions
38 go unnoticed because of a lack of adequate surveillance.

1 To better understand the risk associated with the movement of containers, we utilized data published in
2 New Zealand where a strict surveillance system, including exhaustive cargo inspection and a detailed
3 recording of findings, was implemented at ports of entry (Border Management Group 2003). New
4 Zealand received an annual total of 260,000 loaded sea containers in 2003. More than 11,000 sea
5 containers were inspected by New Zealand's Ministry of Agriculture and Forestry. In the review, it was
6 found that approximately one in five containers contained some form of contamination, and that most
7 of the contamination was inside rather than outside the containers. Vehicles and machinery accounted
8 for 33% of product seizures, with nearly 29% of all vehicles intercepted requiring treatment. Cane ware
9 and used tires that require mandatory fumigation on arrival accounted for 24% of seizures. The Pacific
10 Islands were the region with the highest incidence of risky cargo (72%) and contamination in loaded
11 (40%) and unloaded (22%) containers. Nearly half of empty containers (45.8%) arriving in New Zealand
12 came from the Pacific Islands. Organisms, of which 40% were insects, were found in 6.1% of loaded
13 containers and 1.3% of unloaded containers. Approximately 40% of the containers had live organisms.
14 Organisms were found on the inside and outside of containers (Gadgil et al. 1999). A total of nine
15 containers held mosquitoes, four of them with live specimens (Border Management Group 2003).

16 Despite past occurrence of outbreaks of arboviral diseases on Guam, such as Japanese encephalitis, the
17 occurrence of arboviral diseases in Guam in the last 30 years is rare and mostly related to low-level
18 sporadic transmission of dengue viruses (Gubler 2003). WNV and JEV are pathogens of importance
19 based on the relatively high prevalence of these diseases in parts of the world. They can be introduced
20 via adult infected mosquitoes or eggs and immature forms, as the mosquitoes have been shown to
21 vertically transmit the viruses to their offspring (Rosen et al. 1989; Baqar et al. 1993). It is not always
22 clear whether recent introduction of these arboviruses is due primarily to mosquitoes or to infected
23 birds or humans travelling into new areas, and thereby introducing virus to the local mosquitoes.
24 Humans remain infectious with JEV for a short period of time making transmission back to biting
25 mosquitoes unlikely (Fischer et al. 2009); thus, there is reason to assume that arriving infected
26 mosquitoes have been the source for spread of JEV, similar to the pattern seen with the reintroduction
27 of dengue and spread through the Micronesia Region (Paul et al. 1993; Gubler 2002). The current level
28 of surveillance on Guam is not sufficient for detection and interception of infested cargo, particularly for
29 mosquito eggs and larvae; nor does a surveillance system exist in seaport areas for the detection of
30 newly introduced non-indigenous vectors.

31 As to *Culicoides* species (biting midges), a 2007 assessment of risk for the importation of bluetongue
32 into Ireland from the United Kingdom estimated the risk of transportation of parous infected *Culicoides*
33 in vehicles or containers or in hay straw or plants to be low. There is no evidence from the literature that
34 such accidental transportation of *Culicoides* has ever occurred or that parous female midges could
35 survive the transport conditions (Duignan et al. 2007).

36 ***Traffic Volume***

37 Additional data on cargo imports are presented elsewhere in this document. Guam depends on imports
38 from foreign nations. In the last decade, the total number of sea lift containers increased over 35%

1 (103,000 in 2007) and it is expected to reach 190,000 (84% increase) at the peak of the military
2 relocation.

3 ***Traffic Origin***

4 In 2009, more than half of the total dollar value of imports to Guam came from the United States (53%),
5 with about 30% and 13% coming from Asia and Europe, respectively (BSP 2009b; Ferrier 2009; Guam
6 Visitors Bureau 2009).

7 ***Mitigations***

8 GCQA serves as the primary filter for goods that represent a threat to the agriculture of the island.
9 Agents from GCQA are responsible for inspecting and clearing imports from all vessels, cargo and people
10 entering Guam, whether from the mainland United States or foreign countries. If GCQA agents discover
11 any plants, plants materials, insects or certain types of animal products, they will refer the material to
12 USDA-APHIS-PPQ for further inspection.

13 GCQA requires a manifest from the shipping agent for all incoming cargo. Upon arrival the shipper holds
14 imported goods against a bond. GCQA will always inspect certain types of cargo considered to be of high
15 risk before granting entry. Most of the inspection activities apply only to shipments entering Guam from
16 foreign sources. Inspections are complemented by the use of an x-ray machine. Container inspection
17 takes 30 minutes and most commodity inspections occur during two consecutive weekdays coinciding
18 with the arrival of the majority of domestic cargo from the United States. Low staffing levels relative to
19 the large volume of goods entering Guam do not allow for inspection of all cargo. Instead GCQA relies
20 on documentation such as a manifest for identification and internal inspection of high risk containers. All
21 declared items that include animals, animal products and byproducts, and propagative plant materials
22 are considered risk goods and GCQA agents will inspect them. Holds are placed on shipments of interest
23 that are fully inspected and remain unloaded until cleared. In 2008, 8,985 cargo documents (cargo
24 manifests) were reviewed and cleared and 19,180 cargo inspections were conducted by GCQA; that
25 represents inspection of over 19% of all incoming cargo shipments. Inspections conducted in Guam
26 during fiscal year 2009 found live insects in one cargo shipment. However, we do not know the number
27 of containers that were opened and inspected. We do not have information on the species, number of
28 specimens intercepted, and whether they were dead or alive (GCQA 2009). In Guam, inspections are
29 more stringent for outbound than inbound cargo due to the lack resources and infrastructure (Brown
30 2010a).

31 Military maritime and airport facilities are subject to GCQA inspection, but such inspections are limited
32 due to the lack of staff and difficulties getting permission from military command. GCQA is currently
33 establishing cooperative agreements with military bases that will clarify each agency's inspection and
34 interception responsibilities. Although Guam is a territory of the United States, it is outside of CBP
35 jurisdiction.

36 Relocation of military and dependents to Guam will occur mostly from the mainland United States. If
37 some personnel are transferred from foreign locations, the military has procedures in place to mitigate

1 the risk of introduction of arthropod vectors via this route. Military Customs Inspections inspectors are
2 responsible for implementation of federal customs statutes for transfer of military personnel and goods
3 from overseas destinations into a territory within U.S. jurisdiction. These inspectors will conduct
4 inspections on aircraft arriving from foreign destinations for the presence of insects in cabin areas and
5 spray when necessary. Air Force Joint Instruction (AFJI) 48-104, the Quarantine Regulations of the
6 Armed Forces (DoD 1992), incorporate regulations to mitigate the risk of introduction and dissemination
7 of arthropod vectors by movement of vessels, aircraft, and other transport of the Armed Forces arriving
8 at or leaving installations in the United States and foreign countries, ports or other facilities where
9 arthropod vector-borne diseases are known to exist. The information on the materials and procedures
10 for disinsection can be found in the Military Entomology Operational Handbook (NAVFAC M0-310,
11 Army TM 5-632, Air Force AFM 91-16) (U.S. Navy 1972; USAPHC 2010).

12 ***Summary***

13 The military relocation is expected to be accompanied by a significant increase in cargo imports to
14 Guam. Cargo will likely come from the United States rather than countries of concern for ticks carrying
15 exotic livestock disease. This fact, along with inspection, should adequately mitigate the risk for release
16 of disease-carrying ticks through the movement of cargo.

17 Low numbers of mosquito vectors have been identified hitchhiking on cargo in numerous studies,
18 primarily focused on tires and equipment. Because we expect an increase in cargo coming into the
19 Micronesia Region as a result of the relocation, the probability of introduction of vectors will likely
20 increase concurrently. While vectors may be introduced, the likelihood that an introduced mosquito will
21 be infected with an animal disease agent is reported in multiple studies to be less than 0.1% (Nasci and
22 Mitchell 1996; Kramer and Bernard 2001; O'Leary et al. 2004; Reisen et al. 2004).

23 ***Other Cargo Pathway Release Assessment***

24 The increased risk of release of hazards into the Micronesia Region due to the military relocation
25 through the movement of cargo other than live animals, animal products, or garbage is very low.

26 **A6.3.3.9.3 Exposure Assessment: Other Cargo**

27 ***Biological Factors***

28 Increased risk for the exposure of livestock or poultry to hazards via mosquitoes introduced by this
29 pathway would require an infected mosquito to find its way aboard a conveyance and survive to release
30 a disease agent on Guam. Alternatively, an adult mosquito could lay eggs on that conveyance, and pass
31 the agent along to its offspring through its eggs. The eggs would hatch and complete the cycle to
32 production of adult mosquitoes that will require exposure to a susceptible animal on Guam and in most
33 cases, a competent alternative mosquito host present on the island to maintain infection. Fewer than a
34 dozen mosquito species were reported in the Micronesia Region at the beginning of the 20th century,
35 and no major disease vectors were present. However, in the course of the last century, this number
36 increased four-fold with the introduction of exotic species, such as *Aedes albopictus* and *Aedes aegypti*
37 (Reeves and Rudnick 1951) and numerous *Culex* species, which may be competent alternative hosts for

1 the etiologic agents of several arboviral diseases of human and animal importance (Lounibos 2002), in
2 particular WNV and JEV (Mitchell et al. 1993).

3 **Regional Factors**

4 Mosquitoes released on Guam may be able to bite and infect susceptible populations of wild birds such
5 as pigeons and Eurasian tree sparrows (*Passer montanus*) that are abundant on Guam, and other known
6 susceptible passerine birds, e.g. the Micronesian starling (*Aplonis opaca*) and the Marianas crow (*Corvus*
7 *kubaryi*). There is evidence of the establishment of exotic vectors as a result of accidental introduction
8 related to human activity; however, circumstantial evidence of a disease outbreak via infected vectors
9 has only been seen in the case of malaria (Lounibos 2002). In the case of WNV, spread is more likely to
10 occur from introduction of an infected live bird transmitting the disease agent to an established
11 competent mosquito vector, such as *Aedes albopictus*, *Ae. vexans* and *Ochlerotatus japonicus* (Turell et
12 al. 2005).

13 Backyard and feral pigs serve as amplifying hosts for JEV and are present in sufficient numbers to
14 establish an outbreak, as occurred in 1990 on Saipan (Paul et al. 1993).

15 **Summary**

16 Mosquitoes released on Guam will be able to bite and infect susceptible populations of wild birds,
17 transmitting arboviruses, including WNV and JEV. Competent alternative mosquito vectors are present
18 on Guam, Saipan, and potentially other islands of the Micronesia Region and could sustain infection.
19 Susceptible populations of domestic and feral pigs are present and can serve as amplifying hosts for JEV.
20 Thus, we conclude that the factors necessary for exposure are present.

21 **Other Cargo Pathway Exposure Assessment**

22 The risk of exposure of livestock or poultry to vector hazards released into the Micronesia Region
23 through the movement of cargo other than live animals, animal products, or garbage is medium.

24 **A6.3.3.9.4 Consequence Assessment: Other Cargo**

25 **Biological Consequences**

26 The predominant impacts from the introduction of WNV and JEV would be to humans and to native wild
27 bird populations, with minimal effects on poultry (Ghosh and Basu 2009; OIE 2010d). WNV is a threat to
28 the native wildlife population and may have profound effects on native wild bird populations, resulting
29 in elimination of some susceptible species. Native bird populations on Guam have been severely
30 diminished as a result of invasive species and feral cats and the expected impacts of WNV on remaining
31 native bird populations might result in elimination of some species. Experimental studies have shown
32 that poultry rapidly develop an antibody response capable of neutralizing the virus. Infection in chickens
33 is typically asymptomatic or with minimal clinical signs and pathology, and no mortality (Senne et al.
34 2000).

35 Some deaths have been reported in horses from WNV and JEV infection, though the number of clinical
36 cases is very low compared to the total number of exposed animals (CFSPH 2007h; OIE 2010d). Because

1 of the small number of horses in Guam and relatively low importance of this industry, and the
2 availability of effective vaccines to protect horses against the viruses, we conclude that the biological
3 consequences for introduction of WNV or JEV to the livestock and poultry industries are negligible.

4 As in the continental United States, the major impact of WNV establishment would be to humans. Once
5 established in a tropical environment and in the absence of preventive measures, spread would be
6 expected to be rapid among human populations with no prior exposure or immunity, as would be the
7 case in Guam and throughout the Micronesia Region (Hayes et al. 2005). In humans the ratio of
8 asymptomatic to clinical infection is high and the majority of clinical illness would be limited to mild
9 febrile disease; however about one of every hundred infected may develop severe neurological disease
10 with mortality rates as high as 14% (Madden 2003).

11 Establishment of Japanese encephalitis on Guam would also be of consequence to humans, especially to
12 children. Annually, up to 50,000 cases of Japanese encephalitis are reported worldwide and more than
13 15,000 deaths are reported in eastern and southern Asia. While asymptomatic infection can occur,
14 approximately 30% of Japanese encephalitis cases are fatal and nearly half result in permanent
15 neurological sequelae (Ghosh and Basu 2009). However, any such introduction might well be short lived.
16 In 1990, a rare introduction of Japanese encephalitis on Saipan ended as the population of susceptible
17 pigs which serve as amplifying hosts had been infected and developed immunity, and has not recurred
18 (Paul et al. 1993).

19 ***Environmental Consequences***

20 Native bird populations on Guam have been severely diminished as a result of invasive species and feral
21 cats (Poole 2009). WNV, as with END and HPAI viruses, could decimate remaining populations.

22 ***Economic Consequences***

23 Release and establishment of WNV or JEV would be expected to result in little or no economic loss to
24 the poultry industry or to the few remaining equine operations on Guam; however, significant cost
25 would be incurred for human public health and mosquito vector surveillance, and for vector control to
26 prevent spread throughout the region. A 2005 outbreak of WNV in Sacramento County, California
27 (population 1.3 million) resulted in 163 reported human cases and a response that included emergency
28 aerial spray to control vectors. Costs for aerial spray totaled just over \$700,000 and when added to
29 estimated medical costs and patients' loss in productivity, the total economic impact was estimated at
30 \$2.98 million (Barber et al. 2010).

31 ***Other Cargo Pathway Consequence Assessment***

32 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
33 the Micronesia Region through the other cargo pathway is very low.

34 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
35 exposure to hazards released into the Micronesia Region through the other cargo pathway is very low.

1 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
2 hazards released into the Micronesia Region through the other cargo pathway is very low.

3 ***Other Cargo Pathway Risk Estimation***

4 Because the increased risk of release of hazards into the Micronesia Region due to the military
5 relocation through the other cargo pathway is very low, the risk of exposure of livestock and poultry is
6 medium, and the significance of consequences of livestock and poultry exposure is very low, we
7 conclude that the military relocation-associated overall risk for the other cargo pathway is very low.

8 **A6.3.3.10 Conveyances**

9 In this pathway, we consider the effect of the military relocation on the risk to livestock and poultry
10 health through the movement of conveyances, in which vector hazards are transported at large (in the
11 absence of vertebrate hosts), into the Micronesia Region. For the purpose of this analysis, conveyances
12 are defined as aircraft, maritime vessels, and shipping containers. Vector hazards include mosquitoes,
13 ticks, and other arthropods (see Table A6-6). The relocation will be associated with a substantial
14 increase in conveyance traffic to the Micronesia Region.

15 **A6.3.3.10.1 Hazards Associated with the Conveyances Pathway**

16 Conveyances can transport vectors of disease agents. In this analysis, we consider other conveyances to
17 be a potential source of all vectors (see Table A6-6), including vectors for which conveyances may serve
18 as only a minor or theoretical source.

19 **A6.3.3.10.2 Release Assessment: Conveyances Pathway** 20 ***Likelihood of Hazard Association***

21 Ticks have been found at large in conveyances, including airplanes and containers (USDA-APHIS 2009a).
22 Recently, a soft tick of seabirds, *Carios capensis* (previously, *Ornithodoros capensis*), was identified as a
23 competent vector for transmission of WNV in New Zealand (Spurr and Sandlant 2004; Hutcheson et al.
24 2005). It is not known whether the species currently inhabits Guam or other islands in the Micronesia
25 Region, though it has been sporadically reported in the past (Kohls 1957); it does occur in Hawai'i
26 (Alicata 1948) and seabirds carrying the tick might find their way aboard conveyances.

27 The origin of most military personnel coming to Guam as a result of the relocation will be the
28 continental United States, and for workers, the Philippines (Jimenez et al. 2009), areas of little concern
29 for importation of most important animal disease-transmitting tick species aboard conveyances to
30 Guam. Import records confirm that cargo is most likely to be coming from the United States. While there
31 is evidence of ticks successfully establishing in tropical island ecosystems, introduction is more likely to
32 occur as a result of introduction of infested animals into the region and is considered in the livestock
33 and cats and dogs pathways.

34 Large flies from the Philippines and much of Asia may find their way aboard vessels. Blowflies, including
35 the Old World screwworm (*Chrysomya* spp.), could theoretically reproduce on aircraft, ships, or boats.
36 However, reproduction requires rotting flesh or other sources of filth in which to lay eggs and to

1 maintain optimal temperature, and a prolonged number of days to complete the life cycle (Bram and
2 George 2000). This is a less likely scenario on commercial airlines, commercial ships or military
3 conveyances not transporting animals. The lack of reproduction will reduce the vector numbers at the
4 destination.

5 Based on historical evidence, mosquito vectors are the most likely vectors to be introduced into a new
6 area via this pathway. In 1961, the U.S. Public Health Service published comprehensive survey findings
7 of insects found in aircraft over a 13 year period. Among the more than 20,000 insects were 92 species
8 of mosquito, 51 of which were not known to be present in the United States, Hawai'i, or Puerto Rico.
9 Since then several similar reports have echoed these findings (Gratz et al. 2000). Mosquito species
10 commonly intercepted from flights of Asiatic origin include *Culex pipiens*, *Culex quinquefasciatus*, *Culex*
11 *tritaeniorhynchus*, *Ochlerotatus japonicus*, *Aedes albopictus*, *Aedes aegypti*, and *Anopheles subpictus*
12 *indefinitus* (Joyce 1961; Takahashi 1984; Goh et al. 1985). The variety of mosquitoes on Guam and
13 throughout the Micronesia Region increased nearly six-fold from just prior to World War II to the end of
14 the Vietnam War, and may be traced to increased air and maritime traffic associated with the rapid
15 deployment of troops and equipment (Savidge 1984).

16 The survival of mosquitoes in aircraft in empirical and experimental situations has been extensively
17 studied. Laird (Laird 1947) reported that mosquitoes can survive an air journey under a variety of
18 conditions. He reviewed several studies regarding the ability of mosquitoes to survive air travel. The
19 longest survival period recorded aboard aircraft was 6-1/2 days. Furthermore, adult and newly hatched
20 mosquitoes can survive and go on to breed and lay eggs in other locations (Laird 1947). Mosquitoes tend
21 to remain aboard an airliner despite multiple stopovers. Flights from major Asian countries to Guam are
22 on average less than 5 hours. The cabin in modern commercial aircraft is pressurized and kept at an
23 ambient temperature, which implies that mosquitoes aboard will be able to survive for the duration of
24 the flight.

25 Adult insects travel almost exclusively within the fuselage. It seems that they are attracted more to the
26 illuminated cabins than to the baggage compartments. The exterior surface and wheel housing are of
27 lesser importance (Goh et al. 1985). Several researchers (Sullivan 1958; Russell 1987) have studied
28 mosquito survival rates under various conditions in different compartments of jet aircraft. Russell has
29 shown that *Cx. quinquefasciatus* can survive on a wheel bay during the course of an international flight
30 despite high altitude and external temperatures of less than -40°C.

31 A recent U.S. study determined an average of 0.1 mosquitoes may be found aboard an inbound flight
32 (Board on Environmental Studies and Toxicology 2002). In the same study, the average number of
33 insects recovered per plane ranged from one to 20 and the average percentage of infected aircraft
34 ranged from 10 to 100%.

35 The primary areas of concern for the risk of introduction of mosquito species to Guam are Southeast
36 Asia, Japan, and other Pacific Islands. In a 1974 Japanese study, Joyce and colleagues examined 36
37 passenger and seven cargo aircraft, with over half originating in China or Southeast Asia. A total of 24%

1 carried pests, including numerous mosquitoes, mainly in aircraft originating from Bangkok, Manila, and
2 Hong Kong, which may be attributed to the high prevalence of mosquitoes in these areas (Joyce 1961).

3 The regular occurrence of airport malaria in the United States and Europe suggests that aircraft are a
4 potential pathway for introduction of exotic mosquitoes and vector-borne diseases (Gratz et al. 2000).
5 There is at least one report of airport dengue fever in a German couple who travelled to Hawai'i in 1998
6 (Jelinek et al. 1998). According to the authors, the most plausible explanation is that the couple was
7 bitten by one or more infected mosquitoes on an aircraft in Hawai'i that originated in an Asian country.

8 By contrast, adult mosquitoes are rarely intercepted on maritime vessels. Of the invasive pests and
9 exotic mosquitoes that are intercepted, most are found in containers or commodities, such as tires or
10 plants. Therefore, the role of maritime conveyances in the introduction of exotic mosquito species is
11 mainly the transport of infested goods and materials. As additional evidence, decades of seaport and
12 vessel surveillance in Honolulu have not detected adult or larval mosquitoes aboard sea conveyances
13 (Joyce 1961); other studies have reported low prevalence of people complaining of mosquitoes and
14 other biting insects aboard ferries (Mouchtouri et al. 2008).

15 ***Traffic Volume***

16 The military relocation is expected to increase the volume of maritime and air traffic in the Micronesia
17 Region. Additional data on conveyances are presented elsewhere in this document.

18 ***Traffic Origin***

19 Import records confirm that conveyances carrying cargo are most likely to be coming from the United
20 States, rather than countries of concern for ticks carrying exotic livestock disease, though Asia is an area
21 of concern for the risk of introduction of mosquito species. In 2009, more than half of the imported
22 cargo shipments came from the United States (53%), with about 30% and 13% coming from Asia and
23 Europe respectively (BSP 2009b; Ferrier 2009; Guam Visitors Bureau 2009).

24 ***Mitigations***

25 Mosquitoes can be introduced via ships as either eggs, larvae, or adults travelling inside boat cabins or
26 shipping containers. Of the invasive pests and exotic mosquitoes that are intercepted, most are found in
27 containers or commodities, such as tires or plants, rather than uncontained on maritime vessels. Hitch-
28 hiking adult mosquitoes tend to die after a few days. The great distances between the Micronesia
29 Region and the continents of Asia and North America further diminish the probability of adult mosquito
30 survival (Joyce 1961). Additionally, modern ocean-going vessels have enclosed water supplies and
31 covered lifeboats, and offer very little in the way of mosquito breeding possibilities.

32 Currently in Guam, as with the rest of the United States, commercial aircraft are not disinfected, nor are
33 there specific surveillance activities in place for the detection of mosquitoes in aircraft (Jimenez et al.
34 2009). These circumstances coupled with the expected increase in the number of commercial and
35 military flights to Guam mean that there is an increased risk for introduction of invasive mosquitoes.

1 Presently, the major risk is flights from Asian countries due to the abundance and diversity of mosquito
2 fauna (WHO 1995; Gratz et al. 2000).

3 As for military planes, Military Customs Inspections inspectors are trained to look for prohibited animals
4 and animal products, and will conduct inspection activities in planes arriving from foreign destinations
5 for the presence of insects in cabin areas and spray when necessary. Air Force Joint Instruction (AFJI) 48-
6 104, the Quarantine Regulations of the Armed Forces (DoD 1992), incorporate regulations to mitigate
7 the risk of introduction and dissemination of arthropod vectors by movement of vessels, aircraft, and
8 other transport of the Armed Forces arriving at or leaving installations in the United States and foreign
9 countries, ports, or other facilities where arthropod vector-borne diseases are known to exist. The
10 information on the materials and procedures for disinsection can be found in the Military Entomology
11 Operational Handbook (NAVFAC M0-310, Army TM 5-632, Air Force AFM 91-16) (U.S. Navy 1972,
12 USAPHC 2010).

13 There may be specific issues related to contamination of equipment brought into Guam by the military
14 related to exercises or deployments. The military has specific decontamination procedures designed to
15 mitigate this risk.

16 ***Summary***

17 The number of conveyances coming into Guam is expected to rise due to the relocation. Mosquito
18 vectors have been identified hitchhiking on cargo in numerous studies, primarily focused on tires and
19 equipment. However, the number of mosquitoes found is very low. In addition, it is not clear that
20 infected mosquitoes have ever been the vehicle for introduction of an animal disease agent into a
21 disease-free country, although there is reason to believe that infected mosquitoes on aircraft and on
22 cargo may have spread arboviruses of human significance, including dengue virus and JEV (Mackenzie et
23 al. 2004).

24 Because we expect an increase in conveyances coming into the Micronesia Region as a result of the
25 relocation, the probability of introduction of vectors will likely increase concurrently. While vectors may
26 be introduced, the likelihood that the introduced mosquito will be infected with an animal disease agent
27 is reported in multiple studies to be less than 0.1% (Nasci and Mitchell 1996; Kramer and Bernard 2001;
28 O'Leary et al. 2004; Reisen et al. 2004).

29 As described in elsewhere in the document, imports and people associated with the buildup are most
30 likely to be coming from the United States rather than countries of concern for ticks carrying exotic
31 livestock disease. But over time and in a broader consider, including both civilian and military imports,
32 this may change to some degree. While there is evidence of ticks successfully establishing in tropical
33 island ecosystems, introduction is most likely to occur as a result of importation of infested animals
34 (George et al. 2002).

1 **Conveyances Pathway Release Assessment**

2 The increased risk of release of vector hazards into the Micronesia Region due to the military relocation
3 through the conveyances pathway is very low.

4 **A6.3.3.10.3 Exposure Assessment: Conveyances Pathway**

5 **Biological Factors**

6 Increased risk for exposure of livestock or poultry to disease agents via mosquitoes introduced by this
7 pathway would require an infected mosquito to find its way aboard a conveyance and survive to release
8 a disease agent on Guam. Alternatively an adult mosquito could, in some instances, lay eggs on that
9 conveyance, and pass the agent along to its offspring through its eggs. The eggs would hatch and
10 complete the cycle to production of adult mosquitoes that will require exposure to a susceptible animal
11 on Guam and in most cases, a competent alternative mosquito host present on the island to maintain
12 infection. Fewer than a dozen mosquito species were reported in the Micronesia Region at the
13 beginning of the 20th century, and no major disease vectors were present. However, in the course of
14 the last century, this number increased four-fold with the introduction of exotic species, such as *Aedes*
15 *albopictus* and *Aedes aegypti* (Reeves and Rudnick 1951) and numerous *Culex* species, which may be
16 competent alternative hosts for the etiologic agents of several arboviral diseases of human and animal
17 importance (Lounibos 2002), in particular WNV and JEV (Mitchell et al. 1993).

18 The risk for exposure of livestock or poultry to disease agents via introduced ticks is discussed elsewhere
19 in this document.

20 **Regional Factors**

21 Mosquitoes released onto Guam may be able to bite and infect susceptible populations of wild birds
22 such as pigeons and Eurasian tree sparrows (*Passer montanus*) that seem to be abundant on Guam and
23 other known susceptible passerine birds, e.g. the Micronesian starling (*Aplonis opaca*) and the Marianas
24 crow (*Corvus kubaryi*). There is evidence for the establishment of exotic vectors as a result of accidental
25 introduction from antropogenic activities; however, circumstantial evidence of a disease outbreak via
26 infected vectors was only in the case of malaria (Lounibos 2002). In the case of WNV spread is more
27 likely to occur from introduction of an infected live bird transmitting the disease agent to an established
28 competent mosquito vector, such as *Aedes albopictus*, *Ae. vexans* and *Ochlerotatus japonicus* (Turell et
29 al. 2005).

30 Backyard and feral pigs serve as amplifying hosts for JEV and are present in sufficient numbers to
31 establish an outbreak, as occurred in 1990 on Saipan (Paul et al. 1993).

32 **Summary**

33 Mosquitoes released on Guam will be able to bite and infect susceptible populations of wild birds,
34 transmitting arboviruses, including WNV and JEV. Competent alternative mosquito vectors are present
35 on Guam, Saipan, and potentially other islands of the Micronesia Region to sustain infection. Susceptible

1 populations of domestic and feral pigs are present which may serve as amplifying hosts for JEV. Thus, we
2 conclude that the factors necessary for exposure are present.

3 ***Conveyances Pathway Exposure Assessment***

4 The risk of exposure of livestock or poultry to vector hazards into the Micronesia Region through the
5 movement of conveyances is medium.

6 **A6.3.3.10.4 Consequence Assessment: Conveyances Pathway**

7 ***Biological Consequences***

8 The predominant impacts from the introduction of WNV and JEV would be to humans and to native wild
9 bird populations, with minimal effects on poultry (Ghosh and Basu 2009; OIE 2010d). Experimental
10 studies have shown that poultry rapidly develop an antibody response capable of neutralizing the virus.
11 Infection in chickens is typically asymptomatic or with minimal clinical signs and pathology, and no
12 mortality (Senne et al. 2000).

13 Some deaths have been reported in horses from WNV and JEV infection, though the number of clinical
14 cases is very low compared to the total number of exposed animals (CFSPH 2007h; OIE 2010d). Because
15 of the small number of horses in Guam and relatively low importance of this industry, and the
16 availability of effective vaccines to protect horses against JEV and WNV, we conclude that the biological
17 consequences for introduction of WNV or JEV to the livestock and poultry industries are negligible.

18 As in the continental United States, the major impact of WNV establishment would be to humans. Once
19 established in a tropical environment and in the absence of preventive measures, spread would be
20 expected to be rapid among human populations with no prior exposure or immunity, as would be the
21 case in Guam and throughout the Micronesia Region (Hayes et al. 2005). In humans the ratio of
22 asymptomatic to clinical infection is high and the majority of clinical illness would be limited to mild
23 febrile disease; however about one of every hundred infected may develop severe neurological disease
24 with mortality rates as high as 14% (Madden 2003).

25 Establishment of Japanese encephalitis on Guam would also be of consequence to humans, especially to
26 children. Annually, up to 50,000 cases of Japanese encephalitis are reported worldwide and more than
27 15,000 deaths are reported in eastern and southern Asia. While asymptomatic infection can occur,
28 approximately 30% of Japanese encephalitis cases are fatal and nearly half result in permanent
29 neurological sequelae (Ghosh and Basu 2009). However, any such introduction might well be short lived.
30 In 1990, a rare introduction of Japanese encephalitis on Saipan ended as the population of susceptible
31 pigs which serve as amplifying hosts became infected and developed immunity, and Japanese
32 encephalitis has not recurred (Paul et al. 1993).

33 ***Environmental Consequences***

34 The spread of WNV in the continental United States has caused a marked decline in the number of
35 particular bird species in entire regions, such as the American crow and eastern bluebirds (Rappole et al.

1 2000). Native bird populations on Guam have been severely diminished as a result of invasive species
2 and feral cats (Poole 2009). WNV, as with END and HPAI viruses, could decimate remaining populations.

3 ***Economic Consequences***

4 Release and establishment of WNV or JEV would be expected to result in little or no economic loss to
5 the poultry industry or to the few remaining equine operations on Guam; however, significant cost
6 would be incurred for human public health and mosquito vector surveillance, and for vector control to
7 prevent spread throughout the region. A 2005 outbreak of WNV in Sacramento County, California
8 (population 1.3 million) resulted in 163 reported human cases and a response that included emergency
9 aerial spray to control vectors. Costs for aerial spray totaled just over \$700,000 and when added to
10 estimated medical costs and patients' loss in productivity, the total economic impact was estimated at
11 \$2.98 million (Barber et al. 2010).

12 ***Conveyances Pathway Consequence Assessment***

13 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
14 the Micronesia Region through the conveyances pathway is very low.

15 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
16 exposure to hazards released into the Micronesia Region through the conveyances pathway is very low.

17 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
18 hazards released into the Micronesia Region through the conveyances pathway is very low.

19 ***Conveyances Pathway Risk Estimation***

20 Because the increased risk of release of hazards into the Micronesia Region due to the military
21 relocation through the conveyances pathway is very low, the risk of exposure of livestock and poultry is
22 medium, and the significance of consequences of livestock and poultry exposure is very low, we
23 conclude that the military relocation-associated overall risk for the conveyances pathway is very low.

24 **A6.4 DISCUSSION AND CONCLUSIONS**

25 A summary of our risk analysis results is presented in Table A7-16.

26 We found that any incremental increase in risk for most hazards, specifically related to the relocation,
27 was relatively small in all pathways considered, yet highest in those that afforded opportunities to
28 thwart existing mitigations via illegal movements. We found that in most cases there were measures in
29 place to mitigate the likelihood of the hazard being introduced. However, these same mitigation
30 measures could be bypassed by illegal means in certain pathways, or if the measures were inconsistently
31 or ineffectively applied. Smuggling of poultry or the illegal importation of food and other animal
32 products would bypass the regulations, as might the improper disposal of domestic and international
33 garbage. These actions could result in the introduction and spread of foreign animal disease agents to
34 susceptible domestic and feral animals. The impact of an outbreak could extend beyond Guam and the
35 Micronesia Region, posing a risk for spread to the rest of the United States that could impact trade with

1 other countries. These pathways should receive the most attention as plans proceed. Initial
 2 recommendations follow at the end of this document and are supplemented more extensively in
 3 preceding sections.

4 **Table A7-16: Summary of Risk Analysis Results**

Pathway	Release assessment		Exposure assessment	Consequence assessment			Risk estimation
	Legal introduction	Illegal introduction		Guam	Micronesia Region	United States ^c	
Livestock ^a	Negligible	Negligible	N/A ^b	N/A	N/A	N/A	Negligible
Poultry	Negligible	Very low	Medium	Low	Low	Medium	Low
Non-poultry birds	Negligible	Very low	Very low	Low	Low	Medium	Very low
Cats and dogs	Negligible	Negligible	N/A	N/A	N/A	N/A	Negligible
Other animals ^d	Low	Low	Low	Very low	Very low	Medium	Low
Humans	Negligible	Negligible	N/A	N/A	N/A	N/A	Negligible
Animal products	Negligible	Low	Medium	Low	Low	Medium	Low
Garbage	Negligible	Very low	Medium	Low	Low	Medium	Low
Other cargo	Very low	N/A	Medium	Very low	Very low	Very low	Very low
Conveyances	Very low	N/A	Medium	Very low	Very low	Very low	Very low

5 ^a Domesticated equids.

6 ^b Not applicable. We conducted exposure and consequence assessments only for those pathways for which the
 7 release assessment result was non-negligible.

8 ^c Rest of the United States, other than Guam.

9 ^d Reptiles.

10

11 In interpreting these results, it is important to note that we did not define a baseline risk, but focused
 12 only on that incremental change in risk attributable to the influx of people and the associated changes
 13 that will come during the course of the relocation. The inevitable outcome of this approach is the
 14 paradox that we may conclude a risk to be present or even significant, yet discount it from further
 15 consideration if there is not an increase in risk that we can attribute to the military relocation. For
 16 example, introduction of a disease hazard by the movement of people to and from Guam, who might
 17 unknowingly carry the hazard on their clothing or body, is always a possibility. Yet, if there is not an
 18 increase in people coming to Guam from areas at high risk for exposing them to the hazard as a
 19 consequence of the military relocation, that risk would not be considered further in this assessment. We
 20 also limited our consideration of the impacts to humans and pet dogs, cats, and non-poultry birds, to
 21 those consequences that arise from their association with livestock or poultry disease hazards. Thus,
 22 there are disease hazards of primary human health importance that are not considered here because
 23 they have no association with livestock or poultry health.

24 We based our risk assessment on available data and information that we believe to be accurate to the
 25 period during which it was collected but which could be subject to change. Data were lacking in a
 26 number of areas. In those cases, we supplemented with published reports from other parts of the world,
 27 where available. We assumed that mitigations, including inspection practices and regulatory
 28 enforcement, were consistently applied and that resources were adequate, at a minimum, to meet

1 current demands. Finally, there are related aspects to our risk assessment, including wildlife hazards or
2 those risks arising from introduction of invasive species that are not considered here, but are discussed
3 in other sections of the document. We encourage the reader to review those sections as well.

4 **A6.5 RECOMMENDATIONS**

5 The introduction of many of the diseases of livestock and poultry considered in this risk assessment
6 could have major consequences to animal and human health throughout the Micronesia Region and far
7 reaching impact on trade to the rest of the United States. While federal, territorial, and military
8 regulations serve to mitigate against introduction of hazards, the influx of people and goods associated
9 with the military relocation will strain current systems for inspection and interdiction of illegal goods.
10 We have reason to suspect that there may be current deficiencies in the ability of GCQA personnel to
11 appropriately inspect cargo, passenger baggage, and conveyances. Further, with the expected arrival of
12 increased numbers of pet dogs and cats, we suspect that current resources for inspection and follow-up
13 will be overwhelmed.

14 Currently, there is no ongoing surveillance for livestock and poultry disease on Guam. Therefore, it is
15 difficult to know what disease agents are already present in the Region and to identify the introduction
16 of an exotic disease agent. A lack of a diagnostic laboratory in the Region also diminishes the ability to
17 detect disease agents. Rapid detection is critical in order to mount a timely response to new disease
18 introductions, especially in the case of the highly transmissible exotic diseases considered in this
19 assessment.

20 Specific recommendations to mitigate the risk of release of livestock and poultry disease hazards include
21 measures to address the need for additional resources and improvements in surveillance and
22 communication, and to ensure adequate inspection and follow-up.

23 **A6.5.1 Staffing and Infrastructure**

24 **Ensure sufficient staffing to accomplish all necessary inspection and quarantine activities in the**
25 **Micronesia Region.** Staffing levels will become further strained as a consequence of the military
26 relocation as the workload at airports, maritime ports, and mail facility increases. Quarantine officers
27 must be adequately trained in all aspects of their jobs and should receive periodic refresher training.

28 **Ensure availability of necessary equipment.** Equipment necessary for effective safeguarding must be
29 available to quarantine officers. X-ray machines must be provided where needed. All equipment must be
30 maintained in working order over the long term.

31 **Provide detector dogs and handlers.** An adequate number of teams must be available at airports for
32 screening passenger baggage for animal products.

33 **Ensure there are appropriate resources** to implement response plans.

1 **A6.5.2 Point-of-entry Activities (Cleaning, Inspection, Treatment)**

2 **Carry out inspection of all arriving conveyances, military and non-military, for illegal animals or animal**
3 **products.** In the case of military vessels, either PPQ specialists must be made available to inspect
4 military vessels, or GCQA officers must be allowed to inspect military vessels.

5 **Establish an effective mail inspection system on Guam.** For international mail arriving via Hawai'i,
6 either ensure adequate level of inspection in Hawai'i or else carry out inspection in Guam. Establish
7 effective working relationships to ensure that safeguarding personnel can carry out their
8 responsibilities. Safeguarding personnel must have sufficient access to the postal facility.

9 **A6.5.3 Regulations, Guidelines, and Compliance**

10 **Systematically review all guidelines and SOPs** relevant to livestock or poultry disease. Ensure that they
11 are clear, complete and detailed. Develop guidelines or SOPs where they are lacking.

12 **Enforce full compliance** with all applicable existing federal and territorial regulations, guidelines, and
13 SOPs, and harmonize military guidelines and SOPs with those requirements.

14 **Develop a hazard response plan** in coordination with military and civilian public health authorities for
15 those diseases with serious animal health and zoonotic potential.

16 **A6.5.4 Education and Training**

17 **Provide adequate education** about the potential negative consequences of the introduction of an exotic
18 livestock or poultry disease, especially with respect to smuggled animal products.

19 **Facilitate training/education programs** regarding changes in livestock and poultry hazards for
20 inspectors.

21 **Reinforce enforcement of existing regulations**, such as these:

- 22 • Health certificates must accompany imported livestock and such livestock is subject to health
23 inspection by the territorial veterinarian and quarantine if needed.
- 24 • Imported poultry and eggs must be quarantined, and inspected, and poultry must be vaccinated
25 by the territorial veterinarian for Newcastle disease prior to entry to Guam in accordance with
26 Title 9 of the Guam Administrative Rules and Regulations (9 GARR 1, Division 1, Chapter 1). Use
27 USDA-APHIS-VS import permits for restricted animal products.
- 28 • Enforce Guam Administrative Rules and Regulations requiring a permit, health certificate, and
29 inspection for imported reptiles (9 GARR 1, Division 1, Chapter 1).
- 30 • Enforce current Swine Health Protection regulations requiring cooking of certain types of waste
31 prior to feeding to pigs (9 CFR § 166).

1 **A6.5.5 Additional Safeguarding Practices**

2 **Develop a system of routine systematic surveillance** for livestock and poultry diseases and vector
3 hazards.

4 **Develop situational monitoring** for the occurrence of foreign animal diseases.

5 **Develop procedures** that will allow GCQA and GDOA to react to changing risks posed by arriving
6 travelers, cargo, and conveyances, based on countries of origination or embarkation.

7 **A6.6 ACKNOWLEDGMENTS**

8 We gratefully acknowledge the individuals listed below for their assistance during this project, in
9 particular preparation of Section A6.6 of this terrestrial RA.

10 Paul Bassler, Guam Department of Agriculture

11 Dallas Berringer, USDA-APHIS-PPQ

12 Anne Brooke and Mark Cruz, Naval Facilities Engineering Command

13 Ignacio Dela Cruz, CNMI Department of Lands and Natural Resources

14 Lawrence Duponcheel, Northern Marianas College-Cooperative Research, Extension and Education
15 Service

1 Editors Note: The following sections (A7 through A25) consider some species which either are known invasive species or
2 potential invasive species to micronesia and/or hawai'i. These sections should not be considered as comprehensive for all
3 potential invasive species for the region. These lists should in fact be considered as generic and if fact they actually include
4 species that are already established in parts of the region or which are native to sections of the region. There are various
5 established resources which include information on invasive species for both Micronesia and Hawai'i and these resources
6 should be utilized by policy makers and managers when considering best management practices (for example see the issg ias
7 data set at: <http://www.issg.org/>).
8

9 **A7 EXOTIC PLANT PESTS WITH THE POTENTIAL TO BE INTRODUCED INTO THE**
10 **MICRONESIA REGION**

11 This list contains some plant pests that would cause damage to agricultural crops and native plant
12 species in the Micronesia and Hawai'i if permitted to establish. Structural wood pests, stored-grain
13 pests, and pests of plant pollinators are also included. Shaded rows on the following pages indicate
14 species associated with WPM.

Species	Distribution	Host(s)	References
ARTHROPODS			
Mites			
Mites not only cause direct feeding damage but also frequently vector plant pathogens. Mites are minute and thus difficult to detect. Due to high fecundity and short life cycles, they easily adapt to diverse environmental conditions and can rapidly develop resistance to pesticides (Jeppson et al. 1975, Ochoa 2005). Mites are mainly moved on infested plant materials.			
Acari: Eriophyidae			
<i>Aceria guerreronis</i> Keifer	Africa, Central and South America, India, Sri Lanka United States	<i>Cocos nucifera</i>	(Fernando et al. 2003, Navia et al. 2005, Lawson-Balagbo et al. 2007)
<i>Aceria sheldoni</i> (Ewing)	Africa, Argentina, Australia, Brazil, China, Hawai'i, Southern Europe, United States, Southeast Asia	<i>Citrus</i> spp.	(CAB 1980, Childers and Achor 1999, Hong et al. 2006)
<i>Aceria tulipae</i> (Keifer)	Brazil, China, Cuba, Egypt, Europe, India, Mexico, New Zealand, Thailand, United States	Poaceae, <i>Allium</i> spp., <i>Tulipa</i> spp.	(Somsen and Sill Jr. 1970, Perring 1996, Hong et al. 2006)
<i>Aculops lycopersici</i> (Massee)	Africa, Asia, Australia, Canada, Central and South America, China, Europe, Hawai'i, Melanesia, Mexico, United States	Solanaceae	(CABI 1987, Hong et al. 2006, CABI 2007)

<i>Phyllocoptura oleivora</i> (Ashmead)	Africa, Australia, Caribbean, Central and South America, Cook and Fiji Islands, Hawai'i, Mexico, Middle East, United States, Southeast Asia, Southern Europe	<i>Citrus</i> spp.	(CAB 1970, Jeppson et al. 1975, Hong et al. 2006)

<i>Raoiella indica</i> (Hirst)	Caribbean, India, Malaysia, Mauritius, Middle East, Réunion, Philippines	Arecaceae, Musaceae, Zingiberaceae	(Peña et al. 2006, Vásquez et al. 2008, ISSG 2009)

	Venezuela		
Acari: Tetranychidae			
<i>Amphitetranynchus viennensis</i> (Zacher)	Europe, Middle East	<i>Ficus carica</i> , <i>Plumeria</i> spp.	(Bolland et al. 1998, Navia and Mendonça 2005)
<i>Tetranychus evansi</i> Baker & Pritchard	Africa, Caribbean, Hawai'i, Mediterranean, South America, United States	Solanaceae, <i>Amaranthus</i> spp., <i>Ipomoea batatas</i> , <i>Passiflora foetida</i> , <i>Psidium guajava</i>	(Tsagkarakou et al. 2007, Migeon and Dorkeld 2010)
INSECTS			
Coleoptera: Bostrichidae			
These beetles are important pests of living trees and forest products (Liu et al. 2008). Bostrichids are often moved in WPM, timber, and furniture.			
<i>Dinoderus minutus</i> (F.)	Africa, Caribbean, China, CNMI, Germany, Guam, Israel, Japan, South America, Southeast Asia, United States	<i>Bambusa</i> spp., <i>Dendrocalamus</i> spp., <i>Manihot</i> spp., <i>Phyllostachys</i> spp.	(Chûjô 1958, Stone 1970, Buchelos 1991, CABI 2007, PIER 2010)
<i>Dinoderus ocellaris</i> Stephens	India, New Guinea, Philippines	<i>Bambusa</i> spp.	(Tanaka 1927, Atkinson 1936, Stone 1970, Spilman 1982, CABI 2007, Rajendran and Kumar 2008)
<i>Heterobostrychus aequalis</i> (Waterhouse)	Cuba, India, Indonesia, Madagascar, CNMI, Guam, Malaysia, New Guinea, Philippines, Sri Lanka, Suriname, United States	<i>Albizia</i> spp., <i>Bambusa</i> spp., <i>Canarium</i> spp., <i>Cassia</i> spp., <i>Dalbergia</i> spp., <i>Dendrocalamus</i> spp., <i>Endospermum</i> spp., <i>Leucaena</i> spp., <i>Mangifera</i> spp., <i>Morus</i> spp., <i>Poinciana</i> spp.,	(Chûjô 1958, Stone 1970, Woodruff and Fasulo 2006, Benker 2008)

<i>Heterobostrychus brunneus</i> (Murray)	Sub-Saharan Africa, United States	<i>Pterocarpus</i> spp., <i>Sterculia</i> spp., <i>Tectona</i> spp., <i>Terminalia</i> spp. <i>Albizia</i> spp., <i>Bambusa</i> spp., <i>Canarium</i> spp., <i>Cedrela</i> spp., <i>Dendrocalamus</i> spp., <i>Endospermum</i> spp., <i>Leucaena</i> spp., <i>Mangifera</i> spp., <i>Pterocarpus</i> spp., <i>Sterculia</i> spp., <i>Tectona</i> spp., <i>Terminalia</i> spp.	(Stone 1970, Selander 1986, Pasek 2000, Haack 2006, Schabel 2006, PIER 2010)
<i>Heterobostrychus hamatipennis</i> (Lesne)	China, France, Hawai'i, India, Japan, Madagascar, Malaysia, Mauritius, Philippines, Thailand	<i>Acacia catechu</i> , <i>Bambusa</i> spp., <i>Bombax ceiba</i> , <i>Garuga pinnata</i> , <i>Lithocarpus calanthiformis</i> , <i>Paulownia tomentosa</i>	(Hutacharern and Tubtim 1995, Wang et al. 1998, Fassotte 2005, Halbert 2007, Aberlenc 2008, Benker 2008)
<i>Lyctus africanus</i> Lesne	Africa, India, Israel, Japan, Southeast Asia	<i>Bambusa</i> spp., <i>Dendrocalamus</i> spp.	(Stone 1970, Halperin and Geis 1999, Rajendran and Kumar 2008)
<i>Sinoxylon anale</i> Lesne	Australia, Brazil, China, India, Indonesia, New Zealand, Philippines, Saudi Arabia, Sri Lanka, Southeast Asia, United States, Venezuela	<i>Acacia</i> spp., <i>Albizia</i> spp., <i>Casuarina</i> spp., <i>Dalbergia</i> spp., <i>Delonix</i> spp., <i>Eucalyptus</i> spp.	(Stone 1970, Argaman 1987, Pasek 2000, Teixeira et al. 2002, Karnkowski 2006, CABI 2007, Krehan 2007)

<i>Sinoxylon conigerum</i> Gerstaecker	China, India, Israel, Italy, Japan, South America, Southeast Asia, Spain, Sub-Saharan Africa, United States, Vietnam	<i>Bambusa</i> spp., <i>Hevea</i> spp., <i>Manihot</i> spp.	(Stone 1970, Filho et al. 2006, Haack 2006, Karnkowski 2006, CABI 2007, Benker 2008)
<i>Sinoxylon crassum</i> Lesne	East Africa, India, Pakistan, Southeast Asia	<i>Acacia</i> spp., <i>Albizia</i> spp., <i>Bambusa</i> spp., <i>Cassia</i> spp.	(Stebbing 1914, Stone 1970, Singh and Bhandari 1987, Rathore 1995, Gul and Bajwa 1997, Pasek 2000, Krehan 2007)
<i>Sinoxylon pugnax</i> Lesne	Afghanistan, East Africa, India, New Guinea	<i>Prosopis</i> spp.	(Lesne 1904, Allen 2007b, CABI 2007, PIER 2010)

Coleoptera: Cerambycidae

These beetles are extremely important wood boring pests of live trees. Adults feed on flowers, foliage, and bark; larvae destructively bore into wood (Gillott 1995). Cerambycids are often moved on nursery stock and in WPM.

<i>Anoplophora chinensis</i> (Forster)	China, Hawai'i, Korea, Malaysia, Myanmar, Vietnam	<i>Citrus</i> spp., <i>Cryptomeria japonica</i> , <i>Ficus</i> spp., <i>Hibiscus</i> spp., <i>Mallotus</i> spp.	(CABI/EPPO 1997a, Benker 2008)
<i>Ceresium flavipes</i> (F.)	China, Hong Kong, Philippines, Southeast Asia, Taiwan	<i>Artocarpus</i> spp., <i>Casuarina</i> spp., <i>Citrus</i> spp., <i>Hevea</i> spp., <i>Streblus</i> spp.	(Samuelson and Gressitt 1965, Stone 1970, Allen 2001, Allen and Humble 2002)
<i>Curtomerus flavus</i> (F.)	Caribbean, Central and South America, Hawai'i, Japan, Marquesas Islands, Philippines, United States	<i>Acacia</i> spp., <i>Bidens</i> spp., <i>Eucalyptus</i> spp., <i>Leucaena leucocephala</i> , <i>Nicotiana tabacum</i> , <i>Psidium</i> spp., <i>Sapindus</i>	(Linsley 1963, Gressitt and Davis 1972, Sugiura et al. 2008, Peck 2009)

		spp.	
<i>Psacotheta hilaris</i> (Pascoe)	China, Japan, Taiwan	<i>Ficus</i> spp., <i>Morus</i> spp.	(Allen and Humble 2002, CABI 2007, EPPO 2008)
<i>Rhytidodera bowringii</i> White	China	<i>Anacardium</i> spp., <i>Mangifera</i> spp.	(Stone 1970, FAO 2006b, NAPPO 2006, CABI 2007)
<i>Stromatium barbatum</i> (F.)	Bangladesh, East Africa, India, Myanmar, Pakistan, Sri Lanka	<i>Acacia</i> spp., <i>Bauhinia</i> spp., <i>Citrus</i> spp., <i>Coffea</i> spp., <i>Eriobotrya</i> spp., <i>Grevillea</i> spp., <i>Rosa</i> spp., <i>Tectona</i> spp.	(Stone 1970, CAB 1985, Singh and Bhandari 1987, Phukan et al. 1995, Thakur 1999, Pasek 2000)
<i>Xylotrechus chinensis</i> (Chevrolat)	China, Japan, Korea, Taiwan	<i>Morus</i> spp.	(Gressitt 1951, Benker 2008)
<i>Xystracera globosa</i> (Olivier)	Australia, Caribbean, Egypt, Hawai'i, Israel, Madagascar, Mauritius, New Guinea, Southeast Asia	<i>Acacia</i> spp., <i>Acracarpus</i> spp., <i>Adenanthera</i> spp., <i>Adina</i> spp., <i>Albizia</i> spp., <i>Bauhinia</i> spp., <i>Cassia</i> spp., <i>Duabanga</i> spp., <i>Grewia</i> spp., <i>Haematoxylon</i> spp., <i>Paraserianthes</i> spp., <i>Parkia</i> spp., <i>Salmalia</i> spp., <i>Samanea</i> spp., <i>Xylia</i> spp.	(Mathew 1987, Friedman et al. 2008)
Coleoptera: Curculionidae			
<i>Hypothenemus hampei</i>	Hawai'i, Africa, South and Central America	Rubiaceae	(Vega et al. 2009; Burbano et al. 2011)

Coleoptera: Chrysomelidae			
There are over 35,000 described species of Chrysomelids (leaf beetles). Adults feed on leaves and flowers, and larvae feed on leaves, roots, or stems (Gillott 1995). Leaf beetles are often moved in infested plant material, particularly in ornamental plants.			
<i>Brontispa longissima</i> Gestro	Australia, Cambodia, China, Indonesia, Laos, Malaysia, The Maldives, Myanmar, New Guinea, Philippines, Singapore, Taiwan, Thailand, Vietnam	Arecaceae	(Sankaran 2007, ISSG 2009)
<i>Diabrotica balteata</i> Leconte	Central America, Mexico, South America, United States	Cucurbitaceae, <i>Ipomoea</i> spp., <i>Manihot esculenta</i> , <i>Phaseolus vulgaris</i> , Solanaceae	(Peña and Waddill 1982, CABI 2007)
<i>Diabrotica undecimpunctata</i> Mannerheim	Bermuda, Canada, Central America, Mexico, United States	Cucurbitaceae, <i>Ipomoea</i> spp., <i>Phaseolus vulgaris</i>	(Foster and Brust 1995, CABI 2007)
<i>Diabrotica virgifera</i> LeConte	Canada, Central America, Europe, Mexico, United States	Cucurbitaceae, <i>Glycine max</i> , <i>Helianthus annuus</i> , <i>Zea mays</i>	(CABI/EPPO 1997d, EPPO 2006a, Ciosi et al. 2008, Gray et al. 2009, Meinke et al. 2009)
<i>Microtheca ochroloma</i> Stål	South America, United States	<i>Brassica</i> spp., <i>Raphanus sativus</i> , <i>Rosa</i> spp., <i>Zea mays</i>	(Balsbaugh Jr. 1978, Fasulo 2010)

Coleoptera: Curculionidae

There are over 40,000 species in Curculionidae. Most larvae and adults feed on plant parts including fruits, nuts, stems, and roots. Many Curculionids are very serious plant pests. For example, the red palm weevil, *Rhynchophorus ferrugineus*, a devastating pest of various palm species, has been introduced into several parts of the world; it is not known to occur in Micronesia.

<i>Diaprepes abbreviatus</i> (L.)	Caribbean, United States	<i>Carica papaya</i> , <i>Citrus</i> spp., <i>Ipomoea batatas</i> , <i>Psidium guajava</i> , <i>Saccharum officinarum</i> , <i>Solanum tuberosum</i>	(Ascunce et al. 2009, Weissling et al. 2009)
<i>Metamasius callizona</i> (Chevrolat)	Guatemala, Mexico, United States	Bromeliaceae, <i>Ananas comosus</i>	(Cooper 2008, Frank and Fish 2008, Larson and Frank 2009)
<i>Rhynchophorus ferrugineus</i> (Olivier)	Africa, Asia, Australia, India, Middle East, Spain	Arecaceae, especially <i>Cocos nucifera</i> and <i>Phoenix</i> spp.	(Kehat 1999, CABI 2007)
<i>Rhynchophorus palmarum</i> (L.)	Caribbean, Central and South America, Mexico	Arecaceae	(EPPO 2005a)
Coleoptera: Nitidulidae			
The small hive beetle (<i>Aethina tumida</i>) feeds on pollen and honey, burrowing through honey combs and causing damage to bee colonies. Small hive beetles can be transported in infested fruits, packages of bees, hive equipment, and soil (Neumann and Elzen 2004).			
<i>Aethina tumida</i> Murray	Africa, Australia, Canada, Egypt, Mexico, Portugal, United States	<i>Apis mellifera</i> , <i>Bombus</i> spp.	(Neumann and Elzen 2004)
Coleoptera: Scarabaeidae			
Scarabaeid adults can be serious foliage-feeding pests; larvae damage plant roots (Gillott 1995). These beetles may be introduced in infested propagative material.			
<i>Oryctes rhinoceros</i> (L.)	Asia, Australia, Fiji, Guam, Hawai'i, Indonesia, Palau, Southeast Asia, New Guinea,	Arecaceae	(ISSG 2010)

	Tonga, Vanuatu, Wallis		
<i>Papuana</i> spp.	Papua New Guinea, Solomon Islands, Vanuatu, Fiji and Kiribati	<i>Colocasia, Musa, Canna, Xanthosoma, Solanum, Pandanus, Angiopteris, and Cocos</i>	(SPC 1987; Aloalii et al. 1980)
<i>Cyclocephala pasadenae</i> (Casey)	Hawai'i, Mexico, United States	Poaceae	(Bauernfeind 2001, Jameson et al. 2009, Ratcliffe 2009)

Coleoptera: Scolytidae

Scolytids are very small wood boring beetles (Anderson and Burgin 2002). They complete almost their entire life cycle in the bark or the wood of trees (Rudinsky 1962), making them difficult to detect. Of the total tree mortality in the United States caused by insects, more than 60% is attributable to species of Scolytidae. Scolytidae often vector plant pathogenic fungi. Scolytidae are most frequently intercepted in WPM, but may also be moved in propagative materials and wooden handicrafts.

<i>Coccotrypes dactyliperda</i> (F.)	Australia, Cuba, Egypt, Hawai'i, India, Israel, Japan, Mexico, Panama, South America, Southeast Asia, Sudan, United States	Arecaceae	(Wood 1982, Atkinson and Peck 1994, El-Sherif et al. 1998, Holzman et al. 2009)
<i>Cyrtogenius brevior</i> (Eggers)	Japan	<i>Dipterocarpus</i> spp., <i>Mangifera</i> spp.	(Bright and Skidmore 1997, Brockhoff et al. 2003)
<i>Hypocryphalus mangiferae</i> Eggers	Brazil	<i>Mangifera</i> spp.	(Stone 1970, Haack 2001, CABI 2007)
<i>Hypothenemus birmanus</i> (Eichhoff)	Singapore	<i>Manilkara</i> spp.	(Stone 1970, Haack 2001, CABI 2007)
<i>Xyleborinus saxeseni</i> (Ratzeburg)	Australia, Ecuador, South Africa, United	<i>Eucalyptus</i> spp., <i>Juglans</i> spp., <i>Persea</i> spp.	(Stone 1970, Brockhoff et al. 2003, HEAR 2004, CABI 2007, Haack and Petrice 2009)

	States		
<i>Xyleborus affinis</i> Eichhoff	Africa, Brazil, United States	<i>Dracaena</i> spp., <i>Juglans</i> spp. <i>Macadamia</i> spp., <i>Saccharum</i> spp.	(Stone 1970, Brockerhoff et al. 2003, HEAR 2004, CABI 2007)
<i>Xyleborus glabratus</i> Eichhoff	Bangladesh, India, Japan, Myanmar, Taiwan, United States	Lauraceae, including <i>Persea americana</i>	(Rabaglia et al. 2006, Fraedrich et al. 2007, Cognato 2008, Harrington et al. 2008, Mayfield et al. 2008, Goldberg and Heine 2010)
<i>Xyleborus perforans</i> (Wollaston)	Africa, Asia, New Guinea, Philippines, South America	<i>Citrus</i> spp., <i>Cocos</i> spp., <i>Eucalyptus</i> spp., <i>Mangifera</i> spp., <i>Persea</i> spp.	(Stone 1970, Brockerhoff et al. 2003)
<i>Xyleborus similis</i> Ferrari	Africa, Asia, Australia, FSM, New Guinea, United States	<i>Artocarpus</i> spp., <i>Durio</i> spp., <i>Ficus</i> spp., <i>Mangifera</i> spp., <i>Theobroma</i> spp.	(Stone 1970, Brockerhoff et al. 2003, HEAR 2004, Rabaglia et al. 2006, CABI 2007)
<i>Xyleborus volvulus</i> (F.)	United States	<i>Acacia</i> spp., <i>Bauhinia</i> spp., <i>Citrus</i> spp., <i>Cocos</i> spp., <i>Terminalia</i> spp.	(Stone 1970, Brockerhoff et al. 2003, CABI 2007)
<i>Xylosandrus crassiusculus</i> (Motschulsky)	Africa, Hong Kong, United States	<i>Coffea</i> spp., <i>Eucalyptus</i> spp., <i>Persea</i> spp.	(Stone 1970, Bright and Skidmore 1997, Brockerhoff et al. 2003, HEAR 2004, LaBonte et al. 2005, CABI 2007)
<i>Xylosandrus morigerus</i> (Blandford)	Asia, Europe, Africa, United States, Mexico, Central America, South America, Australia, Guam, CNMI, FSM	<i>Coffea</i> spp., <i>Dendrobium</i> spp., <i>Persea</i> spp., <i>Tectona</i> spp., <i>Theobroma</i> spp.	(Stone 1970, Bright and Torres 2006, CABI 2007)

Diptera: Tephritidae			
Larvae feed inside a large variety of fruit, causing serious crop damage. Fruit flies are introduced into new areas in infested fruit (White and Elson-Harris 1992).			
<i>Bactrocera cucurbitae</i> (Coquillett)	Asia, Guam, Hawai'i, Kenya, Mauritius, New Guinea, Tanzania	Cucurbitaceae, <i>Carica papaya</i> , <i>Phaseolus vulgaris</i> , <i>Vigna unguiculata</i>	(ISSG 2010)
<i>Bactrocera dorsalis</i> (Hendel)	Asia, French Polynesia, Hawai'i	<i>Annona squamosa</i> , <i>Capsicum</i> spp., <i>Solanum lycopersicon</i> , <i>Mangifera indica</i> , <i>Musa paradisiaca</i> , <i>Psidium guajava</i>	(USDA-APHIS-PPQ 1982, Allwood et al. 1999, SPC 2002, Iwaizumi 2004, Aketarawong et al. 2007, Chen et al. 2007)
<i>Bactrocera frauenfeldi</i> (Schiner)	Australia, FSM, Kiribati, Nauru, New Guinea, Palau, RMI, Solomon Islands	<i>Achras sapota</i> , <i>Annona muricata</i> , <i>Artocarpus</i> spp., <i>Averrhoa carambola</i> , <i>Barringtonia edulis</i> , <i>Carica papaya</i> , <i>Citrus</i> spp., <i>Diospyros</i> spp., <i>Eugenia uniflora</i> , <i>Fortunella japonica</i> , <i>Inocarpus fagifer</i> , <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Psidium guajava</i> , <i>Syzygium malaccense</i> , <i>Terminalia</i> spp., <i>Trichosanthes cucumerina</i>	(Hollingsworth et al. 2003, GDOA 2005, Sengebau et al. 2005)

<i>Bactrocera invadens</i> Drew, Tsuruta, & White	Africa, Bhutan, Sri Lanka	<i>Annona</i> spp., <i>Carica papaya</i> , <i>Chrysophyllum albidum</i> , <i>Citrullus lanatus</i> , <i>Citrus</i> spp., <i>Cucumis</i> spp., <i>Diospyros montana</i> , <i>Dracaena steudneri</i> , <i>Eriobotrya japonica</i> , <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Persea americana</i> , <i>Psidium guajava</i> , <i>Sclerocarya birrea</i> , <i>Spondias cytherea</i> , <i>Solanum lycopersicum</i> , <i>Strychnos meliodora</i> , <i>Terminalia catappa</i>	(Drew et al. 2005, Mwatawala et al. 2006, White 2006, Drew et al. 2007, Rwomushana et al. 2008)
<i>Bactrocera latifrons</i> (Hendel)	China, Hawai'i, India, Japan, Laos, Malaysia, Pakistan, Sri Lanka, Taiwan, Thailand	<i>Baccaurea motleyana</i> , <i>Capsicum annuum</i> , <i>Solanum</i> spp.	(White and Elson-Harris 1992, Shimizu et al. 2007)
<i>Bactrocera occipitalis</i> (Bezzi)	Brunei, Malaysia, Palau, Philippines	<i>Mangifera indica</i> , <i>Psidium guajava</i>	(Drew and Hancock 1994, CABI/EPPO 1997b, Iwaizumi 2004, GDOA 2005, Sengebau et al. 2005, Chen et al. 2007)
<i>Bactrocera philippinensis</i> Drew and Hancock	Palau, Philippines	<i>Artocarpus communis</i> , <i>Averrhoa carambola</i> , <i>Carica papaya</i> , <i>Citrus</i>	(Drew and Hancock 1994, CABI/EPPO 1997b, Iwaizumi 2004, GDOA 2005, Sengebau et al. 2005, Chen et al. 2007, USDA NRCS 2009)

		<i>madurensis</i> , <i>Mangifera indica</i> , <i>Pouteria duklitan</i> , <i>Psidium guajava</i> , <i>Syzygium malaccensis</i>	
<i>Bactrocera scutellata</i> (Hendel)	China, Japan, Malaysia, Taiwan, Thailand	Solanaceae, <i>Cucumis sativa</i> , <i>Cucurbita</i> spp., <i>Trichosanthes</i> spp.	(Ohno et al. 2006, CDFA 2009)
<i>Bactrocera synnephes</i> (Hendel)	China, Philippines, Taiwan, Thailand	<i>Diplocyclos palmatus</i> , <i>Luffa cylindrica</i> , <i>Melothria formosana</i>	(Chang et al. 2003, Ohno and Tamura 2008)
<i>Bactrocera tryoni</i> (Froggatt)	Australia, Cook Islands, French Polynesia, New Caledonia, Pitcairn	<i>Annona</i> spp., <i>Capsicum frutescens</i> , <i>Carica papaya</i> , <i>Citrus</i> spp., <i>Coffea arabica</i> , <i>Ficus</i> spp., <i>Mangifera indica</i> , <i>Morus</i> spp., <i>Musa acuminata</i> , <i>Opuntia ficus-indica</i> , <i>Passiflora</i> spp., <i>Persea americana</i> , <i>Phoenix dactylifera</i> , <i>Psidium</i> spp., <i>Solanum</i> spp.	(White and Elson-Harris 1992, ISSG 2009)
<i>Bactrocera zonata</i> (Saunders)	Egypt, India, Indonesia, Laos, Libya, Mauritius, Middle East, Sri	<i>Carica papaya</i> , <i>Citrus</i> spp., <i>Mangifera indica</i> , <i>Momordica</i>	(White and Elson-Harris 1992, White 2006, Duyck et al. 2008)

	Lanka, Thailand, Vietnam	<i>charantia</i> , <i>Phoenix dactylifera</i> , <i>Psidium guajava</i> , <i>Punica granatum</i> , <i>Terminalia catappa</i>	
<i>Ceratitis capitata</i> (Wiedemann)	Australia, Hawai'i, Mediterranean, North Africa, South America, United States	<i>Carica</i> spp., <i>Diospyros</i> spp., <i>Mangifera</i> spp., <i>Musa</i> spp., <i>Persea</i> spp.	(ISSG 2010)
<i>Ceratitis rosa</i> Karsch	Sub-Saharan Africa	<i>Capsicum frutescens</i> , <i>Carica papaya</i> , <i>Citrus</i> spp., <i>Coffea arabica</i> , <i>Ficus carica</i> , <i>Garcinia mangostana</i> , <i>Litchi chinensis</i> , <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Psidium guajava</i> , <i>Solanum</i> spp.	(White and Elson-Harris 1992, Duyck et al. 2008)
Hemiptera: Aleyrodidae			
Aleyrodidae (whiteflies) damage plants through direct feeding and also vector plant viruses. Whiteflies are introduced to new areas on infected plant material (Martin et al. 2000). After introduction into a new area whitefly populations often undergo rapid population growth (Byrne and Bellows Jr. 1991).			
<i>Aleurotrachelus trachoides</i> (Back)	Caribbean, FSM, Guyana, Peru, Réunion, Tahiti	<i>Annona</i> spp., <i>Bidens pilosa</i> , <i>Capsicum frutescens</i> , <i>Casuarina</i> spp., <i>Datura</i> spp., <i>Dioscorea</i> spp., <i>Duranta erecta</i> ,	(Mound and Halsey 1978, Peña and Bennett 1995, SPC 2005)

		<i>Ipomoea batatas</i> , <i>Morinda citrifolia</i> , <i>Solanum</i> spp., <i>Tectona grandis</i> , <i>Piper metisticum</i> (host)	
<i>Paraleyrodes pseudonaranjiae</i> Martin	Bermuda, China, Hawai'i, United States	<i>Annona glabra</i> , <i>Calophyllum inophyllum</i> , <i>Citrus</i> spp., <i>Mangifera indica</i> , <i>Morinda citrifolia</i> , <i>Rhododendron pulchrum</i>	
<i>Trialeurodes vaporariorum</i> (Westwood)	Africa, Australia, Canada, Central and South America, Caribbean, Mexico, Hawai'i, Europe, South Asia, United States	<i>Brassica oleracea</i> , <i>Citrus</i> spp., <i>Cucurbita</i> spp., <i>Diospyros</i> spp., <i>Hibiscus</i> spp., <i>Ipomoea</i> spp., <i>Lonicera</i> spp., <i>Nerium oleander</i> , <i>Passiflora</i> spp., <i>Persea americana</i> , <i>Pittosporum eugenioides</i> , <i>Psidium guajava</i> , <i>Rhododendron</i> spp., <i>Solanum</i> spp.	(Mound and Halsey 1978, Martin et al. 2000, McKee et al. 2009)
Hemiptera: Aphididae			
Aphids are small insects, often with broad host ranges, and move readily with imported horticultural commodities (Messing et al. 2007). Aphids cause direct feeding damage and vector many plant viruses.			
<i>Acyrtosiphon ilka</i> Mordvilko	Middle East, Mediterranean, Southern Russia	Asteraceae, Brassicaceae, Linaceae,	(Blackman and Eastop 2000)

		Papaveraceae, Thymelaeaceae	
<i>Acyrtosiphon kondoi</i> Shinji	Argentina, Asia, Australia, Chile, Hawai'i, New Zealand, United States	Fabaceae	(Rethwisch 1989, Blackman and Eastop 2000)
<i>Aphis coreopsidis</i> (Thomas)	North, Central, and South America	Asteraceae, Malvaceae	(Blackman and Eastop 1994)
<i>Aphis menthaeradicis</i> Cowen	United States	<i>Artemisia</i> spp., <i>Aster</i> spp., <i>Mentha</i> spp., <i>Taraxacum</i> spp.	(Blackman and Eastop 2000)
<i>Aphis nasturtii</i> Kaltenbach	Asia, Chile, Ethiopia, Europe, Kenya, North America, South Africa	Solanaceae, Brassicaceae, Polygonaceae	(Blackman and Eastop 2000)
<i>Aulacorthum circumflexum</i> (Buckton)	Hawai'i	<i>Pinopsida</i> spp., <i>Pteridophyta</i> spp.	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Aulacorthum magnoliae</i> (Essig & Kuwana)	China, India, Japan, Korea	Cucurbitaceae, <i>Citrus</i> spp.	(Blackman and Eastop 2000)
<i>Aulacorthum solani</i> (Kaltenbach)	Africa, Asia, Australia, Central America, Europe, South America, United States	<i>Glycine max</i> , <i>Solanum tuberosum</i>	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Brachycaudus helichrysi</i> (Kaltenbach)	Africa, Asia, Central America, Europe, New Zealand, South America, United States	Asteraceae, Boraginaceae, Cucurbitaceae, Fabaceae, Polygonaceae, Rosaceae, Saxifragaceae,	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)

		Scrophulariaceae	
<i>Cavariella aegopodii</i> (Scopoli)	Asia, Australia, Europe, Hawai'i	Apiaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Cerataphis orchidearum</i> (Westwood)	Africa, Asia, Central America, Hawai'i	Orchidaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Dysaphis apiifolia</i> (Theobald)	Africa, Australia, Central Asia, Europe, Middle East, North and South America	Apiaceae	(Blackman and Eastop 2000)
<i>Dysaphis foeniculus</i> (Theobald)	Africa, Australia, Mediterranean, Middle East, North and South America, South Asia	Apiaceae, Polygonaceae	(Blackman and Eastop 2000)
<i>Dysaphis tulipae</i> (Boyer de Fonscolombe)	India, Jordan, United Kingdom, United States	Araceae, Iridaceae, Liliaceae, Musaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Greenidea mangiferae</i> Takahashi	Taiwan	<i>Euphoria longans</i> , <i>Mangifera indica</i>	(Blackman and Eastop 2000)
<i>Greenidea psidii</i> van der Goot	Asia, Central America, Hawai'i, United States	Clusiaceae, Juglandaceae, Loranthaceae, Lythraceae, Moraceae, Myrtaceae, Rhamnaceae, Rutaceae	(Beardsley 1995, Blackman and Eastop 2000, Halbert 2004, Pérez Hidalgo et al. 2009)
<i>Hyadaphis coriandri</i> (Das)	Africa, Central and South Asia, Mediterranean, Middle East, Peru, United	Amaranthaceae, Apiaceae, Fabaceae, Lamiaceae	(Blackman and Eastop 2000)

	States		
<i>Hyadaphis foeniculi</i> (Passerini)	Egypt, Europe, Middle East, South America, United States	<i>Daucus carota</i> , <i>Foeniculum vulgare</i> , <i>Petroselinum</i> spp., <i>Solanum tuberosum</i> , <i>Viburnum</i> spp.	(Smith and Cermeli 1979, CABI 2007, Kavallieratos et al. 2007, Kaygin et al. 2009)
<i>Hyperomyzus lactucae</i> (L.)	Australia, Central and South Asia, Europe, Hawai'i, Japan, Mediterranean, Middle East, North and South America	<i>Sonchus</i> spp.	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Macrosiphoniella sanborni</i> (Gillette)	Asia, Central America, Europe, South America, United States	Asteraceae	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Macrosiphum euphorbiae</i> (Thomas)	Africa, Asia, Australia, Canada, Central America, Europe, Mexico, New Zealand, South America, United States	Solanaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Macrosiphum rosae</i> (L.)	Africa, Asia, Australia, Canada, Europe, Mexico, New Zealand, South America, United States	Dipsacaceae, Onagraceae, Rosaceae, Valerianaceae	(Blackman and Eastop 2000, CABI 2007)
<i>Melanaphis sacchari</i> (Zehntner)	Australia, Central and South America, Hawai'i,	Poaceae	(Blackman and Eastop 2000, White et al. 2001)

	South Africa, Southeast Asia, United States		
<i>Melanaphis sorghi</i> (Theobald)	Africa, Asia, Middle East	<i>Saccharum</i> spp., <i>Sorghum</i> spp., <i>Zea mays</i>	(Blackman et al. 1990)
<i>Metopolophium dirhodum</i> (Walker)	Africa, Australia, Japan, North and Central America, West and Central Asia	Poaceae	(Blackman and Eastop 2000, CABI 2007)
<i>Metopolophium festucae</i> (Theobald)	Europe	Poaceae	(Blackman and Eastop 2000)
<i>Myzus ascalonicus</i> Doncaster	Canada, Europe, New Zealand, Russia, United States	Polyphagous on many vegetable crops including <i>Allium</i> spp., <i>Beta vulgaris</i> , <i>Fragaria</i> spp., <i>Solanum</i> spp.	(Hill 1983, CABI 2007, Verbeek et al. 2010)
<i>Myzus ornatus</i> Laing	Africa, Australia, Central America, Europe, Mediterranean, South America, United States	Asteraceae, Bignoniaceae, Labiatae, Polygonaceae, Primulaceae, Rosaceae, Violaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Neotoxoptera oliveri</i> (Essig)	Africa, Australia, Bermuda, Brazil, Korea, Mexico, New Zealand, Panama, Pakistan, Portugal, United States	<i>Allium cepa</i> , <i>Stellaria media</i> , <i>Viola</i> spp.	(Blackman and Eastop 2000)
<i>Ovatus</i>	Africa, Europe,	Lamiaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)

<i>Crataegarius</i> (Walker)	Hawai'i, Mexico, United States		
<i>Patchiella</i> <i>reaumuri</i> (Kaltenbach)	Bulgaria, Balkan States, Hawai'i, Solomon Islands, Turkey, Western Europe	Araceae	(Blackman and Eastop 2000)
<i>Pemphigus</i> <i>populitransversus</i> Riley	Azores, North and South America, South Africa	Brassicaceae	(Blackman and Eastop 2000)
<i>Rhopalosiphoninus</i> <i>latysiphon</i> (Davidson)	Africa, Australia, Europe, Hawai'i, North and South America, South Asia	Apocynaceae, Convolvulaceae, Iridaceae, Liliaceae, Myrtaceae, Poaceae, Rosaceae, Solanaceae, Urticaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Rhopalosiphoninus</i> <i>staphylaeae</i> (Koch)	Africa, Australasia, Europe, North America, Peru	Iridaceae, Liliaceae	(Blackman and Eastop 2000)
<i>Rhopalosiphum</i> <i>padi</i> (L.)	Africa, Asia, Australia, Canada, Europe, Mexico, Hawai'i, New Zealand, Puerto Rico, South America, United States	Cyperaceae, Iridaceae, Juncaceae, Poaceae, Typaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Schizaphis</i> <i>graminum</i> (Rondani)	Africa, Asia, North, Central and South America, Southern Europe	Poaceae	(Blackman and Eastop 2000)

<i>Schizaphis rotundiventris</i> (Signoret)	Africa, Asia, Australia, Hawai'i, Southern Europe, United States	Arecaceae, Cyperaceae	(Blackman and Eastop 2000)
<i>Sipha flava</i> (Forbes)	Azores, Western hemisphere	Arecaceae, Cyperaceae	(Beardsley et al. 1992, Blackman and Eastop 2000)
<i>Sitobion luteum</i> (Buckton)	Australia, Central and South America, Europe, Fiji, Hawai'i, India, Madagascar, Mauritius, Singapore, Tahiti, United States	Orchidaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000)
<i>Sitobion miscanthi</i> (Takahashi)	Australia, Cook Islands, Fiji, Hawai'i, Southeast Asia, Tahiti, Tonga	Poaceae, Polygonaceae	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)
<i>Tetraneura nigriabdominalis</i> (Sasaki)	Africa, Asia, Australia, Europe, New Zealand, South America, United States	Poaceae	(Blackman and Eastop 2000)
<i>Tetraneura ulmi</i> (L.)	Eastern Siberia, Europe, North America, West and Central Asia	Poaceae	(Blackman and Eastop 2000)
<i>Therioaphis trifolii</i> (Monell)	Asia, Australia, Hawai'i, Japan, Mexico, South Africa, South America, United States	<i>Astragalus</i> spp., <i>Lotus</i> spp., <i>Medicago</i> spp., <i>Melilotus</i> spp., <i>Onobrychis</i> spp., <i>Ononis</i> spp., <i>Trifolium</i> spp.	(Beardsley Jr. 1979, Blackman and Eastop 2000, CABI 2007)

<i>Toxoptera odinae</i> (van der Goot)	Asia, Sub-Saharan Africa	Anacardiaceae, Araliaceae, Caprifoliaceae, Ericaceae, Pittosporaceae, Rubiaceae, Rutaceae	(Blackman and Eastop 2000)
<i>Wahlgreniella nervata</i> (Gillette)	Africa, England, Hawai'i, North and South America, Pakistan	<i>Rosa</i> spp.	(Beardsley Jr. 1979, Blackman and Eastop 2000)
Hemiptera: Coccidae			
Coccidae (soft scale insects) often live in concealed places on plants and are frequently transported on commodities and plant materials (Miller et al. 2002). Many scale insects are major agricultural pests and have caused serious problems when introduced into new areas (Miller et al. 2005).			
<i>Ceroplastes actiniformis</i> Green	Brazil, Canary Islands, Egypt, India, Indonesia, Israel, Sri Lanka	Polyphagous	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Ceroplastes brevicauda</i> Hall	Africa	<i>Citrus</i> spp., <i>Coffea</i> spp.	Ben-Dov et al. (2009) (Miller and Miller 2003)
<i>Ceroplastes cirripediformis</i> Comstock	Caribbean, Hawai'i, Indonesia, Mexico, South America, Southern Europe, United States	<i>Citrus</i> spp., <i>Ipomoea batatas</i> , <i>Mangifera indica</i> , <i>Passiflora edulis</i> , <i>Psidium guajava</i> , <i>Solanum melongena</i>	(Ben-Dov et al. 2009)
<i>Ceroplastes destructor</i> Newstead	Africa, Australia, India, New Guinea, New Zealand	<i>Citrus</i> spp., <i>Coffea arabica</i> , <i>Diospyros kaki</i> , <i>Psidium guajava</i>	(Miller and Miller 2003, CABI 2007, Ben-Dov et al. 2009)
<i>Ceroplastes floridensis</i> Comstock	Africa, Australia, Caribbean, Central and	Polyphagous on tropical fruits in at least 69 plant	(Ben-Dov et al. 2009)

	South America, Europe, Hawai'i, United States, West, South, and Southeast Asia	families	
<i>Ceroplastes grandis</i> Hempel	South America	<i>Citrus</i> spp., <i>Diospyros kaki</i> , <i>Psidium guajava</i> , <i>Punica granatum</i>	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Ceroplastes japonicus</i> Green	Central and East Asia, England, France, Italy, Russia	<i>Citrus</i> spp.	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Ceroplastes pseudoceriferus</i> Green	South and East Asia	<i>Citrus</i> spp., <i>Mangifera indica</i> , <i>Psidium guajava</i>	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Eulecanium tiliae</i> (L.)	Canada, Europe, South Asia, United States	Polyphagous	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Milviscutulus mangiferae</i> (Green)	Africa, Australia, Central and South America, Hawai'i, Israel, Mexico, Caribbean, Asia, United States	Orchidaceae, <i>Ananas</i> spp., <i>Artocarpus</i> spp., <i>Carica papaya</i> , <i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Eugenia</i> spp., <i>Ficus</i> spp., <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Psidium guajava</i>	(Miller and Miller 2003, CABI 2007, Ben-Dov et al. 2009)
<i>Parthenolecanium persicae</i> (F.)	Asia, Australia, Europe, FSM, Hawai'i, North and South America	<i>Citrus</i> spp., <i>Diospyros kaki</i> , <i>Persea americana</i> , <i>Ficus carica</i> , <i>Magnolia grandiflora</i> , <i>Mangifera indica</i> , <i>Rosa</i> spp.	(Miller and Miller 2003, Ben-Dov et al. 2009)

<i>Philephedra tuberculosa</i> Nakahara & Gill	Africa, Caribbean, Central and South America, Mexico, United States	<i>Annona</i> spp., <i>Carica papaya</i> , <i>Citrus</i> spp., <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Pouteria sapota</i> , <i>Psidium guajava</i>	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Protopulvinaria pyriformis</i> (Cockerell)	Caribbean, Central and South America, Israel, Mexico, Southern Europe, United States	<i>Carica papaya</i> , <i>Citrus</i> spp., <i>Hibiscus sinensis</i> , <i>Mangifera indica</i> , <i>Musa cavendishi</i> , <i>Passiflora</i> spp., <i>Persea americana</i> , <i>Plumeria</i> spp., <i>Psidium guajava</i>	(Miller and Miller 2003, Ben-Dov et al. 2009)
<i>Pulvinaria floccifera</i> (Westwood)	Australia, Canada, Caribbean, Europe, Mexico, South Africa, South America, Southeast Asia, United States	<i>Citrus</i> spp., <i>Nerium</i> spp., <i>Psidium guajava</i>	(Ben-Dov et al. 2009)
<i>Saissetia miranda</i> (Cockerell & Parrott)	Caribbean, Central and South America, Hawai'i, India, Indonesia, Mexico, South Africa, South Pacific Islands, United States	<i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Mangifera indica</i> , <i>Nerium oleander</i> , <i>Persea americana</i> , <i>Plumeria</i> spp., <i>Psidium guajava</i>	(Ben-Dov et al. 2009)
<i>Saissetia neglecta</i> De Lotto	Caribbean, Central and South America,	<i>Annona muricata</i> , <i>Citrus</i> spp., <i>Coffea arabica</i> ,	(Ben-Dov et al. 2009)

	Mexico, United States, Vanuatu	<i>Mangifera indica</i> , <i>Manihot esculenta</i> , <i>Manilkara zapota</i> , <i>Musa</i> spp., <i>Psidium guajava</i> , <i>Tamarindus indica</i>	
<i>Vinsonia stellifera</i> (Westwood)	Africa, Australia, Caribbean, Netherlands, New Guinea, South America, Southeast Asia, Taiwan, United States	<i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Eugenia jambos</i> , <i>Garcinia mangostana</i> , <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Persea americana</i> , <i>Plumeria acutifolia</i>	(Ben-Dov et al. 2009)
Hemiptera: Diaspididae			
There are over 2,500 species of Diaspididae (armored scales) worldwide (Gillott 1995). These insects damage trees and shrubs and are moved to new areas in infested propagative material.			
<i>Aulacaspis tubercularis</i> Newstead	Africa, Asia, Australia, Central America, India, South America, United States	<i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Cucurbita</i> spp., <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Pittosporum undulatum</i>	(Miller et al. 2005, CABI 2007)
<i>Auscalaspis yasumatsu</i> Takagi	Caribbean, CNMI, France, Guam, Hong Kong, New Zealand, Palau, Singapore, Taiwan, United States	Cycadaceae, Stangeriaceae, Zamiaceae	(ISSG 2010)
<i>Aonidiella aurantii</i> (Maskell)	Africa, Australia, Caribbean, FSM, Melanesia,	<i>Acacia</i> spp., <i>Agave</i> spp., <i>Ambrosia</i>	(Miller et al. 2005, CABI 2007, Ben-Dov et al. 2009)

	Mexico, Middle East, South America, South Asia, United States, Western Europe	<i>artemisifolia</i> , <i>Artocarpus</i> spp., <i>Bambusa</i> spp., <i>Brassica nigra</i> , <i>Capsicum frutescens</i> , <i>Carica papaya</i> , <i>Casuarina</i> spp., <i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Cucurbita pepo</i> , <i>Cycas</i> spp., <i>Diospyros kaki</i> , <i>Ficus</i> spp., <i>Hibiscus</i> spp., <i>Jasminum</i> spp., <i>Mangifera indica</i> , <i>Musa sapientum</i> , <i>Nerium oleander</i> , <i>Pandanus tectorius</i> , <i>Persea americana</i> , <i>Poinsettia</i> spp., <i>Psidium guajava</i>	
<i>Chrysomphalus aonidum</i> (L.)	Africa, Australia, Caribbean, Central and South America, China, Europe, FSM, Hawai'i, Melanesia, Mexico, Middle East, South Asia, Taiwan, Vietnam, United States	<i>Acacia</i> spp., <i>Annona</i> spp., <i>Artocarpus</i> spp., <i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Cycas</i> spp., <i>Diospyros kaki</i> , <i>Dodonaea viscosa</i> , <i>Garcinia</i> spp., <i>Gardenia</i> spp., <i>Hibiscus</i> spp., <i>Heliconia</i> spp., <i>Ficus</i> spp., <i>Mangifera indica</i> , <i>Musa</i> spp.,	(Miller et al. 2005, Ben-Dov et al. 2009)

		<i>Nerium oleander</i> , <i>Opuntia</i> spp., <i>Pandanus</i> spp., <i>Persea americana</i> , <i>Phoenix dactylifera</i> , <i>Plumeria</i> spp., <i>Psidium guajava</i> , <i>Punica granatum</i>	
<i>Diaspidiotus perniciosus</i> (Comstock)	Africa, Canada, Europe, Hawai'i, South America, Southeast Asia, United States	<i>Actinidia chinensis</i> , <i>Cannabis sativa</i> , <i>Citrus</i> spp., <i>Diospyros kaki</i>	(Miller et al. 2005, Ben-Dov et al. 2009)
<i>Diaspis boisduvalii</i> Signoret	Africa, Asia, Australia, Canada, Caribbean, Central and South America, Europe, Hawai'i, Mexico, Palau, United States	<i>Agave</i> spp., <i>Ananas comosus</i> , <i>Cattleya</i> spp., <i>Citrus</i> spp., <i>Cocos</i> spp., <i>Garcinia mangostana</i> , <i>Heliconia</i> spp., <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Pandanus</i> spp., <i>Persea americana</i> , <i>Phoenix</i> spp., <i>Strelitzia</i> spp., <i>Vanda</i> spp.	(Miller et al. 2005, Ben-Dov et al. 2009)
<i>Fiorinia theae</i> Green	Caribbean, Central and South America, Mexico, South and East Asia	<i>Camellia</i> spp., <i>Citrus</i> spp., <i>Olea</i> spp., <i>Spondias</i> spp.	(Miller et al. 2005, Ben-Dov et al. 2009)
<i>Gymnaspis aechmeae</i> Newstead	Argentina, Caribbean, Costa Rica, Europe,	Bromeliaceae, <i>Ananas comosus</i> , <i>Cymbidium</i> spp.	(Miller et al. 2005, Ben-Dov et al. 2009)

	Hawai'i, United States		
<i>Lepidosaphes ulmi</i> (L.)	Australia, Canada, China, Europe, Hawai'i, India, Middle East, North Africa, South Africa, South America, Taiwan, United States	<i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Diospyros kaki</i> , <i>Ginkgo</i> spp., <i>Persea</i> spp., <i>Ficus carica</i> , <i>Nerium oleander</i> , <i>Olea europaea</i> , <i>Punica granatum</i>	(Miller et al. 2005, CABI 2007, Ben-Dov et al. 2009)
<i>Lindingaspis rossi</i> (Maskell)	Africa, Australia, Hawai'i, Mexico, New Zealand, New Caledonia, Philippines, Samoa, South America, South and East Asia, Southern Europe, United States	<i>Citrus</i> spp., <i>Cocos nucifera</i> , <i>Cycas</i> spp., <i>Eucalyptus</i> spp., <i>Garcinia</i> spp., <i>Macadamia ternifolia</i> , <i>Mangifera indica</i> , <i>Nerium oleander</i>	(Miller et al. 2005, Ben-Dov et al. 2009)
<i>Parlatoria oleae</i> (Colvée)	Australia, Mexico, Northern Africa, South America, Southern Asia, Southern Europe, United States	<i>Acacia</i> spp., <i>Citrus</i> spp., <i>Dianthus</i> spp., <i>Diospyros kaki</i> , <i>Eriobotrya japonica</i> , <i>Hibiscus syriacus</i> , <i>Jasminum</i> spp., <i>Mangifera indica</i> , <i>Nerium</i> spp., <i>Olea europaea</i> , <i>Oryza sativa</i> , <i>Phoenix</i> spp., <i>Punica granatum</i>	(Miller et al. 2005, Ben-Dov et al. 2009)
<i>Pinnaspis aspidistrae</i> (Signoret)	Africa, Canada, Caribbean, Central and South America,	<i>Acacia</i> spp., <i>Annona</i> spp., <i>Citrus</i> spp., <i>Cocos nucifera</i> ,	(Miller et al. 2005, CABI 2007, Ben-Dov et al. 2009)

	Europe, FSM, Hawai'i, Melanesia, Mexico, Philippines, United States	<i>Cordyline terminalis</i> , <i>Cymbidium</i> spp., <i>Cycas</i> spp., <i>Dracaena</i> spp., <i>Heliconia</i> spp., <i>Hibiscus rosasinensis</i> , <i>Jatropha integerrima</i> , <i>Mangifera indica</i> , <i>Musa paradisiaca</i> , <i>Pandanus odoratissimus</i> , <i>Persea</i> spp., <i>Piper</i> spp., <i>Plumeria acutifolia</i> , <i>Portulaca lutea</i> , <i>Psidium guajava</i> , <i>Solanum</i> spp.	
<i>Unaspis citri</i> (Comstock)	Africa, Australia, Caribbean, Central and South America, FSM, Hawai'i, Melanesia, Mexico, Southeast Asia, United States	<i>Acacia</i> spp., <i>Ananas</i> spp., <i>Annona muricata</i> spp., <i>Citrus</i> spp., <i>Cocos</i> spp., <i>Euonymus</i> spp., <i>Hibiscus</i> spp., <i>Mangifera</i> spp., <i>Musa</i> spp., <i>Persea americana</i> , <i>Psidium guajava</i>	(Miller et al. 2005, Ben-Dov et al. 2009)
Hemiptera: Keriidae			
Kerriidae (Iac scales) are mainly tropical and subtropical in distribution (Gillott 1995) and can be spread to new areas in infested propagative material. They can be serious pests of various plant species.			
<i>Paratachardina lobata</i> (Chamberlin)	Christmas Island, India, Sri Lanka, United States	<i>Acacia</i> spp., <i>Annona</i> spp., <i>Artocarpus</i>	(Howard et al. 2004, Ben-Dov et al. 2009)

		<i>heterophyllus</i> , <i>Bambusa vulgaris</i> , <i>Casuarina</i> spp., <i>Citrus</i> spp., <i>Dimocarpus</i> <i>longan</i> , <i>Diospyros</i> spp., <i>Garcinia</i> spp., <i>Gardenia</i> spp., <i>Litchi</i> <i>sinensis</i> , <i>Mangifera indica</i> , <i>Manilkara</i> spp., <i>Persea</i> spp., <i>Psidium</i> spp., <i>Solanum</i> spp.	
<i>Paratachardina pseudolobata</i> Kondo & Gullan	United States	<i>Mangifera indica</i>	(Ben-Dov et al. 2009, ISSG 2009)
Hemiptera: Miridae			
Many mirids cause severe feeding damage to vegetables, fruits, flowers, and forage crops (Gillott 1995). They are often moved in infested plant materials.			
<i>Lygus hesperus</i> Knight	Canada, United States	<i>Daucus carota</i> , <i>Solanum lycopersicum</i>	(Scott 1977, CABI 2007)
<i>Lygus lineolaris</i> Palisot de Beauvois	Canada, Central America, Mexico, United States	Polyphagous. Hosts include <i>Brassica</i> spp., <i>Cucumis sativus</i> , <i>Dahlia</i> spp., <i>Phaseolus vulgaris</i> , <i>Prunus</i> spp., <i>Solanum</i> spp.	(Young 1986, CABI 2007)
Hemiptera: Orthzeziidae			
Orthzeziidae can live on almost any host plant part, including the roots (Triplehorn and Johnson 2005). These insects can be moved to new areas on infested plant materials.			
<i>Insignorthezia</i>	Africa, Australia,	<i>Artemisia</i> spp.,	(Ben-Dov et al. 2009, ISSG 2009)

<i>insignis</i> (Browne)	Canada, Caribbean, Central and South America, China, Europe, Hawai'i, India, Indonesia, Japan, Malaysia, Mexico, Sri Lanka, Taiwan, United States	<i>Citrus</i> spp., <i>Coffea</i> spp., <i>Euphorbia</i> spp., <i>Geranium</i> spp., <i>Ipomoea</i> spp., <i>Lantana</i> spp., <i>Oxalis</i> spp., <i>Solanum</i> spp., <i>Viola</i> spp.	
Hemiptera: Pseudococcidae			
Pseudococcidae (mealybugs) often attain high population densities, killing their host plants by depleting sap, injecting toxins, transmitting viruses, and/or excreting honeydew (Williams and Granara de Willink 1992). They are moved on infested plant materials.			
<i>Balanococcus poae</i> (Maskell)	New Zealand	Poaceae	(Miller et al. 2002, Ben-Dov et al. 2009)
<i>Dysmicoccus grassii</i> (Leonardi)	Caribbean, Central and South America, France, Italy, Malaysia, Mexico, Nigeria	<i>Ananas comosus</i> , <i>Annona squamosa</i> , <i>Artocarpus</i> spp., <i>Carica papaya</i> , <i>Coffea arabica</i> , <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Passiflora edulis</i> , <i>Persea</i> spp., <i>Punica granatum</i> , <i>Sechium edule</i> , <i>Theobroma cacao</i>	(Ben-Dov et al. 2009)
<i>Dysmicoccus</i> sp. nr. <i>bispinosus</i>	Caribbean, Central America, Mexico, Puerto Rico, South America	<i>Acacia</i> spp., <i>Coffea</i> spp., <i>Citrus</i> spp., <i>Dieffenbachia</i> spp., <i>Inga</i> spp., <i>Musa</i> spp., <i>Psidium guajava</i> ,	(Williams and Granara de Willink 1992, Rung et al. 2007)

		<i>Solanum</i> spp.	
<i>Dysmicoccus texensis</i> (Tinsley)	Central America, Mexico, South America, Trinidad and Tobago, United States	<i>Acacia</i> spp., <i>Coffea</i> spp.	(Williams and Granara de Willink 1992, Santa-Cecília et al. 2002, Miller et al. 2005, Bigger 2009)
<i>Exallomochlus hispidus</i> (Morrison)	Southeast Asia	<i>Annona muricata</i> , <i>Artocarpus heterophyllus</i> , <i>Citrus maxima</i> , <i>Cocos nucifera</i> , <i>Dimocarpus longan</i> , <i>Durio</i> spp., <i>Garcinia mangostana</i> , <i>Manilkara zapota</i> , <i>Nephelium lappaceum</i> , <i>Psidium guajava</i> , <i>Saccharum officinarum</i> , <i>Theobroma cacao</i>	(Miller et al. 2002, Ben-Dov et al. 2009)
<i>Ferrisia malvastra</i> (McDaniel)	Australia, Caribbean, Hawai'i, India, Israel, Mexico, New Guinea, South Africa, South America, United States	<i>Ambrosia artemisifolia</i> , <i>Arachis hypogaea</i> , <i>Brassica rapa</i> , <i>Citrus paradisi</i> , <i>Gossypium hirsutum</i> , <i>Macadamia</i> spp., <i>Manihot esculenta</i> , <i>Persea americana</i> , <i>Phaseolus vulgaris</i> , <i>Punica granatum</i> , <i>Solanum</i> spp., <i>Tectona grandis</i>	(Ben-Dov et al. 2009)

<i>Geococcus coffeae</i> Green	Africa, Australia, Caribbean, Central and South America, FSM, Hawai'i, Mexico, New Guinea, Southeast Asia, United States, Western Europe	<i>Ananas comosus</i> , <i>Dioscorea</i> spp., <i>Acacia koa</i> , <i>Citrus</i> spp., <i>Coffea arabica</i> , <i>Colocasia esculenta</i> , <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Nerium oleander</i> , <i>Theobroma cacao</i>	(Miller et al. 2002, Ben-Dov et al. 2009)
<i>Phenacoccus gossypii</i> Townsend & Cockerell	Caribbean, Japan, Mexico, South America, Southern Europe, United States	<i>Capsicum annuum</i> , <i>Gossypium</i> spp., <i>Helianthus</i> spp., <i>Lantana</i> spp., <i>Mangifera indica</i> , <i>Phaseolus vulgaris</i> , <i>Solanum lycopersicum</i>	(Ben-Dov et al. 2009)
<i>Phenacoccus parvus</i> Morrison	Africa, Australia, Caribbean, Central and South America, India, Indonesia, Israel, Mexico, New Caledonia, Thailand, United States	<i>Actinidia deliciosa</i> , <i>Capsicum</i> spp., <i>Cucumis sativus</i> , <i>Lantana camara</i> , <i>Mangifera indica</i> , <i>Musa</i> spp., <i>Psidium guajava</i> , <i>Saccharum officinarum</i> , <i>Solanum</i> spp.	(Ben-Dov et al. 2009)
<i>Phenacoccus solani</i> Ferris	Caribbean, Central and South America, Hawai'i, India, Italy, Kiribati, North America, RMI, Southern Africa, West and	<i>Artemisia heterophylla</i> , <i>Aster</i> spp., <i>Brassica oleracea</i> , <i>Centaurea diffusa</i> , <i>Chenopodium</i> spp., <i>Chrysanthemum</i>	(Ben-Dov et al. 2009)

	Southeast Asia	<i>morifolium</i> , <i>Citrus aurantifolia</i> , <i>Dendrobium</i> spp., <i>Euphorbia</i> spp., <i>Helianthus</i> spp., <i>Lantana camara</i> , <i>Narcissus</i> spp., <i>Raphanus sativus</i> , <i>Solanum</i> spp., <i>Viola</i> spp.	
<i>Planococcus ficus</i> (Signoret)	Caribbean, Middle East, South America, South Asia, Southern Africa, Southern Europe, United States	<i>Bambusa</i> spp., <i>Ficus</i> spp., <i>Mangifera indica</i> , <i>Nerium oleander</i> , <i>Persea americana</i> , <i>Phoenix dactylifera</i> , <i>Punica granatum</i> , <i>Theobroma cacao</i>	(Ben-Dov et al. 2009)
<i>Planococcus kraunhiae</i> (Kuwana)	China, Japan, Korea, Philippines, Taiwan, United States	<i>Actinidia</i> spp., <i>Agave americana</i> , <i>Artocarpus lanceolata</i> , <i>Casuarina stricta</i> , <i>Citrus</i> spp., <i>Coffea arabica</i> , <i>Cucurbita moschata</i> , <i>Diospyros kaki</i> , <i>Ficus carica</i> , <i>Musa basjoo</i> , <i>Nerium indicum</i> , <i>Pyrus ussuriensis</i>	(Ben-Dov et al. 2009)
<i>Planococcus minor</i> (Maskell)	Australia, Caribbean, Central America, FSM, Guam, Mexico, South	<i>Acacia</i> spp., <i>Aleurites moluccana</i> , <i>Ananas comosus</i> , <i>Annona</i> spp.,	(Miller et al. 2002, Ben-Dov et al. 2009)

	America, Southeast Asia, Taiwan	<i>Artocarpus</i> spp., <i>Brassica</i> spp., <i>Capsicum</i> spp., <i>Citrus</i> spp., <i>Cocos</i> <i>nucifera</i> , <i>Coffea</i> spp., <i>Colocasia</i> <i>esculenta</i> , <i>Cucumis</i> spp., <i>Cucurbita</i> spp., <i>Heliconia</i> spp., <i>Hibiscus</i> spp., <i>Ipomoea</i> spp., <i>Leucaena</i> spp., <i>Manihot</i> <i>esculenta</i> , <i>Mangifera indica</i> , <i>Mimosa</i> spp., <i>Musa</i> spp., <i>Pandanus</i> spp., <i>Passiflora edulis</i> , <i>Persea</i> <i>americana</i> , <i>Plumeria rubra</i> , <i>Psidium guajava</i> , <i>Saccharum</i> <i>officinarum</i> , <i>Solanum</i> spp., <i>Tectona grandis</i> spp., <i>Theobroma</i> <i>cacao</i>	
<i>Pseudococcus</i> <i>calceolariae</i> (Maskell)	Africa, Australia, Caribbean, China, Europe, Indonesia Mexico, United States, South America	<i>Brassica</i> spp., <i>Citrus</i> spp., <i>Helianthus</i> spp., <i>Hibiscus</i> spp., <i>Nerium oleander</i> , <i>Persea indica</i> , <i>Solanum</i> spp., <i>Theobroma</i>	(CABI 2007, Ben-Dov et al. 2009)

		<i>cacao</i> , <i>Trifolium</i> spp.

<i>Rhizoeus falcifer</i> Kunckel	Australia, Caribbean,	<i>Chrysanthemum frutescens</i> , <i>Citrus</i>	(Ben-Dov et al. 2009)

d'Herculis	Europe, Mexico, North Africa, South Africa, Suriname, United States	<i>sinensis</i> , <i>Coffea</i> spp., <i>Convolvulus</i> spp., <i>Cynodon dactylon</i> , <i>Geranium</i> spp., <i>Hibiscus</i> spp., <i>Iris</i> spp., <i>Matthiola</i> spp., <i>Passiflora edulis</i> , <i>Phoenix</i> spp., <i>Prunus persica</i> , <i>Solanum</i> spp., <i>Theobroma cacao</i>	
<i>Ripersiella hibisci</i> (Kawai & Takagi)	Caribbean, China, Hawai'i, Japan, Taiwan, United States	<i>Carex</i> spp., <i>Hibiscus rosa-sinensis</i> , <i>Nerium oleander</i> , <i>Phoenix</i> spp.	(Miller et al. 2002, Ben-Dov et al. 2009)
<i>Vryburgia brevicurvis</i> (McKenzie)	Australia, Europe, Israel, United States	Asclepiadaceae, <i>Gerbera</i> spp., <i>Solanum tuberosum</i> , <i>Taraxacum officinale</i> , <i>Trifolium</i> spp.	(Ben-Dov et al. 2009)

Hemiptera: Psyllidae

The toxic saliva of psyllids may cause galling and stunting of plants (Gillott 1995). These small insects also transmit viruses and phytoplasmas. *Diaphorina citri* vectors 'Candidatus Liberibacter asiaticus', the phytoplasma that causes Huanglongbing (citrus greening) in *Citrus* spp. (Gottwald et al. 2007).

<i>Diaphorina citri</i> Kuwayama	Australia, Central and South America, Guam, Hawai'i, Southeast Asia, United States	<i>Citrus</i> spp.	(Grafton-Cardwell et al. 2006, ISSG 2010)
-------------------------------------	--	--------------------	---

Hemiptera: Triozidae

Trioziidae (jumping plant lice) are small insects that feed on plants, causing galling and stunting (Gillott 1995). The potato psyllid, *Bactericera cockerelli*, feeds on

plants in 20 different plant families, favoring solanaceous plants (Abdullah 2008). Some Triozid species (especially the one included in the assessment) vector disease caused fastidious bacteria (<i>Candidatus Liberibacter solanacearum</i>). There are multiple strains/biotypes of both the Triozid, and the vectored bacteria (Pers Comm. Barbour).			
<i>Bactericera cockerelli</i> (Sulc)	Central America, Mexico, New Zealand, United States, Europe	Polyphageous, favoring Solanaceae	(Abdullah 2008)
Hymenoptera: Formicidae			
At least 90 ant species have been introduced into the Pacific Region, many by human activities (McGlynn 1999); they have had devastating impacts, reducing agricultural productivity and biodiversity (O'Dowd et al. 2003, Krushelnycky et al. 2005, Lester et al. 2009, Savage et al. 2009) and affecting human health. Red imported fire ants (<i>Solenopsis invicta</i>) sting people, often causing severe allergic reactions, and can make public areas, such as parks, unsafe for people (ISSG 2010). Ants are often moved on nursery stock and in many other items, including WPM, shipping containers, soil, construction materials, and vehicles.			
<i>Acromyrmex octospinosus</i> (Reich)	Caribbean, South America		(ISSG 2009)
<i>Lasius neglectus</i> Van Loon, Boomsma, & Andrásfalvy	Europe, Georgia, Kyrgyzstan, Turkey, Uzbekistan		(Seifert 2000, Schultz and Seifert 2005, ISSG 2009)
<i>Linepithema humile</i> (Mayr)	Australia, Bermuda, Hawai'i, Japan, Mexico, New Zealand, South Africa, South America, United Arab Emirates, United States, Western and Southern Europe		(Suarez et al. 2001, Holway et al. 2002, Krushelnycky et al. 2005)
<i>Monomorium pharaonis</i> (L.)	Africa, Asia, Australia, Europe, Galápagos Islands, Hawai'i, North, Central and South		(ISSG 2009)

	America		
<i>Myrmica rubra</i> (L.)	Australia, Canada, Europe, United States		(Grodén et al. 2005, CABI 2007, ISSG 2009)
<i>Solenopsis invicta</i> Buren	Australia, Caribbean, New Zealand, South America, United States		(Vinson 1997, Holway et al. 2002, Morrison et al. 2004b)
<i>Solenopsis richteri</i> Forel <i>Solenopsis papuana</i> Emery	South America, United States American Samoa, Fiji, New Zealand, Hawai'i, United States	<i>Cocos, Colocasia</i>	(ISSG 2009) (SPREP 2000, ISSG 2009)
<i>Tapinoma melanocephalum</i> (Fabricius) <i>Wasmannia auropunctata</i> (Roger)	Australia, Brazil, Canada, Caribbean, Costa Rica, Japan, United States Africa, Caribbean, Central and South America, Galápagos Islands, Hawai'i, New Caledonia, North America, Solomon Islands, Tahiti, Vanuatu		(Holway et al. 2002, Wetterer and Porter 2003)

Lepidoptera: Bedelliidae

Native species in Hawai'i and also found in Fiji

<i>Bedelliidae</i> spp.	Hawai'i and Fiji	Ipomoea	(Englberger, personal communication)
-------------------------	------------------	---------	--------------------------------------

Lepidoptera: Gelechiidae

There are over 4,000 species of Gelechiidae. Larvae cause damage by boring into plant stems, seeds, fruit, flowers, and tubers (Gillott 1995). These small moths

are often moved to new areas in infested plant material.			
<i>Tuta absoluta</i> (Meyrick)	North Africa, South America, Southern Europe	Solanaceae	(EPPO 2005b; CABI/EPPO 2009)
Lepidoptera: Gracillariidea			
The family Gracillariidea contains species of small moths, the larvae of which are leaf miners (Gillott 1995). <i>Marmara gulosa</i> larvae make serpentine mines in the rind of citrus fruits, making the fruit unsellable in the fresh market (Kirkland 2009).			
<i>Marmara gulosa</i> Guillén and Davis	United States	<i>Capsicum</i> <i>annuum</i> , <i>Citrus</i> spp., Cucurbitaceae, <i>Persea</i> <i>americana</i> , <i>Prunus</i> spp., <i>Vitis</i> spp.	(Kirkland 2009)
Lepidoptera: Limacodidae			
Limacodidae (nettle caterpillars) often have stinging hairs or spines, which may cause allergies in humans. Some species feed on palms (Barlow 1982) while other species are abundant in hardwood forests. Limacodidae can be moved to new areas on infested plant material.			
<i>Darna pallivitta</i> (Moore)	China, Hawai'i, Indonesia, Malaysia, Taiwan, Thailand	Arecaceae, Poaceae, <i>Adenostemma</i> spp., <i>Breynia</i> spp., <i>Cordyline</i> <i>terminalis</i> , <i>Ficus</i> spp., <i>Macadamia</i> <i>integrifolia</i>	(Robinson et al. 2001, Nagamine and Epstein 2007, Conant et al. 2008, Jang et al. 2009)
Lepidoptera: Noctuidae			
Noctuid larvae may cause severe damage to many plant species (Barlow 1982). Noctuids are moved to new areas on infested plant material and can be attracted to cargo and conveyances during night loading.			
<i>Autographa californica</i> Speyer	Malaysia, United States	<i>Medicago sativa</i> , <i>Mentha piperita</i> , <i>Solanum</i> <i>lycopersicum</i>	(Pearson et al. 1988, CABI 2007)
<i>Copitarsia corruda</i>	Colombia,	<i>Alstroemeria</i>	(Pogue and Simmons 2008, Gómez et al. 2009)

Pogue & Simmons	Ecuador, Peru	spp., <i>Ammi</i> spp., <i>Asparagus</i> spp., <i>Aster</i> spp., <i>Brassica</i> spp., <i>Callistephus</i> spp., <i>Iris</i> spp., <i>Limonium</i> spp., <i>Lysimachia</i> spp.	
Lepidoptera: Papilionidae			
The lime swallowtail, <i>Papilio demoleus</i> , is a pest of citrus nursery stock. Larvae are capable of defoliating entire nursery groves (Lewis 2009). Larvae can be moved on citrus nursery stock and adults may be deliberately introduced through the hobby trade.			
<i>Papilio demoleus</i> L.	Australia, Caribbean, Indonesia, Middle East, Southern Asia	Rutaceae, Fabaceae	(Guerrero et al. 2004, Eastwood et al. 2006, Lewis 2009)
Lepidoptera: Tineidae			
Tineid larvae are concealed feeders that often mine into plant parts (Gillott 1995). Tineoid moths can be moved to new areas on infested plant materials.			
<i>Opogona sacchari</i> (Bojer)	Africa, Brazil, Caribbean, China, Central America, Europe, Hawai'i, United States	<i>Alpinia</i> spp., <i>Ananas comosus</i> , <i>Bambusa</i> spp., <i>Begonia</i> spp., <i>Bougainvillea</i> spp., <i>Cordyline</i> spp., <i>Dieffenbachia</i> spp., <i>Dracaena</i> spp., <i>Euphorbia</i> <i>pulcherrima</i> , <i>Gloxinia</i> spp., <i>Heliconia</i> spp., <i>Musa</i> spp., <i>Philodendron</i> spp., <i>Saccharum</i> <i>officinarum</i>	(CABI/EPP0 1997f, Nishida 2002, Wang et al. 2008a)

Lepidoptera: Tortricidae			
Larvae of tortricids cause damage by mining into fruits, seeds, and bark, or by defoliating plants (Gillott 1995). Tortricids can be moved to new areas in infested plant material. The light brown apple moth (<i>Epiphyas postvittana</i>) is a significant horticultural and agricultural pest in both its native and introduced ranges and is highly polyphagous with at least 500 host plant species in 121 families.			
<i>Epiphyas postvittana</i> (Walker)	Australia, Hawai'i, Ireland, New Zealand, United Kingdom, United States	Polyphagous, including fruits and cut flowers	(Suckling and Brockerhoff 2010)
Lepidoptera: Yponomeutidae			
Yponomeutidae are small moths. Larvae may be miners, web builders, or exposed feeders (Gillott 1995). <i>Acrolepiopsis</i> species mine into the leaves of <i>Allium</i> spp., which severely weakens the plant (CABI 2007).			
<i>Acrolepiopsis assectella</i> (Zeller)	Algeria, Asia, Canada, Europe, Hawai'i	<i>Allium</i> spp.	(CABI 2007, CABI/EPPO 2007, Jenner et al. 2010)
<i>Acrolepiopsis sapporensis</i> (Matsumura)	East Asia, Hawai'i	<i>Allium</i> spp.	(Landry 2007)
Thysanoptera: Phlaeothripidae			
Thrips damage plants by direct feeding and by vectoring plant viruses. Thrips are extremely difficult to detect in consignments, particularly in bulky shipments (Lewis 1997). Many of the thrips associated with grasses (Poaceae) are readily transported in straw as well as with grass seeds (Mound and Teulon 1995). The habit of crawling into confined spaces makes some species enter packaged goods (Palmer et al. 1989).			
<i>Holopothrips tabebuia</i> Cabrera & Segarra	Caribbean, United States	<i>Amphitecna latifolia</i> , <i>Schefflera actinophylla</i> , <i>Tabebuia</i> spp.	(Gilman and Watson 1994, Cabrera and Segarra 2008, Michel et al. 2008)
<i>Chaetanaphothrips signipennis</i> (Bagnall)	Africa, Australia, Brazil, Fiji, Hawai'i, Honduras, India, Indonesia, New Guinea, Panama, Philippines, Sri	<i>Anthurium palmatum</i> , <i>Alocasia</i> spp., <i>Citrus</i> spp., <i>Cordyline terminalis</i> , <i>Dracaena</i> spp.,	(Lewis 1973, CAB 1981, Denmark and Osborne 1985, Hara et al. 2002, Hussain and Annamalai 2006)

	Lanka, United States	<i>Maranta leuconeura</i> , <i>Musa</i> spp., <i>Phaseolus vulgaris</i> , <i>Solanum lycopersicum</i> , <i>Strelitzia reginae</i>	
<i>Frankliniella cephalica</i> (Crawford)	Caribbean, Central America, Japan, Mexico, United States	<i>Amaranthus spinosus</i> , <i>Ambrosia artemisifolia</i> , <i>Bidens</i> spp., <i>Citrus</i> spp., <i>Commelina diffusa</i> , <i>Euphorbia</i> spp., <i>Heterotheca subaxillaris</i> , <i>Ipomoea</i> spp., <i>Lantana camara</i> , <i>Mangifera indica</i> , <i>Morrenia odorata</i> , <i>Taraxacum officinale</i> , <i>Youngia japonica</i>	(Jeppson 1989, Lamberts and Crane 1990, Nakahara 1997, Masumoto and Okajima 2004, Childers and Nakahara 2006, Ohnishi et al. 2006)
<i>Frankliniella intonsa</i> (Trybom)	Canada, Europe, Israel, New Zealand, South and East Asia, Turkey, United States	Solanaceae	(Nakahara 1997, CABI/EPPO 1999a, Nakahara and Footitt 2007)
<i>Frankliniella occidentalis</i> (Pergande)	Australia, Canada, Caribbean, Central and South America, Europe, Hawai'i, Japan, Korea, Malaysia, Middle East, Mexico,	Cucurbitaceae, <i>Allium cepa</i> , <i>Citrus</i> spp., <i>Daucus carota</i> , <i>Fragaria</i> spp., <i>Gossypium</i> spp., <i>Phaseolus</i> spp., <i>Solanum lycopersicum</i>	(CABI/EPPO 1997e, 1999b, CABI 2007, Funderburk et al. 2009)

	New Zealand, Sri Lanka, Southern Africa, United States		
<i>Scirtothrips dorsalis</i> Hood	Australia, Hawai'i, New Guinea, Solomon Islands, South Africa, South and East Asia, United States	Fabaceae, <i>Allium cepa</i> , <i>Actinidia chinensis</i> , <i>Camellia sinensis</i> , <i>Capsicum</i> spp., <i>Citrus</i> spp., <i>Fragaria</i> spp., <i>Gossypium hirsutum</i> , <i>Hevea brasiliensis</i> , <i>Hydrangea</i> spp., <i>Mangifera</i> spp., <i>Nelumbo</i> spp., <i>Ricinus</i> spp., <i>Rosa</i> spp.	(CABI/EPPO 1997i, Silagyi and Dixon 2006, Funderburk et al. 2009)
MOLLUSKS			
Snails and slugs can cause considerable damage to agriculture and horticulture (Godan 1983) by causing direct feeding damage, and by vectoring or indirectly facilitating the entry of plant pathogens. They can also vector pathogens to humans. Mollusks are often intercepted on WPM. They are also likely to be introduced on agricultural and horticultural commodities, containers and conveyances, vehicles and equipment, items that were stored outdoors, and in potting media (Cowie 2001).			
<i>Achatina fulica</i>	FSM (except Chuuk and Yap), RMI, Palau, Guam, CNMI, American Samoa, French Polynesia, Hawai'i, New Caladonia, Papua New Guinea, Samoa, Vanuatu and Wallis and Fortuna	A wide variety fruit and vegetable crops	(SPC 1999)

<i>Allopeas clavulinum</i> (Potiez and Michaud) [Subulinidae]	American Samoa, East Africa, Fiji, Hawai'i, Japan, United States	Polyphagous	(Auffenberg and Stange 1988, SPREP 2000, Cowie et al. 2008)
<i>Allopeas micra</i> (d'Orbigny) [Subulinidae]	American Samoa, Europe, Galápagos Islands, Hawai'i, United States	Polyphagous	(Auffenberg and Stange 1988; SPREP 2000; Delivering Alien Invasive Species Inventories for Europe 2009)
<i>Arion ater</i> (L.) [Arionidae]	Canada, Europe, United States	Polyphagous	(Godan 1983)

<i>Trochoidea pyramidata</i> (Draparnaud) [Hygromiidae]	Europe	Polyphagous	(Godan 1983, Delivering Alien Invasive Species Inventories for Europe 2009)
<i>Xerolenta obvia</i> (Menke) [Hygromiidae]	Europe, Turkey	Polyphagous	(Shoab and Cagan 2004, Nordsieck 2009)
<i>Xeropicta derbentina</i> (Krynicky) [Hygromiidae]	Greece, Italy, Turkey	Polyphagous	(AFPMB 2008)
<i>Xerotricha conspurcata</i> (Draparnaud) [Hygromiidae]	Europe, Mediterranean, United States	Polyphagous	(Delivering Alien Invasive Species Inventories for Europe 2009)

<i>Zonitoides arboreus</i> (Say) [Gastrodontiidae]	Canada, Caribbean, China, Hawai'i, Israel, Mexico, Philippines, South America, United States	Orchidaceae	(Godan 1983, Cowie 1997, Roll et al. 2009)
<i>Zonitoides nitidus</i> (Müller) [Gastrodontiidae]	Asia, Europe, North America	Orchidaceae	(Godan 1983, Porcelli and Parenzan 1988)

NEMATODES

Nematodes are estimated to cause agricultural losses that exceed 100 billion dollars annually worldwide (Veech and Dickson 1987, Koenning et al. 1999). Soilborne plant parasitic nematodes feed on plant roots causing yellowing, stunting, root deformation, resulting in reduced crop yields and plant death (Perry and Moens 2006). Some nematodes damage above ground plant parts. *Bursaphelenchus cocophilus* infects coconut (*Cocos nucifera*) roots, stems, and leaves, causing red ring disease which can result in crop losses as high as 80 to 98% (Dean 1979). The most likely pathways of introduction for nematodes include plant roots and tubers, growing media, WPM, and articles contaminated with soil (Chen et al. 2004, Perry and Moens 2006). The baggage and footwear of international travelers have also been shown to be pathways for introduction of pest nematodes (Hockland et al. 2008).

<i>Bursaphelenchus aberrans</i> Fang et al.	China, Thailand	Unknown – described from WPM	(Tomiczek et al. 2003, Gu et al. 2006)
<i>Bursaphelenchus arthuri</i> Burgermeister, Gu and Braasch	Korea, Taiwan	Unknown – described from WPM	(Gu et al. 2006)
<i>Bursaphelenchus chengi</i> Li et al.	Taiwan	Unknown – described from WPM	(Li et al. 2008)

FUNGI and STRAMENOPILES

More than 10,000 species of fungi and stramenopiles (fungal-like organisms) cause plant diseases (Agrios 2005), often resulting in lesions, cankers, stunting, necrosis, rots, deformation, dieback, reduced yields, and plant death. Some fungi also produce mycotoxins, which make plants toxic to people and animals (Agrios 2005). Fungi can be moved to new areas on infected plant materials, and with contaminating soil (McCullough et al. 2006).

<i>Armillaria fuscipes</i> Petch	Africa, India	<i>Acacia</i> spp., <i>Cordia</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Armillaria gallica</i> Marxm. & Romagn.	Europe, Japan, South Africa, United States	<i>Diospyros</i> spp., <i>Galeola</i> spp., <i>Prunus</i> spp., <i>Umbellularia</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Armillaria sinapina</i> Bérubé & Dessur.	Canada, Hawai'i, Japan, United States	<i>Acacia</i> spp., <i>Corynocarpus</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Armillaria tabescens</i> (Scop.) Emel	Europe, Fiji, India, Japan, United States	<i>Acacia</i> spp., <i>Aleurites</i> spp., <i>Casuarina</i> spp.,	(USDA-APHIS and USDA-FS 2000, Ramsden et al. 2002, Farr and Rossman 2010)

	Cuba, Europe, Hawai'i, India, Mexico, New Caledonia, Taiwan, United States		
<i>Ophiostoma quercus</i> (Georgev.) Nannf. [Anamorph: <i>Pesotum roboris</i> (Georgescu, Teodoru & Badea) Grobbelaar, Z.W. de Beer & M.J. Wingf.]	China, Europe, Japan, Russia, South Africa, United States	<i>Acacia</i> spp.	(Farr and Rossman 2010)
<i>Ophiostoma stenoceras</i> (Robak) Melin & Nannf.	Europe, Indonesia, New Zealand, South Africa, South America, United States	<i>Acacia</i> spp.	(Farr and Rossman 2010)
<i>Perenniporia medulla-panis</i> (Jacq.) Donk	Chile, Japan, New Zealand, United States	<i>Acacia</i> spp.	(Sinclair and Lyon 2005, Farr and Rossman 2010)
<i>Pestalotiopsis versicolor</i> (Speg.) Steyaert	Africa, China, Mexico, South America, Virgin Islands	<i>Achras</i> spp., <i>Ananas</i> spp., <i>Artocarpus</i> spp., <i>Coccoloba</i> spp., <i>Cocos</i> spp., <i>Elaeis</i> spp., <i>Pandanus</i> spp., <i>Persea</i> spp.	(Sinclair and Lyon 2005, Farr and Rossman 2010)
<i>Phellinus conchatus</i> (Pers. Fr.) Quél.	Canada, China, Japan, New Zealand, South Africa, United States	<i>Acacia</i> spp., <i>Casuarina</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Phellinus lamaensis</i> (Murrill) R. Heim	China, New Zealand, New	<i>Agathis</i> spp., <i>Araucaria</i> spp.,	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)

<i>Phellinus linteus</i> (Berk. & M.A. Curtis) S. Teng.	Caledonia, Palau, New Guinea China, Japan, Pakistan, United States, West Indies	<i>Hevea</i> spp. <i>Cinnamomum</i> spp., <i>Cordia</i> spp., <i>Diospyros</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Phellinus pachyphloeus</i> (Pat.) Pat.	Africa, Australia, New Zealand, Philippines, Southern Asia	<i>Metrosideros</i> spp., <i>Podocarpus</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Phellinus rimosus</i> (Berk.) Pilát	Australia, China, India, Japan, Mexico, Puerto Rico, South Africa	<i>Acacia</i> spp., <i>Casuarina</i> spp., <i>Vatica</i> spp.	(USDA-APHIS and USDA-FS 2000, Farr and Rossman 2010)
<i>Phytophthora heveae</i> Thompson	Australia, Brazil, China, Côte d'Ivoire, Guatemala, India, Malaysia, Philippines, Taiwan, United States	<i>Areca catechu</i> , <i>Bertholletia excelsa</i> , <i>Caesalpinia pulcherrina</i> , <i>Cocos nucifera</i> , <i>Hevea</i> spp., <i>Mangifera indica</i> , <i>Persea americana</i> , <i>Psidium guajava</i> , <i>Theobroma cacao</i>	(Stamps 1978, Chang and Shu 1988, Zhang et al. 1995, Zeng et al. 2009, Farr and Rossman 2010)
<i>Phytophthora megakarya</i> Brasier & Griffin	Africa	<i>Irvingia</i> spp., <i>Theobroma cacao</i>	(Stamps 1984, Guest 2007, Paulin et al. 2008, Farr and Rossman 2010)
<i>Seiridium cardinale</i> (W. Wagener) B. Sutton & I. Gibson	Europe, New Zealand, South Africa, South America, United States	<i>Chamaecyparis</i> spp., <i>Protea</i> spp.	(Sinclair and Lyon 2005, Farr and Rossman 2010)
<i>Seiridium unicorne</i> (Cooke & Ellis) B. Sutton [Teleomorph:	Africa, India, Japan, United States	<i>Chamaecyparis</i> spp., <i>Ixora</i> spp.	(Sinclair and Lyon 2005, Farr and Rossman 2010)

<i>Lepteutypa cupressi</i> (Natrass, C. Booth & B. Sutton) H.J. Swart]			
BACTERIA and PHYTOPLASMAS			
Bacteria and phytoplasmas are microscopic organisms that may infect plants, causing leaf spots, blights, cankers, soft rots, reduced crop yield, and plant death (Agrios 2005). Bacterial plant diseases are often severe in tropical climates. As infected plants may be asymptomatic for a long time, it is often impossible to detect the presence of bacteria or phytoplasmas by visual inspection. Bacteria and phytoplasmas are most likely to be spread to new areas on infected plant material and in soil contaminations.			
<i>Acidovorax avenae</i> subsp. <i>citrulli</i> (Schaad et al.) Willems et al.	Australia, Indonesia, United States	<i>Citrullus lanatus</i> , <i>Cucumis melo</i>	(Saddler 1994, Hopkins et al. 2000)
<i>Erwinia papayae</i> Gardan et al.	Caribbean, Malaysia	<i>Carica papaya</i>	(Gardan et al. 2004, Maktar et al. 2008)
<i>Ralstonia solanacearum</i> race 1 (Smith) Yabuuchi et al.	Africa, Australia, Europe, Canada, Caribbean, Central and South America, FSM, Guam, Hawai'i, Mexico, New Zealand, Southeast Asia, United States	<i>Nicotiana</i> spp., <i>Solanum</i> spp.	(CABI/EPPO 1997h, Cerkauskas 2004, Elphinstone 2005, Hacisalihoglu et al. 2007, Vanitha et al. 2009)
<i>Ralstonia solanacearum</i> race 2, biovar 1 (Smith) Yabuuchi et al.	Africa, Asia, Caribbean, Central America, Guam, Mexico, South America, United States	<i>Heliconia</i> spp., <i>Musa</i> spp.	(CABI/EPPO 1997h, Eyres et al. 2005)
<i>Xanthomonas campestris</i> (Pammel)	Africa, Asia, Canada, Caribbean, Central and South America, Europe, Hawai'i,	<i>Persea americana</i>	(Hayward and Waterston 1965, CAB 1978, Pegg et al. 2002)

	Mexico, United States		
<i>Xanthomonas campestris</i> pv. <i>celebensis</i> (Gäumann)	India, Indonesia	<i>Heliconia</i> spp., <i>Musa</i> spp.	(Bradbury 1986, Eden-Green 1994, Supriadi 2003, Mackie et al. 2007)
<i>Xanthomonas campestris</i> pv. <i>mangiferaeindicae</i> (Patel et al.)	Australia, Brazil, India, Japan, Kenya, New Caledonia, Pakistan, Réunion, South Africa, Southeast Asia, Sudan, Taiwan, United Arab Emirates	<i>Anacardium occidentale</i> , <i>Mangifera indica</i> , <i>Schinus terebinthifolius</i> , <i>Spondias dulcis</i>	(Bradbury 1986, Gagnevin and Pruvost 2001)
<i>Xanthomonas campestris</i> pv. <i>manihotis</i> (Berthet & Bondar)	Africa, Cuba, India, Panama, Southeast Asia, South America	<i>Manihot esculenta</i>	(Bradbury 1986, Lozano 1986)
' <i>Candidatus Liberibacter asiaticus</i> '	China, Indonesia, Belize, Cuba, Iran, Solomon Islands, South America, United States	<i>Citrus</i> spp.	(Da Graca 1991, Gottwald et al. 2007)
Palm lethal yellowing (proposed name: ' <i>Candidatus Phytoplasma palmae</i> ')	Belize, Benin, Cameroon, Caribbean, Ghana, Guyana, Honduras, Mexico, Nigeria, Togo, United States	Arecaceae	(CABI/EPPO 1997g, Harrison and Elliott 2009)
Sweet potato little leaf	Australia, Japan, New Caledonia, Korea, New Guinea, Niue,	<i>Cucurbita maxima</i> , <i>Ipomoea batatas</i> , <i>Solanum lycopersicum</i> ,	(Jackson et al. 1984, Saqib et al. 2006)

	Palau, Solomon Island, Taiwan, Tonga, Vanuatu	<i>Vigna unguiculata</i>	
VIRUSES and VIROIDS			
Viral diseases of plants are second only to fungal infections in terms of economic significance worldwide (Hadidi et al. 1998). Viruses and viroids are often vectored by insects such as aphids, whiteflies, and thrips, but can also be vectored by nematodes and fungi. Virus and viroid infections in plants lead to discoloration, deformation, stunting, reduced vigor, crop losses, and plant death (Hull 2002). If plants become infected with a virus or viroid, the destruction of infected plants is often the only way to control the outbreak (Agrios 2005). The most likely pathway of introduction is infested plant material or the introduction of vector organisms.			
Avocado sunblotch viroid (ASBV)	Australia, Argentina, Ghana, Israel, Mexico, Peru, South Africa, Spain, United States, Venezuela	<i>Persea americana</i>	(Dale et al. 1982, Ploetz et al. 1994, Darvas et al. 1996, Flores et al. 2000, Pegg et al. 2002, Acheampong et al. 2008, De La Torre et al. 2009)
Banana bract mosaic virus (BBrMV)	Central and South America, India, Philippines, Samoa, Sri Lanka, Vietnam	<i>Musa</i> spp.	(Magnaye and Valmayor 1995, Brunt et al. 1996, Thomas and Magnaye 1996, Rodoni et al. 1997)
Banana bunchy top virus (BBTV)	Guam, Hawai'i, southeast Asia, Philippines, Taiwan, numerous islands in the south Pacific, India, and Africa	<i>Musa</i> spp.	(Ferreira et al. 1997; Per. Comm. Englberger)
Bean pod mottle virus (BPMV)	Canada, United States	<i>Desmodium paniculatum</i> , <i>Glycine max</i> , <i>Phaseolus vulgaris</i>	(Brunt et al. 1996, Glesler et al. 2002, Zhang et al. 2009)
Cadang-cadang viroid (CCCVd)	Philippines, Solomon Islands	<i>Cocos nucifera</i> , <i>Corypha elata</i> , <i>Elaeis guineensis</i>	(CABI/EPPO 1997c, Randles 2003, Agrios 2005)

<i>Cassava green mottle virus</i> (CGMV)	Solomon Islands	<i>Manihot esculenta</i>	(Lennon et al. 1987, Frison and Feliu 1991, Brunt et al. 1996)
<i>Cocoa swollen shoot virus</i> (CSSV)	Côte d'Ivoire, Ghana, Nigeria, Sierra Leone, Sri Lanka, Togo	<i>Adansonia digitata</i> , <i>Ceiba pentandra</i> , <i>Cola chlamydantha</i> , <i>Cola gigantea</i> , <i>Sterculia tragacantha</i> , <i>Theobroma cacao</i>	(Brunt 1970, Brunt et al. 1996, ICTVdB Management 2006)
<i>Colocasia bobone disease virus</i> (CBDV)	New Guinea, Solomon Islands	<i>Colocasia esculenta</i>	(Jackson 1978, Zettler et al. 1989, Onwueme 1999, Yang et al. 2003)
<i>Papaya droopy necrosis virus</i> (PDNV)	United States	<i>Carica papaya</i>	(Ploetz et al. 1994, Aires Ventura et al. 2004)
<i>Papaya mosaic virus</i> (PapMV)	South America, United States, and India	<i>Carica papaya</i>	(Pers. Comm. Englberger)
<i>Papaya yellow crinkle virus</i> (PYCV)	Australia	<i>Carica papaya</i>	(Gibb et al. 1996)
<i>Pepino mosaic virus</i> (PepMV)	Canada, Chile, Europe, Peru, United States	<i>Solanum muricatum</i> , <i>Solanum lycopersicum</i>	(Fakhro et al. 2005, EPPO 2006b, Córdoba-Sellés et al. 2007)
<i>Pepper mild mottle virus</i> (PMMoV)	Argentina, Australia, Europe, Japan, United States	<i>Capsicum</i> spp.	(Brunt et al. 1996, Lamb et al. 2001, Zhang et al. 2006a)
<i>Pepper yellow leaf curl virus</i> (PepYLCIV)	Indonesia	<i>Ageratum conyzoides</i> , <i>Capsicum</i> spp., <i>Glycine max</i> , <i>Helianthus annuus</i> , <i>Nicotiana</i> spp., <i>Solanum</i>	(De Barro et al. 2008, Hidayat et al. 2009)

		spp., <i>Vigna</i> spp.	
<i>Tomato spotted wilt virus</i> (TSWV)	Africa, Asia, Australia, Canada, Central and South America, Europe, Mexico, New Zealand, United States	<i>Ananas comosus</i> , <i>Arachis hypogaea</i> , <i>Bidens pilosa</i> , <i>Capsicum annuum</i> , <i>Datura stramonium</i> , <i>Helianthus annuus</i> , <i>Lactuca sativa</i> , <i>Phaseolus vulgaris</i> , <i>Solanum</i> spp., <i>Zinnia elegans</i>	(Zitter et al. 1989, Brunt et al. 1996)
<i>Tomato yellow leaf curl virus</i> (TYLCV)	Africa, Caribbean, Hawai'i, Middle East, United States	<i>Capsicum annuum</i> , <i>Solanum lycopersicum</i> , <i>Solanum melongena</i>	(Navot et al. 1991, Moriones and Navas-Castillo 2000, Melzer et al. 2010)

WEEDS

Agricultural losses due to weeds surpass those caused by any other class of agricultural pest (Pimentel et al. 2001). Weeds may also have enormous ecological impacts by reducing biodiversity, altering fire regimes and hydrological cycles, changing soil chemistry and biology, and promoting siltation or erosion of stream banks and sand dunes. Weeds may also affect human and animal health when they are toxic or cause allergies. Intentional importation of plants for horticultural purposes has been identified as the most important facilitator in the spread of weeds (invasive plants) (Dehnen-Schmutz et al. 2007).

<i>Antigonon leptopus</i>	American Samoa, Fiji, French Polynesia, Guam, Kiribati, RMI, Nauru, CNMI, Palau, Samoa, United States		http://www.issg.org/database/species/distribution.asp?si=203&fr=1&sts=&lang=EN
<i>Bryophyllum daigremontianum</i> (Raym.-Hamet & Perrier) (Crassulaceae)	Australia, Bangladesh, Fiji, Galápagos Islands, Madagascar, New Caledonia, New Zealand,		(McKenzie and Armstrong 1986, Hannan-Jones et al. 2005, Foxcroft et al. 2008, Nahar et al. 2008, USDA NRCS 2009, PIER 2010)

	States		
--	--------	--	--

1 **A8 SPECIES ACCOUNTS**

2 **A8.1 Amphibians**

3 **A8.1.1 *Bufo gargarizans***

4 **Common names:** Asiatic toad, common giant toad

5 **Synonymous scientific names:** *Bufo asiaticus*, *Bufo bufo gargarizans*, *Bufo bufo miyakonis*

6 **Adult description:** 56 to 102 mm (2 to 4 in) in length; females larger; spines on the large dorsal
7 tubercles; dark gray to olive to brown dorsal color; three light longitudinal bands; black band extends
8 from parotid to the flank, turning into spots posteriorly; grayish or yellowish venter

9 **Tadpole description:** no information found in the literature

10 **Reproduction:** reproduces in lakes, ponds, swamps, puddles, riverbeds, ditches, and stagnant to slow-
11 flowing water; lays paired strings of 1,200 to 7,400 eggs; metamorphose in summer; sexually mature in
12 3 to 4 years

13 **Habitat:** vegetative cover, in rock crevices, tree hollows, cultivated areas; common in human-inhabited
14 areas; limited by high temperatures and low humidity

15 **Human health impacts:** secrete toxins that can cause severe illness or death if ingested

16 **Economic impacts:** none found in the literature, but undocumented impacts may exist

17 **Ecological impacts:** predation on native fauna

18 **Pathways:** biocontrol; intentional, for education

19 **Control measures:** no information found in the literature

20 **References:** Brubacher et al. 1999; Lever 2003; Liu et al. 2005; Kraus 2009; AmphibiaWeb 2010; Yu et al.
21 2010

22 **A8.1.2 *Bufo melanostictus***

23 **Common names:** Asian black-spotted toad, Asian common toad, Asian eyebrow-ridge toad, black-lipped
24 toad, black-spined toad, common Indian toad, Indian toad, keeled-nosed toad, South Asian garden toad,
25 southeast Asian common toad, spectacled toad

26 **Synonymous scientific names:** *Ansonia kramlei*, *Bufo scaber*, *Bufo tienhoensis*, *Duttaphrynus*
27 *melanostictus*, *Rana dubia*

28 **Adult description:** females more than 150 mm (6 in) in length; several distinct cranial crests; distinct
29 tympanum; double tubercles under third finger only; elliptical parotid; dark spines on tubercles of

1 flanks; 8 to 9 large tubercles along sides of dorsum; gray dorsum with brown to reddish spots; speckled,
2 whitish ventrum; males have an orange or yellow throat during the breeding season

3 **Tadpole description:** 26 to 27 mm (1 in) in length; dark coloration; bufonid body; broad dorsal fin but
4 narrow ventral fin; finely serrated beak; inhabit side pools or puddles; metamorphosis in approximately
5 25 days

6 **Reproduction:** breeds during the rainy season or throughout the year, depending on location; breeds in
7 any available water; males call from shallow pools; male-male competition; lays paired strings of eggs;
8 metamorphosis occurs in about 25 days

9 **Habitat:** Habitat generalist; ponds, paddy fields, low hills, mountains, coastal plains; under stones, logs,
10 dense vegetation, crevices

11 **Human health impacts:** secrete toxins that can cause severe illness or death if ingested; may be a host
12 for the causative agent of human angiostrongyliasis

13 **Economic impacts:** none found in the literature, but undocumented impacts may exist

14 **Ecological impacts:** consumes agricultural pests

15 **Pathways:** boat, cargo

16 **Control measures:** no information found in the literature

17 **References:** Jorgensen et al. 1986; Ding 1988; Saidapur and Girish 2001; Lever 2003; Keomany et al.
18 2007; Kraus 2009; AmphibiaWeb 2010; Frost 2010

19 **A8.1.3 *Eleutherodactylus coqui*:** established in Hawai'i, individuals have been detected and removed
20 from Guam on multiple occasions.

21 **Common names:** coqui frog, Puerto Rican coqui

22 **Synonymous scientific names:** *Eleutherodactylus martinicensis*, *Eleutherodactylus portoricensis*

23 **Adult description:** males approximately 34 mm (1.3 in) snout to vent length; females approximately 41
24 mm (1.6 in) snout to vent length; well-developed pads at the end of the toes; variable coloration with
25 the upper body usually being a grey or grey-brown uniform color; may also have an "M" shape between
26 the shoulders; two broad, light-colored bars running from the snout through the eye to the axilla of the
27 rear legs that is bordered with black spots; a light bar on top of the head between the eyes; underside is
28 usually light-colored and stippled with brown

29 **Reproduction:** breeds year-round; internal fertilization; lays 1 to 2 dozen eggs; do not need water, may
30 construct nests on the ground or use cavities of birds; males care for the clutches; direct development

1 **Habitat:** Habitat generalist; agricultural areas, natural and planted forests, riparian zones, wetlands,
2 urban areas

3 **Human health impacts:** none found in the literature, but undocumented impacts may exist

4 **Economic impacts:** lowering of property values and tourism due to the high noise level associated with
5 calls

6 **Ecological impacts:** increased nutrient cycling, predation on invertebrates causing declines, prey source
7 to potentially support invasive snake populations

8 **Pathways:** cargo, intentional, nursery trade

9 **Control measures:** bans on importation, hand capture, caffeine, citric acid, cargo restrictions and
10 inspections, citric acid spray for imported plants, public education

11 **References:** Bartlett and Bartlett 1999; Campbell and Kraus 2002; Campbell et al. 2002; Kraus and
12 Campbell III 2002; Beard et al. 2003b; Kaiser and Burnett 2006; Christy et al. 2007a; Christy et al. 2007c;
13 Tuttle et al. 2008; Kraus 2009; AmphibiaWeb 2010; ISSG 2010

14 **A8.1.4 *Eleutherodactylus planirostris*:** established on Guam and in Hawai'i

15 **Common names:** greenhouse frog

16 **Synonymous scientific names:** *Eleutherodactylus ricordii*, *Euhyas planirostris*, *Lithodytes ricordii*

17 **Adult description:** males about 19 mm (0.7 in) in length; females may be greater than 25 mm (1 in) in
18 length; rust, orange, or brown skin, dark, with warts and a whitish or gray venter; either mottled
19 markings or light longitudinal stripes; possible dark triangle between the eyes; enlarged finger pads;
20 elongate toe pads which point toward the tips of the toes

21 **Reproduction:** breeds from late spring to early autumn in Florida; males call from the ground or plants
22 and herbs; reproduces in debris or damp holes; lays 1 to 2 dozen eggs; direct development

23 **Habitat:** Habitat generalist; ubiquitous, diverse habitats; woodlands, scrub, yards, gardens, greenhouses
24 and nurseries; beneath boards or natural objects, in crevices

25 **Human health impacts:** none found in the literature, but undocumented impacts may exist

26 **Economic impacts:** none found in the literature, but undocumented impacts may exist

27 **Ecological impacts:** prey source to potentially support invasive snake populations

28 **Pathways:** cargo, nursery trade

29 **Control measures:** caffeine, hydrated lime (no longer allowed), public education

- 1 **References:** Stevenson 1976; Bartlett and Bartlett 1999; Campbell and Kraus 2002; Kraus and Campbell
2 III 2002; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009; ISSG 2010
- 3 **A8.1.5 *Fejervarya cancrivora*:** established on Guam
- 4 **Common names:** Asian brackish frog, crab-eating frog, mangrove frog, rice field frog
- 5 **Synonymous scientific names:** *Limnonectes cancrivora*, *Rana cancrivora*
- 6 **Adult description:** information not found
- 7 **Reproduction:** reproduces in any available water
- 8 **Habitat:** Habitat generalist; mangrove forests, estuarine habitats, swamps, wet coastal areas; swales;
9 human-inhabited areas, including rice fields, gardens, and urban areas; can tolerate some salinity
- 10 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 11 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 12 **Ecological impacts:** prey source to potentially support invasive snake populations
- 13 **Pathways:** aquaculture contaminant, food
- 14 **Control measures:** no information found in the literature
- 15 **References:** Zhigang et al. 2004; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009
- 16 **A8.1.6 *Fejervarya limnocharis***
- 17 **Common names:** alpine cricket frog, field frog, rice frog
- 18 **Synonymous scientific names:** *Limnonectes limnocharis*, *Rana limnocharis*
- 19 **Adult description:** 39 to 43 mm (1.5 to 1.7 in) in length; pointed snout projects beyond the mouth;
20 obtuse canthus; width of upper eyelid is wider than the internarial distance, which is longer than the
21 interorbital width; distinct tympanum; fingers pointed, toes with obtuse or swollen tips and slightly
22 webbed; males with mottled brown, loose upper throat and w-shaped marking; gray brown or olive
23 skin; dark “v” between the eyes; yellow stripe down the dorsal midline; white venter
- 24 **Tadpole description:** 26 to 27 mm (1 in) in length; long, oval body; convex venter; tail about twice the
25 body length and pointed; dorsal fin broader in the middle, while ventral fin follows the line of the tail;
26 dark tip on tail
- 27 **Reproduction:** breeds during the rainy season; males call from edges of flowing water; lays batches of
28 eggs adhered to grass

1 **Habitat:** habitat generalist; wetlands, plains, alpine; dense vegetation bordering canals, streams,
2 torrents, ponds, puddles, and rice fields; can tolerate some salinity

3 **Human health impacts:** none found in the literature, but undocumented impacts may exist

4 **Economic impacts:** none found in the literature, but undocumented impacts may exist

5 **Ecological impacts:** prey source to potentially support invasive snake populations

6 **Pathways:** aquaculture contaminant, biocontrol, research, pet trade

7 **Control measures:** no information found in the literature

8 **References:** Hutchins et al. 2003a; van Dijk et al. 2004a; Lee et al. 2006; Christy et al. 2007a; Christy et
9 al. 2007c; Kraus 2009; Wu and Kam 2009; AmphibiaWeb 2010

10 **A8.1.7 *Hyla cinerea***

11 **Common names:** American green tree frog, Carolina tree frog, green tree frog, marsh tree frog

12 **Synonymous scientific names:** *Calamita cinereus*, *Calamita lateralis*, *Hyla blochii*, *Hyla carolinensis*, *Hyla*
13 *lateralis*, *Hyla semifasciata*, *Rana bilineata*, *Rana lateralis*

14 **Adult description:** 44.5 to 63.5 mm (1.8 to 2.5 in) in length; females larger; slender body; legs one and a
15 half times the head and body length; pointed head, flat between the eyes; large eyes extend laterally;
16 skin fold over the bronze-colored tympanum to the shoulder; slight webbing of toes; large disks on
17 fingers and toes; bold yellow green to gray green on the dorsum with a white or yellow line along the
18 sides of the head and body; similar colored bands on the posterior of the arm and anterior and posterior
19 of the legs; lower jaw dark; whitish venter; pale yellow throat; can change color from light to dark

20 **Tadpole description:** 4.5 to 5.5 mm (0.2 in) in length at hatching; 60 mm (2.4 in) in length at
21 metamorphosis; color changes throughout development; blotches eventually form the lateral bands; in
22 later stages body is green, venter is yellow to buff, and the long tail is mottled yellow; arched dorsal fin;
23 bulging eyes

24 **Reproduction:** reproduces in floating or emergent vegetation; lays eggs in clutches of 478 to 3,946 eggs;
25 metamorphose in 24 to 45 days

26 **Habitat:** habitat generalist; coastal lowlands, ponds, lakes, swamps, marshes, sloughs, dry streambeds,
27 cultivated areas; water margins; perches on broad leaves

28 **Human health impacts:** none found in the literature, but undocumented impacts may exist

29 **Economic impacts:** none found in the literature, but undocumented impacts may exist

30 **Ecological impacts:** vector of a disease of weedy plants

1 **Pathways:** aquaculture contamination, cargo, nursery trade, pet trade

2 **Control measures:** no information found in the literature

3 **References:** Dickerson 1969; Garton and Brandon 1975; Stevenson 1976; Layne Jr. et al. 1989; Wygoda
4 and Williams 1991; Wygoda and Garman 1993; Lever 2003; Gunzburger 2006; Kraus 2009;
5 AmphibiaWeb 2010; Frost 2010

6 **A8.1.8 *Kaloula picta***

7 **Common names:** painted narrow-mouth toad, slender-digit chorus frog

8 **Synonymous scientific names:** *Callula picta*, *Plectropus pictus*

9 **Adult description:** males 32.8 to 51.2 mm (1.3 to 2 in) in length, with an average of 39.6 mm (1.6 in);
10 females 34.7 to 56.1 mm (1.4 to 2.2 in) in length, with an average of 42.2 mm (1.7 in); females larger on
11 average; dorsal tubercles present; prominent, pointed outer metatarsal tubercle; lateral glandular ridge;
12 glandular venter; stratified coloration on flank and posterior thigh; may have spots on the lower back

13 **Reproduction:** breeds May through February, beginning with the rainy season, and peaks July through
14 October; males call from the water; reproduces in ephemeral pools; lays 812 to 4,029 eggs; one clutch
15 per female per year; eggs hatch within 13 to 15 hours; 3.1-3.3 mm (0.1 in) in length at hatching;
16 metamorphose in 18 days

17 **Habitat:** forests, shrublands, grasslands, wetlands, tropics; most common in human-inhabited areas,
18 including agricultural lands, ditches, artificial ponds, gardens, and urban areas; burrows or hides in logs,
19 dropped coconuts, or stones

20 **Human health impacts:** none found in the literature, but undocumented impacts may exist

21 **Economic impacts:** none found in the literature, but undocumented impacts may exist

22 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

23 **Pathways:** boat, cargo

24 **Control measures:** no information found in the literature

25 **References:** Cendaña and Fermin 1940; Diesmos et al. 2002; Diesmos et al. 2004a; Christy et al. 2007a;
26 Christy et al. 2007c; Kraus 2009; Frost 2010

27 **A8.1.9 *Kaloula pulchra***

28 **Common names:** Asian painted frog, banded bullfrog, beautiful kaloula, Malayan narrow-mouthed frog,
29 Malaysian narrow-mouth toad, Malaysian painted frog, ox frog, painted balloon frog, painted bullfrog,
30 painted burrowing frog, painted microhylid frog, piebald digging frog

1 **Synonymous scientific names:** *Callula macrodactyla*, *Callula pulchra*, *Kaloula aureata*, *Kaloula*
2 *macrocephala*

3 **Adult description:** 54 to 75 mm (2.1 to 3 in) in length; females larger; robust body with short, thick hind
4 legs; rounded snout; two spades on feet for digging; lacks a cervical vertebrae; generally smooth skin;
5 dark grey, light brown or pinkish skin with a large brown spot over much of the back; two large, irregular
6 light-colored bands running from the eye to the groin; snout tan; whitish to yellow brown venter with
7 brown spots; males have a black throat; inflates body when threatened

8 **Reproduction:** breeds during the rainy season or year-round, depending on climate; males call while
9 floating in the water; reproduces in small pools or ponds; rapid larval growth

10 **Habitat:** habitat generalist; wetlands, riverbanks, dry forests; burrow or hide in vegetation; human-
11 inhabited areas, including agricultural, residential, and urban areas; commensal, no longer found in
12 undisturbed habitats

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** possible predation on native fauna, due to its generalist habits; potential carrier of
16 chytridiomycosis; possible competition with native anurans

17 **Pathways:** aircraft, boat, cargo, intentional, pet trade

18 **Control measures:** no information found in the literature

19 **References:** Heyer 1973; Hutchins et al. 2003a; Kuangyang et al. 2004b; Hou et al. 2006; Christy et al.
20 2007a; Christy et al. 2007c; Tyler and Chapman 2007; Page et al. 2008; Kraus 2009; AmphibiaWeb 2010;
21 Frost 2010

22 **A8.1.10 *Limnodynastes tasmaniensis***

23 **Common names:** marbled frog, spotted grass frog, spotted marsh frog

24 **Synonymous scientific names:** *Limnodynastes peronii* var. *tasmaniensis*, *Limnodynastes tasmanicus*

25 **Adult description:** maximum 48 mm (1.9 in) in length; generally Rana-like appearance; green to olive-
26 gray back with dark blotches; white venter; dark line from snout to arm; dark spots anteroventral to the
27 eye; light ridge from the upper jaw to the top of the foreleg; usually a white stripe along the midline of
28 the dorsum; smooth to slightly rough skin; very little webbing on toes

29 **Tadpole description:** dark dorsum with gold spots on the ventrum of the tail

1 **Reproduction:** breeds year-round, with peaks August through March; males call from vegetation on
2 edges of shallow water; aquatic; reproduces in grassy ditches, small pools, grassy marshes, and shallow
3 ponds; lays foam nests of 90 to 1,350 eggs adhering to vegetation; metamorphose in 3 to 5 months or
4 less; sexually mature at 80 to 100 days after metamorphosis

5 **Habitat:** habitat generalist; streams, lakesides, marshes, shrublands; under logs, stones, or debris

6 **Human health impacts:** none found in the literature, but undocumented impacts may exist

7 **Economic impacts:** none found in the literature, but undocumented impacts may exist

8 **Ecological impacts:** known to carry chytridiomycosis, a possible threat to native anurans

9 **Pathways:** cargo

10 **Control measures:** no information found in the literature

11 **References:** Moore 1961; Hutchins et al. 2003a; Hero et al. 2004b; Kraus 2009; AmphibiaWeb 2010;
12 Frost 2010

13 **A8.1.11 *Litoria aurea***

14 **Common names:** golden bell frog, golden frog, golden tree frog, green frog, green and golden bell frog,
15 green and golden swamp frog

16 **Synonymous scientific names:** *Auletris jacksoniensis*, *Hyla aurea*, *Hyla jacksoniensis*, *Hyla jacksonii*, *Rana*
17 *aurea*, *Ranoidea aurea*, *Ranoidea jacksoniensis*, *Ranoidea resplendens*, *Ranoidea ulongae*

18 **Adult description:** about 55 to 108 mm (2 to 4.3 in) in length; females larger; glandular stripe from the
19 mouth to the base of the forearm; fleshy webbing on toes and disks on fingers and toes; cream or yellow
20 fold extending from the eye almost to the groin; fold on chest; sides and abdomen have a rough texture;
21 prominent, gold tympanum; smooth, bright green dorsum with brown blotches; white venter; males
22 have a yellowish throat

23 **Tadpole description:** large at metamorphosis; high tail fin; heavily pigmented

24 **Reproduction:** breed in mid-spring to summer, peaking October-March; males call from water; lays a
25 mat of 2,400 to 11,600 eggs; hatch in 2 to 3 days; metamorphose in about 2, but up to 11, months

26 **Habitat:** habitat generalist; ponds, lakes, streams, grassy marshes, swamps, low-lying grasslands, forest
27 clearings, agricultural lands; prefers isolated, still, shallow, and pristine waters; perches in emergent
28 vegetation

29 **Human health impacts:** carries the pathogen which causes eosinophilic meningitis (EM) in humans

30 **Economic impacts:** none found in the literature, but undocumented impacts may exist

1 **Ecological impacts:** predation on native skinks and other vertebrates; known to carry chytridiomycosis, a
2 possible threat to native anurans

3 **Pathways:** biocontrol, cargo, intentional, pet trade, possibly as food for ducks

4 **Control measures:** no information found in the literature

5 **References:** Moore 1961; Pyke and White 1996, 2001; Lever 2003; Hero et al. 2004d; Vörös et al. 2008;
6 Kraus 2009; AmphibiaWeb 2010; Frost 2010; ISSG 2010

7 **A8.1.12 *Litoria caerulea***

8 **Common names:** Australian green tree frog, Australian tree frog, blue frog, great green tree frog, green
9 tree frog, smiling frog, White's tree frog

10 **Synonymous scientific names:** *Calamita cyanea*, *Calamites coreulea*, *Hyla caerulea*, *Hyla coerulea*, *Hyla*
11 *cyaneus*, *Litoria irrorata*, *Pelodyras caeruleus*, *Pelodyras irrorata*, *Rana austrasiae*, *Rana caerulea*, *Rana*
12 *coerulea*

13 **Adult description:** about 72.4 to 97.7 mm (2.8 to 3.8 in) in length; dorsum solid, leaf green to greenish
14 brown; white venter with greenish throat; anterior and posterior of the thigh is tan or yellow-green;
15 occasionally white spots on the dorsum; large glandular ridge of skin between the eye and shoulder;
16 prominent tympanum; fingers slightly webbed, toes heavily webbed

17 **Reproduction:** breeds October to January in Australia; males call from hiding spots near water;
18 reproduces in ponds; lays clusters of 100 to 200 eggs, with 2,000 to 3,000 eggs total; metamorphose in 6
19 weeks

20 **Habitat:** habitat generalist; deserts, woodlands, grasslands, shrublands, rain forests; often in human-
21 inhabited areas, near buildings or objects holding water; perches on or hides in various objects; does not
22 need a water body, can withstand severe droughts

23 **Human health impacts:** none found in the literature, but undocumented impacts may exist

24 **Economic impacts:** none found in the literature, but undocumented impacts may exist

25 **Ecological impacts:** known to carry chytridiomycosis, a possible threat to native anurans

26 **Pathways:** biocontrol, cargo, intentional, pet trade

27 **Control measures:** no information found in the literature

28 **References:** Moore 1961; Main and Bentley 1964; Buttemer 1990; Christian and Parry 1997; Bartlett and
29 Bartlett 1999; Lever 2003; Hero et al. 2004e; Berger et al. 2005; Kraus 2009; AmphibiaWeb 2010; Frost
30 2010

1 **A8.1.13 *Litoria chloris***

2 **Common names:** Australian red-eyed tree frog, north coast green tree frog, red-eyed green tree frog,
3 red-eyed tree frog, southern orange-eyed tree frog

4 **Synonymous scientific names:** *Dryomantis chloris*, *Hyla chloris*

5 **Adult description:** about 52.7 to 65 mm (2 to 2.6 in) in length; distinct tympanum with a ridge from the
6 eye across the dorsal side of the membrane; rounded canthus; webbed fingers and toes with large disks;
7 leaf green dorsum; white to bright yellow venter; purplish or brown posterior of thigh; inner portion of
8 hands is yellow, whereas the outer portion is green; red eyes

9 **Tadpole description:** medium sized; coloration is light grey to dark brown; may have gold along the
10 sides

11 **Reproduction:** breeds during heavy rains in spring and summer, October to February; males call from
12 the ground or shallow pools beside streams; reproduces in flooded spots, mountain streams, and
13 grasslands; lays single egg or clumps of eggs within vegetation; each female lays over 1,000 eggs per
14 year; sexually mature in 2 to 3 years

15 **Habitat:** coastal rain forests, wet sclerophyll forests, and human-inhabited areas, especially in objects
16 holding water; perches high in trees

17 **Human health impacts:** none found in the literature, but undocumented impacts may exist

18 **Economic impacts:** none found in the literature, but undocumented impacts may exist

19 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

20 **Pathways:** cargo, intentional

21 **Control measures:** no information found in the literature

22 **References:** Moore 1961; Hero et al. 2004c; Morrison et al. 2004a; FAN 2006; Kraus 2009; AmphibiaWeb

24 **A8.1.14 *Litoria ewingii***

25 **Common names:** Australian brown tree frog, brown tree frog, Ewing's tree frog, southern brown tree
26 frog, whistling tree frog

27 **Synonymous scientific names:** *Hyla ewingi*, *Hyla inguinalis*, *Rawlinsonia calliscelis*, *Rawlinsonia ewingi*,
28 *Rawlinsonia parvidens*

29 **Adult description:** 26 to 50 mm (1 to 2 in) in length; short legs and a broad head; toes with small disks
30 and very slight webbing; distinct tympanum; grey to dark brown, smooth dorsum; brown to black patch

- 1 on back extending from between the eyes to the cloaca, often with a light stripe down the midline;
2 white stripe extending from the snout, through the eye and tympanum, to the base of the forelegs;
3 whitish venter; ventral side of thighs bright orange
- 4 **Reproduction:** breeds year-round; males call from the ground or short emergent or floating vegetation;
5 reproduces in still water of various water bodies; lays clumps of eggs, with 500 to 700 eggs total,
6 attached to vegetation below the water surface; metamorphosis varies from 7 to 8 weeks to 6 to 7
7 months
- 8 **Habitat:** habitat generalist; moist environments; streams, lakesides, woods, shrublands, rain forests,
9 alpine lakes and meadows, and human-inhabited areas, including gardens, pasturelands, and urban
10 areas
- 11 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 12 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 13 **Ecological impacts:** known to carry chytridiomycosis, a possible threat to native anurans
- 14 **Pathways:** biocontrol, cargo, intentional, pet releases
- 15 **Control measures:** no information found in the literature
- 16 **References:** Moore 1961; Lever 2003; Hero et al. 2004a; Pauza and Driessen 2008; Kraus 2009;
17 AmphibiaWeb 2010; Frost 2010
- 18 **A8.1.15 *Litoria fallax*:** Established on Guam
- 19 **Common names:** dwarf tree frog, Eastern dwarf tree frog, Eastern sedgefrog
- 20 **Synonymous scientific names:** *Dryomantis fallax*, *Dryomantis glauerti*, *Hyla bicolor glauerti*, *Hyla*
21 *glauerti*, *Hylomantis fallax*, *Litoria glauerti*
- 22 **Adult description:** information not found
- 23 **Reproduction:** breeds during heavy rains of summer; lays clumps of eggs attached to vegetation below
24 the water surface
- 25 **Habitat:** vegetation on margins of swamps, streams, lagoons, ponds, and farm dams; dense populations
- 26 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 27 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 28 **Ecological impacts:** prey source to potentially support invasive snake populations

1 **Pathways:** aircraft, cargo, escape

2 **Control measures:** no information found in the literature

3 **References:** Lever 2003; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009; AmphibiaWeb 2010; Frost
4 2010

5 **A8.1.16 *Microhyla pulchra*:** Established on Guam

6 **Common names:** beautiful pygmy frog, Guangdong rice frog, marbled pygmy frog, painted chorus frog,
7 painted frog, yellow-legged narrow-mouthed frog, yellow-legged pigmy frog

8 **Synonymous scientific names:** *Diploelma pulchrum*, *Engystoma pulchrum*, *Microhyla hainanensis*,
9 *Microhyla major*, *Microhyla melli*, *Microhyla pulchrum*, *Ranina symmetrica*, *Scaptophryne labyrinthica*

10 **Adult description:** about 32 mm (1.3 in) in length; slender with a prominent snout; distance between
11 the upper eyelids does not exceed the interorbital space; lacks disks on digits but has some webbing on
12 toes; large subarticular tubercles; generally smooth, olive, grey, or pinkish brown dorsum; a thin, dark
13 bar between the eyes; dark band extending from the eye to the flank; nested v-shaped markings on the
14 back, with the arms of the v's often breaking up into spots; barred markings on legs; yellowish white
15 venter, with mottling on the throat and chest

16 **Reproduction:** breeds during the rainy season, April to October; reproduces in ephemeral pools, ponds,
17 and paddy fields; metamorphose in about 23 days

18 **Habitat:** habitat generalist; common in forest edges; ponds, mud, brackish marshes, grasslands, and
19 human-inhabited areas including gardens, fields and plantations

20 **Human health impacts:** none found in the literature, but undocumented impacts may exist

21 **Economic impacts:** none found in the literature, but undocumented impacts may exist

22 **Ecological impacts:** prey source to potentially support invasive snake populations

23 **Pathways:** aquaculture contaminant

24 **Control measures:** no information found in the literature

25 **References:** Boring 1934; van Dijk et al. 2004b; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009;
26 Frost 2010

27 **A8.1.17 *Osteopilus septentrionalis***

28 **Common names:** Cuban tree frog, giant tree frog

29 **Synonymous scientific names:** *Hyla dominicensis*, *Hyla septentrionalis*

1 **Adult description:** males 27 to 89 mm (1 to 3.5 in) , and some up to 100 mm (4 in) in length; females 52
2 to 165 mm (2 to 6.5 in) in length; usually warts on dorsum; rounded snout; prominent tympanum; pale
3 green, gray, light brown, or reddish brown to bronze skin; dark reticulations or elongate markings,
4 possibly with lighter cream or yellow markings on the flanks; venter whitish; gray throat common in
5 males; large finger disks with basal webbing; skin on top of head co-ossified with the skull, forming a
6 casque

7 **Tadpole description:** 32 mm (1.3 in) in length; large; ovoid body; small, anteroventral mouth; caudal fins
8 high with pointed tip; black body with grayish caudal musculature; black or brown spots on fins

9 **Reproduction:** breeds throughout the rainy season although males are reported to breed on only a
10 single day; population increases dramatically post-breeding; males call from elevated sites, such as in
11 bushes or trees; reproduce in ephemeral ponds, flooded areas, ditches, swimming pools, and fountains;
12 lays clusters of 25 to 75 eggs, up to more than 200 eggs total

13 **Habitat:** habitat generalist; low to moderate elevations; humid habitats; under objects or in plants;
14 human-inhabited areas, including urban areas, city parks, swimming pools, and gardens

15 **Human health impacts:** skin secretions may cause irritation to mucous membranes in humans; mating
16 calls may be annoying

17 **Economic impacts:** clogged drains; water contamination; cause of short circuits in transformers

18 **Ecological impacts:** predation of native frogs

19 **Pathways:** boat, cargo, intentional, nursery trade, pet trade, vehicle, on/in construction materials

20 **Control measures:** early detection, exclusion, hand capture with euthanasia, plant fumigation

21 **References:** Allen and Neill 1953; Stevenson 1976; Carmichael and Williams 1991; Bartlett and Bartlett
22 1999; Townsend et al. 2000; Savage 2002; Bomford et al. 2005; Owen 2005; Smith 2005; Platenberg and
23 Boulon Jr. 2006; Vargas Salinas 2006; Varnham 2006; Anguilla National Trust 2007; Campbell 2007;

25 **A8.1.18 Polypedates leucomystax**

26 **Common names:** Asian brown tree frog, banana frog, bamboo tree frog, common tree frog, four-lined
27 tree frog, golden foam-nest frog, golden tree frog, jar tree frog, Java whipping frog, Malayan house frog,
28 perching frog, striped tree frog, white-lipped tree frog

29 **Synonymous scientific names:** *Hyla leucomystax*, *Hyla quadrilineata*, *Hyla sexvirgata*, *Polypedates*
30 *rugosus*, *Polypedates teraiensis*, *Rhacophorus maculatus leucomystax*

- 1 **Adult description:** males 50 mm (2 in) in length; females 80 mm (3 in) in length; dorsum various shades
2 of brown; markings range from spots to longitudinal stripes; is able to change color, from light during
3 the day to darker at night
- 4 **Tadpole description:** about 6 to 14 mm (0.2 to 0.6 in) in length; lateral eyes
- 5 **Reproduction:** can breed year-round, depending on climate, but peaks during the rainy season; aquatic;
6 males call from water margins and/or perches in vegetation; reproduces in ephemeral pools; lays a foam
7 nest of 100 to 400 eggs, attached to vegetation; metamorphose in 28 to 33 days
- 8 **Habitat:** habitat generalist; wetlands, forests, edge habitats, beaches, and human-inhabited areas,
9 including agricultural lands, ditches, urban areas, garden ponds, and buildings; commensal
- 10 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 11 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 12 **Ecological impacts:** possible competition with endemic anuran species
- 13 **Pathways:** aircraft, boat, cargo
- 14 **Control measures:** no information found in the literature
- 15 **References:** Heyer 1973; Diesmos et al. 2004b; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009;
16 Kuraishi et al. 2009; AmphibiaWeb 2010; Frost 2010
- 17 **A8.1.19 *Polypedates megacephalus*:** Established on Guam
- 18 **Common names:** Hong Kong whipping frog, hour-glass-marked tree frog, spot-legged tree frog, white-
19 lipped tree frog
- 20 **Synonymous scientific names:** *Polypedates maculates* var. *unicolor*, *Rhacophorus leucomystax*
21 *megacephalus*
- 22 **Adult description:** 40 to 66 mm (1.6 to 2.6 in) in length; x-shaped markings or 4 longitudinal stripes
- 23 **Reproduction:** breeds March to September (in native range); reproduces in shallow, still water with
24 aquatic vegetation; lays foam nests of 300 to 400 eggs, in vegetation overhanging water
- 25 **Habitat:** habitat generalist; wetlands, ponds, marshes, tropical forests, grasslands, shrublands, bamboo
26 groves, and cultivated fields, orchards; dense vegetation;
- 27 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 28 **Economic impacts:** none found in the literature, but undocumented impacts may exist

- 1 **Ecological impacts:** prey source to potentially support invasive snake populations
- 2 **Pathways:** aquaculture contaminant
- 3 **Control measures:** no information found in the literature
- 4 **References:** Lazell et al. 1999; Lau et al. 2004; Lee et al. 2006; Christy et al. 2007a; Christy et al. 2007c;
5 Wu et al. 2007; Kraus 2009; Frost 2010
- 6 **A8.1.20 *Pseudacris regilla***
- 7 **Common names:** Cascade mountain tree frog, northern pacific tree frog, Oregon wood frog, Pacific
8 chorus frog, Pacific hyla, Pacific tree frog, Pacific tree-toad, western Oregon tree frog
- 9 **Synonymous scientific names:** *Hyla regilla*, *Hyla scapularis*, *Pseudacris pacifica*
- 10 **Adult description:** males 25.5 to 48 mm (1 to 1.9 in) in length; females 25 to 47 mm (1 to 1.9 in) in
11 length; toes with large disks and webbing; gray to green to brown dorsum; black stripe extending from
12 the snout, through the eye, to the shoulder; commonly a triangular mark on the head and dark spots
13 across the back and legs; bands or blotches on legs; able to change colors in different environments;
14 males have a wrinkled throat
- 15 **Tadpole description:** 45 to 55 mm (1.8 to 2.2 in) in length at metamorphosis; deep-bodied with a tail
16 twice the body length; black, yellowish brown, or dark brown coloration with black spots; whitish venter
17 with a bronze tint
- 18 **Reproduction:** breeds January to July; aquatic; males call from ponds; male-male competition;
19 reproduces in still or slow-moving waters, often with vegetation; lays clusters of 9 to 80 eggs, with 400
20 to 750 eggs total, often attached to submerged vegetation; each female may lay more than 3 clutches
21 per year; eggs hatch in 1 to 5 weeks; metamorphose in about 2 to 2.5 months; sexually mature in less
22 than 1 year to 2 years
- 23 **Habitat:** habitat generalist; springs, oases, rivers, ponds, marshes, sloughs, forests, grasslands, deserts,
24 and human-inhabited areas, including ditches, plant nurseries, livestock water tanks, and other
25 agricultural areas; most time spent on the ground under vegetation or other cover
- 26 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 27 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 28 **Ecological impacts:** known to carry chytridiomycosis, a possible threat to native anurans; may compete
29 with California tree frogs
- 30 **Pathways:** agricultural trade, cargo, intentional, nursery trade, pet trade

1 **Control measures:** no information found in the literature

2 **References:** Dickerson 1969; Fellers et al. 2001; Rorabaugh et al. 2004; Christy et al. 2007a; Christy et al.
3 2007c; Kraus 2009; AmphibiaWeb 2010; Frost 2010; Somma 2010b

4 **A8.1.21 *Rana catesbeiana***

5 **Common names:** American bullfrog, bullfrog

6 **Synonymous scientific names:** *Lithobates catesbeianus*, *Rana catesbeana*, *Rana catesbyana*

7 **Adult description:** the largest frog in North America; about 101.6 to 165.1 mm (4 to 6.5 in) in length,
8 with a record of 203.2 mm (8 in); skin is various shades of green to dark black; lighter venter; sides of
9 face and lips bright green; may have dark spots on forelimbs and/or bands on hind limbs; yellow throats
10 common in males, whereas females have white throats; has a ridge from the eye down to the top of the
11 foreleg; the longest toe extends beyond the webbing of the foot

12 **Tadpole description:** up to 76.2 mm (3 in) in length; stippled olive with lateral lines and a lighter venter

13 **Reproduction:** males call from sides of water on floating vegetation; male-male competition during the
14 breeding season; aquatic; reproduces in vegetation-choked shallows; lays rafts of up to 20,000 eggs;
15 hatch in 3 to 5 days; metamorphose in 2 months to 2 years, depending on climate

16 **Habitat:** habitat generalist; ponds, lakes, swamps, large ditches, wetlands, canals, slow rivers and
17 oxbows, rice fields, garden ponds; can withstand high salinity

18 **Human health impacts:** none found in the literature, but undocumented impacts may exist

19 **Economic impacts:** consumes agricultural pest insects; damage to aquaculture;

20 **Ecological impacts:** predation on native fauna, especially other herptiles; competition with native
21 anurans, in both larval and adult stages; possible disease transmission to native fauna

22 **Pathways:** aquaculture contaminant, biocontrol, farming/hunting for human consumption, intentional,
23 lab release, pet trade, natural dispersal

24 **Control measures:** Early detection; shooting; use of spears, bow and arrow, clubs, nets, traps; angling;
25 electrofishing; hand capture; fencing; collection of egg masses; draining ponds and excavating
26 sediments; public education; bans on importation

27 **References:** Bartlett and Bartlett 1999; Lever 2003; Kraus 2009; Santos-Barrera et al. 2009;
28 AmphibiaWeb 2010; ISSG 2010

29 **A8.1.22 *Rana guentheri*:** Established on Guam

30 **Common names:** Guenther's amoy frog, Guenther's frog, Guenther's red-and-black frog, barking frog

1 **Synonymous scientific names:** *Hylarana guentheri*, *Rana elegans*, *Sylvirana guentheri*

2 **Adult description:** males 65 to 74 mm (2.6 to 2.9 in) in length; females 61 to 74 mm (2.4 to 2.9 in) in
3 length; flat head with protruding snout; noticeable maxillary glands at the corners of the mouth; fold
4 extending from the tympanum to the shoulder; flattened dorsolateral folds extending from the eye to
5 the hip; robust limbs, with hind limbs up to 1.5 times the total body length; lacks disks on fingers and
6 toes; smooth skin, excepting the posterior; dark mustard to olive or red brown dorsum; yellowish brown
7 to brown dorsum; black marks along the longitudinal folds; lateral black spots; stripes on outside of legs
8 and dark spots on posterior of legs; white venter; metallic platinum to gold upper lip

9 **Tadpole description:** dorsolateral eyes; narrow mouth; relatively high tail fin; speckled grayish green
10 coloration; pointed, speckled brown tail

11 **Reproduction:** breeds May to June; reproduces in still water bodies; lays clutches of 2,000 to 3,000 eggs;
12 females lay once per year; metamorphose in 45 to 60 days

13 **Habitat:** habitat generalist; lowlands, shrublands, grasslands, riverbanks, ponds, marshes, pools, ditches,
14 and paddy fields; disturbed habitats; hides in aquatic vegetation

15 **Human health impacts:** carries the pathogen which causes eosinophilic meningitis (EM) in humans

16 **Economic impacts:** none found in the literature, but undocumented impacts may exist

17 **Ecological impacts:** prey source to potentially support invasive snake populations

18 **Pathways:** aquaculture contaminant

19 **Control measures:** no information found in the literature

20 **References:** Alicata 1991; Lazell et al. 1999; Kuangyang et al. 2004a; Christy et al. 2007a; Christy et al.
21 2007c; Lv et al. 2008; Kraus 2009; AmphibiaWeb 2010; Frost 2010

22 **A8.1.23 *Rana nigromaculata***

23 **Common names:** dark-spotted frog, black-spotted pond frog

24 **Synonymous scientific names:** *Pelophylax nigromaculatus*, *Pelophylax nigromaculata*, *Rana esculenta*

25 **Adult description:** vomerine teeth; posterior part of tongue free and forked; toes webbed; horizontal
26 pupil; dorsal coloration grey, grayish-olive, olive to green with large dark spots which are sometimes
27 absent; numerous longitudinal wrinkles between the dorso-lateral folds; light middorsal line and two
28 lines on dorso-lateral folds usually present; no temporal spot; belly white, sometimes with small amount
29 of dark spots on throat; males differ from females by having white vocal sacs behind the mouth angles
30 and nuptial pads on the first finger

- 1 **Tadpole description:** no information found in the literature
- 2 **Reproduction:** occurs soon after emerging from hibernation; axillary amplexus; 600 to 5,000
3 eggs/clutch; metamorphosis depends on latitude and altitude but occurs between May and August;
4 sexually mature at 2 years
- 5 **Habitat:** habitat generalist; meadows; deserts; forests; shrublands; grasslands; wetlands; pastures;
6 gardens; urban areas; artificial ponds; prefers stagnant water; hibernate in winter
- 7 **Human health impacts:** carrier of the *Spirometra* tapeworm that causes human sparganosis
- 8 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 9 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 10 **Pathways:** food, aquaculture, pet trade
- 11 **Control measures:** no information found in the literature
- 12 **References:** Kuzmin et al. 2004; Li et al. 2009; AmphibiaWeb 2010; Frost 2010
- 13 **A8.1.24 *Rana sylvatica***
- 14 **Common names:** wood frog
- 15 **Synonymous scientific names:** *Lithobates sylvaticus*, *Rana maslini*, *Rana pennsylvanica*, *Rana*
16 *temporaria*
- 17 **Adult description:** 37 to 83 mm (1.5 to 3.3 in) in length; females larger; large dorsolateral folds
18 extending from the eye to the cloaca, with the lateral edge darker than the medial edge; additional,
19 shorter folds along the back; webbed toes; gray to tan to bright reddish brown or golden dorsum; dark
20 marking possible on back and sides; some populations have a white line down the dorsal midline; wide,
21 dark marking from the snout to the tympanum; white, sometimes mottled, venter with a dark pectoral
22 mark
- 23 **Tadpole description:** 50 to 60 mm (2 to 2.4 in) in length at metamorphosis; larger individuals are
24 cannibalistic
- 25 **Reproduction:** breeds after first rains of late winter to early spring, varies from January to June by
26 latitude; aquatic; reproduces in ephemeral pools or ponds; eggs deposited communally; lays clutches of
27 500 to 1,500 eggs each; metamorphose in 65 to 130 days; males sexually mature at 1 to 2 years, females
28 at 2 to 3 years
- 29 **Habitat:** habitat generalist; forests, tundra, subalpine woodlands, willow stands, moist meadows,
30 swamps, and human-inhabited areas; can be far from water sources; terrestrial hibernator

- 1 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 2 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Ecological impacts:** may be a carrier for ranavirus and *Batrachochytrium dendrobatidis* that can infect
4 and kill other amphibians
- 5 **Pathways:** biocontrol, cargo, research
- 6 **Control measures:** no information found in the literature
- 7 **References:** Light 1991; Ouellet et al. 2005; Harp and Petranka 2006; Muir et al. 2007; Kraus 2009;
8 AmphibiaWeb 2010; Frost 2010
- 9 **A8.1.25 *Rhinella marina***
- 10 **Common names:** cane toad, giant toad, marine toad
- 11 **Synonymous scientific names:** *Bufo aqua*, *Bufo marinus*, *Bufo strumosus*, *Chaunus marinus*, *Rana*
12 *marina*
- 13 **Adult description:** heavy body with short legs; up to 150 mm (6 in) in length; weight of females up to 1.5
14 kg (3.3 pounds); females larger; toes are webbed but fingers are not; large cranial crests; has tarsal
15 folds; tan, brown, dark brown, dull green, or black skin with warts; mottled coloration in females; venter
16 mottled whitish color; large parotid glands
- 17 **Tadpole description:** 10 to 25 mm (0.4 to 1 in) in length; ovoid body; subterminal mouth; short tail with
18 pointed caudal fin; dark brown or black body and tail
- 19 **Reproduction:** breeds throughout the rainy season (April to November in Costa Rica); males call from
20 edges of water bodies; strong male-male competition in populations with high densities; reproduce in
21 shallow water with little cover; lays paired strings of 2,500 to 12,500 eggs; hatch in 36 hours to 4 days;
22 metamorphose in 14 to 80 days
- 23 **Habitat:** all lowland and premontane zones, particularly disturbed areas; subtropical forests close to
24 fresh water, rainforests, man-made ponds, gardens, drain pipes, debris, under cement piles and boards,
25 houses, and disturbed areas; able to withstand a high level of salinity; can withstand a broad
26 temperature range
- 27 **Human health impacts:** secrete toxins (bufotenine toxin) from parotid glands that can cause serious
28 illness or death and human fatalities have occurred; reservoirs for *Leptospira interrogans* that causes
29 Weil's disease (infectious jaundice) in humans; calls may disturb sleep
- 30 **Economic impacts:** toxify livestock water sources where they breed and die

- 1 **Ecological impacts:** will eat most anything; competition with native species
- 2 **Pathways:** biocontrol, cargo, seafreight (container/bulk), intentional, natural dispersal, pet trade,
3 vehicles, water currents, zoo trade
- 4 **Control measures:** public education, exclusion; research being conducted: use of parasites and viral
5 vectors, pheromones
- 6 **References:** Hinckley 1963; Pernetta and Watling 1979; Brandt and Mazzotti 1990; Catling et al. 1999;
7 Crossland 2000; Lever 2001; Christy et al. 2007a; Kraus 2009; ISSG 2010
- 8 **A8.2 Birds:** an important species for Micronesia which is not included in this list is the Eurasian
9 Tree Sparrow which is established on various islands within Micronesia including Guam.
10 Various other species could readily be added to this list.
- 11 **A8.2.1 *Columba livia*:** established on numerous islands in the region and the broader Pacific
- 12 **Common names:** common pigeon, domestic pigeon, feral pigeon, rock dove
- 13 **Synonymous scientific names:** no information found in the literature
- 14 **Adult description:** 29 to 36 cm (11.6 to 14.4 in), 194 to 398 g (6.84 to 14.04 oz); variable species,
15 generally blue-grey with green and purple sheen on neck; wings with two black bars; white rump; cere
16 whitish; bill black; the description above refers to the wild form; are many patterns among feral birds
17 from white, red, and black.
- 18 **Reproduction:** most of the year; as many as five broods per year; two eggs per brood; eggs are smooth,
19 white, and glossy; nests on ledges and flat surfaces; new nests are built on top of old nests; nests consist
20 of twigs, roots, pine needles, straw, and grass stems; incubation length is 18 days; hatchlings are
21 altricial; fledging occurs in 25 to 45 days
- 22 **Habitat:** Cities, towns, villages, farms, and cliffs.
- 23 **Human health impacts:** carry up to 60 human pathogens including viruses, bacteria, fungi, and
24 protozoans; reasonable evidence that they are responsible for the spread of several noxious diseases
25 including: psittacosis or ornithosis, cryptococcal meningitis, histoplasmosis, toxoplasmosis, encephalitis,
26 Q fever, chlamydia, campylobacter, diarrheagenic *E. coli*, WNV, *Enterocytozoon bieneusi*, fleas that cause
27 allergies
- 28 **Economic impacts:** nuisance in most of the larger cities in the world because of their fouling of
29 buildings, statues, etc. with droppings; contaminate grain for human consumption; nests clog
30 drainpipes; occasionally interfere with crops; compete with domestic fowl for food.
- 31 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 32 **Pathways:** escaped or run wild, intentional.

1 **Control measures:** exclusion, habitat modification, hazing, repellents, toxicants, fumigants, trapping,
2 shooting, contraception

3 **References:** Long 1981; Lever 1987; Johnston 1992; Williams and Corrigan 1994; To et al. 1998; Stein

7 **A8.2.2 *Dicrurus macrocercus*:** Established on Guam and Rota

8 **Common names:** black drongo, drongo, king crow

9 **Synonymous scientific names:** no information found in the literature

10 **Adult description:** 22.5 to 31 cm (11 to 12.4 in); 38 to 59 g (1.34 to 2.08 oz); black with a bluish gloss;
11 red eyes; usually white spot on nape; prominent rectal bristles; tail deeply forked; bill black.

12 **Reproduction:** breed mainly February to August; amount of eggs variable; 2 to 5 eggs.

13 **Habitat:** open country, marshes, roadsides, cultivated areas, cities, and towns

14 **Human health impacts:** none found in the literature, but undocumented impacts may exist

15 **Economic impacts:** none found in the literature, but undocumented impacts may exist

16 **Ecological impacts:** thought to be responsible for decline of some small passerines in the Marianas

17 **Pathways:** intentional, natural spread

18 **Control measures:** no information found in the literature

19 **References:** Long 1981

20 **A8.2.3 *Francolinus francolinus***

21 **Common names:** black francolin, black partridge, Indian black francolin

22 **Synonymous scientific names:** none

23 **Adult description:** females lighter than males; mostly black below and rufous brown above; crown to
24 nape rufous brown; eye region is black; cheeks and ear-coverts are white; prominent broad chestnut
25 collar on dorsal surface of neck surrounded by white-spotted black feathers; feathers of nape distinctly
26 mottled black and white; back is brown; lower back, rump, chin, throat, and area below the ear-coverts
27 are black; breast is black with oval white spots on sides and flanks; lower breast and thighs are black to
28 reddish brown with large white spots or bars; center of abdomen and vent are lighter chestnut with
29 whitish bars.

1 **Reproduction:** may produce two clutches in India; generally nests in well-concealed areas; ground-
2 nesting; nest consists of a shallow scrape or depression on the bare ground which may or may not be
3 lined sparingly with grass, stems, twigs, leaves, or feathers; eggs are short-subelliptical to short oval and
4 are smooth and glossy; egg coloration dependent on habitat but are pale olive brown to chocolate
5 brown and often have white specks of calcareous deposits; clutch size is usually 6 to 8 eggs; incubation
6 lasts approximately 18 days; hatchlings are precocial.

7 **Habitat:** habitat generalist; dry grasslands, open pasturelands, dry scrubland and savanna, well-
8 vegetated habitats, and areas adjacent to fields

9 **Human health impacts:** none found in the literature, but undocumented impacts may exist

10 **Economic impacts:** none found in the literature, but undocumented impacts may exist

11 **Ecological impacts:** alternative prey source for BTS

12 **Pathways:** introduced as a game bird, natural spread

13 **Control measures:** no information found in the literature

14 **References:** Long 1981; Conry 1988b; Islam 1999; Birdlife International 2009a

15 **A8.2.4 *Lonchura malacca***

16 **Common names:** tricolored munia, black-headed munia, chestnut-breasted munia, chestnut mannikin,
17 black-headed mannikin

18 **Synonymous scientific names:** none

19 **Adult description:** upper parts brown; rump reddish brown; head, neck, and breast black, underparts
20 brown with a black or white patch in the center of the abdomen; vent, thighs, and under tail-coverts
21 black; upper tail-coverts and tail yellow to orange-red; bill silver-grey or slaty blue

22 **Reproduction:** nest is a ball of coarse grass lined with finer grass and contains a lateral entrance hole at
23 the end of a short spout; nest in low bushes, trees, or grass tussocks; clutch size is 4 to 8 eggs

24 **Habitat:** forests, shrublands, wetlands, arable lands, plantations.

25 **Human health impacts:** none found in the literature, but undocumented impacts may exist

26 **Economic impacts:** damage rice

27 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

28 **Pathways:** pet trade, natural spread

1 **Control measures:** hazing, glue-coated perches

2 **References:** Reidinger and Libay 1979; Long 1981; Birdlife International 2009b

3 **A8.2.5 *Padda oryzivora*:** established in Hawai'i and an incipient population on Guam

4 **Common names:** Javan finch, Java sparrow, rice or paddy bird

5 **Synonymous scientific names:** no information found in the literature

6 **Adult description:** 14.5 to 16 cm (5.8 to 6.4 in); head, chin, upper throat, band behind ear-coverts;
7 upper tail-coverts and tail black; sides of face to ear-coverts and under tail-coverts white; remainder
8 grey; belly and lower flanks vinous; bill pink; pure-white form can occur.

9 **Reproduction:** may breed seasonally or year-round depending on location; colonial; nests are bell-
10 shaped or domed with a side entrance and are located 1 to 18 m (3.3 to 60 feet) above ground in natural
11 and artificial crannies; eggs are white, oval, and matte; clutch size: 3 to 8 eggs; may produce a second
12 brood; both sexes incubate; incubation lasts 13 to 15 days; hatchlings are altricial; fledging occurs in 15
13 to 17 days

14 **Habitat:** rice fields, villages, cities, mangroves, open country, and scrub; largely in association with man.

15 **Human health impacts:** none found in the literature, but undocumented impacts may exist

16 **Economic impacts:** destroy agricultural crops, especially rice fields.

17 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

18 **Pathways:** intentional, escaped, imported, religious, ship

19 **Control measures:** no information found in the literature

20 **References:** Long 1981; Lever 1987; Islam 1997

21 **A8.2.6 *Passer domesticus*:** established in Hawai'i

22 **Common names:** English sparrow, European sparrow, house sparrow

23 **Synonymous scientific names:** no information found in the literature

24 **Adult description:** 14.3 to 15.5 cm (5.72 to .2 in). 25 to 37 g (0.88 to 1.3 oz); crown, nape, and lower
25 back dark grey; lores black; nape through eye brown; white stripe over eye; back brown streaked black;
26 wings brown with a single white bar on middle coverts; throat and breast black; cheeks and sides of
27 neck white; belly whitish or grayish; tail dull brown; bill black. Female: generally lacks as much black on
28 throat; upper parts dusky brown; bill brown.

1 **Reproduction:** breed all year; 2 to 3 or more broods per year; breeding times depend on area; clutch
2 size usually 2 to 7 eggs; eggs are glossy and smooth and are oval to long-oval in shape; the eggs are
3 white to greenish white or bluish white with dots or spots of grays or browns particularly around the
4 larger end; nests consist of dried vegetation and are often found in enclosed spaces; incubation lasts 10
5 to 14 days; hatchlings are altricial; fledging occurs at 14 days.

6 **Habitat:** open forest, wooded country, grasslands, cultivated areas, parks, gardens, cities, towns, and
7 everywhere there is human settlement.

8 **Human health impacts:** cause contamination with droppings, and help spread human disease, such as
9 toxoplasmosis, WNV, chlamydiosis, coccidiosis, salmonellosis, transmissible gastroenteritis,
10 shistosomiasis, and trichomoniasis.

11 **Economic impacts:** does harm in arable areas and lands adjacent to these areas, damage wheat and
12 other cereals, damage vegetable crops, dig up newly sown seeds, eat fruit crops, block drain and water
13 pipes with nesting materials, distribute poultry cestodes and nematodes

14 **Ecological impacts:** displace some indigenous insectivorous birds

15 **Pathways:** biocontrol, intentional, ships, cargo vessels, grain boats, followed horses and their food,
16 natural spread

17 **Control measures:** exclusion, removal of roosting sites, hazing, repellents, toxicants, trapping, shooting,
18 and changes in agricultural practices.

19 **References:** Long 1981; Pascual et al. 1999; Komar et al. 2005; Lowther and Cink 2006; Une et al. 2008;
20 Gondim et al. 2010

21 **A8.2.7 *Passer montanus***

22 **Common names:** tree sparrow

23 **Synonymous scientific names:** no information found in the literature

24 **Adult description:** 11.6 to 15 cm (4.64 to 6 in.); 17 to 27 g (0.6 to 0.95 oz); crown and back of head
25 chestnut; lores, line beneath eye to above ear-coverts, chin and throat black; ear-coverts white, with
26 black patch; neck almost surrounded by white collar; upper parts brown, streaked black; underparts
27 whitish or ashy; rump, upper tail-coverts and tail buffish brown, wing with two white bars; bill brown or
28 grayish.

29 **Reproduction:** Breed December to June (September to January in Australia); often colonial; 2 to 3
30 clutches per year; nests are domed and consist of loosely intertwined stems of grass, straw, and roots
31 surrounding a cup lined with soft material (feathers, fur, flower parts, waste paper, cloth, string, green
32 leaves); nest has a side entrance; nests in cavities or dense foliage; clutch size is 4 to 7 eggs; eggs are
33 subelliptical, slightly glossy, and smooth; eggs are white to pale gray and are heavily marked with spots,

- 1 blotches, or speckling of dark brown, purple, or gray (usually heavier on broad end); incubation is
2 approximately 12 days; hatchlings are altricial; fledging occurs around 14 days.
- 3 **Habitat:** wooded regions, open fields, grasslands, parks, gardens, orchards, villages, and towns.
- 4 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 5 **Economic impacts:** damage crop fields; cause damage when grain is drying, being threshed, fed to
6 domestic animals and stored in open grain bins; spoil grain with their manure; cause damage to fruit
7 crops; damage young vegetable seedlings and leaves; cause damage to houses by nesting in them;
8 compete for food with domestic poultry
- 9 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 10 **Pathways:** intentional, ship, boat, steamboat
- 11 **Control measures:** no information found in the literature
- 12 **References:** Long 1981; Lever 1987; Barlow and Leckie 2000
- 13 **A8.2.8 *Pycnonotus jocosus*:** Established in Hawai'i, Fiji, and Majuro
- 14 **Common names:** Red-eared Bulbul, Red-whiskered Bulbul
- 15 **Synonymous scientific names:** no information found in the literature
- 16 **Adult description:** 17.3 to 22 cm (6.92 to 8.8 in); 23 to 42 grams (0.81 to 1.48 ounces); upper parts
17 brown, with crested blackish crown a red patch behind eye; cheeks and throat white; a broken blackish
18 or dark brown band from breast around sides of neck; underparts grayish white; under tail-coverts red;
19 tail brown, tipped white; bill black.
- 20 **Reproduction:** variable, January to August; 2 to 3 broods per season; nests are cup-shaped and consist
21 of rootlets, twigs, dead leaves, and grasses bound by cobwebs on the outside; the nest cup is lined with
22 hair, soft fibers, rootlets, and fine materials; clutch is 2 to 5 eggs; eggs are short oval in shape, and are
23 smooth with little or no gloss; eggs are pale pink to reddish white marked with numerous reddish-brown
24 blotches, spots, and streaks with secondary markings of pale, inky purple; spots on the eggs may form a
25 ring or cap around the broad end; incubation lasts 10 to 14 days; hatchlings are altricial; fledging occurs
26 in approximately 12 days.
- 27 **Habitat:** forest edges, secondary growth, woodland, cultivation, parklands, gardens, and villages.
- 28 **Human health impacts:** none found in the literature, but undocumented impacts may exist

- 1 **Economic impacts:** Not great pests in native range; in non-native range reported damage fruits,
2 vegetables, and flowers; may spread seeds of invasive plants and facilitate germination of those seeds
3 by passage through the gut
- 4 **Ecological impacts:** compete with mockingbirds for berries in Florida
- 5 **Pathways:** Natural spread, escaped, intentional, unauthorized release, ship
- 6 **Control measures:** repellents
- 7 **References:** Long 1981; Lever 1987; Cummings et al. 1994; Islam and Williams 2000; Mandon-Dalger et
8 al. 2004; Linnebjerg et al. 2009
- 9 **A8.2.9 *Streptopelia bitorquata dusimieri***
- 10 **Common names:** Java ring dove, Javan collared dove, Javan turtledove, Javanese collared dove,
11 Philippine turtle-dove
- 12 **Synonymous scientific names:** *Streptopelia bitorquata*
- 13 **Adult description:** 30 cm (12 in); forehead, crown, and nape grey; broad black, white-edged, half collar
14 on hindneck; remainder of neck and upper mantle pinkish, often with rusty tinge; breast mauvish pink;
15 belly and under tail-coverts white or grayish-white; flanks grayish; back brown; primaries and
16 secondaries blackish, remainder of wing blue-grey; rump dark grey-brown; central tail-feathers brown,
17 outer feathers pale grey with basal third dark grey, under tail grayish white with basal third black; bill
18 blackish or dark grey, red at nape.
- 19 **Reproduction:** April to August (eastern Java); Eggs: 2
- 20 **Habitat:** habitat generalist; forest edges, open country with trees, villages, fields, and cultivation.
- 21 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 22 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 23 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 24 **Pathways:** intentional
- 25 **Control measures:** no information found in the literature
- 26 **References:** Long 1981; USGS 2005b

1 **A8.3 Mammals**

2 **A8.3.1 *Clethrionomys rutilus***

3 **Common names:** red-backed vole, red-backed mouse, northern red-backed vole, northern red-backed
4 mouse

5 **Synonymous scientific names:** *Myodes rutilus*

6 **Adult description:** head and body 80 to 110 mm (3.2 to 4.3 in) in length; tail 23 to 44 mm (0.9 to 1.7 in)
7 in length; weight 14.2 to 42.6 g (0.5 to 1.5 oz); sides of body yellow; upper parts bright reddish to rufous;
8 ear brown; dorsum red, or dark brown to blackish; tail densely furred; under tail yellow; feet whitish or
9 buff.

10 **Reproduction:** breed from April to October; gestation is 17 to 20 days; litter size is 1 to 8 pups; produce
11 3 to 4 litters per year; young are born naked and helpless; young weaned at 3 to 4 weeks; mature at 3 to
12 4 months

13 **Habitat:** habitat generalist; forest and taiga, grassland, tundra, woodland, forest, buildings, around
14 decaying stumps.

15 **Human health impacts:** reservoir for tularemia, Lyme disease

16 **Economic impacts:** none found in the literature, but undocumented impacts may exist

17 **Ecological impacts:** may damage trees

18 **Pathways:** plants and nursery trade, with firewood

19 **Control measures:** exclusion, habitat modification, zinc phosphide, anticoagulants, trapping

20 **References:** Nakao et al. 1994: O'Brien 1994: Berdal et al. 1996: Long 2003: Tobin and Fall 2004: Linzey
21 et al. 2008

22 **A8.3.2 *Didelphis marsupialis***

23 **Common names:** American opossum, black-eared opossum, southern opossum, Virginia opossum

24 **Synonymous scientific names:** *Didelphis virginiana*

25 **Adult description:** head and body 300 to 584 mm (11.8 to 23 in) in length; tail 255 to 535 mm (10 to 21
26 in) in length; weight 136 to 504 g (4.8 to 17.8 oz); females smaller than males; fairly heavy-bodied;
27 pointed muzzle with pink nose pad; face is white with black patches around eyes; short, black legs with
28 white toes; coloration varies regionally, ranging between grey, black, brown, reddish, and rarely white;
29 prehensile tail; fur-lined pouch on abdomen of females

1 **Reproduction:** breeds year-round with peaks in January to March and May to July; 1 to 2 litters per year;
2 gestation 8 to 13 days; 4, 8 to 18, or 25 young per litter, but must find mammae to survive; young
3 develop in pouch for 2 months; weaned at 90 to 100 days; males sexually mature at 8 months, females
4 at 6 months

5 **Habitat:** habitat generalist; forest, brush areas, woods near streams, cultivated areas with trees; prefers
6 areas with hollow trees; common in suburban and agricultural areas

7 **Human health impacts:** carriers of parasites that affect public health and poultry; reservoir for
8 leishmaniasis, toxoplasmosis, tularemia, relapsing fever, leptospirosis, and Rocky Mountain spotted
9 fever

10 **Economic impacts:** predation on poultry, eat vegetable and corn crops

11 **Ecological impacts:** predation on birds, such as the ground dove, possibly causing local extinctions;

12 **Pathways:** cargo, boat, escape, intentional, natural spread

13 **Control measures:** exclusion, habitat modification, trapping, shooting

14 **References:** Barr 1963; Henry 1969; McManus 1974; Lins and Lopes 1984; Jackson 1994; Carme et al.
15 2002; Long 2003; Yai et al. 2003; Schallig et al. 2007

16 **A8.3.3 *Herpestes javanicus*:** Established in Hawai'i and Fiji

17 **Common names:** Indian mongoose, small Indian mongoose

18 **Synonymous scientific names:** *Herpestes auropunctatus*

19 **Adult description:** head and body of males 250 to 350 mm (10 to 13.8 in) in length; tail 200 to 310 mm
20 (8 to 12 in) in length; tail shorter than head and body length; weight 312 to 1,300 g (11 to 46 oz);
21 females smaller than males; body slender with short legs; elongated head with a pointed muzzle; tail has
22 a muscular base; coloration ranges from buff to dark gray-brown; coat has a speckled or grizzled
23 appearance

24 **Reproduction:** 2 litters per year; gestation 42 to 43 days; 1 to 5 young per litter, with an average of just
25 over 2; altricial; weaned at 4 to 5 weeks; sexually mature in first year

26 **Habitat:** open dry bush and savannah; cultivated and disturbed areas; near villages; lives in burrows and
27 crevices but climbs well

28 **Human health impacts:** carries diseases transmissible to humans and pets, including rabies,
29 leptospirosis, canine distemper, canine hepatitis, toxoplasma, salmonella, feline panleukopenia,
30 streptococcus, and pulmonary virus

- 1 **Economic impacts:** predation on poultry, eggs, and small livestock
- 2 **Ecological impacts:** predation on native wildlife, causing the near extinction of many ground-dwelling
3 species of frogs, reptiles, mammals and ground-nesting birds
- 4 **Pathways:** biocontrol, intentional, natural spread
- 5 **Control measures:** trapping, poisoning (diphacinone), and bounties
- 6 **References:** Baker and Russell 1979; Nellis and Small 1983; Coblenz and Coblenz 1985; Nellis 1989;
7 Smith et al. 2000; Krebs et al. 2003; Long 2003; Morley 2004; Blanton et al. 2006; Hays and Conant 2007;
8 Watari et al. 2008; Leighton et al. 2009; ISSG 2010

9 **A8.3.4 *Macaca fascicularis***

10 **Common names:** Crab-eating Macaque. Long-tailed Macaque, Cynomolgus Monkey, Kera

11 **Synonymous scientific names:** *M. cynomolgus* or *M. irus*

12 **Adult description:** Body length in adult 38-55 cm with comparable short arms and legs. Tail is longer
13 than body, 40-60 cm. Females weight 3-6 kg, while males range from 5-9 kg. "In addition to being taller
14 and heavier, males have much larger canine teeth than females. Macaques have cheek pouches in which
15 they can store food as they forage, and transport it away from the foraging site to eat." (Cawthon Lang
16 K.A., 2006). Life span 31 years.

17 **Reproduction:** Gestation ranges from 167 to 193 days. Females give birth to one infant.

18 **Habitat:** "Long-tailed macaques live in primary, secondary, coastal, mangrove, swamp, and riverine
19 forests from sea level up to elevations of 2000 m (6561 ft). They prefer forested areas near water and
20 are found in higher densities near riverbanks, lakeshores, or along the seacoast. They preferentially
21 utilize secondary forest, especially if it borders human settlement, where they have access to gardens
22 and farms to crop-raid. Long-tailed macaques are widespread throughout the islands of Southeast Asia
23 into mainland Asia." (Cawthon Lang K.A., 2006)

24 **Human health impacts:** Carrier of B-virus (Cercopethecine herpesvirus 1), which can be transmitted to
25 humans, and is estimated to be lethal in 70-80% of untreated human cases (Cohen et al. 2002). Most
26 macaques carry B virus without any overt signs of disease (Huff & Barry 2003). Macaques bite and
27 scratch humans, which can result in traumatic injury, and can lead to serious infections. They can also
28 carry a number of other human and zoonotic diseases, and, "in addition to viruses that have been
29 identified, there is the potential for previously unknown diseases to transfer from the monkeys to
30 humans posing a serious health risk to nearby communities and beyond." (Cawthon Lang K.A., 2006)

31 **Economic impacts:** In their native range, they are known as crop raiders, having impacts on agriculture,
32 including fruit crops, root crops such as cassava and sweet potato, and many others. These macaques
33 also enter houses when people are not at home and raid food and damage clothing, etc. On the island
34 of Angaur, where they are introduced, these macaques have made crop production virtually impossible,

1 except for small gardens next to people’s homes, and even these are damaged when the residents are
2 away from home.

3 **Ecological impacts:** Known predator of bird nests; populations of several native birds on the island of
4 Angaur in Palau have been severely impacted – either severely reduced in population or completely
5 absent. These macaques also prey on insects and small reptiles, as well as small crustaceans, but their
6 impact on these species is unknown. Since they are largely frugivorous, they contribute to the spread of
7 seeds of some tree species, and can perhaps alter forest composition and structure. “Where they forage
8 in mangroves, long-tailed macaques spend time consuming crabs and have also been seen eating frogs,
9 shrimp and octopus.” (Cawthon Lang K.A., 2006)

10 **A8.3.5 *Microtus californicus***

11 **Common names:** California vole, California meadow vole, Amargosa vole

12 **Synonymous scientific names:** none

13 **Adult description:** 139 to 207 mm (5.5 to 8 in) total length; tawny olive to cinnamon brown with brown
14 to black overhairs; grayish underparts; bicolored tail; pale feet

15 **Reproduction:** can breed every 3 weeks in good conditions; breeding season varies depending on
16 region; year-round breeders in coastal populations; nests are located under logs, boards, or a few
17 centimeters under the earth’s surface; nests are made with dried grasses and forbs; produce 1 to 11
18 offspring; gestation lasts approximately 22 days; young are altricial at birth; young weaned in
19 approximately 2 weeks; young generally independent at 2 weeks; sexual maturity at approximately 3
20 weeks for females and 5 weeks for males.

21 **Habitat:** broad-leafed chaparral, oak woodlands, grasslands, marshy ground, wet meadows, coastal
22 wetlands, agricultural areas, and dry, grassy hillsides.

23 **Human health impacts:** vectors of plague, tularemia, hantavirus, and Lyme disease

24 **Economic impacts:** girdle seedlings and mature trees; damage or destroy crops such as alfalfa, clover,
25 grain, potatoes, and sugar beets; damage irrigation systems; damage lawns, golf courses, and ground
26 covers

27 **Ecological impacts:** girdle seedlings and mature trees; may compete with other rodents

28 **Pathways:** nursery trade

29 **Control measures:** exclusion, habitat modification, repellents, zinc phosphide, anticoagulants, trapping

30 **References:** Greenwald 1956; Jameson Jr. 1958; Stark 1963; Kartman and Hudson 1971; Hudson et al.
31 1972; Heske et al. 1984; O'Brien 1994; Song et al. 1995; Bennett et al. 1999; Peronne 2002; Long 2003;
32 Vredevoe et al. 2004; Álvarez-Castañeda et al. 2008

1 **A8.3.6 *Mus musculus***

2 **Common names:** common mouse, house mouse

3 **Synonymous scientific names:** *Mus domesticus*

4 **Adult description:** head and body 70 to 102 mm (2.8 to 4 in) in length; tail 65 to 95 mm (2.6 to 3.7 in) in
5 length; weight 8.5 to 41.5 g (0.3 to 1.5 oz); body brownish grey with a paler venter; coloration ranges
6 from light brown to dark grey; ears and muzzle pointed; large eyes; the semi-naked tail is as long as the
7 head and body

8 **Reproduction:** r-selected with high reproductive capacity; often continuous breeding; generally 6 to 8
9 litters per year, but can be as high as 11; gestation 13 to 31 days; 4 to 12 young per litter; altricial;
10 weaned at 21 days; sexually mature in 3 to 8 weeks

11 **Habitat:** habitat generalist; found in every habitat type and on every continent, including Antarctica;
12 found especially in human-inhabited places; can maintain populations in extreme conditions; island
13 populations often thrive even more than those on the mainland

14 **Human health impacts:** reservoir for various disease organisms and parasites that can affect humans
15 such as plague, salmonella, leptospirosis, toxoplasmosis, and rickettsial pox

16 **Economic impacts:** agricultural damage, especially to grains and legumes; consumption and
17 contamination of stored foods and livestock feed; nuisance noise, odors, and droppings; economic costs
18 due to damage to insulation, wiring, and farm machinery

19 **Ecological impacts:** predation on native plants and wildlife, including seabird chicks and eggs,
20 invertebrates, and reptiles; extinction of native island vertebrates

21 **Pathways:** aircraft, boat, cargo, escape, natural spread, vehicle

22 **Control measures:** anticoagulants, fumigants, traps, repellents, exclusion

23 **References:** Timm 1994a: Long 2003: Witmer and Jojola 2006: Meerburg et al. 2009: ISSG 2010

24 **A8.3.7 *Myotis lucifugis***

25 **Common names:** little brown bat, little brown myotis

26 **Synonymous scientific names:** *Myotis lucifugus*

27 **Adult description:** 60 to 102 mm (2.4 to 4 in) in length; 222 to 269 mm (8.7 to 10.6 in) wingspan; weight
28 5 to 14 g (0.2 to 0.5 oz); pale tan through reddish brown to dark brown depending on geographic
29 location; ventral side is lighter in color; fur is glossy and sleek

- 1 **Reproduction:** produce 1 to 2 offspring; gestation lasts 50 to 60 days; young are weaned at 3 to 4
2 weeks; young are independent at 4 weeks; sexual maturity at approximately 7 months
- 3 **Habitat:** habitat generalist; buildings, trees, under rocks, in piles of wood, abandoned mines or caves,
4 forested lands near water
- 5 **Human health impacts:** reservoirs for coronavirus, polyomavirus, rabies; guano is associated with
6 histoplasmosis, associated with bat-aircraft strikes
- 7 **Economic impacts:** may roost in dwellings associated with humans leaving rub marks, guano, and urine;
8 noise may be bothersome to some people; associated with bat-aircraft strikes
- 9 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 10 **Pathways:** cargo, ships, aircraft, natural dispersal
- 11 **Control measures:** exclusion, repellents, trapping
- 12 **References:** Fenton and Barclay 1980; Burnett 1989; Greenhall and Frantz 1994; Constantine 2003;
13 Havens and Myers 2006; Arroyo-Cabrales and Castaneda 2008; Misra et al. 2009; Peurach et al. 2009
- 14 **A8.3.8 *Pipistrellus javanicus***
- 15 **Common names:** Javan pipistrelle
- 16 **Synonymous scientific names:** *Pipistrellus babu* Thomas, 1915; *Pipistrellus camortae* Miller, 1902;
17 *Pipistrellus peguensis* Sinha, 1969; *Scotophilus javanicus* Gray, 1838
- 18 **Adult description:** 75 to 90 mm (3 to 3.5 in) total length; weighs 4 to 7 g (0.1 to 0.2 oz); dark brown fur
19 that is darker at the base; fur is lighter ventrally; flat head with a broad muzzle that appears swollen;
20 short ears
- 21 **Reproduction:** have 3 breeding seasons; produce 2 offspring/breeding season
- 22 **Habitat:** habitat generalist; common in urban and agricultural areas; primary and secondary lowland
23 montane forest, caves
- 24 **Human health impacts:** associated with bat-aircraft strikes
- 25 **Economic impacts:** associated with bat-aircraft strikes
- 26 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 27 **Pathways:** cargo, ships
- 28 **Control measures:** no information found in the literature

1 **References:** Daniel and Yoshiyuki 1982; Constantine 2003; Bates et al. 2005; Francis et al. 2008; Peurach
2 et al. 2009

3 **A8.3.9 *Rattus exulans***

4 **Common names:** kiore, little rat, Maori rat, Pacific rat, Polynesian rat

5 **Synonymous scientific names:** *Mus exulans*, *Mus maorium*

6 **Adult description:** head and body 80 to 140 mm (3.2 to 4.1 in) in length; tail 108 to 147 mm (4.3 to 5 in)
7 in length; weight 30 to 180 g (1 to 6 oz); dorsum brown or grey brown, venter whitish; pointed muzzle
8 and large ears; tail dark with fine scales; smaller than the black and Norway rats

9 **Reproduction:** breeds year-round, peaks in spring to late summer; 1 to 6 or more litters per year;
10 gestation 19 to 30 days; altricial; weaned at 4 weeks; mature in 8 to 12 months

11 **Habitat:** habitat generalist; bush, scrub, grassland, forest; under logs and rocks; houses, clearings,
12 gardens, paddy fields

13 **Human health impacts:** carries zoonotic diseases including leptospirosis, plague, lungworm, and others;
14 create breeding sites for mosquitoes by knocking coconuts to the ground

15 **Economic impacts:** damages rice, maize, sugarcane, coconut, cacao, pineapple, mangoes, passion fruit,
16 paw paw, cassava, kumarans, and root crops

17 **Ecological impacts:** preys on native birds, lizards, and turtle eggs; consumption of native flora

18 **Pathways:** boat, cargo, food

19 **Control measures:** habitat alteration, snap traps, zinc phosphide, anticoagulants, compound 1080 not
20 effective

21 **References:** Kepler 1967; Tobin 1994; Vickery 1994; Spennemann 1997; Robinet et al. 1998; Campbell
22 and Atkinson 1999; SPREP 2000; Atkinson and Towns 2001; Worthy and Holdaway 2002; Long 2003;
23 Meerburg et al. 2009; ISSG 2010

24 **A8.3.10 *Rattus norvegicus***

25 **Common names:** brown rat, common rat, Norway rat

26 **Synonymous scientific names:** none

27 **Adult description:** head and body 165 to 280 mm (6.5 to 11 in) in length; tail 122 to 230 mm (4.8 to 9 in)
28 in length; weight 120 to 580 g (4.2 to 20.4 oz), up to 909 g (32 oz); robust body; coloration grey to
29 grayish brown on dorsum, with a white venter; ears, feet and tail flesh-colored; blunt muzzle and small
30 ears and eyes

- 1 **Reproduction:** breeds year-round; 6 litters per year; gestation 20 to 26 days; 5 to 10, and up to 22,
2 young per litter; altricial; weaned at 28 days; mature in 3 to 4 months
- 3 **Habitat:** habitat generalist; found everywhere except deserts and polar regions
- 4 **Human health impacts:** consumption and contamination of stored foods; chew through power cables;
5 fleas are vectors of plague; vector of hantavirus
- 6 **Economic impacts:** damage to sugarcane;
- 7 **Ecological impacts:** reduced Canada goose populations in the Aleutian Islands; decimation and
8 extinction of native plant, mammal, reptile, bird and invertebrate populations
- 9 **Pathways:** boat, natural spread, seafreight (container/bulk)
- 10 **Control measures:** exclusion, habitat modification, toxicants, fumigants, traps
- 11 **References:** Timm 1994b; Long 2003; Meerburg et al. 2009; ISSG 2010
- 12 **A8.3.11 *Rattus rattus***
- 13 **Common names:** black rat, house rat, roof rat, ship rat
- 14 **Synonymous scientific names:** none
- 15 **Adult description:** head and body of males 165 to 254 mm (6.5 to 10 in) in length; tail 140 to 252 mm
16 (5.5 to 10 in) in length; weight 85 to 350 g (3 to 8.8 oz); sleek body; coloration blue-black, black or brown
17 on dorsum and grey, buff, or whitish on venter; pointed muzzle with black snout; large eyes and ears;
18 black or brown tail, mostly naked with fine scales; feet with five toes; similar to the Asian house rat
19 (*Rattus tanezumi*)
- 20 **Reproduction:** breeds year-round; 5 to 6 litters per year; gestation 21 to 30 days; 1, 5 to 8, or 12 young
21 per litter; weaned at 21 to 28 days; sexually mature in 3 to 4 months; polygamous; makes a spherical
22 nest of loose vegetation and other material
- 23 **Habitat:** habitat generalist; not found in deserts; prefers rivers, streamsides, and human-inhabited
24 areas, such as orchards and gardens
- 25 **Human health impacts:** reservoir of zoonotic diseases, including leptospirosis and trichinosis; rat fleas
26 are vectors for pasteurella, murine typhus, and plague
- 27 **Economic impacts:** agricultural damage to poultry operations and crops such as rice, sugarcane, coconut
28 and macadamia orchards; consumption and contamination of stored foods; economic costs from
29 damage to structures and materials
- 30 **Ecological impacts:** predation on and extinction of native rats, bats, turtles, tortoises, and endemic birds

1 **Pathways:** cargo, natural dispersal, seafreight (container/bulk), road vehicles

2 **Control measures:** Exclusion, habitat modification, toxicants, fumigants, traps

3 **References:** Marsh 1994; Vanderwerf 2001; Long 2003; Meerburg et al. 2009; ISSG 2010

4 **A8.3.12 *Rattus tanezumi***

5 **Common names:** Asian house rat, Oriental house rat, tanezumi rat

6 **Synonymous scientific names:** *Rattus rattus mindanensis*

7 **Adult description:** males about 191 mm (7.5 in) in length; females about 182 mm (7 in) in length; weight
8 150 to 280g (5.3 to 10 oz); males larger; reddish to grayish brown or darker dorsum; lighter venter;
9 morphologically similar to the black rat; *R. tanezumi* females have 5 pairs of teats in a different
10 configuration than the 6 pairs found on *R. rattus* females; the two species are separated based on
11 genetic analysis

12 **Reproduction:** breeds during growth of rice crops; gestation 21 to 29 days; 4 to 10, with an average of 7
13 young per litter; polyestrous, possibly up to 6 litters per year; females sexually mature at 2 to 4 months

14 **Habitat:** habitat generalist; disturbed lowlands, grasslands, shrublands, various forests; especially found
15 in human-inhabited areas, including agricultural lands, villages, gardens, and urban areas

16 **Human health impacts:** reservoir for hanta virus, Bartonella, scrub typhus, leptospirosis, and
17 Cryptosporidium

18 **Economic impacts:** damage to rice, sugarcane, and coconut crops; consumption and contamination of
19 stored foods; consumption of livestock feed

20 **Ecological impacts:** likely preys on birds and bird eggs

21 **Pathways:** unknown

22 **Control measures:** removal; zinc phosphide, racumin; clearing vegetation; scrub burning; fencing;
23 research being conducted: timing of application (just prior to the breeding season), cost-benefit analysis
24 (Control measures beneficial when crop losses exceed 5%), trap-barrier systems

25 **References:** Coleman et al. 2003; Long 2003; Singleton et al. 2003; Tobin and Fall 2004; Wilson and
26 Reeder 2005; Li et al. 2007; Miller 2007; Stuart et al. 2007; Heaney and Molur 2008; Jittapalapong et al.
27 2009; Lv et al. 2009; Meerburg et al. 2009; Plyusnina et al. 2009; Johansson et al. 2010

28 **A8.3.13 *Suncus murinus*:** Established on Guam and in the CNMI

29 **Common names:** Asian musk shrew, brown musk shrew, house shrew, Indian musk shrew, large musk
30 shrew, money shrew, musk shrew

1 **Synonymous scientific names:** *Crocidura murina*, *Sorex murinus*, *Suncus caeruleus*

2 **Adult description:** head and body 50 to 150 mm (2 to 6 in) in length; tail 46 to 100 mm (1.8 to 4 in) in
3 length; weight of males 30 to 147 g (1 to 5 oz), females 20 to 82 g (0.7 to 2.9 oz); females smaller;
4 coloration pale grey to brown or black with lighter venter; long, pointed nose; prominent, round,
5 human-like ears; mostly naked tail with thick base and thin tip; musky odor from sweat glands on throat
6 and behind ears

7 **Reproduction:** breeding varies from seasonal to year-round, depending on location; gestation 29.6 to
8 30.3 days; 1 to 6 or 8 young per litter; altricial; sexually mature at 36 days

9 **Habitat:** habitat generalist; open grassy areas, swamps, pond margins, grassland, deserts, and human-
10 inhabited areas, such as houses, warehouses, drains, croplands, and gardens

11 **Human health impacts:** reservoir for plague, hantavirus, Q fever, and probably salmonella; nuisance
12 odors

13 **Economic impacts:** consumption of stored foods; possible predation on poultry; damage to seeds, young
14 plants, and grass

15 **Ecological impacts:** competition and predation on invertebrates and vertebrates (particularly lizards);
16 damage to seeds, young plants, and grass

17 **Pathways:** biocontrol, boat, cargo, seafreight (container/bulk), vehicle

18 **Control measures:** exclusion, habitat alteration, traps, anticoagulants

19 **References:** Cavanaugh et al. 1969; Yadav et al. 1979; Rodda and Fritts 1992; Fritts and Rodda 1998;
20 SPREP 2000; Varnham et al. 2002; Long 2003 Duplantier et al. 2005; Seymour et al. 2005; Henttonen et
21 al. 2008; Meerburg et al. 2009; ISSG 2010

22 **A8.4 Reptiles:** Some species missing from the follow list of possible reptile invaders include
23 Iguana iguana (a known invader in Puerto Rico, Florida, Fiji and other locations with at least one
24 individual having been found on Guam) and *Varanus indicus* (which is known from some islands
25 of Micronesia but not all suggesting that it might be able to travel and establish on current
26 monitor free islands if permitted). There are probably other species which should also be
27 added to this list.

28 **A8.4.1 Agama agama**

29 **Common names:** African red-headed Agama, Agama lizard, common agama, rainbow lizard

30 **Synonymous scientific names:** *Agama boensis*, *Agama colonorum*, *Agama picticauda*, *Agama smithii*,
31 *Lacerta agama*, *Oreodeira gracilipes*, *Tropidolepis africanus*

1 **Adult description:** whitish underside; buff brown back limbs and tail with a slightly lighter stripe down
2 the middle and six to seven dark patches to the side of this stripe. There is some sexual dimorphism. The
3 subordinate males, females, and adolescents possess an olive green head. A blue body and yellow tail
4 and head characterize the dominant male. Has a large head separated from the body, a long tail, well-
5 developed external ear openings and eyelids. The maximum size for male lizards is 25 cm (9.8 in); female
6 lizards are 20 cm (7.9 in) in length.

7 **Reproduction:** Females reach sexual maturity at age fourteen to eighteen months, males at two years;
8 reproduce during wet season although are capable of reproducing nearly year round in areas of
9 consistent rainfall; female lays her eggs in a hole she digs with her snout and claws; hole is five
10 centimeters deep and is found in sandy, wet, damp soil that is exposed to sunlight nearly all day and
11 covered by herbage or grasses; eggs are usually laid in clutches ranging from five to seven ellipsoidal
12 eggs; thermoregulated embryo species resulting in all males at 29° C and all females at 26 to 27° C eggs
13 hatch within 8 to 10 weeks. Hatchlings will be between 3.7 and 3.8 cm (1.5 in) snout-vent plus their 7.5
14 cm (3 in) tail. They will almost immediately start eating rocks, sand, plants, and insects.

15 **Habitat:** habitat generalist; any area with enough vegetation for reproduction (including human
16 inhabited areas).

17 **Human health impacts:** none found in the literature, but undocumented impacts may exist

18 **Economic impacts:** none found in the literature, but undocumented impacts may exist

19 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

20 **Pathways:** cargo, pet trade

21 **Control measures:** no information found in the literature

22 **References:** Hilgris 2000; Lever 2003; Kraus 2009; Uetz 2010

23 **A8.4.2 *Anolis carolinensis*:** already established in parts of the region

24 **Common names:** Green anole

25 **Synonymous scientific names:** *Anolis bullaris*, *Anolis porcatus*, *Anolis principalis*, *Dactyloa (Ctenocercus)*
26 *carolinensis*, *Lacerta principalis*

27 **Adult description:** between 127 to 203 mm (5 to 8 in) in length; females are smaller than males; ability
28 to change color; color depends on mood, temperature, humidity and health; resting or content anoles
29 are brown or bright green; they are darker in color when cold, and pasty gray when overly warm.
30 Females have a light vertebral line; displaying males can erect a low vertebral crest on the nape and
31 anterior trunk. They have adhesive lamellae on their foot pads; tails and bodies are long and slender,
32 and their heads have pointed snouts; keeled scales; rounded tail that is longer than snout-vent length
33 (75 mm).

- 1 **Reproduction:** One egg is laid at 14 to 17-day intervals throughout the warm months of the year; eggs
2 need moist soil and foliage; incubation varies between just over a month and 2 months. Breeds from
3 March to October.
- 4 **Habitat:** habitat generalist; arboreal; favors tall native grasses, shrubs, and trees. Requires greenery,
5 some shade and a moist environment; also can be found on walls and fences.
- 6 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 7 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 8 **Ecological impacts:** decline of native insects such as buprestid, cerambycid, cucurliionid, and melandryid
9 beetles; lycaenid and papilionid butterflies; bees; and odonates.
- 10 **Pathways:** nursery trade, pet trade, biocontrol
- 11 **Control measures:** no information found in the literature
- 12 **References:** Stevenson 1976; Jenssen et al. 1996; Bartlett and Bartlett 1999; Smith 1999; Abe et al.
13 2008; Kraus 2009; Uetz 2010
- 14 **A8.4.3 *Anolis cristatellus***
- 15 **Common names:** crested anole, Puerto Rican crested anole, greater Antillian anole
- 16 **Synonymous scientific names:** *Anolis cozumelae*, *Anolis lindeni*, *Ctenonotus cristatellus*, *Ptychonotus*
17 *(Istiocercus) cristatellus*, *Xiphosurus cristatellus*
- 18 **Adult description:** medium-sized anole; trunk-ground ecomorph. Females can reach 50 mm (2 in) in
19 snout to vent length. Males may reach 74 mm (3 in) in length and have dark-bordered dewlaps that
20 range in color from olive-green to yellow or orange. Males typically have a wavy tail crest, and the
21 vertebral and nape crests can be erected by muscular contraction. The dorsal color ranges from olive-
22 tan to almost black, with lighter colored anoles exhibiting dark bars or blotches on the trunk and tail.
- 23 **Reproduction:** reproductive seasonality observed; seasons depend on elevation, photo thermal period
24 and temperature; ample rainfall is not an indicator of successful clutch survival.
- 25 **Habitat:** habitat generalist; native to dry forests but can adapt to any habitat; montane habitats, shrubs,
26 fence posts, building walls, brush piles, and rock piles; open areas in higher elevations; Low density
27 suburban development, areas peripheral to core urban areas; small towns, agricultural habitat, and
28 recently disturbed, early successional community; ability to shift and modify structural habitats in
29 response to competitive interactions thus displacing less adaptable anoles
- 30 **Human health impacts:** none found in the literature, but undocumented impacts may exist

- 1 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 2 **Ecological impacts:** possible displacement of native Anolis species
- 3 **Pathways:** cargo, intentional, pet trade escapees
- 4 **Control measures:** no information found in the literature
- 5 **References:** Gorman and Licht 1974; Light 1974; Genet 2002; Malhotra et al. 2007; Kraus 2009; FLWCC
6 2010b; Uetz 2010

7 **A8.4.4 *Anolis distichus***

8 **Common names:** Bahaman Bark Anole, bark anole, Hispaniolan gracile anole

9 **Synonymous scientific names:** *Anolis distichoides*, *Anolis dominicensis*

10 **Adult description:** smaller scales than other lizards; granular, double row of unkeeled scales on the
11 back; blunter head; protruding eyes; dark crossbar between the eyes and four dark Vs on the back;
12 yellowish dewlap; snout-vent length about 40 mm (1.6 in); tail somewhat longer.

13 **Reproduction:** no information found in the literature

14 **Habitat:** shaded, covered areas; forests; trunk ecomorph (middle of tree trunks); uses steep, long
15 perches

16 **Human health impacts:** none found in the literature, but undocumented impacts may exist

17 **Economic impacts:** none found in the literature, but undocumented impacts may exist

18 **Ecological impacts:** competition with native anoles

19 **Pathways:** cargo, intentional, nursery

20 **Control measures:** no information found in the literature

21 **References:** Stevenson 1976; Williams and Case 1986; Lever 2003; Mattingly and Jayne 2004; Kraus
22 2009; Uetz 2010

23 **A8.4.5 *Anolis extremus***

24 **Common names:** Barbados anole

25 **Synonymous scientific names:** *Anolis roquet*

26 **Adult description:** males can reach 83 mm (3.3 in) snout-vent length and females can reach 60 mm (2.4
27 in) snout-vent length. females are smaller and less colorful than males. Olive-brown to olive-green in

1 color, and patterned with dark blotches and light spots; greenest on the sides and posterior dorsum. The
2 venter is a sunny yellow, and the head is gray to gray-brown.

3 **Reproduction:** no information found in the literature

4 **Habitat:** closed areas; edges; inhabits darker, more shaded places in patchy habitats. Trunk-ground
5 species; residential areas with plant cover (such as ornamental palms and citrus trees)

6 **Human health impacts:** none found in the literature, but undocumented impacts may exist

7 **Economic impacts:** none found in the literature, but undocumented impacts may exist

8 **Ecological impacts:** may displace native anoles

9 **Pathways:** cargo, pet trade, research

10 **Control measures:** no information found in the literature

11 **References:** Schoener 1970; Bartlett and Bartlett 1999; Kraus 2009; Uetz 2010

12 **A8.4.6 *Anolis porcatius***

13 **Common names:** Cuban green anole

14 **Synonymous scientific names:** *Anolis principalis*

15 **Adult description:** not found

16 **Reproduction:** reproductive seasonality; reproduce during rainy season; oviductal eggs form in April;
17 ovulation occurs April to October; clutch size of one egg;

18 **Habitat:** uses the trunk and canopy of trees from 1 to 6 m (3.3 to 19.7 feet) above the ground; Low
19 density suburban development, areas peripheral to core urban areas, and small towns

20 **Human health impacts:** none found in the literature, but undocumented impacts may exist

21 **Economic impacts:** none found in the literature, but undocumented impacts may exist

22 **Ecological impacts:** possible competition with other anoles

23 **Pathways:** cargo

24 **Control measures:** no information found in the literature

25 **References:** Ochotorena et al. 2005; Kraus 2009; FFWCC 2010a; Uetz 2010

26 **A8.4.7 *Anolis sagrei*:** established in Hawai'i

27 **Common names:** brown anole, Cuban brown anole

1 **Synonymous scientific names:** *Norops sagrei*

2 **Adult description:** males can reach up to 64 mm (2.5 in) weighing 6 to 8g (0.2 to 0.3 oz); females only
3 reach up to 48 mm (1.9 in) weighing 3 to 4g (0.1 oz). Brown in color; males have bands of light yellow
4 spots and are dorsally dark. Males erect a nuchal, vertebral, and anterior caudal ridge. Females and
5 juveniles have a dark, scalloped-edged, light vertebral stripe; laterally compressed, keeled tail; orange
6 dewlap; snout-vent length 50 mm (2 in), but tail longer.

7 **Reproduction:** breed during the summer; becomes sexually active and establishes territories in March
8 or April, and defends territories through August or September. Females lay eggs singly on an
9 approximately weekly basis for the entire summer by alternating the use of their left and right ovaries.

10 **Habitat:** habitat generalist—likes disturbed habitats; forms territory among shrubs, vines, fences and
11 trees; terrestrial inhabiting open vegetation as well as moist forested areas; can also occupy the higher
12 niches in trees. Prefers semi-tropical environment

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** reduction of spider populations, competition with native anoles, predation of native
16 anoles and lizards

17 **Pathways:** cargo, intentional, nursery trade, pet trade, ship, vehicle

18 **Control measures:** no information found in the literature

19 **References:** Stevenson 1976; Spiller and Schoener 1988; Lee et al. 1989; Spiller and Schoener 1990,
20 1994; Bartlett and Bartlett 1999; Gerber and Echternacht 2000; Campbell 2001; Greene et al. 2002;
21 Wardle 2002; Lever 2003; Varnham 2006; Masterson 2007; Huang et al. 2008; Huang et al. 2009a; Kraus
22 2009; ISSG 2010

23 **A8.4.8 *Boa constrictor***

24 **Common names:** boa, boa constrictor

25 **Synonymous scientific names:** *Boa constrictor constrictor*, *Boa diviniloqua*, *Boa diviniloquax*, *Boa*
26 *orophias*, *Boa ortonii*, *Constrictor auspex*, *Constrictor diviniloquus*, *Constrictor formosissimus*, *Constrictor*
27 *occidentalis*, *Constrictor rex serpentum*, *Epicrates sabogae*, *Euncetes murinus*

28 **Adult description:** no labial pits, a dark brown middorsal stripe running from the snout onto the neck,
29 head surface covered by small smooth scales, the dorsal scales small and smooth, and the subcaudals
30 single. Can reach 4.5 m (14.8 feet) in length with females being larger than males; head distinct from
31 neck; body somewhat compressed, stout; tail short and prehensile; eye small, with vertically elliptical
32 pupil; 2 or 3 nasal scales; no distinct loreal; no enlarged chin shields, distinct mental groove bordered by
33 small scales; pelvic spurs visible. Ground color light brown to gray; head usually with a median elongate
34 dark mark, sometimes bifurcate posteriorly or forming cross between eyes; side of head usually with a

1 distinct downward-slanting dark postorbital stripe that is continuous through eye with a distinct broad
2 dark brown blotch that extends from lip nearly to nostril; usually a narrow vertical dark brown bar below
3 eye; dorsum with 22 to 35 dark brown or black dorsal blotches and similarly colored smaller lateral
4 blotches; dorsal blotches usually with an elongate cream or yellow spot laterally and frequently
5 vertebrally; lateral blotches usually with light centers; dorsal blotches frequently fusing to create a chain
6 of dark figures surrounding a series of oval light areas on middle of back at least anteriorly; tail usually
7 banded with black, yellowish, and red; venter gray with paired lateral dark spots; subcaudal area with a
8 series of median black spots; iris beige, transected by a narrow dark brown horizontal bar.

9 **Reproduction:** boas at higher latitudes tend to breed in the cool season and give birth in the warm
10 season, but seasonality in precipitation may be more important in low-latitude areas; reproductive
11 seasonality is incredibly variable; extended gestational durations mean that an entire reproductive cycle
12 may take at least a year for females, considering follicular growth, mating, ovulation, gestation, and
13 parturition. Copulation is rarely observed in the field, and it is difficult to tell whether groups of boas
14 constitute mating aggregations; Reproduction occurs in winter and is synchronized, resulting in mid-
15 spring ovulation. Although based on a small number of neonates, parturition is inferred to be at the end
16 of the wet season (February to March) extends this period through April. Litter sizes vary from 20 to 64.

17 **Habitat:** habitat generalist; occurs in agricultural areas, desert, natural forests, planted forests,
18 range/grasslands, ruderal/disturbed, scrub/shrublands, urban areas

19 **Human health impacts:** may attack small children

20 **Economic impacts:** predation of pets and small animals; carriers of ticks that may impact livestock

21 **Ecological impacts:** predation of native fauna; competition with native reptiles; non-native boas may
22 transmit foreign pathogens to U.S. populations of squamate reptiles

23 **Pathways:** cargo, escape, intentional, pet trade

24 **Control measures:** Capture and euthanasia

25 **References:** Martínez-Morales and Cuarón 1999; BurrIDGE et al. 2000; Savage 2002; BurrIDGE and
26 Simmons 2003; Cuarón et al. 2004; Quick et al. 2005; Reed 2005; Romero-Nájera et al. 2007; Kraus 2009;
27 Reed and Rodda 2009; ISSG 2010; Uetz 2010

28 **A8.4.9 *Boiga irregularis*:** established on Guam

29 **Common names:** brown catsnake, brown treesnake, catsnake, mangrove snake

30 **Synonymous scientific names:** *Boiga flavescens*, *Coluber irregularis*, *Dendrophis (Ahetula) fusca*,
31 *Dipsadomorphus irregularis*, *Dipsas boydii*, *Dipsas irregularis*, *Dipsas ornate*, *Hurria pseudoboiga*,
32 *Pappophis flavigastra*, *Pappophis laticeps*, *Triglyphodon flavescens*, *Triglyphodon irregular*

33 **Adult description:** nocturnal, opisthoglyphic, euryphagic; slender; vertical elliptical pupils; set in large
34 eyes; short, blunt heads that are noticeably larger than their necks; arboreal; markings range from vague

1 to distinct dark blotches on a background of brown to yellow. Slender tail that average 21% of their total
2 length; slightly venomous

3 **Reproduction:** Oviparous; Reproduction occurs during the wetter, warmer months which could be any
4 time of year in Guam. Gravid females are less active or more secretive; courtship includes male
5 mounting female, rubbing her body with his chin, and progressing in a jerky motion toward her head
6 while attempting to lift her tail with his tail. Females have ability to store sperm over extended periods
7 of time. Females lay eggs in holes and crevices or underground; clutch sizes are 4 to 12 eggs

8 **Habitat:** habitat generalist; habitat includes: agricultural areas, coastland, natural forests, planted
9 forests, range/grasslands, riparian zones, ruderal/disturbed, scrub/shrublands, urban areas, and
10 wetlands.

11 **Human health impacts:** envenomation of humans; increased insect populations carrying diseases

12 **Economic impacts:** power outages; loss of tourism; preys on poultry

13 **Ecological impacts:** reduction in native biodiversity

14 **Pathways:** aircraft stowaway, cargo, military exercises, natural dispersal, pet trade, seafreight
15 (container/bulk), translocation of machinery, vehicles

16 **Control measures:** fence barriers, electric barriers, fence line searches, traps, detector dogs, methyl
17 bromide, acetaminophen, reduction of prey base

18 **References:** Savidge 1987; Fritts et al. 1990; Fritts and McCoid 1991; Rodda and Fritts 1992; Rodda et al.

26 **A8.4.10 *Calotes versicolor*:** a single individual has been removed from the wild on Saipan in the CNMI
27 (Stanford, personal communication) and it is established in multiple locations with SE Asia and on the
28 island of Diego Garcia.

29 **Common names:** bloodsucker lizard, changeable lizard, crested tree lizard, Eastern garden lizard, garden
30 lizard, Indian tree lizard, Oriental garden lizard

31 **Synonymous scientific names:** *Agama tiedemanni*, *Agama versicolor*, *Agama vultuosa*, *Calotes cristatus*,
32 *Calotes gigas*, *Calotes viridis*

33 **Adult description:** about 284 to 378 mm (11 to 15 in) in total length, snout-vent length 81 to 140 mm
34 (3.2 to 5.5 in), tail length 203 to 295 mm (8 to 11.6 in); large and shoulder, expandable dewlaps, and a

1 slender tail; body compressed laterally; males have a conspicuous dorsal crest; 35 to 52 scales over the
2 body; lateral scales point backwards and upwards; two spines above the tympanum; lacks an oblique
3 fold; lacks a pit anterior to the shoulder; coloration dull brown, gray, or olive with various brown spots
4 or bars; males have a pale yellow body with black throat patches and crimson areas on the anterior
5 during breeding

6 **Reproduction:** oviparous; lays eggs late May to October; 1 to 23 eggs per clutch, may have multiple
7 clutches per year; elliptical, white eggs; eggs average 10-13 x 4-10 mm (0.4-0.5 x 0.2-0.4 in) and increase
8 in size after being laid; hatch in 40 to 47 days; lacks an egg-tooth; precocial; hatchlings 22 to 27 mm (0.9
9 to 1 in) in length; under unfavorable conditions, females are able to retain eggs over 6 months by
10 arresting embryo development

11 **Habitat:** common in human-inhabited areas, including parks, gardens, agricultural areas, waste lands,
12 open forests; near water sources; bask on vegetation and roost in shrubs or trees

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** displaces native lizard and skink species

16 **Pathways:** biocontrol, cargo, intentional, nursery trade, pet trade

17 **Control measures:** no information found in the literature

18 **References:** Pandha and Thapliyal 1967; Erdelen 1984; Lever 2003; Enge and Krysko 2004; Kraus 2009;
19 Uetz 2010

20 **A8.4.11 *Carlia ailanpalai*:** established on Guam, Rota, and several islands in the FSM

21 **Common names:** curious skink

22 **Synonymous scientific names:** *Carlia fusca*, *Carlia fuscum*

23 **Adult description:** 32 to 66 mm (1.3 to 2.6 in) snout vent length; dorsum and sides mostly brown, but
24 occasionally have a few white, single-scaled spots or narrow brown lines; dorsolateral white stripe, if
25 present, is faded and confined largely to the neck and axilla; lateral brown band similarly uncommon,
26 faded, and darkest on neck to axilla; midlateral stripe absent; venter cream to ivory

27 **Reproduction:** no information found on wild populations

28 **Habitat:** open, grassy ruderal habitats

29 **Human health impacts:** none found in the literature, but undocumented impacts may exist

30 **Economic impacts:** none found in the literature, but undocumented impacts may exist

31 **Ecological impacts:** serves as a prey source for BTS; competes with native lizards

1 **Pathways:** ecosystem disturbance

2 **Control measures:**

3 **References:** Case and Bolger 1991; Rodda et al. 1991; Rodda and Fritts 1992; Fritts and Rodda 1998;
4 Rodda et al. 1999a; Rodda et al. 1999b; Lever 2003; Zug 2004; Bomford et al. 2005; Pitt et al. 2005;
5 Buden 2009; Kraus 2009

6 **A8.4.12 *Chondrodactylus bibronii***

7 **Common names:** Bibron's gecko, Bibron's thick-toed gecko, cape button-scaled gecko

8 **Synonymous scientific names:** *Pachydactylus bibronii*, *Tarentola bibronii*

9 **Adult description:** 140 to 200 mm (5.5 to 7.9 in) in total length, snout-vent length 75 to 100 mm (3 to 4
10 in), tail roughly the same length as the body; large head and stout body; covered with tough tubercles;
11 segmented body with even, keeled scales; enlarged toe pads with 10 to 12 transverse lamellae under
12 the middle toes; ventral scales do not overlap; lacks loose skin flaps; coloration tan to brown to gray
13 with irregular dark bars and white spots; 8 to 10 white bands on the tail of juveniles; white venter

14 **Reproduction:** breeds in spring; lays pairs of eggs; two clutches per female per year; hatch in late
15 summer; hatchlings 63 mm in length

16 **Habitat:** arid climates, agricultural areas; terrestrial, among rocks, vertical surfaces

17 **Human health impacts:** none found in the literature, but undocumented impacts may exist

18 **Economic impacts:** urine and feces in structures

19 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

20 **Pathways:** cargo, intentional, pet trade

21 **Control measures:** no information found in the literature

22 **References:** Griffin 2002; Cape Nature 2007; Kraus 2009; GeckoWeb 2010; Uetz 2010

23 **A8.4.13 *Cnemidophorus lemniscatus***

24 **Common names:** rainbow lizard, rainbow whiptail, tropical racerunner

25 **Synonymous scientific names:** *Cnemidophorus cryptus*, *Cnemidophorus gramivagus*, *Cnemidophorus*
26 *picturatus*, *Cnemidophorus pseudolemniscatus*, *Cnemidophorus sctitata*, *Lacerta lemniscata*

27 **Adult description:** snout-vent length 35 to 90 mm (1.4 to 3.5 in), tail length 136 to 175 mm (5.4 to 6.9
28 in), weight 4 to 10 g (0.1 to 0.4 oz); males larger; females with 9 dorsal stripes which may diffuse into
29 spots; males with 3 dorsal stripes, rows of dorsolateral white and yellow spots, sides with areas of
30 green, yellow, and gray, sides and bottom of head blue with white spots, and venter a combination of
31 ivory, blue, and green with spots

1 **Reproduction:** bisexual and parthenogenetic populations; breeds during the wet season, August-
2 September in Amazonia; possibly multiple clutches per female; lays 1 to 4 eggs per clutch; snout-vent
3 length 26 to 45 mm (1 to 1.7 in), and weight 0.9 g (0.03 oz) at hatching; white to pale yellowish dorsal
4 stripes on a dark background; light brown venter; stripe down the dorsal midline; dark hind legs with
5 spots

6 **Habitat:** coastal scrub, beach strand, savannah, grasslands, forest edges, and human-inhabited areas,
7 including suburban/urban areas; near water; on the ground or in perches

8 **Human health impacts:** none found in the literature, but undocumented impacts may exist

9 **Economic impacts:** none found in the literature, but undocumented impacts may exist

10 **Ecological impacts:** competition with native lizards

11 **Pathways:** cargo, pet trade, intentional

12 **Control measures:** no information found in the literature

13 **References:** Serena 1984; Vitt et al. 1997; Lever 2003 Mesquita and Colli 2003; van Buurt 2006;
14 Montgomery et al. 2007; Kraus 2009; Uetz 2010

15 **A8.4.14 *Cryptoblepharus carnabyi***

16 **Common names:** Carnaby's wallskink, spiny-palmed snake-eyed skink

17 **Synonymous scientific names:** *Cryptoblepharus plagiocephalus*

18 **Adult description:** information not found

19 **Reproduction:** information not found

20 **Habitat:** open forests with or without a dense understory, rocky outcrops; utilizes tree hollows; avoids
21 grazed areas; will utilize restored habitats

22 **Human health impacts:** none found in the literature, but undocumented impacts may exist

23 **Economic impacts:** none found in the literature, but undocumented impacts may exist

24 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

25 **Pathways:** cargo

26 **Control measures:** no information found in the literature

27 **References:** Asher and Bell 1998; Gibbons and Lindenmayer 2002; Cunningham et al. 2007; Kraus 2009;
28 Michael et al. 2010; UniProt 2010b

1 **A8.4.15 *Cryptoblepharus poecilopleurus***

2 **Common names:** mottled snake-eyed skink, snake-eyed skink

3 **Synonymous scientific names:** *Ablepharus boutonii poecilopleurus*, *Ablepharus heterurus*, *Ablepharus*
4 *poecilopleurus*, *Cryptoblepharus boutoni*

5 **Adult description:** 46 to 48 mm (1.8 in) in length, weight 1.2 to 1.5 g (0.05 oz); stationary, transparent
6 scale over the eye and lower eyelid unable to close; small eye surrounded by small scales; front- and
7 interparietal shields usually fused into diamond shape; large, shiny scales; coloration olive; indistinct
8 white stripe along each side of the back bordered with brown splotches; all dorsal surfaces with small
9 brown and white spots; whitish venter

10 **Reproduction:** information not found

11 **Habitat:** open, disturbed, grassy woodlands, rocky areas; near coasts

12 **Human health impacts:** none found in the literature, but undocumented impacts may exist

13 **Economic impacts:** none found in the literature, but undocumented impacts may exist

14 **Ecological impacts:** significant prey source for BTS

15 **Pathways:** boat, cargo, possibly natural colonization

16 **Control measures:** no information found in the literature

17 **References:** Garman 1901; Crombie and Steadman 1986; Gill 1993; Fritts and Rodda 1998; Lever 2003;
18 USGS 2005c; McCoy 2006; Kraus 2009; Uetz 2010

19 **A8.4.16 *Cryptoblepharus plagiocephalus***

20 **Common names:** Callose-palmed shinning-skink, Peron's snake-eyed skink

21 **Synonymous scientific names:** *Ablepharus boutonii punctatus*, *Ablepharus boutonii plagiocephalus*,
22 *Ablepharus peronii*, *Cryptoblepharus burtonii*, *Cryptoblepharus carnabyi*, *Scincus plagiocephalus*

23 **Adult description:** snout-vent length 30 to 55 mm (1.1 to 2.2 in); shallow head and short legs;
24 stationary, transparent scale over the eye; ear opening present; pale, acute plantar scales; coloration
25 grayish to dark brown with irregular stripes

26 **Reproduction:** reproduces year-round with a peak September-January; eggs 13 x 5 mm (0.5 x 0.2 in); 2
27 eggs per clutch

28 **Habitat:** open woodlands; arboreal, utilizes tree hollows; inhabit diverse environments

29 **Human health impacts:** none found in the literature, but undocumented impacts may exist

30 **Economic impacts:** none found in the literature, but undocumented impacts may exist

1 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

2 **Pathways:** cargo

3 **Control measures:** no information found in the literature

4 **References:** Davidge 1980; James and Shine 1985; Gibbons and Lindenmayer 2002; Sullivan 2005; Kraus
5 2009 JCU 2010a Uetz 2010)

6 **A8.4.17 *Cryptoblepharus virgatus***

7 **Common names:** cream-striped shinning-skink, fence skink, wall skink

8 **Synonymous scientific names:** *Ablepharus boutoni pulcher*, *Ablepharus boutoni virgatus*, *Ablepharus*
9 *boutonii clarus*, *Ablepharus virgatus*

10 **Adult description:** snout-vent length less than 40 mm (1.6 in), tail equally long; blunt snout; granules
11 partially surround the eye; small ear opening; rounded, pale plantar scales; smooth lamellae beneath
12 the digits; 22 rows of smooth or slightly keeled scales on the body; coloration gray to yellowish brown;
13 sides of head brown; brown marking down the dorsal midline; smooth, narrow brown longitudinal
14 stripes; small brown and white spots on flanks and toes; white venter

15 **Reproduction:** breeds August-January or year-round, depending on latitude

16 **Habitat:** woodland, saltmarshes, shrublands, habitat edges, and human inhabited areas, including
17 agricultural and urban areas; arboreal, utilizes tree hollows

18 **Human health impacts:** none found in the literature, but undocumented impacts may exist

19 **Economic impacts:** none found in the literature, but undocumented impacts may exist

20 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

21 **Pathways:** cargo, railways

22 **Control measures:** no information found in the literature

23 **References:** Garman 1901; Clerke and Alford 1993; Gill et al. 2001; Anderson and Burgin 2002; Gibbons
24 and Lindenmayer 2002; Garden et al. 2007 JCU 2007; Kraus 2009; Spencer et al. 2009; Macdonald 2010;
25 Uetz 2010

26 **A8.4.18 *Cyrtopodion scabrum***

27 **Common names:** rougtail gecko, rough-tailed gecko

28 **Synonymous scientific names:** *Cyrtodactylus basoglui*, *Cyrtodactylus scaber*, *Cyrtopodion scaber*,
29 *Gymnodactylus scaber*, *Stenodactylus scaber*, *Tenuidactylus scaber*

1 **Adult description:** rather prickly looking lizard. Rows of prominent pointed keeled scales covering the
2 tail, along with enlarged warty tubercles on the body. A medium-sized gecko, 7.5 to 11.7 cm (3 to 4.6 in)
3 with enlarged toe pads and immovable eyelids, it is sand colored above with small dark brown spots.
4 The tail has dark rings. Nocturnal.

5 **Reproduction:** no information found in the literature

6 **Habitat:** in and around buildings, where it feeds on insects and other arthropods

7 **Human health impacts:** none found in the literature, but undocumented impacts may exist

8 **Economic impacts:** none found in the literature, but undocumented impacts may exist

9 **Ecological impacts:** displaces Mediterranean gecko (another invasive)

10 **Pathways:** cargo

11 **Control measures:** no information found in the literature

12 **References:** Kraus 2009; GeckoWeb 2010; Uetz 2010

13 **A8.4.19 *Diadophis punctatus***

14 **Common names:** ring-necked snake, southern ring-necked snake

15 **Synonymous scientific names:** *Ablabes punctatus*, *Calamaria punctata*, *Coluber punctatus*, *Homalosoma*
16 *punctata*, *Natrix punctatus*

17 **Adult description:** small; greenish-gray or blackish dorsal coloration, yellow to reddish ventrally, yellow
18 color extending dorsally to form a ring around the neck, sometimes interrupted middorsally; maximum
19 length about 38 cm (15 in). Some may have spots on venter; 13 to 17 anterior rows of body scales, 14 to
20 17 rows at mid-body and 13 to 15 rows anterior to anal vent; scales are smooth but with an apical pit;
21 anal plate is divided. Each maxillary has 12 to 21 teeth; those anterior are slender and erect, the 2 most
22 posterior teeth are longer, thicker and directed backward, and separated from the anterior teeth by a
23 diastema. Males have ridges on the body scales near anal vent.

24 **Reproduction:** females mature by 2nd spring; ovulation occurs in June; reproduce annually; oviparous;
25 embryos are somewhat more advanced than other oviparous snakes; aggregations occur in the spring
26 and fall and mating may occur during these times also; egg laying occurs in June or July; nesting sites are
27 under rocks, leafpiles, or fallen bark, in rotting logs and stumps, sawdust piles, or in the walls of animal
28 burrows. 2 to 10 eggs are laid in one clutch (average 3 to 4); larger females lay more eggs; eggs are
29 white, rough, leathery and elongate; hatching occurs in late August or September after an incubation
30 period of 46 to 60 days; hatching process takes several hours.

31 **Habitat:** woodlands; shrublands; meadows; prairies; hides in rocks, logs, stumps, fallen bark or human
32 debris; moist habitats

- 1 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 2 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 4 **Pathways:** cargo, nursery trade
- 5 **Control measures:** no information found in the literature
- 6 **References:** Stevenson 1976; Ernst and Barbour 1989; Kraus 2009; FMNH 2010b
- 7 **A8.4.20 *Dinodon rufozonatum***
- 8 **Common names:** red banded snake
- 9 **Synonymous scientific names:** *Coronella striata*, *Dinodon cancellatum*, *Dinodon rufozonatus*,
10 *Eumesodon striatus*, *Lycodon rufo*, *Lycodon rufozonatus*
- 11 **Adult description:** 800 mm (31 in) in length; nocturnal
- 12 **Reproduction:** no information found in the literature
- 13 **Habitat:** widely distributed from the periphery of croplands to forest
- 14 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 15 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 16 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 17 **Pathways:** unknown
- 18 **Control measures:** no information found in the literature
- 19 **References:** Atsuo 2004; Uetz 2010
- 20 **A8.4.21 *Elaphe carinata***
- 21 **Common names:** Chinese king ratsnake, keeled ratsnake, king ratsnake, Taiwan stink snake, stinking
22 goddess
- 23 **Synonymous scientific names:** *Coluber camillo*, *Coluber phyllophis*, *Elaphe osborni*, *Phyllophis carinata*,
24 *Spaniopholis kreyenbergi*, *Spaniopholis Souliei*
- 25 **Adult description:** large, impressive, heavy-bodied constrictor; habit of eating other snakes; heavily
26 keeled scales that give the skin a rough texture; distinctive habit of releasing a strong, offensive odor
27 from post-anal glands when handled or otherwise threatened; undergoes a rather radical color
28 transformation from relatively non-descript tan-colored juveniles into dark brown or black adults with a
29 striking pattern of bright yellow highlights; tear-drop shaped pupil; can reach 240 cm (94 in) in length.

1 **Reproduction:** Mating usually occurs in spring, with 6 to 12 eggs being laid in early to mid-summer; 40
2 to 60 days incubation before hatching

3 **Habitat:** terrestrial; known to inhabit open forests, fields, meadows and bamboo thickets, although it
4 has also been collected near houses

5 **Human health impacts:** none found in the literature, but undocumented impacts may exist

6 **Economic impacts:** none found in the literature, but undocumented impacts may exist

7 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

8 **Pathways:** pet trade

9 **Control measures:** no information found in the literature

10 **References:** Arkive 2010; Uetz 2010

11 **A8.4.22 *Elaphe guttata***

12 **Common names:** chicken snake, corn snake, red corn snake, red rat snake

13 **Synonymous scientific names:** *Collopeltis guttatus*, *Coluber carolinianus*, *Coluber compressus*, *Coluber*
14 *floridanus*, *Coluber guttatus*, *Coluber guttatus guttatus*, *Coluber guttatus sellatus*, *Coluber laetus*,
15 *Coluber maculates*, *Coluber molossus*, *Coluber pantherinus*, *Coluber rosaceus*, *Coryphodon pantherinus*,
16 *Elaphe emoryi intermontana*, *Elaphe guttata guttata*, *Elaphe guttata rosacea*, *Elaphe laeta*, *Elaphe*
17 *rosacea*, *Elaphe rosaliae*, *Elaphis alleghanensis*, *Elaphis guttatus*, *Natrix guttatus*, *Natrix maculatus*,
18 *Natrix pantherinus*, *Pantherophis guttata*, *Pantherophis guttatus*, *Pituophis guttatus*, *Scotophis guttatus*,
19 *Scotophis laetus*

20 **Adult description:** gray with black-bordered orange or red dorsal blotches and spots, black spots on the
21 lips, and large black squared-blotches on a white venter. A prominent black-bordered, spear-shaped
22 blotch extends forward from neck between eyes, and another black-bordered stripe extends back-ward
23 from the eye past the corner of the mouth and onto the neck. Underside of tail is dark striped; pitted
24 body scales are keeled and occur in 25 rows anteriorly, 27 at mid-body, and 19 at the anal vent; divided
25 anal plate; no sexual dimorphism; 9 to 12 smooth, equal-sized teeth on each maxilla; nocturnal.

26 **Reproduction:** females reach sexual maturity at 16 to 18 months, males at 18 months; mating occurs
27 from March to May; ovulation occurs in late May; gestation period between copulation and oviposition
28 is 35 to 68 days; eggs are laid in late May or June; nest sites are in mammal burrows, sawdust piles, and
29 rotting stumps and logs; eggs are white and elongated and tough; clutch size ranges from 3 to 30 eggs
30 (average of 10 to 15 eggs). Incubation is 51 to 58 days; hatching occurs July to early September. Females
31 can lay one or two clutches per year.

32 **Habitat:** brush fields, pine barrens, open deciduous woodlands, canyons, rocky ledges, caves, around
33 trash dumps and old buildings; often in trees or bushes; occasionally swimming across small streams;

1 swamps; agricultural fields; residential areas; pinelands; hardwood hammocks; man-made structures
2 such as erosion control rocks

3 **Human health impacts:** none found in the literature, but undocumented impacts may exist

4 **Economic impacts:** none found in the literature, but undocumented impacts may exist

5 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

6 **Pathways:** cargo, nursery trade (such as in the root ball of plants), pet trade

7 **Control measures:** no information found in the literature

8 **References:** Ernst and Barbour 1989; Lever 2003; Henderson 2004; Sperry and Taylor 2008; Kraus 2009;
9 FMNH 2010a

10 **A8.4.23 *Elaphe taeniura friesi***

11 **Common names:** beauty snake, Taiwan beauty snake

12 **Synonymous scientific names:** *Coluber taeniurus*, *Coluber taeniurus var. friesei*, *Coluber schmackeri*,
13 *Elaphe schmackeri*, *Elaphe taeniura*, *Elaphe taeniura friesi*, *Elaphe taeniura grabowskyi*, *Elaphe taeniura*
14 *mocquardi*, *Elaphe taeniura ridleyi*, *Elaphe taeniura schmackeri*, *Elaphe taeniura yunnanensis*, *Elaphe*
15 *taeniura vaillanti*, *Elaphe taeniurus*, *Elaphis grabowskyi*, *Elaphis taeniurus*, *Elaphis yunnanensis*,
16 *Orthriophis taeniurus*, *Orthriophis taeniurus friesi*, *Orthriophis taeniurus ridleyi*, *Orthriophis taeniurus*
17 *yunnanensis*

18 **Adult description:** variable in color, but usually has light and dark shades of brown and yellow; the
19 anterior part of the snake has a pattern of splotches and banding; the tail is just striped.

20 **Reproduction:** oviparous; Eggs: 4 to 5

21 **Habitat:** forests

22 **Human health impacts:** none found in the literature, but undocumented impacts may exist

23 **Economic impacts:** none found in the literature, but undocumented impacts may exist

24 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

25 **Pathways:** cargo, pet trade

26 **Control measures:** no information found in the literature

27 **References:** Kraus 2009; Oakland Zoo 2010; Uetz 2010

28 **A8.4.24 *Elgaria multicarinata***

29 **Common names:** southern alligator lizard

1 **Synonymous scientific names:** *Gerrhonotus multicoloratus*

2 **Adult description:** Adult length up to 53 cm (21 in); half of total length is its long, slim tail; small legs
3 when compared to body size; light or medium brown to yellow ochre in color with variable cross-bars on
4 the back and some black and white spots along the sides; have a fold of skin along the lower sides where
5 the scales of the belly meet the scales of the back; faint, thin black stripes on belly that run through the
6 middle of each scale row; scales on the back are large with very distinct keeling; skin texture appears
7 rough; have large, triangular-shaped heads (more pronounced in males).

8 **Reproduction:** oviparous; mate in May; up to 20 eggs laid in June or July.

9 **Habitat:** habitat generalist, dry, open woodlands of ponderosa pine and oak; often found among rocks,
10 and the leaf litter of oaks, wild grapes, other vines, and poison oak; frequently found in coastal plains as
11 well as in mountainous regions up to 2,286 m (7,500 feet) in elevation; adapted to living in urban
12 habitat; often seen in yards, gardens, in garages, and under piles of wood, rocks, and debris

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

16 **Pathways:** cargo, possibly in aircraft

17 **Control measures:** no information found in the literature

18 **References:** Mahoney et al. 2003; BMNHC 2006; Kraus 2009

19 **A8.4.25 *Emoia cyanura***

20 **Common names:** azure-tailed skink, bluetail emo skink, copper-tailed skink, white-bellied skink

21 **Synonymous scientific names:** *Emoia pheonura*, *Eumeces lessonii*, *Eusoma lessonii*, *Lygosoma arundelii*,
22 *Lygosoma cyanurum*, *Lygosoma cyanurum schauinslandi*, *Lygosoma impar*, *Scincus cyanurus*, *Tiliqua*
23 *kienerii*, *Tiliqua lessonii*

24 **Adult description:** small, striped skink; has 65 to 70 scales on the underside of the fourth toe. When
25 compared to *Emoia caeruleocauda*, the bluetail emo skink has a vertebral stripe that is wider on the
26 head and the stripes are whiter. Also, there is a pineal eye spot that is visible in the middle of the head
27 behind the eyes. The scales of the vertebral stripe are unfused which means that median scales are not
28 present. The belly and underside of the thighs are white. The tail will never be a bright blue color;
29 instead it is a pale blue-green. The belly will also never be bright green.

30 **Reproduction:** no information found

31 **Habitat:** forest, grassy and rocky areas near seashore, and gardens. In areas where it exists with *Emoia*
32 *caeruleocauda*, the bluetail emo skink can usually be found living at the forest edge and not in the

1 interior. On the islands in American Samoa it occurs in most habitats, but is less abundant in dense
2 forest at higher elevations

3 **Human health impacts:** none found in the literature, but undocumented impacts may exist

4 **Economic impacts:** none found in the literature, but undocumented impacts may exist

5 **Ecological impacts:** may be contributing to the naturalization of species that prey on it

6 **Pathways:** cargo, personal effects

7 **Control measures:** no information found in the literature

8 **References:** Gill 1993; Schwaner and Ineich 1998; Lever 2003; USGS 2005c Kraus 2009; Uetz 2010;
9 UniProt 2010a

10 **A8.4.26 *Eulamprus tenuis***

11 **Common names:** bar-sided forest skink, bar-sided skink, barred-sided skink

12 **Synonymous scientific names:** *Lygosoma erucata*, *Lygosoma (Sphenomorphus) tenue*, *Lygosoma tenue*,
13 *Sphenomorphus tenuis*, *Tiliqua tenuis*

14 **Adult description:** no information found

15 **Reproduction:** no information found

16 **Habitat:** open habitat, disturbed areas, areas with open canopies, and wet habitats like rainforests and
17 wet sclerophyll forests. They are arboreal.

18 **Human health impacts:** none found in the literature, but undocumented impacts may exist

19 **Economic impacts:** none found in the literature, but undocumented impacts may exist

20 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

21 **Pathways:** cargo

22 **Control measures:** no information found in the literature

23 **References:** Kraus 2009; Uetz 2010

24 **A8.4.27 *Gehyra mutilata*:** established on numerous islands within Micronesia and the broader Pacific
25 region

26 **Common names:** common four-clawed gecko, mutilating gecko, stump-toed gecko

27 **Synonymous scientific names:** *Dactyloperus insulensis*, *Gecko pardus*, *Gehyra beebei*, *Gehyra harrieti*,
28 *Gehyra insulanus*, *Gehyra insulensis*, *Gehyra mugtilata (sic)*, *Gehyra mutilate*, *Gehyra packardii*,
29 *Hemidactylus mutilates*, *Hemidactylus navarii*, *Hemidactylus navarri*, *Hemidactylus Peronii*, *Hemidactylus*

1 (*Peropus*) *mutilates*, *Hemidactylus platurus*, *Hemidactylus pristiurus*, *Peripia mutilate*, *Peripia Peronii*,
2 *Peropus (Dactyloperus) Peronii*, *Peropus mutilates*, *Peropus multilatus (sic)*, *Peropus packardii*

3 **Adult description:** Total adult length is between 8.5 to 11.5 cm (3.4 to 4.5 in); absence or near-absence
4 of a claw on the inner digit of its fore and hind feet; stout body; row of enlarged scales running along the
5 underside of tail; during day they are gray to grayish brown in color, but fade to whitish when active at
6 night; head and body speckled with light and dark spots; very thin light lines ring the tail; dark-edged
7 light line runs through eyes; has a flattened tail that is constricted at the base so that it has a carrot-like
8 shape; skin is somewhat translucent.

9 **Reproduction:** females lay two round eggs that are adherent to each other and to the substrate.

10 **Habitat:** habitat generalist; may occur in natural forests, disturbed garden areas, and urban areas. They
11 are arboreal.

12 **Human health impacts:** none found in the literature, but undocumented impacts may exist

13 **Economic impacts:** none found in the literature, but undocumented impacts may exist

14 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

15 **Pathways:** cargo, pet trade, zoo trade

16 **Control measures:** no information found in the literature

17 **References:** Fisher 1997; Kraus 2009; Rocha et al. 2009; GeckoWeb 2010; Uetz 2010

18 **A8.4.28 Gekko gekko:** established in Hawai'i

19 **Common names:** Tokay gecko

20 **Synonymous scientific names:** *Gekko reevesii*, *Gekko verticillatus*, *Gekko aculeatus*, *Gekko annulatus*,
21 *Gekko guttatus*, *Gekko indicus*, *Gekko perlatus*, *Gekko tenuis*, *Gekko teres*, *Gekko verticillatus*, *Gekko*
22 *verus*, *Gymnodactylus tenuis*, *Lacerta gekko*, *Platydactylus guttatus*

23 **Adult description:** one of the largest gecko species in the world reaching nearly 305 mm (12 in) in
24 length. Orange and white markings against a gray or blue-gray ground color; upperparts ultramarine
25 with numerous spots of rusty red or orange; the protuberant eyes may vary from yellow-green to
26 orange. The pupils are complex and vertically elliptical; no eyelids; toe pads are large and easily visible.
27 Nocturnal; head relatively large and triangular; tail banded with dark pigment; total length up to 350
28 mm (13.8 in).

29 **Reproduction:** may lay several clutches annually; the young exceed 76 mm (3 in) at hatching; communal
30 nesting occurs; the hard-shelled, paired, adhesive-shelled eggs are deposited in secluded areas of
31 buildings, tree hollows, or other like spots; females lay pairs of eggs communally; as many as 140 eggs
32 have been found in one nest

- 1 **Habitat:** urban
- 2 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 4 **Ecological impacts:** preys upon native lizard and frog species
- 5 **Pathways:** biocontrol, cargo, intentional, pet trade
- 6 **Control measures:** no information found in the literature
- 7 **References:** Stevenson 1976; Meshaka Jr. et al. 1997; Bartlett and Bartlett 1999 Kraus 2009; GeckoWeb
8 2010; Uetz 2010
- 9 **A8.4.29 *Gekko hokouensis***
- 10 **Common names:** Kwangsi gecko
- 11 **Synonymous scientific names:** *Gekko japonicas*, *Gekko liboensis*, *Luperosaurus amissus*
- 12 **Adult description:** small; arboreal; insectivorous; nocturnal; possessing a single process in each side of
13 the base of tail, and limbs covered only with granular scales; has a single spur on each side of the base of
14 the tail; tubercles are absent on the four limbs, and relatively few around the middle of the body.
- 15 **Reproduction:** females have oviductal eggs in April and may have multiple clutches until the end of July,
16 when egg production ceases. This pattern of Reproduction differs from the continuous Reproduction
17 seen in tropical geckos, and is common to other subtropical and temperate geckos. Cessation of
18 ovulation during the late summer when temperature is still high may result from selection caused by the
19 low tolerance of developing embryos against lower temperature in autumn, as in a few other East Asian
20 geckos.
- 21 **Habitat:** montane environments
- 22 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 23 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 24 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 25 **Pathways:** nursery trade, cargo
- 26 **Control measures:** no information found in the literature
- 27 **References:** Zhou et al. 1982; Okada et al. 2002; Bauer and Baker 2008; Kraus 2009; Uetz 2010
- 28 **A8.4.30 *Gonatodes albogularis***
- 29 **Common names:** yellow-headed gecko

1 **Synonymous scientific names:** *Gonatodes fuscus*

2 **Adult description:** Has round pupils and lacks toe pads; very dimorphic, it is only the dark bodied males
3 (with a bluish sheen, especially at night) that have the yellow head and a dark shoulder spot sometimes
4 outlined with blue. The male's tail is yellow and if not regenerated, will have white tip. Coloration is
5 brightened during breeding season. Females are gray with a lighter collar; markings on body may have a
6 light crossbanded effect. Belly is usually light. Diurnal; snout-vent length is 38 mm (1.5 in) with tail about
7 the same length; head and body slightly depressed and limbs well developed; hind legs noticeably
8 stouter than the forelegs; very large eyes that lack lids.

9 **Reproduction:** lays a single egg at a time; each female can produce several eggs annually; incubation
10 lasts a little more than 2 months; eggs are large compared to the size of the animal; are white and
11 brittle; hatchlings are about 15 mm (0.6 in) long from snout to vent; may reproduce year-round, but
12 Reproduction decreases during the dry season

13 **Habitat:** inhabiting large-diameter, rough-barked, horizontal limbs; rock and rubble piles and behind
14 exfoliating tree bark; found inside and outside dwellings or other buildings; prefers dry microhabitats

15 **Human health impacts:** none found in the literature, but undocumented impacts may exist

16 **Economic impacts:** none found in the literature, but undocumented impacts may exist

17 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

18 **Pathways:** cargo, pet trade

19 **Control measures:** no information found in the literature

20 **References:** Smith 1946; Stevenson 1976; Bartlett and Bartlett 1999; Krysko 2005 Kraus 2009

21 **A8.4.31 *Hemidactylus frenatus*:** established on numerous islands in Micronesia as well as the broader
22 Pacific region

23 **Common names:** Common house gecko

24 **Synonymous scientific names:** *Hemidactylus mabouia*

25 **Adult description:** average length is 76 to 102 mm (3 to 4 in) and can reach 114 mm (4.5 in). Ashy gray
26 dorsal color with an irregular pattern of obscure darker pigment; lighter color at night; ventral surface is
27 nearly white; a gray lateral line may be present; scales are mostly smooth, and six rows of pronounced
28 spinous scales on tail.

29 **Reproduction:** eggs are only weakly adhesive and are usually placed in crevices or beneath loose ground
30 debris. Females produce several clutches are produced annually; communal nesting; 48-day incubation
31 period; 51 mm (2 in) long hatchlings.

32 **Habitat:** habitat generalist

- 1 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 2 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Ecological impacts:** competition with native geckos; has displaced to some extent the gecko species
- 4 *Nactus coindemirensis*; predation on native geckos; host of the pentasome parasites *Raillietiella frenatus*
- 5 and *Waddycephalus* species; carries the red gecko mite *Geckobia bataviensis*
- 6 **Pathways:** boat, cargo, intentional, natural dispersal, nursery trade, pet trade, seafreight
- 7 (container/bulk)
- 8 **Control Methods:** exclusion, euthanasia
- 9 **References:** Case and Bolger 1991; Case et al. 1994; Hanley et al. 1995 Petren and Case 1996 Canyon
- 10 and Hii 1997; Hanley et al. 1998; Bartlett and Bartlett 1999; Brown et al. 2002; Jones and Cole 2004;

- 14 **A8.4.32 Hemidactylus garnotii**
- 15 **Common names:** fox gecko, Garnot's house gecko, Indo-Pacific gecko
- 16 **Synonymous scientific names:** *Doryura garnotii*, *Doryura gaudama*, *Doryura vulpecula*, *Hemidactylus*
- 17 *blanfordii*, *Hemidactylus (Doryura) mandellianus*, *Hemidactylus garnetii*, *Hemidactylus guadama*,
- 18 *Hemidactylus ludekingii*, *Hemidactylus mortoni*, *Hemidactylus peruvianus*, *Hoplopodion (Microdactylus)*
- 19 *peruvianum*, *Hoplopodion (Onychopus) garnotii*, *Lepidodactylus garnotii*, *Nycteridium gaudama*
- 20 **Adult description:** small with a sharply denticulate lateral fringe on the strongly depressed tail and claws
- 21 on the inner fingers and toes; large divided digital pads and no retractile claws. All are females. 65 mm
- 22 (2.6 in); dorsum with small flat granular scales except along sides, where small tubercles present; two or
- 23 three pairs of large chin shields. Dorsum uniform grayish tan or marbled with darker brown, usually with
- 24 small whitish spots of various sizes and shapes; venter yellow, underside of tail pale red.
- 25 **Reproduction:** Parthenogenetic; motions of courtship are still indulged and may be necessary to
- 26 stimulate egg development. Several sets of two eggs are produced annually; breeds year-round in warm
- 27 areas; eggs are placed in crevices; incubation lasts for 7 weeks; hatchlings are 51 mm (2 in) long.
- 28 **Habitat:** buildings, trees, fences and similar structures
- 29 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 30 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 31 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 32 **Pathways:** cargo, intentional, nursery trade, zoo trade

1 **Control methods:** no information found in the literature

2 **References:** Stevenson 1976; Lazell Jr. 1989; Bartlett and Bartlett 1999; Savage 2002; Kraus 2009 Uetz
3 2010

4 **A8.4.33 *Hemidactylus platyurus***

5 **Common names:** flat-tailed house gecko

6 **Synonymous scientific names:** *Cosymbotus platyurus*, *Gecko marginatus*, *Hemidactylus marginatus*,
7 *Hemidactylus platyurus*, *Lomatodactylus platyurus*, *Platyurus marginatus*, *Stellio platyurus*

8 **Adult description:** nocturnal; snout longer than the distance between the eye and the ear-opening, one
9 time and a half the diameter of the orbit; forehead concave; ear-opening small, oval, oblique. Rostral
10 four-sided, not twice as broad as high, with median cleft above; nostril bordered by the rostral, the first
11 labial and three nasals. Tail depressed, flat inferiorly, with sharp denticulated lateral edge, covered
12 above with uniform small granules, below with a median series of transversely dilated plates. Body
13 depressed; limbs moderate, depressed; digits strongly dilated, about half-webbed, inner well developed;
14 3 to 6 lamellae under the inner, 7 to 9 under the median digits. Grey above, marbled with darker grey;
15 generally a dark streak from eye to shoulder; lower parts white; length of head and body 61 mm (2.4 in);
16 tail 66 mm (2.6 in); lateral skin flaps on the body.

17 **Reproduction:** mating does not take place seasonally, and copulation occurs when the ovarian eggs are
18 small, indicating that viable spermatozoa may be retained by the females for considerable periods of
19 time. Reproduce at any time of the year without undergoing a definite seasonal cycle; lay pairs of eggs in
20 crevices above ground.

21 **Habitat:** bright commercial areas such as walls of warehouses

22 **Human health impacts:** none found in the literature, but undocumented impacts may exist

23 **Economic impacts:** none found in the literature, but undocumented impacts may exist

24 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

25 **Pathways:** cargo, pet trade

26 **Control methods:** no information found in the literature

27 **References:** de Rooij 1915; Church 1962; Kraus 2009; Biolib 2010 GeckoWeb 2010

28 **A8.4.34 *Hemidactylus turcicus***

29 **Common names:** Mediterranean gecko, Mediterranean house gecko

30 **Synonymous scientific names:** *Gecko meridionalis*, *Gecko verrucosus*, *Gecko verruculatus*, *Gecus*
31 *cyanodactylus*, *Hemidactylus exsul*, *Hemidactylus granosus*, *Hemidactylus karachiensis*, *Hemidactylus*
32 *robustus*, *Hemidactylus verruculatus*, *Lacerta turcica*

1 **Adult description:** large eyes, toe pads, and size (maximum snout-vent length is 60 mm, tail about the
2 same); transverse lamellae divided medially. This is the most warty species of the four species of house
3 geckos, its head, body, legs and tail covered with prominent tubercles. Adults may reach 13 cm (5 in).
4 Like all house geckos they are rather flattened, with large heads, bulging eyes with vertical pupils and
5 covered with an immovable clear spectacle. It is usually darker brown or gray with darker spots by day
6 than at night, when it may appear a ghostly white. Irregular dark markings across the head and back
7 may disappear at night. The tail has dark bands, which are especially prominent in juveniles. The belly is
8 white and somewhat translucent.

9 **Reproduction:** Females lay pairs of oval white hard shelled eggs above ground, under loose bark, palm
10 fronds or other protected location. They are a communal nesting species. A female's clutch of two eggs
11 may amount to 25% or more of her body weight.

12 **Habitat:** often found lurking on walls or ceilings near lights, waiting to ambush moths and other insects

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** outcompetes native nocturnal climbing geckos

16 **Pathways:** biocontrol, cargo, intentional, pet trade, vehicle

17 Control methods: no information found in the literature

18 **References:** Stevenson 1976; Kraus 2009; GeckoWeb 2010; Uetz 2010

19 **A8.4.35 *Hemiphyllodactylus typus***

20 **Common names:** common dwarf gecko, Indo-pacific tree gecko

21 **Synonymous scientific names:** *Hemiphyllodactylus albostictus*, *Hemiphyllodactylus ceylonensis*,
22 *Hemiphyllodactylus crepuscularis*, *Hemiphyllodactylus insularis*, *Hemiphyllodactylus leucostictus*,
23 *Hemiphyllodactylus margarethae*, *Lepidodactylus auranticus*, *Lepidodactylus ceylonensis*, *Lepidodactylus*
24 *crepuscularis*, *Platydactylus crepuscularis*, *Ptyodactylus gracilis*, *Spathodactylus mutilates*,
25 *Spathoscalabotes mutilates*

26 **Adult description:** tiny; secretive; nocturnal; slender, translucent body covered in tiny granular scales;
27 lacks the warty tubercles and spines found on many other geckos; relatively long thin body and
28 proportionately short legs, but only reaches 6 to 9 cm (2.4 to 3.5 in); rudimentary, clawless inner toe on
29 the forefoot; color varies from almost white at night to light or dark gray or brown; tiny white flecks and
30 irregular black smudges are scattered along the back; there is a thin black line running from the snout
31 through the eye and across the neck and shoulder; underside of the tail is orange.

32 **Reproduction:** all are females; lay fertile eggs without copulating with a male. Each gecko lays pairs of
33 adherent eggs under bark or other protected location.

- 1 **Habitat:** forested areas and valleys, not around urban areas
- 2 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 4 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 5 **Pathways:** cargo, nursery trade, zoo trade
- 6 **Control methods:** no information found in the literature
- 7 **References:** Kraus 2009; GeckoWeb 2010 Uetz 2010
- 8 **A8.4.36 *Lampropholis delicata***
- 9 **Common names:** dark-flecked garden sun skink, delicate skink, garden skink, penny skink, rainbow skink
- 10 **Synonymous scientific names:** *Leiolopisma delicata*
- 11 **Adult description:** snout-vent is 4 to 5 cm (1.6 to 2 in); tail is 6 cm (2.4 in); active during the day as well
12 as the night; upper portion of the body is darker than the underside, and there is often a white line
13 present on the flank; lower eyelid is movable; plain-looking with short limbs, a small head and a small
14 ear. Usually rich brown above, sometimes bordered on the edges of the back by a narrow, often broken,
15 narrow line of paler color; no vertebral stripe; narrow black stripe runs back from the tip of the snout,
16 through the eye, often breaking up above the ear before reforming into a dark band on the upper sides;
17 sides dark dorsally, becoming paler toward the belly. Uniform coloration on side of neck; head is
18 generally not distinct from the neck; cream colored below, without any trace of orange or pink.
- 19 **Reproduction:** share an egg-laying site; clutch sizes range from 3 to 6 eggs.
- 20 **Habitat:** generalist; widespread; often seen foraging in gardens for small insects in gardens where there
21 is moisture; occur most commonly in dry areas amongst open grassy woodland at low altitudes
- 22 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 23 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 24 **Ecological impacts:** possible competition with native reptiles
- 25 **Pathways:** cargo, nursery trade
- 26 **Control methods:** no information found in the literature
- 27 **References:** Baker 1979; Howard et al. 2003; Lever 2003; Peace 2004 NZHS 2008; TPWS 2008; Kraus

- 12 **References:** Zug 2006; Kraus 2009
- 13 **A8.4.38 *Lepidodactylus lugubris*:** Established on numerous islands of Micronesia as well as the broader
- 14 Pacific
- 15 **Common names:** common smooth-scaled gecko, mourning gecko
- 16 **Synonymous scientific names:** *Amydosaurus lugubris*, *Dactyloperus Pomareae*, *Gecko harrieti*, *Gecko*
- 17 *lugubris*, *Gehyra neglecta*, *Gehyra ogasawarasimae*, *Gehyra variegata ogasawarasimae*, *Gymnodactylus*
- 18 *candeloti* (sic), *Gymnodactylus caudeloti*, *Hemidactylus meijeri*, *Lepidodactylus candeloti*, *Lepidodactylus*
- 19 *ceylonensis*, *Lepidodactylus crepuscularis*, *Lepidodactylus divergens*, *Lepidodactylus lugubris*,
- 20 *Lepidodactylus mysorensis*, *Lepidodactylus roseus*, *Lepidodactylus woodfordi*, *Peripia cantoris*, *Peripia*
- 21 *lugubris*, *Peripia meyeri*, *Peripia mysorensis*, *Peripia ornate*, *Peropus neglectus*, *Peropus roseus*, *Peropus*
- 22 *variegatus ogasawarasimae*, *Platydactylus (Lepidodactylus) crepuscularis*, *Platydactylus lugubris*
- 23 **Adult description:** nocturnal; large digital pads, non retractile claws on the outer digits, the first digit
- 24 clawless, and basally webbed digits. Males are 35 to 39 mm (1.5 in) in standard length and females are
- 25 31 to 45 mm (1.2 to 1.8 in) in length. Digits webbed basally; dorsal scales homogeneous, granular; chin
- 26 shields small, several in contact with infralabials; ventral scales flat, rounded, imbricate; tail flattened
- 27 beneath with some-what serrate margin, covered with small flat scales; subcaudal scales somewhat
- 28 enlarged. Skin on back is satiny and lacks tubercles. Dorsum pale light pinkish gray to light brown,
- 29 sometimes uniform but usually with prominent pair of brown spots just anterior to forelimbs; often with
- 30 scattered small dark spots and/or irregular lines or chevrons; a wide dark band from snout through eye
- 31 to forelimb; tail usually with dark markings; venter creamy white.

1 **Reproduction:** an all-female species, the uni-sexual mourning geckos are communal nesters, laying pairs
2 of eggs in favored locations such as tree cavities, in leaf axils or under loose bark. Some females seem to
3 take on a dominant role, even showing courtship-like behavior. Eggs are saltwater tolerant.

4 **Habitat:** arboreal and found in and around residences

5 **Human health impacts:** none found in the literature, but undocumented impacts may exist

6 **Economic impacts:** none found in the literature, but undocumented impacts may exist

7 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

8 **Pathways:** cargo, pet trade, zoo trade

9 **Control methods:** no information found in the literature

10 **References:** Savage 2002; Kraus 2009; GeckoWeb 2010; Uetz 2010

11 **A8.4.39 *Lipinia noctua*:** Native to parts of Micronesia

12 **Common names:** moth skink

13 **Synonymous scientific names:** *Euprepes novarae*, *Leiolopisma noctua*, *Lygosoma (Leiolopisma) miotis*,
14 *Lygosoma (Leiolopisma) noctua*, *Lygosoma (Leiolopisma) subnitens*, *Lygosoma (Lipinia) aurea*, *Lygosoma*
15 *miotis*, *Lygosoma noctua*, *Lygosoma vertebrale*, *Scincus noctua*

16 **Adult description:** small, 55 mm (2.2 in); has paired scales; yellow spot on the top of the head, which
17 may be contiguous with a narrower yellow mid-dorsal stripe continuing onto the body but fading before
18 reaching the base of the tail. It also has an interparietal scale and lacks supranasal scales, small scales
19 between the scale containing the nostril and the internasals on the top of the snout. Overall, the
20 coloration is brown or tan flecked with lighter and darker marks. A thick black line runs from the snout
21 to the eye and onto the lateral body, fragmenting before reaching the base of the hindlimb. The lips are
22 marked with alternating black and white bars. The belly is yellow to orange under the body and legs,
23 fading to a pale bluish green under the tail and chin. This lizard will break its toes as well as its tail to
24 escape the grasp of a potential predator.

25 **Reproduction:** gives birth to live young; ovoviparous; both oviducts are functional

26 **Habitat:** habitat generalist; found on the ground or low in trees; walls of buildings; has terrestrial and
27 arboreal habits

28 **Human health impacts:** none found in the literature, but undocumented impacts may exist

29 **Economic impacts:** none found in the literature, but undocumented impacts may exist

30 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

31 **Pathways:** cargo

1 **Control methods:** no information found in the literature

3 **A8.4.40 *Lycodon aulicus*:** This species has been captured several times including a probable record from
4 Yap (Stanford, personal communication)

5 **Common names:** common wolf snake, Indian wolf snake, wolf snake

6 **Synonymous scientific names:** *Lycodon aulicus capucinus*

7 **Adult description:** nocturnal; large front teeth; enlarged, non-grooved rear maxillary teeth. The
8 common wolf snake is a relatively slender-bodied snake with a ventrolateral keel along the body
9 commonly associated with arboreal snakes. It also has a head that is distinctly wider than the neck, a
10 vertically elliptical pupil, 17 longitudinal rows of smooth dorsal scales at midbody, dorsal scales with
11 apical scale pits, 181 to 211 ventral scales, 56 to 70 subcaudals, a divided anal scale, a weak
12 ventrolateral keel on lateral margins of ventrals, a preocular scale, a loreal scale in broad contact with
13 divided internasal scales, and a snout somewhat flattened and protruding beyond lower jaw. The dorsal
14 coloration is variable, usually brown with a reticulation of fine white lines, and occasionally with white
15 crossbars. The reported maximum size is variable and may be related to the abundance and diversity of
16 prey. Females may attain larger sizes than males with a maximum length of 50 to 84 cm (19.7 to 30 in)
17 (depending on the location).

18 **Reproduction:** oviparous with up to a dozen eggs laid at one time up to twice per year. Clutch size is
19 correlated to female body size. Females have been discovered curled around eggs and males are known
20 to stay in close association with females after mating.

21 **Habitat:** habitat generalist; in and around rock walls, stone piles, and trash piles; in drier areas where
22 lizards are abundant. Usually found around urban areas and human-made structures. They occupy
23 terrestrial and arboreal habitats as well as almost any kind of disturbed habitat

24 **Human health impacts:** none found in the literature, but undocumented impacts may exist

25 **Economic impacts:** none found in the literature, but undocumented impacts may exist

26 **Ecological impacts:** possible detrimental effect on gecko, mouse, skink, and frog populations

27 **Pathways:** cargo, natural dispersal

28 **Control methods:** no information found in the literature

29 **References:** Mehrtens 1987; Fritts 1993; Kraus 2009

30 **A8.4.41 *Mabuya multifasciata***

31 **Common names:** common sun skink, East Indian brown mabuya, many-lined sun skink, rough mabuya

1 **Synonymous scientific names:** *Euprepes sebae*, *Eutropis multifasciata*, *Eutropis multifasciatus*, *Mabuia*
2 *monticola*, *Mabuia multifasciata*, *Plestiodon sikkimensis*, *Scincus multifasciatus*, *Tropidolepisma*
3 *macrurus*

4 **Adult description:** 30 to 34 mid-body scale rows; 43 to 45 paravertebral scale count; 3 dorsal keels;
5 reduced size of the first supraocular, not in contact with the frontal; upper secondary temporal overlaps
6 the parietal. Relatively large; slight sexual dimorphism occurs where males are generally larger than
7 females; males can reach 117 mm (4.6 in) and females can reach 116 mm (4.6) in length.

8 **Reproduction:** viviparous; parturition begins in early May and females can produce up to 2 litters each
9 breeding season; litter size ranges from 2 to 7;

10 **Habitat:** terrestrial; open sunny space; prefers disturbed habitats such as forest edges and riverbeds;
11 gardens; rice fields

12 **Human health impacts:** none found in the literature, but undocumented impacts may exist

13 **Economic impacts:** none found in the literature, but undocumented impacts may exist

14 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

15 **Pathways:** cargo, pet trade

16 **Control methods:** no information found in the literature

17 **References:** Pauwels et al. 2003; Ji et al. 2006; Howard et al. 2007; Kraus 2009 Uetz 2010

18 **A8.4.42 *Naja kaouthia***

19 **Common names:** Bengal Cobra, Monocellate Cobra, Monocled cobra, Thailand Cobra

20 **Synonymous scientific names:** *Naja naja sputatrix*, *Naja tripudians* var. *fasciata*

21 **Adult description:** have a single circular mark on dorsal hood; relatively placid; has spitter fangs but
22 rarely spits. Throat pale, with scarcely any dark mottling, often followed by a single dark band. Vento-
23 lateral throat spots distinct and remainder of venter is pale or increasingly cloudy with darker
24 pigmentation towards rear. Hood markings are usually distinct and is usually a pale, oval, or circular
25 marking with a dark center and occasionally a narrow dark outer border. Medium to large in length,
26 heavy bodied snake with long cervical ribs capable of expansion to form a hood when threatened. Body
27 is compressed dorsoventrally and sub-cylindrical posteriorly. Can grow to a maximum of about 2 m (6.6
28 feet) but rarely exceeds 1.6 m (5.2 feet). Head is elliptical, depressed, slightly distinct from neck with a
29 short, rounded snout and large nostrils. Eyes are medium in size with round pupils. Dorsal scales are
30 smooth and strongly oblique. Underside of tail is usually light, but often suffused with dark pigment.
31 Nocturnal.

32 **Reproduction:** the female will lay about 25 to 45 eggs and she usually stays with them until they hatch.
33 The offspring are independent as soon as they are born.

1 **Habitat:** adaptable to a wide range of terrain including grassland plains, jungle, open fields and even
2 heavy populated regions. Usually found at elevations below about 700 m (2,296 feet). Often found in
3 tree holes and areas where rodents are plentiful.

4 **Human health impacts:** venomous; bites are potentially fatal

5 **Economic impacts:** none found in the literature, but undocumented impacts may exist

6 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

7 **Pathways:** cargo

8 **Control methods:** no information found in the literature

9 **References:** Looareesuwan et al. 1988; Greene 1997; Wüster 1998 Khandelwal et al. 2007; Amin et al.
10 2008; Kraus 2009; Kulkeaw et al. 2009; UAA 2010; Uetz 2010

11 **A8.4.43 *Pelodiscus sinensis***

12 **Common names:** Chinese soft-shell turtle, Chinese softshell

13 **Synonymous scientific names:** *Trionyx spiniferus*

14 **Adult description:** carapace length averages 112 to 250 mm (4.4 to 10 in); carapace is oval with a
15 marginal ridge; carapace smooth except for a few enlarged blunt knobs on the anterior rim above the
16 neck; head and limbs olive to yellowish-white; head and neck may have fine black lines; throat is either
17 light with vermiculations or dark with yellow spots; often fine black lines radiating from the eye; tubular
18 snout with a lateral ridge projecting from each side of the nasal septum; fleshy lips; ventral surface pale
19 or white; cluster of wattles between neck and carapace lacking or underdeveloped

20 **Reproduction:** males produce mature sperm in October to November; female may retain viable sperm
21 for up to one year; females ovulate 2 to 5 times a year; mating May to August depending on region; nest
22 squarish hole with corners rounded out; clutch size 7 to 30 eggs; eggs are white and spherical to oval;
23 eggs weighing 3.3-6.2 g (0.1 to 0.2 oz) and 17.6-22.2 mm (0.7 to 0.9 in) in diameter; incubation lasts 23
24 to 89 days depending on soil temperature; sexually mature in 4 to 6 years

25 **Habitat:** habitat generalist; lowland aquatic habitats; rivers; lakes, ponds, canals, and creeks with slow
26 currents; marshes; drainage ditches

27 **Human health impacts:** potential reservoir for cholera

28 **Economic impacts:** none found in the literature, but undocumented impacts may exist

29 **Ecological impacts:** may negatively impact native freshwater fish; carriers of iridovirus

30 **Pathways:** pet trade, food, religious, ecosystem disturbance

31 **Control methods:** no information found in the literature

1 **References:** ATWG 2000; Tokita and Kuratani 2001; Wong et al. 2002; Ji et al. 2003; Lever 2003; Zhang
2 et al. 2008; Huang et al. 2009b; Kraus 2009; Chen and Lue 2010; Somma 2010a

3 **A8.4.44 *Python molurus bivittatus***

4 **Common names:** Asian rock python, Burmese python, Indian python, Indian rock python, rock python

5 **Synonymous scientific names:** *Boa albicans*, *Boa castanea*, *Boa cinerea*, *Boa orbiculata*, *Boa ordinata*,
6 *Coluber boaeformis*, *Coluber molurus*, *Python bivittatus*, *Python bivittatus bivittatus*, *Python bora*,
7 *Python jamesonii*, *Python molurus*, *Python tigris*, *Python trivittatus*

8 **Adult description:** have light-colored skin with a characteristic pattern of many dark brown patches
9 bordered in black. A non-venomous constrictor having short prehensile tail; heavy body; large, angular
10 but supple skull with high counts of small, severely recurved teeth; vertical pupils; temperature-sensing
11 thermal pits in their lips; narrow belly scales; bodies circular in cross section; flanks with many rows of
12 tiny scales; males are 2.0 to 4.5 m (6.6 to 14.8 feet) in length and between 5 and 50 kg (11 to 110
13 pounds); females are 2.6 to 8.2 m (8.5 to 27 feet) in length and between 10 and 182 kg (22 to 401
14 pounds); Females usually larger than males.

15 **Reproduction:** hatchlings are independent, grow rapidly, mature in a few years and reproduce. Females
16 brood their eggs, enclosing the eggs in their coils for incubation, raising their body temperature if
17 necessary by shivering thermogenesis. Courtship occurs as temperatures warm (March/April). Females
18 shed their skin, males rub on female, if receptive, female opens cloaca and intromission occurs. Females
19 have ability to fertilize own eggs. Female fasts prior to oviposition and brooding. Clutch size varies
20 between 8 and 107, however, average clutch size is towards the low end of that range; females produce
21 one clutch per year; 60 to 90 day gestation period.

22 **Habitat:** habitat generalist

23 **Human health impacts:** could attack humans

24 **Economic impacts:** predation on livestock; attacks on livestock; carrier of ticks that could harm livestock

25 **Ecological impacts:** predation and competition with native fauna; reduction in native biodiversity;
26 transmission of Inclusion Body Disease to native reptiles

27 **Pathways:** cargo, escape, natural dispersal, pet trade, intentional release by pet owners

28 **Control Methods:** radio telemetry, pheromones, traps, detector dogs, hand capture, acetaminophen

29 **References:** Burrige and Simmons 2003; Lovgren 2005; Reed 2005 Schumacher 2006; Pitt and Witmer
30 2007; Beck et al. 2008; Kraus 2009; Reed and Rodda 2009; ISSG 2010; Mauldin and Savarie 2010; Uetz

32 **A8.4.45 *Ramphotyphlops braminus*:** widespread throughout the Pacific region including Micronesia

33 **Common names:** blind snake, Brahminy blindsnake, flower pot snake

1 **Synonymous scientific names:** *Argyrophis bramicus*, *Argyrophis truncatus*, *Eryx braminus*, *Glauconia*
2 *braueri*, *Onychocephalus capensis*, *Ophthalmidium tenue*, *Tortrix russelii*, *Typhlina braminus*, *Typhlops*
3 *braminus*, *Typhlops limbrickii*, *Typhlops russeli*, *Typhlops (Typhlops) euproctus*, *Typhlops (Typhlops)*
4 *inconspicuus*, *Typhlops pseudosaurus*

5 **Adult description:** 6.35 to 16.5 cm (2.5 to 6.5 in); small, thin, and shiny silver gray, charcoal gray, or
6 purple; head and tail-tip indistinct; neck not narrow; eyes are small dot-like remnants under the scales;
7 tail is tipped with a tiny pointed spur; head scales are small and similar to body scales; grayish to brown
8 belly; scales smooth and shiny; 14 dorsal scale rows along entire body.

9 **Reproduction:** lays eggs or may be live-bearing; individuals are all female and reproduce unisexually;
10 parthenogenic and up to eight genetically identical female offspring are produced; species is a complex
11 of unisexual and bisexual species

12 **Habitat:** habitat generalist; urban and agricultural areas. Lives in soil and leaf litter, and found under
13 rotting logs, leaves, and trash. Also found in gardens.

14 **Human health impacts:** none found in the literature, but undocumented impacts may exist

15 **Economic impacts:** none found in the literature, but undocumented impacts may exist

16 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

17 **Pathways:** cargo, nursery trade

18 **Control measures:** no information found in the literature

19 **References:** Nussbaum 1980; Kamosawa and Ota 1996; Kraus 2009; FLMNH 2010

20 **A8.4.46 *Saprosincus mustelina***

21 **Common names:** southern weasel skink, weasel shadeskink, weasel skink

22 **Synonymous scientific names:** *Lampropholis mustelina*, *Lygosoma (Leiolopisma) mustelinum*, *Lygosoma*
23 *(Liolepisma) pseudotropis*, *Lygosoma (Mocoo) lacrymansm*, *Lygosoma (Mocoo) orichalceum*, *Lygosoma*
24 *(Mocoo) sonderi*, *Lygosoma paraeneum*, *Mocoo mustelina*, *Saprosincus mustelinus*

25 **Adult description:** snout to vent length from 45 to 160 mm (1.8 to 2.3 in); body is coppery brown with
26 darker flecks on the back; ventral surface is cream colored; has a prominent white spot below and
27 immediately behind the eye; has a dark streak through the eye; the color of the tail is similar to the
28 back, but with a short, paler, dark edged streak starting immediately in front of the hind limb and
29 continuing onto the upper section of the tail.

30 **Reproduction:** females lay eggs in a communal nest that contains the eggs of many females; up to four
31 eggs per clutch.

1 **Habitat:** Prefers habitat with fallen timber or rotting vegetation; found among leaf litter in wet
2 sclerophyll forests

3 **Human health impacts:** none found in the literature, but undocumented impacts may exist

4 **Economic impacts:** none found in the literature, but undocumented impacts may exist

5 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

6 **Pathways:** cargo, nursery trade

7 **Control measures:** no information found in the literature

8 **References:** MNP 1999; Gill et al. 2001; Kraus 2009; Uetz 2010

9 **A8.4.47 *Sceloporous occidentalis***

10 **Common names:** coast range fence lizard, Great Basin fence lizard, Island fence lizard, northwestern
11 fence lizard, Pacific blue-bellied lizard, San Joaquin fence lizard, Sierra fence lizard, western fence lizard

12 **Synonymous scientific names:** *Sceloporus becki*, *Sceloporus biseriatus nigro-ventris*, *Sceloporus*
13 *biseriatus* var. *A*, *azureus*, *Sceloporus frontalis*, *Sceloporus longipes*, *Sceloporus occidentalis*, *Sceloporus*
14 *occidentalis becki*, *Sceloporus occidentalis biseriatus*, *Sceloporus occidentalis bocourtii*, *Sceloporus*
15 *occidentalis longipes*, *Sceloporus occidentalis occidentalis*, *Sceloporus occidentalis taylori*, *Sceloporus*
16 *occidentalis* var. *b*, *variegates*, *Sceloporus smaragdinus*, *Sceloporus undulatus biseriatus*, *Sceloporus*
17 *undulatus occidentalis*

18 **Adult description:** snout-vent length is 89 cm (3.5 in); 15 to 25 cm (6 to 10 in) in total length; scales are
19 keeled and somewhat spiny; color ranges from light gray to black with dark blotches on the back that
20 continue down the tail; males have bright blue, sometimes greenish, bellies and the underside of their
21 legs are yellow; females lack this decorative coloring.

22 **Reproduction:** breed in May or June; up to 10 eggs per clutch that can be laid as early as July, producing
23 hatchlings as early as mid-August.

24 **Habitat:** habitat generalist; found from the coast to the highest mountain areas at over 1,829 m (6,000
25 feet); ranging from coastal sage scrub and chaparral on the coast and foothills, to the forests of higher
26 elevations; found near ground in rock and wood piles, tree trunks, and lower branches of shrubs; urban
27 areas; desert landscapes

28 **Human health impacts:** none found in the literature, but undocumented impacts may exist

29 **Economic impacts:** none found in the literature, but undocumented impacts may exist

30 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

31 **Pathways:** cargo, research

1 **Control measures:** no information found in the literature

2 **References:** Kraus 2009; NVDoW 2010; Uetz 2010

3 **A8.4.48 *Sphaerodactylus argus***

4 **Common names:** common ocellated gecko, ocellated gecko

5 **Synonymous scientific names:** *Sphaerodactylus argus argus*, *Sphaerodactylus henriquesi*

6 **Adult description:** 5 to 6 cm (2 to 2.5 in) in length; have small toe pads and eyelash-like scales projecting
7 above each eye; Adults and juveniles have similar coloration. They are brownish in color with light dorsal
8 and lateral spots from head to tail. The ocelli on head and neck tend to form a lineate pattern. Have a
9 coral red tail and has small, keeled and slightly overlapping dorsal scales. Occasionally individuals are
10 almost patternless.

11 **Reproduction:** females lay single eggs at intervals (in the Caribbean).

12 **Habitat:** is found around buildings, in vacant lots, and stands of Australian pine

13 **Human health impacts:** none found in the literature, but undocumented impacts may exist

14 **Economic impacts:** none found in the literature, but undocumented impacts may exist

15 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

16 **Pathways:** cargo

17 **Control measures:** no information found in the literature

18 **References:** Krysko and King 2002; Kraus 2009; GeckoWeb 2010; Uetz 2010

19 **A8.4.49 *Sphaerodactylus elegans***

20 **Common names:** ashy gecko, Cuban ashy gecko

21 **Synonymous scientific names:** *Sphaerodactylus alopex*, *Sphaerodactylus cinereus*, *Sphaerodactylus*
22 *elegans elegans*, *Sphaerodactylus elegans punctatissimus*, *Sphaerodactylus punctatissimus*,
23 *Sphaerodactylus [sic] elegans*, *Sphaerodactylus [sic] punctatissimus*

24 **Adult description:** total length is 7 cm (2.75 in); are dark gray-brown in color with head, body, tail, and
25 legs covered with a network of tiny salt and pepper spots; can be paler at night; smooth granular scales
26 along the back, with a small spine-like scale over each eye. Are distinguished by having a vertical pupil,
27 digits without widened subdigital lamellae, and dorsal scales relatively small, smooth, granular, and
28 juxtaposed. They also have numerous light dorsal and lateral ocelli each comprised of only one scale.

29 **Reproduction:** females lay single eggs under loose bark or other cover objects; eggs are sometimes laid
30 communally; have been found together with those of common and Amerafrican house geckos.

- 1 **Habitat:** trees, buildings, vacant lots, and stands of Australian pine
- 2 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 3 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 4 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 5 **Pathways:** cargo
- 6 **Control measures:** no information found in the literature
- 7 **References:** Krysko and Daniels 2005; Kraus 2009; GeckoWeb 2010; Uetz 2010
- 8 **A8.4.50 Tarentola mauritanica**
- 9 **Common names:** common wall gecko, Moorish gecko
- 10 **Synonymous scientific names:** *Gecko fascicularis*, *Gecko muricatus*, *Gecko stellio*, *Lacerta mauritanica*,
11 *Platydactylus facetanus*, *Platydactylus mauritanicus*, *Platydactylus muralis*, *Tarentola mauritanica*
12 *mauritanica*, *Tarentola mauritanica subvar. Atlantica*, *Tarentola mauritanica subvar. Lissoide*, *Tarentola*
13 *saharae*, *Tarentola (Tarentola) mauritanica*, *Tarentola tuberculata*
- 14 **Adult description:** up to 15 cm (6 in) in total length; has golden, vertically slit eyes with red veins;
15 distinct rows of large tubercles shingle the back, pointed tubercles cover the neck and legs, and whorls
16 of tubercles on the tail give it a spiny, armored appearance; is sandy gray in color; paler at night; belly is
17 white with overlapping ventral scales; males are larger and have broader heads; have enlarged,
18 undivided toe pads; large, bulging eyes with a fixed transparent covering.
- 19 **Reproduction:** Females lay pairs of eggs.
- 20 **Habitat:** habitat generalist; In the United States it is confined to the walls of buildings; It is found in
21 warm, dry coastal regions around the Mediterranean, in stone walls, boulders, and wood piles
- 22 **Human health impacts:** none found in the literature, but undocumented impacts may exist
- 23 **Economic impacts:** none found in the literature, but undocumented impacts may exist
- 24 **Ecological impacts:** none found in the literature, but undocumented impacts may exist
- 25 **Pathways:** cargo, intentional, nursery trade, pet trade
- 26 **Control measures:** no information found in the literature
- 27 **References:** Mahrtdt 1998; Vogrin et al. 2008; Kraus 2009; GeckoWeb 2010; Uetz 2010

1 **A8.4.51 *Tiliqua scincoides***

2 **Common names:** common bluetongue, eastern bluetongue, eastern blue-tongued lizard, northern
3 bluetongue

4 **Synonymous scientific names:** *Cyclodus boddaertii*, *Lacerta scincoides*, *Scincus crotaphomelas*, *Scincus*
5 *tuberculatus*, *Tiliqua scincoides chimaerea*, *Tiliqua scincoides intermedia*, *Tiliqua whitii*

6 **Adult description:** Is a large, flattened, terrestrial lizard with small limbs; snout to vent length is
7 approximately 400 mm (15.7 in); weight up to 700 g (25 oz); blue colored tongue; color patterns can
8 vary between individuals where some have banded markings while others have blotchy markings;
9 typical color pattern is a white ventrolateral region, stopping at the dorsoventral scales, and a brown
10 dorsolateral surface; head pale brown to gray and this color decreases in intensity posteriorly; also has
11 dorsal transverse pale markings and oblique dorsolateral black markings that interrupt this coloration;
12 body has wide yellow-orange large bands or blotches as well; limbs are tertiary gray.

13 **Reproduction:** viviparous; 10 to 20 individuals per litter; a female will produce a litter every 1 to 2 years;
14 individuals are born precocious; breeding occurs in the spring; males exhibit mate guarding.

15 **Habitat:** suburban gardens, urban areas, seasonally wet and dry savannah woodlands, coastal
16 heathlands, montane wet sclerophyll woodlands, and fringes of rainforests. Common in highly disturbed
17 areas

18 **Human health impacts:** none found in the literature, but undocumented impacts may exist

19 **Economic impacts:** none found in the literature, but undocumented impacts may exist

20 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

21 **Pathways:** cargo, intentional

22 **Control measures:** no information found in the literature

23 **References:** Carpenter and Murphy 1978; Lissone 1999; Koenig et al. 2001; Kraus 2009; Uetz 2010

24 **A8.4.52 *Trachemys scripta***

25 **Common names:** red-eared slider, common slider, Cumberland slider turtle, slider, yellow-bellied slider

26 **Synonymous scientific names:** *Chrysemys scripta*, *Chrysemys scripta elegans*, *Chrysemys picta*, *Emys*
27 *cumberlandensis*, *Emys elegans*, *Emys troostii*, *Pseudemys ornate*, *Pseudemys scripta*, *Testudo scripta*,
28 *Trachemys scripta elegans*

29 **Adult description:** carapace length is 125 to 289 mm (5 to 11 in); prominent yellow to red patches on
30 each side of the head; carapace and skin are olive to brown with yellow stripes or spots; males smaller
31 than females with a longer, thicker tail

1 **Reproduction:** mating may occur in both spring and fall; nesting April to July in temperate zones,
2 December to May in the tropics; females may store sperm up to 79 days; nests are flask-shaped with a
3 chamber 11 to 21 cm (4 to 8 in) deep; may have up to 6 clutches; 2 to 30 eggs per clutch depending on
4 size of female; incubation 59 to 112 days; timing of sexual maturity highly variable

5 **Habitat:** habitat generalist; lakes, riparian zones, water courses, wetlands; prefers large, quiet bodies of
6 water with soft bottoms; can tolerate brackish water

7 **Human health impacts:** carrier of *Salmonella enterica*; host to *Gnathostoma binucleatum*, the causative
8 agent of gnathostomosis

9 **Economic impacts:** none found in the literature, but undocumented impacts may exist

10 **Ecological impacts:** competes with and may displace native turtles

11 **Pathways:** pet trade, intentional release, religious, zoo trade, natural dispersal

12 **Control measures:** trapping; use of detector dogs to locate turtles and nests; egg removal

13 **References:** TFTSP 1996; Cadi and Joly 2003; Lever 2003; Cadi and Joly 2004; Nagano et al. 2006; Scalera
14 2006; Guerrero and Alba-Hurtado 2007; Gaertner et al. 2008; Polo-Cavia et al. 2008; Kraus 2009; ISSG

16 **A8.4.53 *Trimeresurus elegans***

17 **Common names:** elegant pit viper, Sakishima habu

18 **Synonymous scientific names:** *Craspedocephalus elegans*, *Lachesis lutea*, *Lachesis luteus*, *Lachesis*
19 *mucrosquamatus*, *Protobothrops elegans*, *Trimeresurus luteus*

20 **Adult description:** resembles the Okinawan Habu (*Trimeresurus flavoviridis*) in color and pattern, but is
21 smaller in size (usually 91 cm [3 feet] long).

22 **Habitat:** found on Irimote, Ishigaki, and Miyako Islands; found in several types of terrain and active
23 mainly at night

24 **Human health impacts:** venomous (have a hemorrhagic toxin)

25 **Economic impacts:** none found in the literature, but undocumented impacts may exist

26 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

27 **Pathways:** exhibit, as food, in medicinal drinks

28 **Control measures:** no information found in the literature

29 **References:** Keegan and Yoshino 1959; Mehrtens 1987; Nikai et al. 1991; Rodda et al. 1999b; Chijiwa et
30 al. 2006; Kraus 2009; Uetz 2010

1 **A8.4.54 *Trimeresurus flavoviridis***

2 **Common names:** Habu, Okinawan habu

3 **Synonymous scientific names:** *Lachesis flavoviridis*, *Protobothrops flavoviridis*, *Trimeresurus flavoviridis*
4 *flavoviridis*, *Trimeresurus riukiuanus*

5 **Adult description:** average length is 122 to 152 cm (4 to 5 feet), but they have been known to exceed
6 213 cm (7 feet) in length. They are the largest of the Asian terrestrial pit vipers; usually pale or dark
7 brown, greenish-brown, or olive in color; has a pattern of irregular blotches that vary in shades of green
8 or brown and bordered with yellow or grayish-yellow (this pattern can represent a marbled effect);
9 large, triangular head attached to a slim neck.

10 **Reproduction:** mate in early spring and a female may lay up to 18 eggs in mid-summer. The eggs hatch
11 after 5 to 6 weeks of incubation. The hatchlings are ten inches in length and are identical to the adults.

12 **Habitat:** sparsely wooded plains and fields adjacent to forests; brushy, rocky hillsides

13 **Human health impacts:** venomous; bites cause permanent physical damage or impairment; bites may
14 sometimes be fatal

15 **Economic impacts:** none found in the literature, but undocumented impacts may exist

16 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

17 **Pathways:** cargo

18 **Control measures:** electric fencing, traps

19 **References:** Hayashi et al. 1980; Hayashi et al. 1983; Mehrtens 1987; Ford and Seigel 1989; Shiroma and
20 Akamine 1992; Yokoyama and Yoshida 1994; Sawai et al. 1996; Rodda et al. 1999b; Yamamoto et al.

22 **A8.4.55 *Trimeresurus mucrosquamatus***

23 **Common names:** brown-spotted pit viper, pointed-scaled pit viper, Taiwan habu

24 **Synonymous scientific names:** *Lachesis mucrosquamatus*, *Protobothrops mucrosquamatus*,
25 *Trionocephalus mucrosquamatus*, *Trimeresurus mucrosquamatus*

26 **Adult description:** adult length: males 1122 mm (44 in) and females 1160 mm (46 in); tail length: males
27 195 mm (7.7 in) and females 205 mm (8 in); sharp, triangular head with a thick black-brown lateral band
28 behind eyes; mottled top of head, below is whitish; body is yellow-brown with large black patches on
29 back; patches on dorsal side of body usually form a wave-like pattern that serve as camouflage; belly is
30 white in color, but heavily powdered with light brown; tail is brownish in color with dark dorsal spots
31 (but the tail can possibly be pink during their life). The scales are in 25 longitudinal rows at midbody; the
32 scales on the upper surface of head are small and each scale is keeled posteriorly; internasals are 5 to 10
33 times the size of adjacent scales and are separated by 3 to 4 scales; supraoculars are long, narrow, and

1 undivided and there are 14 to 16 small interocular scales in line between them; are two scales in line
2 between upper preocular and nasal; has 9 to 11 upper labials and the first upper labial is separated from
3 the nasal by a suture; are 2 to 3 small scales between upper labials and subocular; 2 to 3 smooth rows of
4 temporal scales above the upper labials, but above those the scales are keeled.

5 **Reproduction:** eggs: 3 to 15 per nest; laid in summer; females show egg protecting behavior.

6 **Habitat:** mountainous habitat, cultivated land, houses, farms, bushes, barns

7 **Human health impacts:** venomous; bites may cause death without the proper antivenom

8 **Economic impacts:** none found in the literature, but undocumented impacts may exist

9 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

10 **Pathways:** unknown

11 **Control measures:** no information found in the literature

12 **References:** Smith 1943; Leviton et al. 2003; Hung 2004; Kraus 2009; Uetz 2010

13 **A8.4.56 *Uta stansburiana***

14 **Common names:** northern ground uta, northern side-blotched lizard, side-blotched lizard, western
15 ground uta

16 **Synonymous scientific names:** *Uta antique*, *Uta mannophorus*, *Uta stellata*

17 **Adult description:** mostly brown, with five, light-colored, dorsal stripes running from the head at least to
18 the beginning of the tail (these stripes are sometimes indistinct); during the breeding season, males
19 often take on a distinctly bluish hue on the head, tail, top of the back, and sides.

20 **Reproduction:** breeding begins early in spring. Females typically lay 1 to 2 clutches from spring to
21 midsummer; 3 to 4 eggs per clutch; females in warmer climates may lay up to 7 clutches in one year;
22 most eggs hatch from June to August and the offspring mature quickly.

23 **Habitat:** lives in flat desert habitat, rocky outcrops, hills, and mountainous regions. Prefer sites with
24 some vegetation

25 **Human health impacts:** none found in the literature, but undocumented impacts may exist

26 **Economic impacts:** none found in the literature, but undocumented impacts may exist

27 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

28 **Pathways:** cargo, possibly in aircraft, possibly in construction materials

29 **Control measures:** no information found in the literature

1 **References:** Nussbaum 1981; Ferguson et al. 1990; Hutchins et al. 2003b; Mahoney et al. 2003; Kraus
2 2009; Uetz 2010

3 **A8.4.57 *Xenochrophis piscator***

4 **Common names:** Asiatic water snake, checkered keelback

5 **Synonymous scientific names:** *Amphiesma flavipunctatum*, *Col. Quincunciatus*, *Hydrus piscator*, *Natrix*
6 *piscator*, *Nerodia (Tropidonotus) piscator*, *Tropidonotus piscator*, *Tropidonotus quincunciatus*

7 **Adult description:** Total length: males up to 947 mm (37 in) and females up to 1,020 mm (40 in); chess-
8 like pattern on the body, sometimes with broad blotches and very conspicuous and sometimes with
9 smaller blotches; large, cloudy cream or pale gray dorsolateral blotches; nuchal marking often absent (if
10 not absent then present as an inverted V); subocular streaks are faint, reduced to a blotch or absent; a
11 venter uniform, with the ventrals darker only on the outermost edges; a high number of ventral and
12 subcaudal scales in males.

13 **Reproduction:** clutch size ranges from 9 to 74; clutch size increases with increasing body size

14 **Habitat:** lowland habitat; mangroves; occurs close to water quite often, although they are not strongly
15 aquatic

16 **Human health impacts:** none found in the literature, but undocumented impacts may exist

17 **Economic impacts:** none found in the literature, but undocumented impacts may exist

18 **Ecological impacts:** none found in the literature, but undocumented impacts may exist

19 **Pathways:** unknown

20 **Control measures:** no information found in the literature

21 **References:** IUCN 2009, Vogel and David 2006; Brooks et al. 2009; Uetz 2010

22 **A9 CRITERIA QUESTIONS USED TO EVALUATE RISK OF TRANSPORTING**
23 **VERTEBRATE INVASIVE SPECIES**

24 A risk level was assigned to each pathway based on 16 criteria questions pertaining to probability of
25 species transport, invasive potential of species, the pathway's conduciveness to transport species, and
26 control-interdiction-eradication methods. These 16 evaluated criteria questions are as follows:

27 **3. Introducing invasive species on a frequent basis?**

28 Extremely high frequency ranking is defined, in relative terms, as introducing numerous invasives (i.e.,
29 10 or more) that have had either human health pandemic implications resulting in deaths; moderate is 5
30 or more that have caused serious **Economic impacts** on (i.e., failure of) major industries; low is 2 or
31 more introduced invasives that negatively impacted 2 or more ecological niches).

- 1 **4. Transmitting a large number of different viable species?**
- 2 Extremely High (i.e., ranking of 10) infers a pathway capable of transferring 100 or more viable invasives
3 species in a single event.
- 4 **5. Transmitting a large number of viable individuals per invasive species?**
- 5 Extremely High infers the pathway transmits numerous (i.e., 100 plus) viable populations that can
6 readily be established. Extremely low infers that only 1 to 2 specimens capable of
7 establishment/**Reproduction** are transmitted. Zero is 'no risk'; infers no specimen survival.
- 8 **6. Introducing invasive species into hospitable ecosystems or Habitats?**
- 9 Level 10 infers exact ecosystem match with invasive species' natural **Habitat**; plentiful food sources, no
10 predators or ecosystem controls. Zero (0) risk is when environmental factors preclude invasive species
11 establishment.
- 12 **7. Introducing invasive species at multiple entry points?**
- 13 Level 10 equals 100% likelihood of invasive species survival due to hospitable pathway ecosystem. Level
14 1 equates to pathway that by nature (i.e., travel through arctic climes) will result in invasive mitigation.
- 15 **8. For transmitting invasive species, based on standard treatment measures?**
- 16 Level 10 infers multiple entry points (4 or more) that expand across the continental United States; Level
17 1 infers single, localized entry point.
- 18 **9. To assist spread of invasive species to uncontaminated shipments during transport or storage?**
- 19 Zero (0) level indicates all IS are dead upon arrival; 3 indicates most (60%) of the invasive species are still
20 reproductively viable; 5 indicates 100% of invasive species are alive, and have expanded populations,
21 colonies or enhanced invasiveness capabilities).
- 22 **10. For transmitting invasive species based on current screening techniques?**
- 23 High reflects a pathway that commingles multi-source vectoring agents with multiple dissemination
24 points i.e., multi-source, commingled WPM in a cargo hold with multiple dissemination points. Low
25 equates to no cross-contamination or spread.
- 26 **11. Transporting an invasive species that is difficult to detect once in the destination ecosystem?**
- 27 A rating of zero (0) indicates that virtually all invasives are detected prior to or during transit. A rating of
28 5 indicates that there are no detection methods for the invasives prior to or during transit.
- 29 **12. Transmitting invasive species that are capable of surviving in multiple Habitats?**

1 Zero (0) indicates that all invasives are detected immediately at the pathway endpoint. A rating of 5
2 indicates the species is/are so difficult to detect, there is a 100% likelihood they will be disseminated
3 without detection.

4 **13. Transmitting invasive species into ecosystems conducive to natural spread?**

5 An assessment of zero (0) indicates the pathway does not transmit any generalists. An assessment of 5
6 indicates the majority of invasives transmitted by this pathway are generalists with at least 3 or more
7 populations capable of surviving in any of the pathway endpoints.

8 **14. Transmitting invasive species that are further spread by human activities?**

9 A rating of zero (0) indicates the pathway transmits invasives with low reproductive rates or ones that
10 are fragile in any ecosystem other than that of origination. A ranking of 5 indicates the pathway
11 transmits multiple (i.e., 10 or more) invasives that are highly mobile; spread by wind, water; have/high
12 reproductive rates in multiple ecosystems.

13 **15. Introducing invasive species that are known to be invasive in similar ecosystems but are not
14 yet in the endpoint ecosystem?**

15 A rating of zero (0) indicates that humans or human activities do not spread the invasive species. A
16 rating of 5 indicates humans or human activities are the primary agent for the rapid spread of pandemic
17 invasive species.

18 **16. Transmitting invasive species that are novel and have limited scientific data upon which to
19 develop control methods?**

20 Zero (0) indicates the pathway transmits no compatible IS; 3 rating indicates the pathway transmits
21 invasives that are in some, not all, U.S. ecoregions, but are not yet present in the pathway endpoint
22 ecosystem. Level 5 infers the pathway transmits viable invasive species into pristine ecosystems.

23 **17. Transmitting an invasive species for which existing control options are too expensive to
24 implement?**

25 Zero (0) indicates there are comprehensive control options to mitigate all invasives transmitted. Level 5
26 indicates there are no existing control options.

27 **18. To what degree does the pathway's own ecosystem enhance the viability of opportunity for
28 transmission of invasive species?**

29 Level 0 equates to a pathway that by nature results in mitigation (i.e., no movement of invasive species).
30 Level 5 equals 50% likelihood in invasive species survival. In other words, some species may be able to
31 survive in the pathway ecosystem whereas others cannot. Level 10 equals 100% likelihood of invasive
32 species survival due to a hospitable pathway ecosystem.

1 **A10 UMBRELLA CATEGORY PATHWAY OUTLINE**

2 Major **Pathways** were organized under three umbrella categories: Transportation, Living Industry, and
3 Miscellaneous, and further divided into sub- and nested **Pathways** identified as being pertinent to the
4 military mission.

5 **(T) TRANSPORTATION Pathways and Sub-pathways**

6 T. 1. Modes of Transportation

7 T.1.1 Air Transportation

8 T.1.1.1 Commercial Air Traffic

9 T.1.1.2 Military Air Traffic

10 T.1.2 Water Transportation

11 T.1.2.1 Commercial Maritime Traffic

12 T.1.2.2 Military Maritime Traffic

13 T.2 Military Travel and Transportation of Military Vehicles

14 T.2.1 Military Cargo and Vehicles Used in Training Exercises

15 T.3. Items Used in the Shipping Process

16 T.3.1 Cargo Containers

17 T.3.2 Wood Packaging Materials

18 T.4. Travel/Tourism/Relocation

19 T.4.1 Household Goods and Personal Vehicles

20 T.5. Transportation of Construction Materials, Equipment, and Vehicles

21 **(L) LIVING INDUSTRY Pathways and Sub-pathways**

22 L.1 Plant **Pathways**

23 L.1.1 Plant Materials and Plant and Nursery Trade

24 L.2 Food **Pathways**

25 L.2.1 Aquaculture

26 L.2.2 Plants and Plant Parts as Food

27 **(M) MISCELLANEOUS Pathways and Sub-pathways**

28 M.1 Ecosystem Disturbance

29 M.1.1 Natural Spread of Established Populations

30 M.1.2 Man-made and Natural Disturbances

1 M.2 Garbage

1 **A12 PRELUDE TO THE DRAFT PATHWAY ANALYSIS FOR HAWAI'I**

2 **A12.1 WHAT IS THE PATHWAY ANALYSIS OF INVASIVE SPECIES INTRODUCTION INTO THE**
3 **STATE OF HAWAII?**

4 The Pathway Analysis of Invasive Species Introduction into the State of Hawai'i is a working document
5 that was created by the United States Department of Agriculture (USDA), Animal Plant Health Inspection
6 Service (APHIS), Plant Protection Quarantine (PPQ) to assist in identifying terrestrial biological risks to
7 Hawai'i. It is important to note that this document is a "Pathway Analysis" and not a "Pest Risk
8 Assessment" (PRA or "risk analysis" in Intergovernmental Panel on Climate Change terms). A Pathway
9 Analysis uses available science, information, and technology to determine appropriate measures to
10 mitigate risks of sometimes multiple pests and commodities moving via a specific pathway. A pathway is
11 any means that allows the entry or spread of a pest. This includes travelers, conveyances, commodities,
12 cargo, military movements, and others. A PRA uses available science, information, and technology to
13 determine appropriate measures to address specific risks associated with specific pests or commodities.

14 Hawai'i is unique in that it has different ecosystems and vulnerabilities than the rest of the United
15 States. For example, although Hawai'i is one of the smallest states in the United States, comprising just
16 0.2% of its total land mass, more than 25% of the endangered species in the United States occur there
17 (OTA 1993). Hawai'i is infamous not only as "the extinction capital of the United States," with 72% of the
18 country's recorded extinctions (Gagné 1988; OTA 1993) but also as the location with the greatest
19 species extinction rate per square mile of anywhere in the world
20 (<http://hbs.bishopmuseum.org/endangered/>).

21 Hawai'i imports the majority of agriculture products consumed. Commodities have been imported into
22 Hawai'i before PRAs were completed on individual commodities. Because of Hawai'i's location,
23 commercial and private conveyances arrive there from a variety of locations. Many of the originating
24 locations are without sound quarantine and export practices. Other originating locations are without a
25 complete understanding of the pests present in their countries or of the pest pressures on their
26 countries.

27 APHIS developed this Pathway Analysis to assist PPQ in developing approaches and strategies to
28 minimize all risks within its authority, and to further develop effective actions to prevent the
29 introduction and spread of pests and to promote appropriate measures for their control.

30 **A12.2 WHY RELEASE IN DRAFT FORM?**

31 With the exception of Chapter B5, the quantitative data sufficient for statistical analysis were not
32 available, especially for domestic arrivals (and the suspected foreign origin commodities arriving through
33 domestic trade). Despite these shortcomings (that kept the analysis in draft form), APHIS has enhanced
34 and implemented actions and fortified partnerships to address key elements in the pathway analysis.
35 Entities outside of APHIS believe their activities may benefit, as APHIS has benefited, from the draft
36 information. Thus, APHIS is releasing the draft. APHIS believes the release of this information is timely to
37 the completion of the Micronesian Biosecurity Plan and fits well with the information in that document.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 In understanding the information and risks, it is beneficial for the reader to understand that preventing
2 pest and invasive species from entering Hawai'i falls mainly on two agencies. There are many agencies
3 within Hawai'i that work on protecting resources from invasive species; USDA-APHIS and HDOA are the
4 two agencies that specifically handle prevention through import inspections. USDA-APHIS-PPQ holds
5 authority and by a Memorandum of Agreement, holds joint responsibility with Customs and Border
6 Protection for quarantine activities and actions as they relate to foreign arrivals of people, commodities,
7 and conveyances. Because the State of Hawai'i is under official quarantine for a variety of pests, APHIS
8 also holds authority and responsibility for reducing the risks of pests moving from Hawai'i to the U.S.
9 mainland. The State of Hawai'i holds the authority and responsibility for reducing the risks of pests
10 entering Hawai'i from other U.S. states. While USDA and the Hawai'i Department of Agriculture (HDOA)
11 have different authorities and responsibilities, both agencies have entered in to a Memorandum of
12 Understanding (MOU) that generally describes shared roles, responsibilities, resources, and enabling
13 authorities, and facilitates cooperation in phytosanitary issues and risk mitigation activities.

14 **A12.3 ACTIONS BASED ON THE PATHWAY ANALYSIS**

15 While additional, yet unavailable, information could be used to gain a more complete understanding of
16 the pest pressures on Hawai'i, PPQ has used the available information presented in this document to
17 strengthen and create programs that reduce the risks and close pathways for pests entering Hawai'i
18 regardless of what the pests are or their origin. PPQ is present on the islands of Hawai'i, Kauai, Lanai,
19 Maui, Molokai, and Oahu with an outlying work unit in Guam where it works closely with state, private
20 and federal partners to achieve the reduction of risks. PPQ–Hawai'i also supports operations in the
21 Commonwealth of Northern Mariana Islands (CNMI) and American Samoa. Together many agency
22 programs serve as a safety net to reduce risks from entering Hawai'i. Some of the activities PPQ has
23 undertaken to address the risks identified in this document are outlined below.

24 **A12.3.1 Cooperative Agriculture Pest Survey Program**

25 PPQ funds the Cooperative Agriculture Pest Survey (CAPS) program and works with the HDOA, the
26 University of Hawai'i, the Guam Department of Agriculture, the University of Guam, the CNMI
27 Department of Land and Natural Resources, the Northern Mariana College, the American Samoa
28 Department of Agriculture, and the Samoa Community College to determine if pests of concern have
29 entered the island ecosystems. In fiscal year (FY) 2011, PPQ entered into 24 agreements (including Farm
30 Bill and CAPS agreements), totaling \$1.2 million. This included working with six agencies from Hawai'i,
31 Guam, the CNMI, and American Samoa. These agreements covered surveys for various pests including
32 citrus greening and imported fire ants. These cooperative surveys allow for early detection of invasive
33 species and quick response to reduce pest risk to the State of Hawai'i. For FY 12, there are 29
34 agreements, totaling \$1.6 million. Actions of PPQ and other agencies may be based on the information
35 that is produced by the CAPS program.

36 **A12.3.2 Smuggling Interdiction and Trade Compliance**

37 PPQ's Smuggling Interdiction and Trade Compliance (SITC) program is very active in Hawai'i and the
38 American Pacific with the purpose of detecting and closing pathways in which restricted or prohibited

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 agricultural commodities make illegal entry into the United States and its territories. More funding and
2 capacity is needed for similar programs in the non-US jurisdictions covered by this plan if the FSM, Palau
3 and the RMI are to establish similar standards. SITC partners with various agencies including other USDA
4 agencies, the Department of Homeland Security's (DHS) Customs and Border Protection (CBP), the U.S.
5 Fish and Wildlife Service (USFWS), the U.S. Department of Health and Human Services, Food and Drug
6 Administration (FDA), various Hawai'i state agencies, and the University of Hawai'i at Manoa to achieve
7 its goal of closing pathways. PPQ strengthened the Hawai'i SITC team by shifting employees to the
8 program and allowing employees from other operations to assist when needed. Hawai'i SITC also
9 conducted PPQ officer and safeguarding training in American Samoa, Guam, and the CNMI Departments
10 of Agriculture for local quarantine officers. SITC established a network of informants, importers,
11 retailers, and joint federal/state/county agency contacts that allows for the quick acquisition of
12 intelligence, making APHIS' mission objectives more easily achieved. SITC and the cooperating agencies
13 provide outreach to industry and market owners about pest risk concerns. SITC works to identify and
14 close pathways. This work assists to mitigate pests that are not detected during the entry process. SITC
15 Hawai'i created a searchable and user-friendly database (PPQ287), used specifically for mail
16 interceptions that has become a module in the national Agricultural Quarantine Activity System (AQAS)
17 system. The PPQ287 Mail Interception Database provides a means to do the following in the event of a
18 mail interception:

- 19 • Electronically generate a notification (Form 287) to be provided to the intended recipient
20 and the sender. These notifications indicate that an unauthorized material—animal
21 products, animal byproducts, plants, plant products, plant pests, or soil—was removed from
22 the mail package, and why.
- 23 • Record the regulatory action that CBP took when intercepting the mail.
- 24 • Provide a means to prepare monthly and quarterly reports.
- 25 • Centralize the management of all mail interceptions into a single database. This greatly
26 improved the accessibility and quality of data gathered for intercepted mail.

27 While the database is now used nationally, the Honolulu Post Office became the postal location where
28 most pests and pest risks are intercepted. Hawai'i SITC also conducts joint activities with the HDOA to
29 mitigate pest risk concerns and to support HDOA-led operations such as the Maritime Agriculture Risk
30 Survey in which red imported fire ants (RIFA) (*Solenopsis invicta* Buren) were targeted in cargo
31 containers that are not traditionally inspected. Again, while this appears to be a very worthwhile
32 program, the non-US jurisdictions of Micronesia are not covered by it and would be greatly assisted in
33 helping to protect the entire region if they could develop similar initiatives.

34 **A12.3.3 Funding and Grants**

35 USDA provides funding through the Farm Bill to develop Pest Management Practices for non-native
36 pests on nursery plants. In addition, Hawai'i is applying for new funds to develop similar strategies for
37 cut flower and foliage production. Hawai'i will be applying for future USDA funding for these
38 management programs.

1 **A12.3.4 Emergency Response**

2 PPQ-Hawai'i takes a lead role in emergency response exercises in cooperation with HDOA, the University
3 of Hawai'i at Manoa, and Hawai'i industry representatives. These exercises, which practice the use of
4 the Incident Command System, are designed to enable quick and effective responses from all regulatory
5 agencies to effectively and swiftly address ecological, agrosecurity emergencies.

6 **A12.3.5 Containment Facilities**

7 As the lead regulatory agency, APHIS has many programs to ensure the safe trade and movement of
8 commodities, people, and conveyances to Hawai'i. Regulated containment facilities are used so
9 commodities with restricted market access may enter prior to being cleared for movement to
10 consumers. Some commodities are stored in containment facilities until they are transferred from
11 Hawai'i under safeguarded conditions. In addition to increasing the number of inspections of existing
12 containment facilities to verify compliance with permit conditions, PPQ-Hawai'i has trained additional
13 containment facility inspectors to oversee new and existing facilities that house imported plant pests
14 and diseases not known to occur in Hawai'i. Increased interaction with HDOA has been achieved to
15 assist stakeholders by streamlining the containment facility inspection process.

16 **A12.3.6 Post-entry Quarantine and Inspections**

17 At HDOA's request PPQ maintains a strong post-entry program. APHIS also regulates all post-entry
18 activities where plants and plant cuttings that have the potential to harbor unseen diseases, viruses,
19 plasmas, etc. are brought into Hawai'i under quarantine conditions to be grown out until the plants are
20 at a stage where symptoms occur and contaminated plants can be identified. PPQ-Hawai'i conducts joint
21 inspections with HDOA that allow for more thorough inspections and also strengthen state and federal
22 roles in the program. The quarantined products are only released from quarantine after both APHIS and
23 HDOA are confident that the product is pest-free. PPQ-Hawai'i regularly conducts Field Plant Pathology
24 Training to improve inspecting capabilities of inspecting officers.

25 **A12.3.7 Biotechnology**

26 PPQ strictly regulates biotechnology activities in Hawai'i. APHIS' Biotechnology Regulatory Service (BRS)
27 reviews all potential risk of biotech materials being spread and/or released in Hawai'i. Strict guidelines,
28 regulations, and protocols are considered and developed jointly by BRS and HDOA. Only materials
29 approved by both Hawai'i and BRS are considered for approved for growing in Hawai'i. PPQ-Hawai'i
30 developed a tracking system that allows monitoring biotech activities at a local level. HDOA is invited to
31 jointly conduct inspections with PPQ. Biotech training is held in Hawai'i every 3 years to certify that
32 inspecting officers are current in all laws, regulations, and protocols.

33 **A12.3.8 Convention on International Trade in Endangered Species of Wild Fauna and Flora**
34 **Materials**

35 PPQ facilitates legal and safe trade of Convention on International Trade in Endangered Species of Wild
36 Fauna and Flora (CITES) materials by maintaining CITES protocols and abilities at the USDA Honolulu
37 Plant Inspection Station. All CITES shipments entering Hawai'i are inspected for proper documentation

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 and all materials are inspected for quarantine pests to ensure protection of Hawai'i's agricultural and
2 nursery industries. Over the last year 393,242 plants have been inspected with 47 plants refused entry.
3 All CITES plants seized due to lack of CITES documentation are sent to authorized Plant Resource Rescue
4 Centers.

5 **A12.3.9 Import Permits**

6 To further close pathways, PPQ and HDOA require permits to be obtained for the importation, transit,
7 domestic movement, and environmental release of foreign organisms that could impact the ecosystem
8 and agriculture if permitting requirements are not established. Permits are issued in consultation with
9 HDOA and in accordance with federal regulation and under the authority of the Plant Protection and
10 Honeybee Acts. Other actions taken in responses to the information gained from the analysis include
11 adding additional information in import permits for palm seeds entering Hawai'i, training CBP
12 Agriculture Inspectors on the requirements and inspection of seeds entering Hawai'i under special
13 Import Permits, and working closely with CBP Agriculture Inspectors at the U.S. Postal Service (USPS)
14 facility identifying plants and plant products that are admissible or prohibited into Hawai'i. All of these
15 achievements further contribute to the reduction of the movement of pests into Hawai'i.

16 **A12.3.10 Fruit Fly Detection Program**

17 PPQ maintains a Fruit Fly Detection Program (FFDP) in Hawai'i that is designed to detect exotic fruit fly
18 species in high-risk areas and to provide a "first alert" trigger for swift emergency actions in cooperation
19 with HDOA. This program collaborates with groups like the HDOA, USDA's Agricultural Research Service,
20 and PPQ's Center for Plant Health Science and Technology (CPHST) to develop and implement new
21 control technologies for invasive fruit fly pests. Examples include developing traps and lures for
22 surveillance and detection, as well as methods for the mass rearing of sterile insects to be released in
23 combat against invasive fruit fly species. PPQ maintains the USDA Fruit Fly Facility in Waimanalo, Hawai'i
24 and collaborates with the California Department of Food and Agriculture Fruit Fly Facility, the University
25 of Hawai'i, and CPHST to sterilize fruit fly pupae for programs that use the Sterile Insect Technique to
26 rear larvae for USDA sterilized fruit fly release programs. Furthermore, since the analysis was conducted,
27 PPQ's FFDP has participated in the evaluation of Oahu to determine which areas are at the highest risk
28 for possible introduction of new fruit fly species. The FFDP focuses on these areas with year-round fruit
29 fly trap monitoring. With its expertise, the Hawai'i FFDP also assists with other pest detection/trapping
30 programs as needed including the Nettle Caterpillar (*Darna pallivitta* Moore) Survey, European Pepper
31 Moth (*Duponchelia fovealis*) Survey, Coconut Pest Survey (Coconut Rhinoceros beetle *Oryctes*
32 *rhinoceros*), and Red Palm Weevil (*Rhynchophorus ferrugineus*) Survey.

33 **A12.3.11 Key Partnerships**

34 PPQ works to identify high-risk commodities and associated pathways, adapt targeting and compliance
35 methodologies, utilize risk analysis in determining inspectional processes, and provide cross-training at
36 the port level. This work is carried out in partnership with a number of organizations in APHIS and
37 federal and state agencies discussed below. PPQ takes a lead role in the Hawai'i Risk Assessment
38 Committee meetings, where federal and state regulatory agencies meet to discuss new and emerging

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 risks and collaborate to develop mitigations. In this venue, PPQ partners with Veterinary Services,
2 Wildlife Services (WS), DHS CBP, FDA, USFWS, and HDOA to identify high-risk commodities and
3 associated pathways, adapt targeting and compliance methodologies, utilize risk analysis in determining
4 inspectional processes, and in providing cross-training at the port level. For example; PPQ developed
5 and delivered pest detection and pest identification training to CBP Agricultural Specialists working in
6 foreign passenger baggage, air cargo, maritime, and the mail branch. Included in the training were
7 modules addressing pests of concern that are seen at ports of entry, most common pests of concern
8 intercepted at the Port of Honolulu, insect and federal noxious weed identification, and disease
9 symptom recognition. By offering continual training opportunities, PPQ is strengthening working
10 relationships with CBP and improving the ability to effectively exclude exotic pests.

11 PPQ is a steering committee member in the Coordinating Group on Alien Pest Species (CGAPS), where
12 management-level staff from every major agency and organization in Hawai'i, including federal, state,
13 county, and private entities influence policy and funding decisions, improve communications, increase
14 collaboration, and promote public awareness as it relates to quarantine and in invasive species work.
15 CGAPS provides policymakers with information for decision making, and works closely with legislators to
16 write and introduce new legislation to address safeguarding, quarantine, eradication, and preventative
17 actions and abilities. CGAPS successfully secured a new funding mechanism from the legislature in 2007
18 and 2008 to pay for cargo inspection and associated infrastructure. It plays a key role in facilitating
19 communication and cooperation among federal and state agencies, and developed the Silent Invasion
20 public education campaign, which includes television, print media, and direct community outreach by
21 staff. CGAPS has reduced the risk of the brown treesnake (BTS) (*Boiga irregularis* [Merrem]) becoming
22 established in Hawai'i by training state-wide rapid-response search teams and supporting interdiction
23 measures. As a proactive measure, CGAPS has developed a rapid-response plan to eradicate incursions
24 by the RIFA. CGAPS also worked to create the Hawai'i Invasive Species Council (HISC) for the special
25 purpose of engaging cabinet-level leadership to provide policy direction, coordination, and planning
26 among state departments, federal agencies, and international and local initiatives. The HISC approves an
27 annual budget to support invasive species prevention, control, research and technology, and public
28 outreach projects across the state. Funded projects include the county-based Invasive Species
29 Committees, Aquatic Invasive Species team and hull fouling/ballast water coordinator, the Weed Risk
30 Assessment program, and the Hawai'i Ant Lab. For FY 13, HISC funded a project in conjunction with the
31 Hawai'i Biodiversity Information Network to create an interagency pest notification system and link
32 online reporting to the pest hotline.

33 PPQ is working with HDOA to address its concern for improved notification procedures of the possible
34 importation of federal non-actionable pests that may not have significant impacts to the nation's
35 agriculture industry, but may have significant impacts to Hawai'i's agriculture and natural resources.
36 These non-actionable pests are imported into Hawai'i, either accidentally or intentionally through the air
37 and maritime pathways.

38 Key partners in Hawai'i should be more connected with regional entities involved with IAS such as RISC,
39 SPREP, SPC, PIP and others.

1 **A12.3.12 Pacific Safeguarding Initiative**

2 Recognizing the uniqueness of Hawai'i and the pest pressures from the Pacific and Asia Regions, PPQ
3 established the Pacific Safeguarding Initiative (PSI), which is designed to reduce or eliminate risks before
4 they approach the shores of the United States. The PSI accomplishes this by building a coordinated
5 framework and partnership network with national plant protection organizations, regional plant
6 protection organizations, universities, non-government organizations (domestic and foreign), U.S.
7 Embassy staffs, and other organizations. Its goal is to strengthen regional and national pest exclusion
8 activities within the Asia and Pacific Region, enhance pest detection activities within the region,
9 strengthen pest mitigation and suppression activities, and enhance communication and reporting of
10 pest detection and mitigation activities within the region. Further, PSI works to build the capacity of
11 national and regional plant protection organizations as well as key stakeholders to effectively manage
12 current and future pest risks, and to negotiate with other U.S. agencies to elevate invasive species issues
13 within their departments.

14 In the past year the PSI has:

- 15 • Co-drafted a resolution for the Micronesian Chief Executives in which the Chief Executives of
16 Guam, the CNMI, Palau, the Federated States of Micronesia and the Republic of the
17 Marshall Islands resolve that they shall, among other things, integrate invasive species
18 concerns into national and regional efforts and provide dedicated staff to work on
19 Micronesia Regional Invasive Species Council initiatives to reduce the movement of pests
20 into and out of their respective countries and the region. This resolution was signed by all
21 Presidents and Governors in the region.
- 22 • Led discussions and actions with HDOA, the National Invasive Species Council (NISC), The
23 Nature Conservancy, and the Coordinated Group on Invasive Species to develop a more
24 efficient method of evaluating plant pests that are not known to occur in Hawai'i for
25 potential federal action and to harmonize actionable pest lists.
- 26 • Worked with airlines to reduce risk in international passenger flights in the region.
- 27 • Met with members of the Pacific Plant Protection Organization (PPPO) to help draft the
28 PPPO 2012-2018 Strategic Framework (adopted), and to develop a 3-year implementation
29 plan (adopted).
- 30 • Assumed the USDA lead role in the Micronesia Biosecurity Plan.

31 All these activities and programs are accomplished to reduce risk to Hawai'i while maintaining
32 transparency. Not only do these activities result in increased safe trade, they also result in the
33 protection of American agriculture and natural resources in Hawai'i, the Pacific, and the U.S. mainland
34 from threats posed by foreign invasive and agricultural pests.

1 **A13 PATHWAY ANALYSIS OF INVASIVE SPECIES INTRODUCTION INTO THE STATE** 2 **OF HAWAI'I**

3 **A13.1 INTRODUCTION**

4 **A13.1.1 Rationale for Pathway Analysis of Invasive Species Introduction into Hawai'i**

5 Three characteristics contribute to the uniqueness of the Hawai'ian Archipelago: 1) the islands are
6 arranged linearly in chronological order; 2) there is a large number of endemic species, many of which
7 are numerically dominant and display traits distinct from related taxa; and 3) evolutionary phenomena
8 characteristic of island environments in general, such as adaptive shifts, loss of dispersal ability, and
9 arborescence, are developed to an extraordinary degree (Simon 1987). The features of island life—
10 isolation, specialization, limited mobility, and lack of defenses (e.g., toxins, thorns)—have rendered it
11 vulnerable to various kinds of disturbance. For example, unlike the organisms that have originated on
12 continents, most species endemic to Hawai'i and other oceanic islands have evolved in isolation from
13 certain evolutionary pressures, such as grazing and trampling by ungulate mammals; predation by
14 rodents, ants, amphibians, reptiles, and carnivorous mammals; virulent diseases; and frequent and
15 intense fires (Westbrooks 1998). Because of this, the biota of oceanic islands is thought to be
16 comparatively fragile—lacking defenses against introduced predators, parasites, pathogens, and grazers,
17 and adaptations to allow coexistence with introduced competitors (Simberloff 1995). Thus, like other
18 oceanic islands, Hawai'i is particularly vulnerable to biological invasions. For example, although Hawai'i
19 is one of the smallest states in the United States, comprising just 0.2% of its total land mass, more than
20 25% of the endangered species in the United States occur there (OTA 1993). Hawai'i is infamous as “the
21 extinction capital of the United States,” with 72% of the country's recorded extinctions (Gagné 1988;
22 OTA 1993).

23 A growing recognition of Hawai'i's unique status and the vulnerability of its agriculture and other
24 economic sectors, as well as its natural environment, to biological invasion has prompted legislative
25 action. On July 27, 2005, former Congressman Ed Case (2nd District, Hawai'i) introduced the Hawai'i
26 Invasive Species Prevention Act (H.R. 3468) to the U.S. House of Representatives. The purpose of this bill
27 was “to recognize the unique ecosystems of the Hawai'ian Islands and the threat to these ecosystems
28 posed by non-native plants, animals, and plant and animal diseases, to require the Secretary of
29 Agriculture and the Secretary of the Interior to expand federal efforts to prevent the introduction in
30 Hawai'i of non-native plants, animals, and plant and animal disease, and for other purposes.” The bill
31 concluded that “the current Federal statutory and regulatory regime is not sufficient to minimize the
32 introduction of invasive species into Hawai'i and the environmental, economic, and social harm that
33 would result from the introduction of additional invasive species.” Among other things, the bill proposed
34 “rules regarding the establishment of a system of post-arrival quarantine protocols for all persons,
35 baggage, cargo, containers, packing materials, and other items traveling or being shipped to Hawai'i
36 from domestic and foreign locations” and the establishment of “an expedited process for the State of
37 Hawai'i and its political subdivisions to seek the approval of the Secretaries to impose general or specific
38 prohibitions or restrictions upon the introduction or movement of invasive species or diseases from
39 domestic or foreign locations to Hawai'i....”

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 In order to address the invasive species problem in Hawai'i, the origins of alien species, and the means
2 or "pathways" by which they are introduced into the state, must be examined. To date, no pathway
3 analysis has been conducted by the USDA to assess and quantify the risks posed by invasive species to
4 Hawai'i's agriculture and natural environment, and to provide a sound basis for science-based decision
5 making. The objectives of this study, requested by the Deputy Administrator of the USDA-APHIS-PPQ
6 branch, were several. The study sought to answer the following questions:

- 7 • What are the major pathways by which invasive species are introduced into Hawai'i?
- 8 • What is the present risk to Hawai'i of introduction and establishment of invasive species
9 from foreign countries and from the U.S. mainland and its overseas territories?
- 10 • What are the current sanitary and phytosanitary regulations, practices, and resources in
11 Hawai'i?

12 The present report is divided into two broad sections. In the first section, providing background
13 information, invasive species already established in Hawai'i and their consequences are discussed
14 (Chapter B3). Next, an outline of state and federal programs for alien species interdiction in Hawai'i is
15 presented (Chapter B4). Chapters B5 through B9 in the second section present results of analyses of the
16 risks of quarantine material and invasive pests entering the State of Hawai'i via the airline passenger,
17 cargo, "hitchhikers," wood packaging material, and military pathways, respectively. Lastly, a discussion
18 of some species with potential to invade Hawai'i, including potential consequences, is presented
19 (Chapter B10).

1 **A14 INVASIVE SPECIES IN HAWAI'I AND THEIR CONSEQUENCES**

2 As a tourist destination and center for commerce at the “crossroads of the Pacific,” Hawai'i has always
3 been vulnerable to the introduction and establishment of exotic organisms. Based on current estimates,
4 the total number of plant species present in the Hawai'ian Islands exceeds 11,000, of which
5 approximately 8,000 to 10,000 (72 to 90%) have been introduced (Staples et al. 2000; Staples and Cowie
6 2001; Eldredge 2006). This amounts to an average of more than 40 new plant introductions per year
7 over the past two centuries (Loope 1998). Of the more than 2,100 introduced species that constitute the
8 more commonly cultivated plants in Hawai'i, at least 470, or 22%, are considered invasive or potentially
9 invasive (Staples et al. 2000). At least 79 of the exotics have been officially designated as noxious weeds
10 by the HDOA (Hawai'i Administrative Rules § 4-68).

11 An estimated 9,277 terrestrial arthropod species are known from Hawai'i, of which 3,432 (37%) are
12 nonindigenous (Eldredge 2006). The first alien insects undoubtedly were brought with the early
13 Hawai'ians, who introduced fleas and the head louse (*Pediculus humanus capitis* De Geer) to the islands;
14 later, European explorers and whalers introduced other noxious arthropod pests, such as mosquitoes
15 (probably *Culex quinquefasciatus* Say), first recorded in 1826 from Lahaina on the island of Maui
16 (Pemberton 1964). Immigrants comprise 6% (133 species) of the estimated total of 2,171 mollusc
17 species. In all, some 500 species of arthropods and molluscs in Hawai'i can be classified as pests
18 (Beardsley 1991). Of these, 98% have been introduced. In recent years, the rate of new pest arthropods
19 and molluscs establishing in Hawai'i has averaged 3.5 species annually (Beardsley 1991). Over 1,100
20 plant parasitic and pathogenic species (nematodes, bacteria, fungi, and other microorganisms) are
21 known to occur in Hawai'i (Raabe et al. 1981). Most of these are non-indigenous.

22 **A14.1 IMPACT ON THE ENVIRONMENT**

23 At least one half of the wild species in Hawai'i today are non-indigenous (OTA 1993). No other area in
24 the United States has as great a proportion of established non-indigenous species (OTA 1993). They
25 have had a profoundly negative effect on natural environments in Hawai'i; natural areas that still
26 support indigenous species in relatively intact habitats make up only about 25% of Hawai'i (OTA 1993).
27 For all natural areas, the control and management of invasive species consumes the vast bulk of
28 resource management budgets (OTA 1993).

29 Introduced arthropods have been implicated in the decline or extinction of rare native plant and animal
30 species through direct feeding, predation, or parasitization; disruption of pollination; transmission of
31 pathogens; and competition (e.g., Warner 1968; Howarth 1985; van Riper et al. 1986; Gambino et al.
32 1987; Gambino 1992; Howarth et al. 2001; Oboyski et al. 2004; Johnson and Denslow 2005). Some of
33 the greatest harm visited upon native species and ecosystems, directly or indirectly, has resulted from
34 invasion by ants (Krushelnycky et al. 2005), no species of which occurred in Hawai'i before the arrival of
35 humans (Wilson 1996). Similarly, the introduction of alien snails has led to drastic declines or extinctions
36 in endemic snail species (Hadfield and Mountain 1980; Cowie 1998).

37 Invasive plants, many of which were intentionally introduced, are systematically altering the basic
38 properties of some of Hawai'i's ecosystems, such as light availability, soil water-holding capacity,

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 nutrient uptake, and other microclimatic variables (Vitousek 1992; Cordell et al. 2002). Non-native
2 grasses have played a major role in altering the natural fire regime in Hawai'i (Staples 2001; Benton
3 2006). Smith (1985) discussed the characteristics of 86 alien plant species that have become significant
4 pests of native ecosystems in Hawai'i, many displacing populations of less competitive native plants.
5 Additional plant species with the potential to become invasive continue to be introduced into the state
6 (e.g., Staples et al. 2006), a major route being the trade in horticultural plants (Staples and Cowie 2001).

7 Plant invasions in Hawai'i often have been facilitated by the grazing and other disturbances to native
8 habitat caused by introduced ungulate mammals (Stone 1985). Although single-species invasions in
9 Hawai'i, such as those involving plants, in themselves may be devastating to native biota or ecosystems
10 (e.g., Vitousek et al. 1987; Hughes and Denslow 2005), invasive species (e.g., alien grasses and vines,
11 mammals, predatory and parasitic Hymenoptera) also may act in concert to threaten native species,
12 such as birds, drastically restricting their foraging ranges (e.g., Banko et al. 2002).

13 The precarious state of the endemic Hawai'ian biota has been summarized thusly (OTA 1993): "By many
14 measures, the Hawai'ian Islands represent the worst-case example of the Nation's [nonindigenous
15 species] problem. No other area in the United States receives as many new species annually, nor has as
16 great a proportion of [nonindigenous species] established in the wild. At the same time, Hawai'i, the
17 Nation's so-called extinction capital, has the greatest concentration of threatened and endangered
18 species in the United States and the greatest number of extinct species as well. While habitat
19 destruction has been and continues to be a main factor in the demise of the indigenous biota,
20 [nonindigenous species] have been identified as an important, if not the most important, current
21 threat."

22 **A14.1.1 Impact on Agriculture**

23 All of the crops cultivated and livestock raised in Hawai'i are introduced species, and virtually all of the
24 agricultural pests in Hawai'i have been introduced as well (OTA 1993). Invasive pests impact agriculture
25 directly by destroying crops and increasing costs of production, and by limiting markets in mainland and
26 foreign areas that have imposed quarantines on produce from Hawai'i because of the threat of new
27 pests (OTA 1993). For example, because of a federal quarantine, fruit fly host products can only be sold
28 in the rest of the United States if they have undergone some type of quarantine treatment (e.g.,
29 fumigation, irradiation). Quarantine treatments are generally required even for commodities, to which
30 the damage caused by pests of concern is insignificant or rare. Quarantine treatments add significant
31 costs to these commodities, which reduce their competitiveness in the global marketplace (McGregor
32 2004).

33 Although the full economic impact of invasive species on Hawai'i's agriculture is unknown, the presence
34 of non-indigenous quarantine pests in Hawai'i was estimated to result in a \$300-million annual loss of
35 agricultural export revenue from the closure of U.S. mainland and foreign markets alone (USDA 2006b).

36 Additionally, invasive pests have had a profound impact on shaping Hawai'i's agriculture as a whole. For
37 example, McGregor (2004) noted that, although the agronomic conditions are favorable in Hawai'i for a

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 variety of fruit crops, these crops are never seriously considered for commercial development in Hawai'i
2 because of the imposing nature of fruit fly damage, quarantine restrictions, and costly post-harvest
3 treatments. In particular, the loss of export markets, resulting from quarantine restrictions in the U.S.
4 mainland and some foreign countries, is often cited as the main barrier to the expansion of Hawai'i's
5 diversified agriculture (OTA 1993).

6 **A14.1.2 Case Studies**

7 **A14.1.2.1 Plants**

8 **A14.1.2.1.1 *Miconia calvescens* DC (Melastomataceae) (miconia, velvet tree)**

9 **Origin:** Tropical America: Mexico, Central and South America

10 **Mode of introduction:** Introduced intentionally as an ornamental plant in the 1950s or 1960s.

11 **Environmental impacts.** *Miconia* has been spreading aggressively in both native and disturbed forests
12 since its introduction, threatening many of Hawai'i's remaining native plants (Staples and Cowie 2001;
13 Kaiser 2006). This invasive weed has the potential of completely dominating all of Hawai'i's native wet
14 forests, as it has in Tahiti, where dense, monotypic stands of the tree now cover 65% or more of the
15 main island after the introduction of just a single specimen in 1937 (Kaiser 2006). *Miconia*'s ability to
16 out-compete native plants is well documented: it forms dense thickets that block sunlight and crowds
17 out other plants, and it produces an enormous number of seeds that are spread by birds and rats, and
18 remain viable in soil for many years (Staples 2001). Additionally, it promotes erosion because its shallow
19 root system does not hold soil on steep slopes, particularly in heavy rains (Reaser et al. 2007).

20 **Economic impacts.** *Miconia* is not an agricultural pest per se, and it is difficult to measure its economic
21 impact because damages are indirect, impacting ecosystem services and non-market goods, such as
22 biodiversity (Kaiser et al. 2006; Kaiser 2006). Kaiser (2006) attempted to quantify such damages, and
23 estimated that if *miconia* were to become established throughout its potential range in Hawai'i, total
24 damages could reach an average of \$377.4 million per year.

25 *Miconia* was targeted for eradication in the Hawai'ian Islands in 1991, and there is an active campaign to
26 remove it from all islands where it occurs and to prevent its spread. While the budget for the program
27 on all islands is unknown, Kaiser et al. (2006) reported that the Oahu Invasive Species Committee
28 allocated \$321,000 to *miconia* control in 2005 and that Maui expends approximately \$1 million per year
29 on *miconia*-related activities. Tavares (1998) reported that, between 1995 and 1997, approximately
30 \$500,000 was spent on *miconia* control and research programs on the Big Island of Hawai'i. Currently
31 *Miconia* is not considered eradicable from Hawai'i Island and not likely eradicable from Maui. If a
32 successful biocontrol could be developed then eradication might become a more feasible option.

33 **A14.1.2.1.2 *Psidium cattleianum* Sabine (Myrtaceae) (strawberry guava)**

34 **Origin:** Brazil

35 **Mode of introduction:** Originally introduced for cultivation in the 1800s.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 **Environmental impacts.** Strawberry guava was introduced intentionally as a fruit tree, but since has
2 become one of the islands' worst pests (Smith 1998; Staples 2001), especially in native rain forests
3 where it infests thousands of hectares (Johnson and Denslow 2005). Its dense thickets suppress native
4 species, and the plant is adapted to disturbance (Jacobi and Warshauer 1992). Strawberry guava may
5 build up an enormous seed bank in the soil, and seeds tend to germinate at higher rates in areas subject
6 to disturbance, such as that caused by feral pigs. In areas where strawberry guava is established, the
7 ground may be carpeted with highly shade-tolerant seedlings, which release compounds into the soil
8 that prevent other species from germinating (Staples 2001; Johnson and Denslow 2005), an adaptation
9 termed allelopathy. Additionally, strawberry guava plants produce an enormous number of fruit, which
10 are eaten by birds and other animals, and which, in turn, spread the seeds (Staples 2001).

11 The displacement of native trees is also facilitated by the interaction of strawberry guava with two
12 invasive species of ginger: *Hedychium gardnerianum* Shepard ex Ker-Gawl. (kahili ginger) and *Hedychium*
13 *coronarium* Koenig (white ginger). These species tend to cover and strangle the seedlings of both native
14 trees and strawberry guava, but guavas are more tolerant of the cover, and are better able to survive
15 than are native trees (Cox 1999).

16 **Economic impacts.** As with miconia, it is difficult to measure the economic impacts of strawberry guava.
17 In addition to the damages caused to ecosystem services and biodiversity, the numerous fruit produced
18 by a single plant provide a major food resource to fruit fly pests of Hawai'ian agriculture, which
19 increases the difficulty and cost of controlling these species (Johnson and Denslow 2005). Unfortunately,
20 strawberry guava, and its congener, *Psidium guajava*, the common guava, are still planted as
21 ornamentals and fruit trees (Staples and Cowie 2001).

22 **A14.1.2.1.3 *Pennisetum setaceum* (Forssk.) Chiov (Poaceae) (fountain grass)**

23 **Origin:** Northern Africa

24 **Mode of introduction:** Introduced as an ornamental grass around 1914.

25 **Environmental impacts.** Fountain grass is one of several non-native grasses that have played a major
26 role in altering the natural fire regime in Hawai'i. Lightning is uncommon on oceanic islands; therefore,
27 in contrast to many other terrestrial environments, fire has not played much of an evolutionary role in
28 the native ecosystems of Hawai'i (Westbrooks 1998). Thus, few Hawai'ian endemic plant species possess
29 adaptations to fire. Humans are the cause of most fires in Hawai'i, and these fires are fueled primarily by
30 non-native grasses (Brooks et al. 2004).

31 Like other invasive grasses in Hawai'i, fountain grass is a highly aggressive, fire-adapted colonizer of
32 pastures and grasslands that readily out-competes and replaces native plants and rapidly re-establishes
33 after burning. In the summer, when the grass dries out, it becomes a fire hazard. The grass burns quickly
34 with intense heat, resulting in severe damage to native forest species, which are not adapted to such
35 extreme fire regimes (Staples 2001; Benton 2006). Fountain grass out-competes other grasses by
36 regenerating quickly after burning; native grasses and many forage grasses do not have this capacity
37 (Staples 2001).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 In addition to increasing the frequency and intensity of fires, there is some evidence that fountain grass
2 also alters basic ecosystem properties, such as light availability, soil water holding capacity, nutrient
3 uptake, and other microclimatic variables (Cordell et al. 2002). Fountain grass is also an aggressive
4 invader of bare lava flows, where it reportedly interferes with normal plant succession (Tunison 1992;
5 Staples and Cowie 2001). Its seeds are dispersed by wind, water, humans, vehicles, and birds (Tunison
6 1992), but because of an active control program to prevent it from spreading to other islands, so far,
7 extensive damage has been limited to the Big Island (HDLNR 2007).

8 **Economic impacts.** Control of fountain grass is difficult and expensive, often costing more than \$12,000
9 per hectare (Cordell et al, 2002).

10 **A14.1.2.2 Arthropods**

11 It has been estimated that since European contact with the Hawai'ian Islands in the 18th century,
12 approximately 15 to 20 new species of insect immigrate to Hawai'i each year (Beardsley 1962; 1979).

13 **A14.1.2.2.1 *Bactrocera dorsalis* (Hendel) (Diptera: Tephritidae) (oriental fruit fly)**

14 **Origin:** Southern Asia

15 **Mode of introduction:** Military air transport from Saipan (Jang and Harris 2005).

16 **Environmental impacts.** The oriental fruit fly is widespread in native forests, and feeds on both native
17 and introduced fruits. Efforts to control fruit fly populations, particularly with organophosphate
18 pesticides, may severely impact native species.

19 **Economic impacts.** The oriental fruit fly was introduced into Hawai'i around 1945, and quickly displaced
20 the Mediterranean fruit fly, *Ceratitis capitata* (Wiedemann) (introduced around 1910 [Clausen et al.
21 1965]), throughout most of its range (Vargas et al. 2001; Jang and Harris 2005). Along with the melon fly,
22 *B. cucurbitae* (Coquillett), the oriental fruit fly is the most damaging of Hawai'i's exotic fruit flies. It has a
23 wide host range, and is a major pest of almost every variety of fruit grown commercially in Hawai'i
24 (Harris 1989). Guava, mango, papaya, carambola, passion fruit, citrus, tomato and breadfruit are
25 particularly susceptible, and, left uncontrolled, oriental fruit flies can damage up to 100% of fruit in a
26 production area (CABI 2006).

27 In Hawai'i, producers suffer significant direct and indirect economic losses from fruit fly damage
28 (Hendrichs 1996). Even with control, annual losses in fruit crops resulting from infestations by the
29 oriental fruit fly may exceed 13% (Culliney 2002), undoubtedly an underestimate. Globally, *B. dorsalis*
30 causes millions of dollars worth of damage each year (SPC 2002b). Additionally, fruit flies can have a
31 significant impact on crop values, even when they do not actually infest the fruit. Fruit quality can be
32 reduced due to fruit fly oviposition punctures ("stings"), which affect the appearance of fruit, even in
33 fruits unfavorable for larval survival (Harri 1989). Moreover, many fruits, including papayas and
34 tomatoes, are harvested before they are ripe, in part to avoid fruit fly stings and infestations. Harvesting
35 these fruits early affects their taste. Papayas, for example, increase in sugars and sweetness as they
36 mature on the tree. McGregor (2004) estimated that growers could expect about \$.11 more per

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 kilogram (kg) for tree-ripened papaya than papaya picked green, which would translate into approximately \$750,000 per year for the industry.

3 Strict quarantine regulations are necessary to prevent the movement of fruit flies from the Hawai'ian Islands to fruit fly-free areas, and fruit producers have had to invest in expensive post-harvest treatments and facilities to disinfest fruit cargoes before or during shipment (Hendrichs 1996; Howarth et al. 2001). Costs of post-harvest treatments can be significant. Additionally, millions of dollars continue to be spent on fruit fly-related research, including research on various control techniques (e.g., area-wide pest management, sterile insect technology) and alternative post-harvest treatments.

9 In addition to these direct costs, there are immeasurable indirect costs associated with lost markets and industries. McGregor (2004) speculated that these costs are likely to be much greater than the direct costs mentioned above. A study conducted by the Nature Conservancy of Hawai'i (Miller and Holt 1992) postulated, based on industry estimates, that oriental and melon flies cost Hawai'i \$300 million per year in lost markets. While there are few data available to confirm this estimate, it is clear that the presence of exotic fruit flies is a significant deterrent to the research and development of crop industries that are significant hosts of fruit flies. For example, in Hawai'i, practically all guavas are processed—none is sold for fresh consumption—due to high oriental fruit fly infestations (McGregor 2004).

17 ***A14.1.2.2 Aleurodicus dispersus Russell (Hemiptera: Aleyrodidae) (spiral whitefly)***

18 **Origin:** Central America and the Caribbean

19 **Mode of introduction:** Accidentally introduced about 1978, probably on flowers or produce (Howarth et al. 2001).

21 **Environmental impacts.** The spiraling whitefly has a broad host range. It is generally found in coastal areas (Howarth et al. 2001), but environmental impacts due to the introduction of this pest seem to have been minimal.

24 **Economic impacts.** The spiraling whitefly has been recorded on more than 100 species of plant, belonging to 38 genera and 27 families, and commonly attacks many vegetable, ornamental, fruit, and shade tree crops in Hawai'i (Kessing and Mau 1993; CABI 2006), including annona, avocado, banana, bird-of-paradise, breadfruit, citrus, coconut, eggplant, guava, kamani, Indian banyan, macadamia, mango, palm, paperbark, papaya, pepper, poinsettia, rose, sea grape, and tropical almond (Kessing and Mau 1993).

30 Following its introduction into Hawai'i, *A. dispersus* became a major economic pest, and the HDOA and its cooperators conducted extensive searches for biological control agents that could be introduced to reduce its populations. Several natural enemies were introduced into Hawai'i from the Caribbean in the early 1980s. The biological control program seems to have been successful, and at least one agent was documented to reduce populations by as much as 79% at lower elevations and 99% at higher elevations. At present, the spiraling whitefly is generally considered only a minor pest (Kessing and Mau 1993). Infestations can have serious economic impacts in at least three ways:

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

- 1 • Direct damage to the plant caused by feeding: *A. dispersus* larvae (and to a lesser degree, adults) cause damage by sucking sap from leaves. Direct feeding can cause premature leaf drop, which may reduce plant vigor and yields, but rarely kills plants outright (CABI 2006).
- 4 • Indirect damage to the plant caused by excreted honeydew: Damage is caused when sooty molds develop on honeydew excreted by the insects. Sooty molds covering leaves can hinder photosynthesis and reduce yields (CABI 2006).
- 7 • Cosmetic damage to the fruit: Damage is caused by both sooty molds and the white flocculent wax secreted by immature stages. Although cosmetic damage does not affect the plant itself, it can significantly reduce the market-value of crops (CABI 2006).

10 *Aleurodicus dispersus* is a quarantine pest for other countries, and is listed as a reportable/actionable pest for the contiguous United States (despite its presence in Florida) (USDA 2007a). Crop exports are sometimes rejected at a mainland port due to the presence of this pest (Staples and Cowie 2001), meaning lost income for Hawai'i growers.

14 **A14.1.2.2.3 *Coptotermes formosanus* Shiraki (Isoptera: Rhinotermitidae) (Formosan**
15 **subterranean termite)**

16 **Origin:** Taiwan or South China

17 **Mode of introduction:** Accidentally introduced via shipping (Staples and Cowie 2001).

18 **Environmental impacts.** There are seven species of termite in Hawai'i, all of them introduced (Woodrow et al. 1999). Although, in general, *C. formosanus* is an urban pest, it has also been found attacking living plants (especially trees), resulting in damage to all parts of the plant, but in particular the heartwood, roots and branches (Lai et al. 1983). In New Orleans, an estimated 30 to 50% of the historic live oak trees are infested with *C. formosanus* (Anonymous 2007). Similar estimates for Hawai'i were not available, but Lai et al. (1983) reported several instances in Hawai'i in which apparently healthy trees were hollowed out by termites, causing them to fall.

25 Additionally, increased use of pesticides to control termite populations has led to negative effects on the environment, including contamination of water supplies caused by runoff (Anonymous 2007).

27 **Economic impacts.** *Coptotermes formosanus* commonly attacks structural timbers, books, and other finished wood or paper products. The termite is considered the single most costly economic pest in Hawai'i, causing over \$150 million worth of damage each year to buildings, furnishings, and trees (Woodrow et al. 1999; Staples and Cowie 2001). Moreover, this species is not believed to have reached its full distribution in Hawai'i, and it is believed that costs will probably increase in the future as 1) the termite moves into areas in Hawai'i where it does not yet occur; 2) the colony density increases in areas where the termite does occur; 3) the values of existing buildings increase; and 4) additional buildings are constructed, putting more buildings at risk (Yates 1992).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 One of the reasons for the high costs associated with this insect stems from the fact that *C. formosanus*
2 is an aggressive pest that leaves little evidence of attack until considerable damage has been done.
3 According to Yates (1992), “often the first indication of an infestation is a sagging floor or door, leaking
4 roof, warping of walls, hollow sounding beams, short circuits, telecommunication blackouts, etc.”
5 Colonies of *C. formosanus* are large: in Hawai’i, an average colony contains over 2 million individuals,
6 and some may have as many as 10 million individuals. Because of their numbers, a great deal of damage
7 can occur in a short amount of time. In some cases, unprotected homes built over strong existing
8 colonies have been almost completely destroyed in 2 years (Yates 1992).

9 **A14.1.2.2.4 Ants (Hymenoptera: Formicidae)**

10 There are 43 species of ant in Hawai’i, all of them introduced. In terms of environmental impact, they
11 are arguably the most harmful invasive insect species in Hawai’i. After being introduced into a new area,
12 many species of ant are able to establish colonies quickly in a variety of habitats. They prey on other
13 invertebrates or feed on the seeds of plants, and often out-compete native species for food and space.
14 In Hawai’i, they have been directly associated with the destruction of many native insect species
15 (Staples and Cowie 2001).

16 **A14.1.2.2.5 *Pheidole megacephala* (Fabricius) (bigheaded ant)**

17 **Origin:** Tropical Africa

18 **Mode of introduction:** Accidentally

19 **Environmental impacts.** This ant is widely considered a serious threat to biodiversity and one of the
20 “world’s worst invaders” (Hoffman 2006). In the environment, it is a major predator implicated in the
21 extermination of many lowland insects (Staples and Cowie 2001). Evidence also exists of reductions in
22 vertebrate populations in areas where this ant is extremely abundant. Additionally, it is known to
23 facilitate the invasion of introduced plant species (Hoffman 2006).

24 **Economic impacts.** The bigheaded ant is often a household pest, with large, inter-connected colonies
25 that are difficult and expensive to control (Staples and Cowie 2001). It is also known to chew on
26 irrigation lines, telephone cabling, and electrical wires (Hoffman 2006).

27 In agriculture and horticulture, bigheaded ants can be serious pests, either directly, by collecting and
28 harvesting seeds, or indirectly, by protecting and tending phytophagous Homoptera, such as the pink
29 pineapple mealybug, resulting in population increases of these pests and consequent reductions in plant
30 productivity (Staples and Cowie 2001; Hoffman 2006).

31 **A14.1.2.2.6 *Linepithema humile* (Mayr) (Argentine ant)**

32 **Origin:** Brazil and Argentina

33 **Mode of introduction:** Accidentally

1 **Environmental impacts.** The Argentine ant was introduced into Hawai'i about 1940 (Staples and Cowie
2 2001). Although it is generally associated with disturbed habitats throughout its introduced range, it has
3 also invaded native habitats that have experienced little human disturbance (Krushelnycky 2006).

4 Native arthropods are greatly threatened by Argentine ants. They compete aggressively with native
5 arthropods for limited food resources and nesting sites. For example, in South Africa, the Argentine ant
6 can collect up to 42% of available nectar before bees can forage (Krushelnycky 2006). In Hawai'i, the
7 Argentine ant is believed to be responsible for declines in populations of many native arthropods,
8 including moths and bees, which are essential pollinators of native plants (Cole et al. 1992; Staples and
9 Cowie 2001; Krushelnycky 2006). In addition to out-competing native arthropods, Argentine ants
10 actively prey on a number of native arthropod species, and have even been reported attacking the eggs
11 of the native Hawai'ian goose, or nene, *Branta sandvicensis* (Vigors) (Cole et al. 1992; Krushelnycky
12 2006). The pest has not yet reached its full potential distribution in the islands (Staples and Cowie 2001).

13 **Economic impacts.** Argentine ants do not appear to be important agricultural pests. However, they may
14 have an indirect, negative impact on agriculture and horticulture because they attack the predators and
15 parasitoids of scale insects, causing the scales to multiply and become more serious pests of crops and
16 horticultural plants (Staples and Cowie 2001).

17 **A14.1.2.2.7 *Varroa destructor* Anderson & Trueman (Parasitiformes: Varroidae) (varroa mite)**

18 **Origin:** Far East

19 **Mode of introduction:** Unknown; smuggling, honey bee swarms aboard ships, and shipments of bees
20 transiting Hawai'i are possible sources

21 **Environmental impacts.** The varroa mite is recognized as the most serious pest of the western honey
22 bee, *Apis mellifera* L., worldwide (Anderson and Trueman 2000; Sammataro et al. 2000). Australia and
23 Hawai'i were among the last few areas known to be free of infestation (Culliney 2003). However, in April
24 2007, varroa mites were detected in three abandoned hives on Oahu (Hao 2007).

25 In parasitizing the immature stages of the honey bee, *V. destructor* often kills its host outright (De Jong
26 et al. 1982). If the host survives, the resulting adult bee usually is deformed in some way and incapable
27 of contributing to colony welfare. Colony population size dwindles over time, and, left untreated, a
28 heavy infestation can kill a colony within 3 to 4 years. The mite is known to be a vector for at least four
29 honey bee viruses: sacbrood, acute paralysis, black queen cell, and deformed wing (the latter three not
30 known to occur in Hawai'i), some of which may cause severe mortality in colonies (Bailey and Ball 1991).
31 To combat the parasite, beekeepers must resort to the use of expensive pesticides, although there now
32 are clear indications that the mite is developing resistance to these (Sanford 1998). Wild bee colonies
33 have no defense; they have been reported to be dying out in the continental United States, where *V.*
34 *destructor* is well-established (Kraus and Page 1995).

35 Varroa disperses locally through phoresy, attaching itself to worker and drone honey bees, as well as to
36 a variety of other flower-frequenting insects, including other species of bee, flies, and beetles; flowers

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 may thusly be used by the mite as way stations to transfer to new insect vehicles (Kevan et al. 1990).
2 Spread of the mite over wide areas within countries results from migratory beekeeping (De Jong 1990).
3 The post-World War II increase in international travel and commerce has facilitated the spread of *V.*
4 *destructor* globally (Sammataro et al. 2000). First recorded on *A. mellifera* in Asia around 1960 (De Jong
5 1990), at present, the species is almost cosmopolitan in distribution (Anderson and Trueman 2000). That
6 this pernicious parasite has dispersed so widely and quickly attests to the ease with which it surmounts
7 geographic barriers and thwarts international quarantines.

8 **Economic impacts.** As agriculture in Hawai'i depends heavily on the pollination services provided by the
9 large feral honey bee population, it could be severely impacted should *V. destructor* become
10 established. For example, since its first detection in 2000, the total economic impact of *V. destructor* on
11 agriculture in New Zealand has been estimated at \$251 to \$566 million (Canyon et al. 2002).

12 The Hawai'i legislature recently passed legislation appropriating \$650,000 to be spent on training and
13 pesticides, and to reimburse beekeepers for mite control costs among other measures (Hao 2007).

14 **A14.1.2.3 Molluscs**

15 **A14.1.2.3.1 *Achatina fulica* Bowdich (*Achatinidae*) (*giant African snail*)**

16 **Origin:** East Africa, but introduced from Japan

17 **Mode of introduction:** Intentionally introduced on more than one occasion as a human food item and as
18 a pet species (Staples and Cowie 2001).

19 **Environmental impacts.** The giant African snail was first introduced into Hawai'i in the 1930s. Since that
20 time, it has become widespread (CABI 2006). Although *A. fulica* is primarily found in disturbed low- to
21 mid-elevation sites in Hawai'i, it has also been observed as an invader of primary or secondary forests
22 (Raut and Barker 2002). Large numbers in native ecosystems pose a threat to native plants, and it may
23 compete with native snails for food and space (Staples and Cowie 2001).

24 **Economic impacts.** The giant African snail is a generalist feeder and is a major crop and garden pest,
25 requiring frequent use of snail bait for control. As Raut and Barker (2002) noted, there are three main
26 costs associated with this pest in tropical agriculture. First, there is a loss of productivity caused by direct
27 feeding on crop plants or on other plants that provide shade or soil enrichment. The snails may also
28 transmit plant pathogens. Secondly, there are costs associated with management of this pest both in
29 terms of labor and in materials. Finally, there are opportunity costs associated with changes in
30 agricultural practices, such as planting only crop species resistant to *A. fulica* (Raut and Barker 2002).
31 The extent to which Hawai'i has incurred such costs is unknown.

32 Additionally, the snail is an intermediate host of the parasitic nematode, *Angiostrongylus cantonensis*
33 (Chen), or rat lungworm, which causes the disease eosinophilic meningoencephalitis in humans (Staples
34 and Cowie 2001).

1 **A14.1.2.3.2 *Euglandina rosea* Ferussac (*Spiraxidae*) (rosy wolf snail)**

2 **Origin:** Latin America, southeastern United States

3 **Mode of introduction:** Intentionally introduced to control African snails.

4 **Environmental impacts.** This snail was introduced into Hawai'i in 1955 as a potential biological control
5 agent against the giant African snail (Cox 1999; Staples and Cowie 2001). It is found in damp places in
6 both disturbed areas and native forests. Instead of controlling African snails, the rosy wolf snail has
7 devastated native snails, eliminating up to half of the 800 snail species endemic to Hawai'i, and is the
8 most serious predator of *Achatinella* spp. (Cox 1999), listed as endangered in Title 50, Part 17, Section
9 11 of the United States Code of Federal Regulations (50 CFR § 17.11).

10 **A14.1.2.3.3 *Pomacea canaliculata* (Lamarck) (*Ampullariidae*) (channeled or golden apple snail)**

11 **Origin:** South America, but probably introduced to Hawai'i from Southeast Asia (Staples and Cowie
12 2001)

13 **Mode of introduction:** Intentionally as a potential human food item for home consumption and as an
14 exotic escargot for the restaurant trade (Staples and Cowie 2001).

15 **Environmental impacts.** The channeled apple snail was introduced into Hawai'i about 1989. Since that
16 time, it has become increasingly widespread in taro growing areas, ponds, streams, and wetlands
17 (Staples and Cowie 2001). It has reached most wet areas on the islands of Kauai, Oahu, Maui, Lanai, and
18 Hawai'i (Levin 2006). According to Levin, almost 4,400 hectares of wetlands, ponds, streams, taro-
19 growing systems, and other habitats are at risk or have already been invaded by this pest. There is little
20 information available on the impact of this snail on freshwater wetland ecosystems and watersheds.
21 However, one recent study suggested that, in Thailand, high densities of *P. canaliculata* were associated
22 with the almost complete absence of aquatic plants, high nutrient concentrations, and subsequent
23 phytoplankton blooms (Carlsson et al. 2004; Levin 2006).

24 **Economic impacts.** *Pomacea canaliculata* is a general feeder that has been recorded on various aquatic
25 weeds, ong choi, and watercress (Levin 2006). It is a major pest of rice throughout much of Japan and
26 Southeast Asia (Staples and Cowie 2001; Cowie 2002). In Hawai'i, it is a serious pest of taro, feeding on
27 the stem, corms, and other plant parts (Staples and Cowie 2001), and accounts for yield losses ranging
28 from 18 to 25% annually (Levin 2006). Mitigation of the impact of this pest has increased labor, time,
29 and cash inputs by as much as 50% above traditional production costs (Levin 2006). Additionally, taro is
30 a crop of considerable cultural importance to Hawai'i (Ooka and Brennan 2000).

1 **A14.1.2.4 Vertebrates**

2 **A14.1.2.4.1 *Eleutherodactylus coqui* Thomas (coqui frog)**

3 **Origin:** Caribbean

4 **Mode of introduction:** Believed to have entered Hawai'i on uninspected potted plant material from
5 Puerto Rico about 1988 (HDOA 2007a).

6 **Environmental impacts.** *Eleutherodactylus coqui* is a small frog (less than 2.5 cm [about 1 inch] in
7 length) with a loud call (Staples and Cowie 2001). Aside from being a major nuisance pest, coqui frogs
8 pose a major threat to Hawai'i's native biota. For example, the population established in Hawai'i is
9 estimated to consume as many as 125,000 insects per hectare per night (CTAHR 2006; HDOA 2007a).
10 Additionally, the frogs compete with Hawai'i's native birds and other fauna that rely on insects for food
11 (Staples and Cowie 2001; CTAHR 2006). Thus, large frog populations could have adverse effects on these
12 species—many of them already threatened or endangered. The frogs also are known to increase soil
13 fertility by converting arthropod biomass into nutrients more readily available to plants, thus potentially
14 altering plant species composition and providing conditions favorable to weed invasion (Beard and Pitt
15 2005).

16 Coqui frogs are quite adaptable to the varied ecological zones and topography in Hawai'i. Whereas, in
17 Puerto Rico, frog populations are kept in check by predators, such as owls, snakes, tarantulas, and
18 scorpions, in Hawai'i, the coqui frog has no natural enemies (CTAHR 2006; HDOA 2007a). Populations
19 have exploded in the last 15 years; there are now over 200 infestations on the Big Island alone, and
20 Maui has over 40 infestations. The Coqui has been found on Oahu in at least five locations (CTAHR
21 2006), but currently there are no established populations. Coqui have been declared eradicated from
22 Kauai as of mid-2012. was recently discovered on Kauai In some areas where Coqui have been able to
23 establish, populations exceed 25,000 frogs per hectare (HDOA 2007a).

24 **Economic impacts.** There is little information on the actual economic consequences of the introduction
25 of this species. However, there is some speculation that, as populations of the frog increase, tourism
26 may be negatively impacted due to the extremely loud noise levels produced by this frog: calls can be as
27 loud as 80 to 90 decibels, about the same as a lawn mower (Staples and Cowie 2001; HDOA 2007a).
28 Since this frog is active at night, many residents and visitors in coqui-infested areas have complained
29 that they are unable to sleep due to the noise produced by the frogs (HDOA 2007a). Beyond potential
30 impacts on tourism, there is a possibility that Hawai'i's nursery industry could be negatively impacted by
31 the presence of this frog if exports are banned because of quarantine restrictions (Staples and Cowie
32 2001). An impact which has not been fully examined is the requirement of property owners to disclose
33 the existence of this species on their property.

1 **A14.1.2.4.2 *Sus scrofa* Linnaeus (feral pig)**

2 **Origin:** East Indies

3 **Mode of introduction:** Intentionally by the Polynesians for food.

4 **Environmental impacts.** Feral pigs represent one of the major threats to forests and other natural areas
5 (OTA 1993). In the process of rooting for food, they damage ground-level plant cover and greatly assist
6 in germination and spread of invasive plants, including strawberry guava. They also topple and eat
7 native tree ferns (Kishinami 2001).

8 **Economic impacts.** Pigs are considered the number one economic and environmental threat to
9 watersheds in Hawai'i, reducing the extent of plant cover, which impacts freshwater resources
10 (Kishinami 2001). Estimated damages from feral pigs range from \$1 million to almost \$24 million per
11 year (Kaiser et al. 1999). A further \$450,000 per year is spent to control pigs in national parks in Hawai'i
12 (Pimentel et al. 2000).

13 **A14.1.2.5 Conclusions**

14 Invasive species have caused hundreds of millions of dollars worth of damage in Hawai'i in terms of crop
15 losses, increased production costs, and lost markets. The sheer number of invasive species makes it
16 nearly impossible to evaluate the full impact of past biological invasions on the Hawai'ian economy.
17 From the few studies that have been conducted, it is clear that the impact must be considerable. For
18 example, fruit flies alone have been estimated to result in a \$300-million annual loss of agricultural
19 export revenue from the closure of U.S. mainland and foreign markets (Miller and Holt 1992). Potential
20 damages to the Hawai'i economy associated with the invasive weed, *Miconia calvescens* DC., have been
21 projected to exceed \$377 million per year (Kaiser 2006). Exotic termites cause more than \$150 million in
22 damage annually to structures throughout the state (Howarth et al. 2001). Estimated damages from
23 feral pigs range from \$1 million to almost \$24 million per year (Kaiser et al. 1999).

24 Perhaps more serious, invasive species have been responsible for endangering and causing the
25 extinction of native species—many of which are not found anywhere else in the world—and for the
26 destruction of native forests and other natural areas.

27 A summary of the impacts associated with the selected non-indigenous species reviewed in this chapter
28 is presented in Table B3-1. The introduction and establishment of other invasive pests, such as RIFA,
29 West Nile virus, and BTS, likely would have a similar or greater impact on Hawai'i's economy, and
30 further endanger the archipelago's endemic biota as well (Choo 2004) (see also Chapter 10).

31

1 **Table B3-1: Summary of Some of the Impacts Associated with Selected Non-indigenous**
 2 **Species in Hawai'i**

Name	Origin	Mode of Introduction	Economic impact	Environmental impact
<i>Miconia calvescens</i> (miconia, velvet tree)	Tropical America	Intentionally, as an ornamental	Almost \$2 million was allocated for control programs in 2005	Forms dense thickets that block sunlight and crowd out other plants; promotes erosion
<i>Psidium cattleianum</i> (strawberry guava)	Brazil	Intentionally, for cultivation	Costly to control	Dense thickets suppress native species; adapted to disturbance
<i>Pennisetum setaceum</i> (fountain grass)	Northern Africa	Intentionally, as an ornamental	Costly to control	Changes the fire regime; out-competes native plants
<i>Bactrocera dorsalis</i> (oriental fruit fly)	Southern Asia	Accidentally on military transports	An estimated \$300 million per year in lost market access; significant crop losses; significant costs of control	Attacks native fruits; large quantities of insecticide are used to control this pest
<i>Aleurodicus dispersus</i> (spiraling whitefly)	Central America and the Caribbean	Accidentally, probably on cut flowers or fresh produce	Considered a major economic pest until biological control agents were introduced	Probably unimportant
<i>Coptotermes formosanus</i> (Formosan subterranean termite)	Taiwan or South China	Accidentally, probably via shipping material	An estimated \$150 million worth of damage every year to wooden structures and other products	May attack living trees; large quantities of insecticide are used to control this pest
Ants (<i>Pheidole megacephala</i> and <i>Linepithema humile</i>)	Africa (<i>P. megacephala</i>); Brazil and Argentina (<i>L. humile</i>)	Accidentally	Household pests that are costly and difficult to control; have indirect impacts on agriculture	Responsible for the extinction or endangerment of several species of endemic insects
<i>Varroa destructor</i> (varroa mite)	Far East	Unknown; smuggling, swarms aboard ships, and shipments of bees transiting Hawai'i are possible sources	New introduction; total economic impact in New Zealand was estimated at \$251 to \$566 million; potential threat to Hawai'i agriculture	Could devastate wild bee populations; plants that depend on pollination for reproduction may be negatively impacted

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

Name	Origin	Mode of Introduction	Economic impact	Environmental impact
<i>Achatina fulica</i> (giant African snail)	Africa; probably introduced into Hawai'i from Japan	Intentionally, for food and as a pet species	Can be a major crop and horticultural pest	Competes with native snails for food and space
<i>Euglandina rosea</i> (rosy wolf snail)	Latin America	Intentionally, as a biological control agent for the giant African snail	Probably unimportant	Has devastated Hawai'i's native snails, eliminating up to half of the 800 species endemic to Hawai'i
<i>Pomacea canaliculata</i> (channeled or golden apple snail)	South America, but probably introduced into Hawai'i from Southeast Asia	Intentionally, for food	Has a major effect on taro production in Hawai'i; increases costs of production as much as 50%	May be devastating to communities of aquatic plants
<i>Eleutherodactylus coqui</i> (coqui frog)	Caribbean	Accidentally, probably on plants imported from Puerto Rico	Potential impact on nursery trade if quarantines are put in place; potential impact on tourism	Poses a threat to native Hawai'ian insect populations, including plant pollinators; may compete with native birds for food
<i>Sus scrofa</i> (feral pig)	East Indies	Intentionally, for food by Polynesians	Costly to control	Damaging to indigenous plants; in altering plant cover, indirectly may affect watersheds

1

1 **A15 PROGRAMS FOR ALIEN SPECIES INTERDICTION IN HAWAI'I**

2 **A15.1 HAWAI'I DEPARTMENT OF AGRICULTURE, PLANT INDUSTRY DIVISION, PLANT** 3 **QUARANTINE BRANCH**

4 Among its many responsibilities, the HDOA is charged with preventing the introduction and
5 establishment of alien species in the state. Because of Hawai'i's geography and diverse climatic zones
6 (tropical to temperate), the state is vulnerable to the entry and establishment of more foreign pests
7 than are mainland states. HDOA collaborates with federal agencies to prevent introduction of regulated
8 invasive pests. Similarly, HDOA inspectors involve federal agencies if a detected organism is an
9 endangered species and subject to provisions of the CITES or other federal restrictions.

10 The Plant Quarantine Branch (PQ) of HDOA regulates the importation and movement within the state of
11 all plants and exotic animals (vertebrate and invertebrate). Its primary goal is to prevent the
12 introduction of harmful insects, plant pathogens, illegal animals, and other pests into Hawai'i. HDOA PQ
13 also provides clearance for exporting horticultural products from the state (e.g., rooted plants), and may
14 inspect cut flowers and foliage under cooperative agreement with the USDA.

15 **A15.1.1 Overview of Regulatory Authority**

16 Hawai'i Revised Statutes (HRS) §§ 141 and 150A define the regulatory authority of HDOA. HRS § 141
17 authorizes HDOA to quarantine, inspect, fumigate, disinfect, destroy, or exclude commodities infested
18 with pests or any article which is, in itself, a pest, which may be injurious to the agricultural industries
19 and forest resources of the state. Further, HRS § 141 authorizes HDOA to enforce applicable regulations
20 governing the importation into Hawai'i of any agricultural commodities from anywhere outside of the
21 state, at any time or place within the state.

22 HRS § 150A authorizes HDOA to regulate plant, animal, and micro-organism importation into the state,
23 including conditions of importation; the listing of prohibited, restricted, and conditionally approved
24 plants, non-domestic animals, and microorganisms; as well as issuance of permits, collection of user
25 fees, application of interim rules, and imposition of penalties.

26 **A15.1.2 Plant Quarantine Duties and Operations**

27 For imported commodities moving domestically via incoming cargo from the U.S. mainland, HDOA has
28 oversight of all rules and regulations pertaining to airport and sea operations. With regard to export or
29 movement of agricultural commodities from Hawai'i to the U.S. mainland, HDOA complies with federal
30 regulations as stipulated in 7 CFR § 318.13.

31 Shippers of domestic cargo bound for Hawai'i by air or sea must notify HDOA of incoming goods
32 requiring inspection (Miller and Holt 1992). If such freight arrives during nonworking hours, the shipping
33 company must hold the cargo until the next business day to provide PQ inspectors adequate
34 opportunity to examine it. Low staffing levels relative to the large volume of goods entering the state do
35 not allow for inspection of all cargo. Instead, inspectors separate incoming goods into one of three risk
36 categories: high, medium, and low risk, and systematically inspect the items in decreasing order of risk.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 The record of past interceptions also influences the selection of items for inspection. For high-risk
2 goods, such as all animals (including fish) and all propagated plants, PQ will inspect 100% of the declared
3 items. For items considered to be of medium or low risk, the inspectors will randomly inspect two or
4 three boxes from a particular cargo lot. Medium-risk goods include cut flowers and foliage, whereas
5 produce is considered to be low risk. Commodities, such as livestock feed, coffee beans, organic
6 fertilizer, and planting media, fall along a continuum between medium and low risk. Lacking any
7 prescribed method or basis for a statistical sampling process, the level of inspection devoted to these
8 spot checks depends on the availability of inspectors.

9 In recent years, PQ also has initiated an Agricultural Quarantine Inspection Monitoring (AQIM) program,
10 in which statistically valid, random sampling techniques are employed to estimate pest incidence in
11 maritime containerized cargo from the mainland. Sampling and data collection follow protocols
12 specified in the USDA-APHIS-PPQ AQIM manual (USDA 2006a).

13 ***A15.1.2.1 Airport Inspection***

14 Currently, PQ inspectors are assigned to inspect domestic incoming articles at various facilities in or
15 around the airport, including airline cargo stations, baggage claim areas, the USDA mail cargo inspection
16 station at the USPS facility, Federal Express (FedEx) and United Parcel Service (UPS) facilities, and the
17 HDOA airport animal quarantine holding facility. All articles regulated by the state must be inspected by
18 a PQ inspector before they can be released to the importer. Requests for inspection are called in to the
19 PQ airport office, and inspectors are dispatched to each inspection site in the order in which the calls are
20 received.

21 PQ inspectors screen packing lists and cargo manifests for commodities that might be hosts of specific
22 pests, based on previous interceptions or interception records. Labels specifying the identity of
23 commodities and their origins are also factors in determining if the commodities in cargo require
24 increased scrutiny. All restricted items are inspected for pests, and the required documents, such as
25 permits, phytosanitary certificates, and certificates of treatment, are verified before the shipment is
26 released.

27 ***A15.1.2.2 Maritime Inspection***

28 Maritime inspections usually involve plant-related commodities only (e.g., produce with longer shelf
29 lives, such as bananas, and materials, such as planting media and organic fertilizer), whereas airport
30 inspections include items of both plant and animal origin, as most fish and other seafood, animals and
31 perishable produce, and plants are air-shipped. PQ inspects containerized freight (other than dry goods)
32 and vehicles upon arrival; dry goods inspection was discontinued years ago because of staff shortages.

33 Through an agreement between HDOA and certain ocean carriers, fully loaded, refrigerated maritime
34 containers that may contain perishable items are allowed to be taken out of the container yard for
35 inspection at a separate, authorized facility, which may be a warehouse, packing and distribution facility,
36 or a repacking facility. Similarly, containers only partially loaded with agricultural commodities may be

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 delivered to a freight forwarding company where the individual shipments are broken down and set
2 aside for inspection.

3 ***A15.1.2.3 Inter-island Inspection***

4 As required by statute (Hawai'i Administrative Rules § 4-72), all plants and propagative plant parts, and
5 non-domestic animals, including mammals, birds, fish, reptiles, amphibians, and insects, require
6 inspection and certification prior to shipping from Oahu to the outer islands. No inspection is required
7 for seeds, cut greens (including Christmas trees), flowers, and leis, or for pigeons, domestic rabbits,
8 poultry, horses, cattle, cats, and dogs.

9 Private, non-commercial shipments are transported to either the airport or maritime offices for
10 inspection and certification. Large commercial shipments may be inspected at their point of origin
11 before being loaded into containers for inter-island barge transport.

12 ***A15.1.2.4. Military Inspection***

13 Military maritime and airport facilities are subject to PQ inspection, but such inspections are limited due
14 to staff shortages. The branch has established cooperative agreements with military bases clarifying
15 each agency's inspection and interception responsibilities. In addition, PQ has assigned one supervisor
16 full-time responsibility for coordination with military bases.

17 Since 1992, PQ has conducted inspections for detection of BTS in commercial aircraft and ships arriving
18 from Guam. For the purpose of snake detection, PQ attempts to meet and inspect all flights from Guam,
19 with the result that 97 to 98% of arriving flights are inspected. PQ also inspects all military aircraft and
20 ships arriving from Guam. Snake inspection is conducted through visual inspection and sometimes with
21 the help of the BTS canine unit. Aircraft wheel wells are inspected with dogs. For military flights, PQ
22 inspectors do a walk-through of the cargo hold without dogs, and use dogs to check cargo when it is off-
23 loaded. Commercial flights are handled similarly, with cargo checked by dogs when it is off-loaded.
24 During the 6-month period prior to April 25, 2004, PQ inspected 267 commercial flights, 323 military
25 flights, and seven private flights for BTS (Loope and VanGelder 2005).

26 The funding for BTS inspection and interdiction had been subsidized by the Department of the Interior
27 and USDA-APHIS-WS until the current fiscal year. Due to the loss of WS funding, the State of Hawai'i will
28 provide or obtain the necessary funds to continue the operations.

29 ***A15.1.2.5 Passenger Inspection***

30 All passengers, officers, and crew members arriving in Hawai'i via commercial aircraft or vessels, and
31 carrying plants, animals, microbial cultures, or soil must complete an HDOA declaration form and submit
32 the imported items for inspection. This and an in-flight informational film are the only means the state
33 currently has to make travelers from the U.S. mainland aware of restrictions on what can be brought
34 into the state, enabling PQ to inspect and, if necessary, seize prohibited items. Passengers arriving from
35 the mainland by private aircraft or boat also must complete the declaration forms. Private boat owners

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 arriving at any of the harbors must report to the harbormaster, who, in turn, directs them to PQ for
2 inspection.

3 Airline passenger declaration forms were the sole basis for inspection of incoming passenger baggage
4 until late 1989, when HDOA initiated a citation program and retained a small cadre of trained beagle
5 dogs to inspect checked baggage and express parcels (Miller and Holt 1992). The citation of airlines that
6 were derelict in passing out and collecting declaration forms, in combination with the use of the beagles,
7 resulted in a substantial increase in the number of passengers declaring agricultural items when
8 entering the state.

9 Persons importing illegal species into Hawai'i have been subject to penalties, such as fines or
10 imprisonment, since 1927. Currently, fines range from \$100 to \$25,000 and prison sentences from 30
11 days to 1 year. An amnesty provision exempts from penalties persons who voluntarily surrender, prior
12 to the beginning of any seizure action, a prohibited animal or a restricted animal, for which they have no
13 permit.

14 ***A15.1.2.6 Species Importation Permitting***

15 The Hawai'i Board of Agriculture (BOA) is responsible for establishing the broad operating policies of
16 HDOA, including the species permit application process (Miller and Holt 1992). By law (Hawai'i
17 Administrative Rules § 4-71), the ten-member, governor-appointed board maintains three lists
18 pertaining to the importation of animals and micro-organisms. Listed species are: 1) those conditionally
19 approved (permit required for importation); 2) those restricted (permit required for both importation
20 and possession); and 3) those prohibited. The law makes clear that any animal or micro-organism not on
21 the first two lists also is prohibited. Any violation of permits issued for restricted or conditionally
22 approved organisms is a violation of law. BOA also is responsible for determining additional micro-
23 organism and animal species that are prohibited or approved entry into the state. Under existing rule-
24 making procedures prescribed by the Hawai'i Administrative Practices Act, whenever the lists are
25 revised, they must go through public notice, hearings, and comment.

26 In addition to the animal and micro-organism lists, state law provides for two lists for exotic plants: one
27 for species that may be imported with a permit and one for those that are prohibited. However, unlike
28 the regulation of imported animals and micro-organisms, there is no statutory language that states that
29 plants not appearing on the approved list cannot be imported.

30 ***A15.1.2.6.1 Species Permit Application Process***

31 To prevent introductions of pest species, HDOA has developed a permitting process involving technical
32 review and BOA approval. All individuals requesting to import a plant, animal, or microbial species must
33 file an application with PQ. If an applicant is requesting to import an animal or micro-organism that is
34 not on the conditionally approved or restricted list, a revision must be made to the appropriate list
35 before the species may be imported. All revisions to the animal and micro-organism list must go through
36 the administrative rule-making process. Plants not on the permitted or prohibited lists are not required
37 to go through this process, and may be imported.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 If the request is for a species that is on an animal or micro-organism list and has received prior approval
2 by BOA, or is a plant that has received such approval, PQ can issue the permit. If, however, an applicant
3 is requesting a permit for a species that has not received prior BOA approval, PQ will conduct a three-
4 tiered review process to bring the request before the Board.

5 First, the application is submitted to BOA's Technical Advisory Subcommittees. The five subcommittees
6 (Land Vertebrates, Invertebrates and Aquatic Biota, Entomology, Microorganisms, and Plants) are
7 composed of biologists, industry representatives, and government officials. The subcommittees evaluate
8 the application along technical or scientific lines, particularly with regard to the organism's potential
9 impacts. The subcommittees then pass their analyses to the Plant and Animals Advisory Committees,
10 which consider the application and the subcommittee findings, weighing the potential harmful impacts
11 against potential benefits. BOA then reviews the Advisory Committees' recommendation and issues the
12 final decision on the application.

13 BOA may impose permit conditions, such as cage requirements or limitations on breeding or sale of the
14 organism. If an animal is listed in Hawai'i Administrative Rules § 4-71-7 as requiring a bond, it will either
15 be in the amount of \$250, if the importer has a USDA license for the animal under the federal Animal
16 Welfare Act, or \$1,000. PQ also inspects and approves facilities (e.g., laboratories) of applicants before
17 issuing permits for restricted organisms.

18 ***A15.1.2.6.2 Permitted Species Inspection Activities***

19 Once a permit is issued, PQ will inspect and clear a new organism prior to its introduction into the state.
20 This inspection verifies that the species arriving in Hawai'i is in fact the permitted species, and that it
21 does not carry any pests or diseases. PQ conducts port-of-entry inspections at BOA-designated ports.
22 Presently, five harbors (Hilo, Honolulu, Kahului, Kawaihae, and Lihue) and four airports (Honolulu
23 International, Kona, Kahului, and Lihue) are primary port-of-entry inspection sites. Time and manpower
24 permitting, PQ inspectors also may conduct follow-up, post-entry inspections to enforce any permit
25 conditions.

26 ***A15.1.2.6.3 On-Site Inspection Process***

27 In addition to inspecting permitted organisms for compliance with state regulations, PQ conducts on-site
28 inspections of cargo and passengers entering Hawai'i to detect species entering the state without a
29 permit. Inspections are conducted at the nine BOA-designated ports listed above.

30 ***A15.1.2.7 Other Regulatory Programs***

31 **Biotechnology Program:** HDOA participates in the permit review process, subject to federal oversight,
32 while promoting public confidence in the regulatory system. A PQ inspector accompanies the APHIS-PPQ
33 Hawai'i Safeguarding Specialist to perform inspections of genetically modified organism (e.g., GMO
34 corn) field trials.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 **Pest Surveys and Control and Eradication Programs:** PQ surveys for new pest introductions, as well as
2 newly detected pests. Information obtained is used to develop aggressive control or eradication
3 strategies.

4 **Rapid Response Programs:** PQ has developed a statewide program aimed at mobilizing a rapid response
5 to snake sightings. PQ and other agency's staffs have attended 3-week early detection and rapid
6 response training on Guam for alien snakes. Rapid response teams are mobilized following credible
7 reported sightings of snakes or other invasive species.

8 **Diagnostics:** PQ provides positive identification of intercepted pests; identification is required before
9 enforcement of any applicable regulatory action.

10 **Compliance and Enforcement:** HDOA compels compliance and enforcement of quarantine laws and
11 regulations through penalties and fines.

12 ***A15.1.2.8 Inspection Procedures During Regularly Scheduled Quality/Efficiency Assessments***

13 HDOA has conducted regularly scheduled, quality/efficiency assessments (so-called risk assessments)
14 throughout the state to evaluate the quality of inspection at ports, determine invasive species
15 pathways, and target commodities that are of the highest pest risk. These operations are performed
16 using a standardized inspection protocol for incoming passengers and cargo. Based on staff availability,
17 multiple teams are dispatched to various inspection targets (e.g., passengers and baggage, cargo, and
18 aircraft), with concentration on higher-risk commodities and other articles.

19 There are several inspection sites. Inspection of air and maritime cargo is performed at the port-of-
20 entry, including, but not limited to, individual airline cargo facilities, express mail stations, or produce
21 distribution sites that meet food safety standards (also known as transitional facilities). The inspection of
22 air cargo, typically arriving in air containers, such as LD3s and LD8s, and ocean cargo, arriving in 20-, 24-
23 and 40-foot-long shipping containers, follows the following general procedures.

24 Inspection teams acquire a packing manifest detailing the exact content and quantity of the
25 commodities in each lot to be inspected. Restricted and prohibited items are refused entry or destroyed.
26 All (100%) commodities deemed high-risk are inspected. Higher-risk commodities include propagative
27 plant materials, various types of cut flowers, leafy vegetables, certain fruits, and organic produce. Upon
28 completing inspection of higher-risk products, 10 to 50% of the volume of lower-risk commodities are
29 inspected.

30 Inspection of aircraft and passengers is conducted as follows: inspectors board the aircraft, obtain and
31 examine the mandated Agricultural Declaration Forms for declared items, walk through the cabin, and
32 check cargo holds and wheel wells. Inspectors monitor passengers and baggage in the baggage claim
33 area. Recorded data include airline and flight number, date of inspection, arrival time, number of
34 passengers and crew, number of collected and completed Agricultural Declaration Forms, number of
35 declared agricultural commodities, and number of intercepted agricultural commodities. Pest
36 interception data are also recorded.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Additional inspection is performed by an inspector and a detector dog. The focus is on monitoring
2 passenger baggage in the baggage claim areas and the small packages arriving via FedEx, UPS, and other
3 package and mail carriers.

4 **A15.1.2.9 Standard Operating Procedures**

5 PQ utilizes a standard operating procedures (SOP) manual that was last revised in November 1989.
6 Several sections in the manual are outdated or no longer apply to PQ’s current facilities, operations, or
7 staff. The branch would benefit greatly from a professional manual writer; however, in lieu of that
8 option, a team made up of program specialists, operations supervisors, and inspectors is collaborating
9 on revising the SOP manual. Based on the current implementation of the HDOA Biosecurity Program,
10 developed in 2005, the existing SOPs are being revised and amended.

11 **A15.1.3 Inspection Facilities**

12 The major ports-of-entry for the State of Hawai’i are located in the major cities on four of the main
13 islands: Hawai’i, Maui, Oahu, and Kauai (Table A15-1). The ports are the major commercial entry points
14 and the foci of inspections in the state for imported and exported goods.

15 **Table A15-1: Major Ports-of-entry in Hawai’i**

Island	Airport	Seaport
Hawai’i	Hilo International Airport (ITO)	Hilo Harbor
	Kona International Airport at Keahole (KOA)	Kawaihae Harbor
Maui	Kahului Airport (OGG)	Kahului Harbor
Oahu	Honolulu International Airport (HNL)	Honolulu Harbor
	Hickam Air Force Base (part of HNL)	Kalaeloa Harbor
Kauai	Lihue Airport (LIH)	Nawiliwili Harbor

16

17 **A15.1.3.1 Minimal Inspection Facility Requirements**

18 HDOA has determined its minimal inspection facility requirements, and the document detailing these
19 requirements is in preparation. The minimal inspection facility requirements include: enclosed cargo
20 inspection areas, including equipment for washing and sterilizing cargo if needed, with adequate lighting
21 and temperature control; computer equipment; refrigerated storage, with adequate volume to hold
22 “pending” items awaiting action; treatment facilities, such as freezers, autoclaves, and garbage
23 disposals; kennels, if dogs teams are at that port; and passenger inspection stations.

24 The size of each port’s inspection facility would need to be based on the expected volume of incoming
25 cargo. Ports receiving high-risk commodities would have provisions for various treatment facilities. For
26 export inspection, large-volume shipments will be inspected and certified at the point of origin, e.g., in
27 packing houses and greenhouses, and not at the port. Inspection of small-volume export cargo will be
28 conducted at the ports; therefore, inspection and consolidation areas are a necessity. Depending on the
29 commodity, the consolidation areas should be properly equipped to maintain quality and quarantine
30 security.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 A15.1.3.2 Existing Facilities

2 Not a single port in Hawai'i meets the minimal facility requirements for PQ inspection and quarantine
3 purposes. None of the ports, except Kahului Airport, has adequate facilities to destroy incoming infested
4 commodities. None of the ports has enclosed inspection areas.

5 HDOA does not have fumigation (methyl bromide) chambers or an incineration facility to destroy
6 infested commodities under quarantine supervision. Methyl bromide fumigation is outsourced to a
7 private, certified pesticide applicator based on the applicators' availability. Incineration is provided by a
8 private company without PQ supervision.

9 A15.1.3.3 Facilities Proposed and Under Construction

10 HDOA has begun discussions with various regulatory agencies in Hawai'i on a proposal for a
11 multiagency-use facility at Honolulu International Airport (HNL). HDOA contends that multiagency-use
12 facilities would enhance information sharing and collaboration among federal and state plant
13 quarantine agencies in Hawai'i.

14 New facilities are being constructed at the Kahului Airport to optimize the interdiction of alien species
15 on Maui. These facilities will house two fully-enclosed inspection rooms, a screened inspection area for
16 low-risk commodities, a laboratory, plant and animal holding rooms, kennels, and office space for HDOA,
17 USDA, and DHS CBP personnel.

18 The HNL Master Plan has identified a probable location for a joint inspection facility in the cargo area,
19 which, if realized, would provide space for HDOA, APHIS-PPQ, USFWS, and CBP. This planned multi-
20 agency facility would be co-located with the major international air cargo carriers. A smaller satellite
21 facility is planned for inter-island and domestic cargo inspection. The HNL Master Plan will include an
22 irradiation facility, both for quarantine treatment of fruits and vegetables for export and for imported
23 commodities moving within-state that have insect infestations or diseases.

24 The proposed HNL inspection facility would have a size of about 1 hectare under roof, with enclosed
25 inspection rooms, refrigeration, freezer, autoclave, offices, kennels, and space for other support
26 functions. The master planning process has just begun for the Kona International Airport Master Plan.
27 Kona's is the second busiest international airport in the state, and accommodates a number of overseas
28 domestic and international flights; thus, a joint inspection facility is considered a necessity. Treatment
29 and disposal of garbage are a particular concern at the Kona airport.

30 At Honolulu and Kahului Harbors, the volume of cargo is immense, the ports handling over 10 million
31 and 2 million tonnes, respectively, per year (HDOT 2002; Anonymous 2006). At both ports, space is a
32 primary concern, as there is no room for expansion and immediate solutions are not available.
33 Construction of new cargo facilities has been proposed.

1 **A15.1.4 Staffing**

2 **A15.1.4.1 Existing Personnel**

3 Table A15-2 shows pre-2006 staff and 2007 staffing levels. The 2007 staffing levels indicate increases in
 4 staff resulting from increased funding through the Biosecurity Program Initiative. 2007 staffing levels
 5 are not current levels. In 2009 there was a large reduction in force size by Hawai'i Department of
 6 Agriculture. The discrepancy between 2007 and current numbers is not addressed in this section. The
 7 current number of front line inspectors is lower than that expressed for 2007. Of special notice is that
 8 HDOA currently has no canine program whereas in 2007 there were 6 dog handlers.

9 **Table A15-2: Pre-2006 and 2007 Staff of the Plant Quarantine Branch of the HDOA**

Position	Pay schedule	Pre-2006	2007
Supervisor, Plant Quarantine Inspector V	SR-24	4	4
Master Journeyman, Plant Quarantine Inspector IV	SR-22	9	10
Inspector, Plant Quarantine Inspector III	SR 20	39	62
Dog Handler, Plant Quarantine Inspector III	SR 20	3	6
Technician	SR-11		
Administrative		0	1
Operations		1	14
Dog		0	1
Specialist		1	3
Subject Matter Specialist, Plant Quarantine Inspector V	SR-24	5	7
Accountant		0	1
Management Analyst		0	1
Total		62	110

10
 11 At the 2007 level of staffing, PQ had begun to implement Phase I of its Biosecurity Program, which if and
 12 when completed would result in:

- 13 • Systematic, intense inspection of all high-risk pathways and spot checks of low-risk
 14 pathways
- 15 • Quarterly quality/efficiency assessments (so-called risk assessments or “blitzes”)
- 16 • Compliance agreements
- 17 • Rule changes
- 18 • Control programs for the little fire ant, nettle caterpillar, and coqui frog
- 19 • Military and private jet inspections
- 20 • Inter-island inspections
- 21 • Shared data management with other regulatory agencies
- 22 • Nursery monitoring and assistance

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

- 1 • Regular monitoring and surveillance of all air- and seaports for the RIFA

2 **A15.1.4.2 Proposed Levels**

3 Based on the port efficiency and overall staffing evaluations conducted by HDOA, PQ will be seeking an
4 additional 111 positions for administrative, diagnostic, and inspection functions (these are positions
5 above and beyond the 2007 levels, current levels are lower). The additional inspection staff will be
6 servicing the airport and the harbor facilities state-wide. New identifiers and diagnosticians will provide
7 support to the branch’s inspection and monitoring efforts.

8 **A15.1.5 Biosecurity Program**

9 Session Laws of Hawai’i 2006, Act 160, established HDOA’s Biosecurity Program by appropriating \$2.9
10 million to hire new staff and enhance the invasive species program. The 2006 legislative session
11 provided general funds to implement Phase I of the program, i.e., hiring new staff and providing support
12 for statewide pest detection, prevention of spread of incipient infestations, and control programs for
13 incipient and established invasive pest populations. Phase II of the program has the objective of
14 developing strategies to prevent the intentional or unintentional introduction of invasive species at
15 ports-of-entry or, once introduced, to reduce their impacts.

16 The program incorporates HDOA’s mandates, rules, and regulations into a comprehensive program to
17 protect the state’s agriculture and natural resources from invasive pest species and to facilitate trade by
18 providing export compliance as required by Hawai’i’s trading partners.

19 **A15.1.5.1 Components**

20 The program weaves together various components of the traditional aspects of alien species interdiction
21 known as pre-entry, port-of-entry, rapid response, and eradication, with the development of
22 replacement and export crops to facilitate economic growth. The program’s elements are:

- 23 • Prevention
24 • Diagnostics
25 • Detection
26 • Rapid response
27 • Monitoring
28 • Biological sampling
29 • Restoration
30 • Research and development
31 • Educational outreach
32 • Partnerships and cooperative activities

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

- 1 • Information management
- 2 • Quality control programs

7 ***A15.1.5.2 Increasing Capacity for Preventing Intentional Introductions or Reducing their Impacts***

8 Emergency response capability is an integral component of HDOA’s Biosecurity Program. The proposed
9 additional staff, particularly inspectors and diagnosticians, will allow for effective interagency
10 coordination with CBP and APHIS. Incident Command Training is being implemented cooperatively at
11 federal and state levels. HDOA sought the support of Hawai’i’s congressional delegation for the
12 proposed multi-agency use inspection facility at HNL. HDOA has also proposed construction of a
13 treatment and destruction facility for commodities or articles detected at the ports with pest infestation
14 or disease infection, or both. Currently, destruction and treatment of detected pests and pathogens are
15 extremely limited and not easily available to CPB, APHIS, and HDOA.

16 ***A15.1.5.3 Increasing Capacity for Preventing Unintentional Introductions***

17 Preventing invasive species from entering and establishing in Hawai’i is vital to protecting the
18 environment, public health, and economy; invasive species have direct, negative impacts on agricultural
19 industries and tourism.

20 Hawai’i is dependent on imported food, construction materials, medical supplies, and other
21 commodities; this dependency demands essential transportation infrastructure. However, Hawai’i’s
22 ports have not kept pace with current infrastructural demands and those anticipated in the future. To
23 counter the overcapacity at the harbors, steps are being taken to release containers at the ports for
24 immediate inspection at transitional facilities partially to resolve the capacity problem. HDOA is
25 currently working with the carriers and importers to investigate the use of electronic manifests that will
26 allow quick release of commodities and other articles at the docks without compromising the efficacy of
27 pest detection.

28 ***A15.1.5.3.1 Brown Treesnake and Red Imported Fire Ant***

29 During the past few years, HDOA has been attuned to the need to address the heightened risks posed by
30 introduction of certain targeted invasive pest species, such as BTS and RIFA. Intensified military activities
31 in the Pacific have substantially increased BTS risk, challenging the state’s capacity to prevent its entry.
32 Should it become established in Hawai’i, the potential economic impact of BTS has been conservatively
33 estimated at \$485 million annually, resulting from power outages, medical costs, lost tourism revenue,
34 and devastation of native species (HDOA unpublished data). A subsequent detailed study by Swiff et al.
35 (2010) which examined the economic impact of BTS establishing in the State of Hawai’i in regards to

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 medical treatment, power outages and decreases in tourism placed the total annual damage to Hawai'i
2 at between \$593 million and \$2.14 billion. Accordingly, training specifically for detection of, and rapid
3 response to, BTS introductions should be strengthened. The program for BTS interdiction will be
4 augmented significantly by the proposed additional inspectors and detector dogs in the canine unit.

5 RIFA's geographic distribution has expanded from the Americas to Asia and parts of the Pacific, further
6 increasing its threat to Hawai'i. RIFA is both an agricultural pest and a pest of medical concern. The
7 potential impact to Hawai'i's economy resulting from RIFA establishment has been estimated at \$197
8 million annually (HDOA unpublished data). To counter the threat, HDOA works with CPB and APHIS to
9 intercept ants from foreign and U.S. mainland sources. The proposed increase in staffing will allow
10 increased scrutiny of high-risk commodities and articles from RIFA-infested geographic areas.

11 ***A15.1.5.3.2 Port of Honolulu***

12 The large volume of goods coming into the state cannot be adequately inspected by the present level of
13 port staffing. For maritime cargo, a lack of harbor space also contributes significantly to PQ's inability to
14 perform adequate inspections.

15 With ever-increasing numbers of aircraft and ships arriving, it is envisioned that Honolulu port
16 operations will become a 24-hour, 7-day-a-week activity; currently the airport operates for 20 hours
17 every day. Maritime inspection is currently an 8-hour, 5-day-per-week operation. The future cargo
18 inspection workload will include inspections at approved transitional facilities.

19 The Honolulu staff will be divided into shifts that will work at the airport and maritime offices on a
20 rotational basis. Workload will include meeting aircraft at the gates, which has not been done due to
21 lack of staff, and using detector dogs to interdict undeclared items, including cargo at baggage claim
22 areas; UPS, FedEx, and other express mail carrier inspection stations; and commercial and military flights
23 from the South Pacific and Guam that are considered high-risk for BTS.

24 At seaports, the maritime inspection workload will increase with the required inspection of the
25 Superferry's inter-island cargo. Inspection at transitional facilities should help alleviate problems
26 associated with increasing ship traffic.

27 ***A15.1.5.3.3 Port of Maui***

28 The majority of quarantine inspections are performed at Kahului Airport and Kahului Harbor, which, by
29 volume, are the second busiest airport and third busiest harbor in the state (HDOT 2002). Other ports in
30 the county include Kaulamapau Harbor (Lanai), Lanai Airport, Kalaupapa Harbor (Molokai), Kalaupapa
31 Airport (Molokai), and Kaunakakai Harbor (Molokai). Kahului Airport was the site of a risk assessment,
32 conducted as part of the State Department of Transportation's (DOT) Alien Species Action Plan, which
33 identified cargo as a high-risk pathway (HDOA 2002).

34 Although PQ staffing on Maui has increased with the addition of DOT-funded PQ positions, these
35 positions have been staffed only at the airport.

1 **A15.1.5.3.4 Port of Kona**

2 HDOA is collaborating with DOT in the planning and design of improvements in infrastructure at Kona
3 International Airport and Kawaihae Harbor to enhance both quarantine and export capabilities. The new
4 facilities will include adequate space for offices, inspection stations, and commodity treatment.

5 The number of commercial flights, passengers, and private jets, and the volume of cargo arriving at Kona
6 International Airport have increased steadily over the years (HDOA 2002). The increased traffic at this
7 airport and Kawaihae Harbor have overwhelmed the current staff, preventing effective inspection and
8 monitoring. Ships, aircraft, or cargo may go uninspected, depending on the current inspection priority.
9 The proposed increase in staff should help to mitigate the risks of alien species introduction at the Port
10 of Kona.

11 **A15.1.5.3.5 Port of Hilo**

12 Hilo Port aims to expand export certification capabilities for agricultural commodities, as exports are a
13 major contributor to Hilo's economy. The proposed additional PQ staff will perform the necessary
14 inspections at nurseries prior to movement of propagative and non-propagative plants through the port.

15 **A15.1.5.3.6 Port of Kauai**

16 This port includes Lihue Airport, Nawiliwili Harbor, and Port Allen Harbor. Lihue is the only commercial
17 airport on the island, and receives incoming direct international, domestic, and inter-island flights.
18 Nawiliwili Harbor is the larger of two commercial harbors, and receives the majority of goods shipped
19 into Kauai. Current staffing is inadequate to cover the basic plant quarantine functions, especially as the
20 number of direct overseas flights to the island increases. HDOA has proposed additional staff for the
21 Port of Kauai.

22 **A15.1.6 HDOA Regulations and Federal Pre-emption**

23 USDA-APHIS-PPQ enforces regulations under the authority of the Plant Protection Act of 2000 to
24 safeguard agriculture and natural resources from the risks associated with the entry, establishment, and
25 spread of harmful foreign pests, noxious weeds, and plant diseases. Since March 2003, CBP, under a
26 Memorandum of Agreement between USDA and DHS, has the mandate to inspect and clear foreign
27 passengers and non-propagative agricultural commodities. PPQ continues to perform the inspection and
28 release functions for propagative plant materials. APHIS has the principal responsibility of preserving the
29 marketability of U.S. agricultural products by stopping and controlling the movement of harmful invasive
30 pests that enter the country.

31 HDOA enforces regulations under various plant and non-domestic animal quarantine statutes to prevent
32 the introduction and establishment in Hawai'i of any organism that is harmful to agriculture, animal or
33 public health, or natural resources, including native biota. Hawai'i is quarantined with respect to the U.S.
34 mainland primarily due to the occurrence of pestiferous tephritid fruit fly populations.

35 Under the Plant Protection Act of 2000, 7 USC §7756 subdivision (a), "[no] State or political subdivision
36 of a State may regulate in foreign commerce any article, means of conveyance, plant, biological control

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 organism, plant pest, noxious weed, or plant product in order (1) to control a plant pest or noxious
2 weed; (2) to eradicate a plant pest or noxious weed; or (3) to prevent the introduction or dissemination
3 of a biological control organism, plant pest, or noxious weed.”

4 HDOA has argued that conflicts in regulation and enforcement exist between it, USDA, and DHS. HDOA
5 further contends that Hawai’i will always be vulnerable to incursions by invasive pests because of
6 inherent safeguarding weaknesses resulting from the federal pre-emption of state quarantine
7 regulations.

8 **A15.2 UNITED STATES DEPARTMENT OF HOMELAND SECURITY, BUREAU OF CUSTOMS AND**
9 **BORDER PROTECTION**

10 **A15.2.1 Overview of Regulatory Authority**

11 Historically, APHIS-PPQ agricultural quarantine inspection (AQI) was responsible for preventing the
12 introduction of harmful, alien agricultural pests and diseases into the United States. With the
13 establishment of DHS, the Homeland Security Act of 2002 transferred the foreign import inspection
14 duties from USDA to DHS. A MOU between USDA and DHS, signed in 2003, articulated the details of
15 responsibilities, operating procedures, working relationships, communication, and framework necessary
16 for APHIS and CBP successfully to perform their agricultural inspection missions (USDA 2003b). Among
17 the agricultural import inspection functions transferred from USDA to DHS are the following:

- 18 • Reviewing passenger declarations and cargo manifests, and, utilizing USDA pest risk data,
19 targeting for inspection high-risk passengers or cargo
- 20 • Inspecting international passengers, luggage, cargo, mail, and means of conveyance
- 21 • Holding cargo and articles of suspected quarantine significance
- 22 • Referring propagative and other designated materials to USDA for inspection, control, and
23 disposition
- 24 • Seizing materials in violation of USDA regulations, safeguarding them to prevent pest
25 escape, and destroying or re-exporting them
- 26 • Collecting and preparing or preserving pest and disease samples for analysis
- 27 • Submitting to USDA intercepted pest and disease specimens for identification
- 28 • Collecting, submitting, and reporting program information
- 29 • Maintaining, monitoring, and enforcing existing compliance agreements
- 30 • Monitoring transit shipments and verifying exit
- 31 • Reviewing import permits and certificates for validity and compliance

32 Among the agricultural inspection and trade functions retained by USDA are:

- 33 • Providing risk analysis guidance and setting inspection protocols

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

- 1 • Applying remedial measures other than destruction and re-exportation
- 2 • Providing specialized inspection of propagative plant material and pest identification
- 3 services at plant inspection stations and other facilities
- 4 • Conducting inter- and intra-state inspection of passengers, commodities, and conveyances,
- 5 including pre-clearance of passengers in Hawai'i destined to the U.S. mainland
- 6 • Performing inspection and related activities, such as compliance with requirements of
- 7 agricultural protocols and systems, in connection with the pre-clearance of commodities in
- 8 foreign countries
- 9 • Verifying compliance with trade protocols, including, but not limited to, conducting
- 10 domestic market and transit surveys and outreach to the private sector as part of the APHIS
- 11 SITC programs
- 12 • Investigating and adjudicating AQI violations
- 13 • Issuing phytosanitary (plant health) and animal by-product certificates for U.S. agricultural
- 14 exports
- 15 • Developing regulations, policy, and procedures to establish and enhance coordination
- 16 between USDA and DHS
- 17 • Managing the AQI performance measurement system in consultation with DHS

18 Tables A15-3 and A15-4 show the number of agricultural inspection staff of APHIS-PPQ and CBP,
 19 respectively, in Hawai'i. PPQ has offices at five ports in Hawai'i: Honolulu, Maui, Kauai, Hilo, and Kona.
 20 CBP has Agriculture Specialists in Honolulu and Kona.

21 **Table A15-3: APHIS-PPQ Staff in the Ports of Honolulu, Maui, Kauai, Hilo, and Kona**

Staff	Position	Number of permanent, full time employees ^a
Administrator	State Plant Health Director	1
SOSO	State Operational Support Officer	2
Administrative Assistants		11
Supervisors	Port Directors, Port Supervisors	21
Specialists	Pest Survey Specialist, Pest Identifiers, Export Certification Specialist	6
Inspectors	PPQ Officers and Plant Health Safeguarding Specialists	88
Technicians	Permanent and Temporary ^b	98
SITC	SITC Manager and Officers	3
Total		230

4 Specialists on an as-needed basis.
5

6 **A15.2.2 Quarantine and Inspection Activities**

7 At U.S. ports-of-entry (including Honolulu), CBP Agriculture Specialists and cross-trained CBP Officers
8 inspect air and sea cargo, air and sea carriers, and international mail, and clear air and sea passengers,
9 crew, and their luggage arriving from foreign countries to detect prohibited articles (including plant and
10 animal products); ensure that regulated articles comply with federal regulations; treat and dispose of
11 regulated garbage; and intercept regulated pests and diseases. CBP has broader powers of search and
12 seizure than many agencies involved in pest detection and interdiction. For example, the agency does
13 not need a search warrant or to show probable cause to carry out its duties, such as inspection of
14 foreign mail. All packages mailed from outside the United States must have customs declarations that
15 clearly state the nature of the contents. CBP can inspect any mail from foreign points of origin.
16 (Domestic first-class mail may not be inspected without a federal search warrant.) All foreign mail
17 arrives at a central mail facility in Honolulu. CBP conducts inspections at all military installations in
18 Hawai'i when vessels or aircraft arrive from foreign points of origin.

19 A percentage of incoming air passenger baggage, air cargo, maritime cargo, and mail from foreign
20 countries undergoes actual inspection at Hawai'i's international ports-of-entry. The various manuals
21 furnished by USDA determine the percentage of cargo for examination and the risk management
22 principles for use in determining inspections. Items are chosen for inspection based on risks, as
23 determined by risk assessments, past interceptions, and other available information. Articles are
24 inspected for pests and diseases, and may be released, treated based on quarantine requirements prior
25 to release, re-exported, or confiscated and destroyed. The primary aims of quarantine and inspection
26 are to prevent entry of agricultural pests and diseases and to intercept these threats at ports-of-entry
27 while facilitating and promoting worldwide agricultural trade and travel. Any penalties levied are based
28 on the applicable statutes and regulations of USDA, CBP, and USFWS.

29 CBP Agriculture Specialists and cross-trained CBP Officers follow procedures outlined in the Manual for
30 Agricultural Clearance (USDA 2006c) and other applicable USDA manuals. For example, the Fresh Fruits
31 and Vegetables Import Manual (USDA 2007c) lists by country fruits and vegetables that are admissible
32 into the United States, including the required quarantine treatments, if any, and the methods of
33 sampling and inspection intensity. Thus, commercial non-propagative fruits and vegetables arriving at

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 the ports are inspected and cleared by CBP according to the language and stipulations of the Fresh Fruits
2 and Vegetables Import Manual.

3 CBP makes referrals to the HDOA for pests not covered by quarantines enforced by CBP. These have
4 included ticks, spiders, and reptiles.

5 CBP in Hawai'i collaborates with a Pest Risk Committee (PRC) with two subcommittees covering animal
6 diseases and plant pests. Meetings are attended by both state and federal agencies and departments.
7 Activities of the PRC have included many special operations conducted jointly by CBP, APHIS-PPQ, USDA
8 Food Safety and Inspection Service, FDA, and USFWS involving certain kinds of cargo making entry, with
9 the aim of collecting pest information on particular commodities, interdicting potential smuggling,
10 responding to national alerts, identifying high-risk commodities, and enforcing applicable regulations.
11 The PRC distributes information on pests and diseases known to be of interest to the State of Hawai'i;
12 emerging animal diseases and changing disease status for various countries, state, and federal pest and
13 plant material seizures; and extends outreach to other federal and state agencies. CBP uses this
14 information in its targeting of cargo, and adjusts tactics when new information becomes available.

15 CBP requires a manifest from the shipping agent for all incoming cargo. Cargo entering the United States
16 by way of Honolulu is held by the shipper against a bond. CBP inspects certain types of cargo, such as
17 fresh fruit and vegetables, handicrafts, seeds, animal products and by-products, cut flowers and
18 greenery, heavy equipment and farm machinery for soil, household goods, certain kinds of stone and
19 containers for hitchhiking snails, and other agricultural or food items before granting entry. Other cargo,
20 such as new automobiles, are rarely inspected. When conducting inspections, CBP scrutinizes wood
21 packaging material (WPM) branding and enforces WPM regulations, re-exporting non-compliant
22 materials in accordance with national guidelines. CBP also enforces the CITES, inspecting and seizing
23 non-living CITES-regulated plant shipments and, following safeguarding procedures, delivering living
24 CITES-regulated plants to the APHIS Plant Inspection Station. Through its computerized tracking system,
25 CBP classifies all cargo to determine its rate of duty and to track import quotas and other items of
26 concern. This system stores any special information about an item and identifies those items requiring
27 inspection or approval by any other federal agency. USDA and USFWS have the opportunity to review all
28 incoming plant or animal materials for CBP.

29 CBP uses the Automated Commercial System and the Automated Targeting System for cargo and
30 passengers to identify certain regulated, high-risk agricultural cargo, or passengers with previous
31 violations. Various targeting criteria can identify potential violators, smugglers, and other anomalies that
32 could result in examinations. Holds on cargo can be initiated automatically both nationally and locally.
33 CBP also uses USDA databases for data input and analysis. These include Work Accomplishment Data
34 System (WADS), AQIM, EANs, 280s, and Pest ID. Use of all systems and databases provides CBP detailed
35 information to identify potential cargo, passengers, aircraft, or vessels for examination. CBP has
36 dedicated Agriculture Specialists performing agriculture targeting for the air cargo, sea cargo, and
37 passenger pathways. These efforts are augmented by CBP Officers performing targeting duties at the
38 same locations. In 2006, through such operations, CBP prevented the entry of nearly 50 tonnes of
39 animal products and by-products into Honolulu.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Even before the creation of DHS, the former Customs Service of the U.S. Department of the Treasury, in
2 1991, inaugurated a policy that facilitated minimal inspection of incoming passengers arriving from
3 certain low-risk areas or countries. Passengers who have visited high-risk areas of the world (e.g., those
4 in which highly significant pests or diseases occur, or associated with the smuggling of drugs and other
5 contraband) receive a more careful examination.

6 **A15.2.3 APHIS-PPQ’s Agricultural Quarantine Inspection Monitoring and CBP**

7 The purpose of the AQIM program is to gather data regarding AQI effectiveness (USDA 2006a). The data
8 are used to define and document various pest risk pathways, determine the likelihood for agricultural
9 pests and diseases to enter the United States through various identified routes, and communicate to
10 CBP those agricultural risks that require its attention. At each selected airport (including HNL) and mail
11 facility, CBP officers each year conduct random inspections of passenger baggage and mail. At cargo
12 facilities, various types of cargo shipments are randomly selected each year for complete inspection.
13 Results of passenger baggage inspections are used to estimate the rate of quarantine material arriving
14 at each port. This estimate is used to gauge program effectiveness. For cargo, results are used to
15 estimate the rate of cargo shipments requiring action as they arrive at a port, and the percentage of
16 units approaching with significant pests. Such estimates can be used by ports to gauge their
17 effectiveness in managing pest risk in cargo, and to evaluate the relative risks of various known pest
18 entry pathways.

1 **A16 AIRLINE PASSENGERS**

2 It is worth noting that the information in the section is based on data from prior to 2008.

3 **A16.1 OBJECTIVE**

4 The objective of this chapter is to estimate the likelihood of quarantine plant materials and pests
5 entering Hawai'i with airline passenger baggage, thereby providing a basis for decision making towards
6 phytosanitary improvements, as well as a starting point for discussion and further analysis. It should be
7 noted that data used in this section is not current but comes from a variety of sources, the most recent
8 being a 2007 compilation.

9 **A16.2 ANALYSIS METHODS**

10 AQIM data collected by the DHHS CBP were used to estimate approach rates of quarantine plant and
11 animal materials (QMs) and pests. If sampling procedures are followed correctly, AQIM data are
12 collected through a detailed inspection of randomly selected sampling units. This means that, in contrast
13 to regular, targeted quarantine inspections, AQIM sampling is unbiased and is therefore suitable for risk
14 quantification. Details on AQIM data sets and sampling protocols can be found in the USDA AQIM
15 Handbook (USDA 2006a).

16 AQIM data were available only for HNL, which accounts for the majority of all international airline traffic
17 into Hawai'i. In order to minimize the effects of sampling protocol inconsistencies, we used only the two
18 most recent complete data sets (FY 2005 and FY 2006). The available data set pertains only to
19 international airline passenger baggage; no comparable information was available for visitors from the
20 U.S. mainland.

21 The QM approach rate is defined as the proportion of sampling units in which plant QMs were found.
22 The sampling unit in this case was the group of airline passengers (one to many individuals) traveling
23 together under one U.S. Customs manifest. In order to express the level of uncertainty associated with
24 QM approach rate estimates, they are presented as 95% binomial confidence intervals, i.e., the limits
25 within which the actual approach rates lie with 95% certainty (Steel et al. 1997). For small sample sizes,
26 the uncertainty associated with the approach rate estimate is large (i.e., the binomial confidence
27 intervals become wide). For sample sizes under 20, assumptions regarding statistical distributions may
28 not be accurate (Jones 2007), and uncertainty is so high that these cases are not included in either the
29 discussion of results, or in the figures and tables.

30 We calculated approach rates by country of passenger origin, by travel reason, and by calendar month
31 of travel using the RELIABILITY, MEANS, TABULATE and SQL procedures in SAS® 9.1.3 (SAS Institute
32 2007). The data for FY 2005 and FY 2006 were combined to increase the sample sizes. In order to arrive
33 at an estimate of the total number of QMs that annually enter Hawai'i, we multiplied approach rates by
34 the average number of QMs per interception (source: AQIM data) and the average number of passenger
35 groups entering annually. This last number was calculated by dividing the number of annual visitors by
36 the average passenger group size indicated by AQIM data. The annual number of visitors was obtained
37 from the 2005 Annual Visitors Research Report of the Hawai'i Department of Business, Economic

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Development and Tourism (HDBEDT), referred to as the “DBEDT data set” throughout this document
2 (HDBEDT 2005b).

3 Because the DBEDT data set provided country-specific visitor numbers for only some of the countries in
4 the AQIM data set (those considered major market areas for Hawai’i), we estimated the number of
5 visitor groups for the remaining countries by multiplying the number of passengers sampled during
6 AQIM data collection by 140. This number (with a standard deviation of 97) represents the average ratio
7 of

8
$$\frac{\text{(number of international passenger groups entering Hawai’i)}}{\text{(number of international passenger groups sampled during AQIM)}}$$

9

10 for those countries where visitor numbers were available from the DBEDT data set. As AQIM data are
11 based on a random sampling scheme, this ratio should be approximately constant among countries
12 (though the high standard deviation indicates that this may not be the case). However, for lack of more
13 reliable data, we used this estimate to extrapolate the number of visitor groups for those countries of
14 origin that are not included in the DBEDT data set, and presented the results as point estimates together
15 with their associated standard deviations. The values that are based on this extrapolation are shaded
16 grey in Table B5-1 (below).

17 For the analysis by travel reason, some categories had to be combined, both in the AQIM and in the
18 DBEDT data set in order to make the two data sets match each other. The categories “Business/Work”
19 and “Uniformed crew” of the AQIM data set were combined into one category that was considered
20 equivalent to “MC&I, and Other Business” in the DBEDT data set. The category “Government/Military”
21 in the DBEDT data set was treated as equivalent to “Military” in the AQIM data set. The categories “Visit
22 friends” and “Family visit” of the AQIM data set were combined into one category that was considered
23 equivalent to “Friends and relatives” in the DBEDT data set. The categories “Pleasure” (which includes
24 the sub-categories “Vacation,” “Honeymoon,” and “Wedding”) and “Sports events” of the DBEDT data
25 set were combined into one category that was considered equivalent to the combined categories
26 “Tourism” and “Other” of the AQIM data set.

27 For estimates of pest approach rates, we used a combination of different source data sets, each of
28 which was associated with some uncertainty: AQIM data, USDA-APHIS-PPQ Pest ID, which contains
29 records of all pest interceptions made by PPQ or CBP at U.S. ports-of-entry since 1985 (USDA 2007a),
30 and the DHS CBP WADS, which provides information on the number of certain tasks (e.g., inspections)
31 performed by port inspectors (USDA 2007b). For this analysis, a pest is defined as a species of
32 arthropod, mollusc, weed, nematode, or plant pathogen that is injurious to plants or plant products.

33 **A16.3 RESULTS AND DISCUSSION**

34 **A16.3.1 International Passengers by Country of Origin**

35 QM approach rates for the various countries of origin ranged between zero and approximately 25%
36 (Table B5-1, Figure B5-1). In many cases, the 95% binomial confidence intervals were rather large, due to
37 small sample sizes. For Malaysia, Indonesia, New Zealand, Fiji, and Taiwan, the binomial confidence

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 intervals included zero (i.e., the approach rates were not significantly different from zero). The lower
2 95% binomial confidence limit (i.e., the estimated minimum approach rate) was highest for Guam,
3 followed by Thailand. Japan, the origin for approximately 70% of all international Hawai'i visitors
4 (HDBEDT 2005b), had a QM approach rate of 1.7%, which was significantly lower than those of Guam,
5 Thailand, and Australia. In spite of its moderate QM approach rate, Japan is the source of the highest
6 number of QMs, due to the large number of visitors from Japan. Approximately 16,000 to 25,000 QMs
7 from Japan, 3,400 to 9,700 QMs from Australia, and 1,200 to 4,000 QMs from Guam are estimated to
8 enter Hawai'i per year; most other countries contribute 2,000 or fewer QMs annually. Most frequent
9 among the plant QMs intercepted from Japan during AQIM data collection (Table B5-5) were species of
10 *Citrus*, which represent a risk of introducing various quarantine pests, especially scales such as *Unaspis*
11 *yanonensis* (Kuwana) (Homoptera: Diaspididae) and the plant bacterial pathogen *Xanthomonas*
12 *axonopodis* *pv.* *citri* (Hasse) Vauterin et al. In fact, during FYs 2005 and 2006, *U. yanonensis* had been
13 intercepted more than 20 times in Japanese air passenger baggage at Hawai'i ports-of-entry (USDA
14 2007a).

15 **A16.3.2 International Passengers by Travel Reason**

16 Due to a relatively small sample size, the category "Military" has a very large confidence interval (2 to
17 18%), which is not extremely informative. It can be said, however, that military travel is associated with
18 QM approach rates that are significantly different from zero. Apart from military travel, the category
19 "Visit friends and family" was associated with the highest QM approach rates (Table B5-2, Figure B5-3).
20 This corroborates the intuitive assumption that international passengers visiting friends and family are
21 more likely than tourists or business travelers to carry QMs because they bring food items as gifts. The
22 QM approach rates for the categories "Tourism" and "Business/Work" were quite similar to each other
23 (though "Tourism" had a narrower 95% binomial confidence interval because of a larger sample size).

24 As tourists represent the majority of all travelers to Hawai'i (i.e., their approach rate is multiplied by the
25 largest number of passengers), they are the group that introduces by far the most QMs into the islands.
26 It must be noted that AQIM and DBEDT data are not in agreement with regard to the numbers of visitors
27 in the various categories. Based on AQIM data, there should be approximately four times as many
28 tourists as there are people visiting friends or family. However, according to DBEDT data, the number of
29 tourists is 18 times higher than the number of people visiting friends or family. We are not sure about
30 the reasons for this discrepancy; our estimates are based on DBEDT data.

31 **A16.3.3 International Passengers by Month**

32 Overall QM approach rates in September were significantly higher than in May (Table A16-3, Figure A16-
33 5). Otherwise, QM approach rates were not significantly different between months. As the number of
34 travelers is more or less constant among months (Table A16-3), the estimated number of QMs entering
35 (Figure B3-5) is proportional to the respective QM approach rates (Figure A16-6).

1 **A16.3.4 All International Passengers**

2 In total, there were 2,114,064 international visitors to Hawai'i in 2005 (HDBEDT 2005b), with an overall
3 QM approach rate of 0.022 to 0.027 (95% binomial confidence interval). This leads to an estimate of
4 40,369 to 54,458 QMs per year being brought into the islands by international airline passengers (Table
5 B5-4). Based on WADS data, an annual average of 17,000 QMs were intercepted by CBP during FYs 2005
6 and 2006 (USDA 2007b), which means that only 31 to 42% of all QMs were intercepted by CBP. This
7 would leave approximately 23,000 to 37,500 QMs entering Hawai'i undetected every year. This estimate
8 of interception efficiency is higher than those from other, similar analyses (e.g., Meissner et al. 2003).

9 **A16.3.5 Pest Approach Rates**

10 In the AQIM data set we analyzed, there were no plant pest interceptions recorded for the over 7,000
11 passenger groups sampled. This means that an estimated 0 to 0.04% (95% binomial confidence limits) of
12 all international air passenger groups brought plant pests into Hawai'i. As 1,360,120 passenger groups
13 visited the state during 2005 and 2006 (Table B5-4), between 0 and 540 plant pests would have arrived
14 with them. We know that, contrary to AQIM sampling guidelines (USDA 2006a), searching for pests is
15 often not performed during AQIM data collection. It may therefore be assumed that the above pest
16 approach rate is a substantial underestimate. From Pest ID data (USDA 2007a), we know that pests are
17 reaching Hawai'ian ports-of-entry; therefore, an estimate of zero for the pest approach rate must be
18 inaccurate. In fact, 426 pests are recorded in the Pest ID database for FYs 2005 and 2006, during which
19 time approximately 4 million international air passengers entered Hawai'i. Based on the calculations
20 above, only about 20% of all QMs are intercepted by CBP. For pests, the interception efficiency likely is
21 considerably lower, since they may not be detected on intercepted QMs, either because they are hidden
22 (e.g., internal feeders) or because the inspector discards the QM without looking for pests. If, therefore,
23 we generously assume that 5% of all pests that are present in air passenger baggage actually are
24 detected and recorded in the Pest ID database, we arrive at an estimate of 8,520 pests entering per 4
25 million passengers (i.e., 4,275 pests per year). This would translate into a pest approach rate of 0.2%
26 (versus the 0 to 0.04% predicted by AQIM data). The probability of establishment after introduction is a
27 function of both the rate of entry and the population size required for persistence (Bartell and Nair
28 2003), and will be different for each pest species. A general and often cited estimate is that about 10%
29 of all non-indigenous insect species introduced into a new range become established (NRC 2002).
30 However, based on Bartell and Nair (2003), this estimate may be too high for some species, so we are
31 here conservatively assuming that between 0.1% and 1% of the arriving pests manage to establish
32 populations in Hawai'i within 25 years of first introduction. Thus, we would expect approximately four 4
33 to 40 pest establishments per year as a result of international air travel alone.

34 In addition to the 2 million international travelers, Hawai'i received about 5.3 million visitors from the
35 U.S. mainland in 2005. It is impossible to quantify the risks associated with the domestic visitors because
36 no randomly collected data are available. However, quarantine inspections by the HDOA have resulted
37 in over 300 pest interceptions in domestic air passenger carry-on baggage between 1995 and 2006
38 (HDOA 2007c) (Table A16-6), demonstrating that visitors entering by air from the U.S. mainland may be
39 a significant pathway for the introduction of exotic pests. One of the more frequently intercepted

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 species was the Argentine ant, *L. humile*, an extremely invasive tramp species, which has become
2 established and is wreaking ecological havoc in Hawai'i (Cole et al. 1992). Due to a number of biological
3 traits, this and other ant species have a high probability of introduction, so that establishment may
4 easily result from a small number of individuals, provided that a reproductive female (gyne) is among
5 them. Given the low interception efficiency of CBP on international visitors and the relatively small
6 workforce HDOA has available to prevent exotic introductions, it is unlikely that the existing pest risk
7 associated with international and domestic airline passengers can be mitigated effectively under present
8 conditions.

9 **A16.3.6 Summary**

- 10 • For all countries of passenger origin with a sample size of 20 or more, estimated plant QM
11 approach rates were between 0 and 25%. Differences in approach rates between countries
12 of origin were complex, with no country being significantly different from all other
13 countries.
- 14 • For the different travel reasons with a sample size of 20 or more, estimated plant QM
15 approach rates from foreign countries were between 0.4 and 12%. All travel reasons had
16 QM approach rates that were significantly different from zero.
- 17 • For the different months of the year, estimated plant QM approach rates from foreign
18 countries were between 1 and 7%. All months had QM approach rates that were
19 significantly different from zero. December and January were associated with higher
20 approach rates than the summer months.
- 21 • There was not a single pest interception recorded in the AQIM data set. Based on other
22 available information, this seems to be a data quality problem.
- 23 • More than 4,000 plant pest organisms may be entering Hawai'i with foreign airline
24 passengers every year, which may translate into between 4 and 40 pest establishments
25 annually.
- 26 • The percentage of arriving pest species already established in Hawai'i is unknown.
- 27 • The international airline passenger pathway presents a significant pest risk to Hawai'i.
- 28 • Although the pest risk associated with domestic airline passengers cannot be quantified due
29 to a lack of data, it likely is significant.

30 Table A16-1 details AQIM of international air passengers arriving at HNL in FYs 2005 and 2006 by
31 country of passenger origin. The table shows only countries for which the AQIM sample size was at least
32 20. The sampling unit is the group of passengers traveling together under one U.S. Customs manifest.
33 The table shows the country of origin,¹⁰ the number of passenger groups that were found to have
34 quarantine materials (QMs),¹¹ the number of passenger groups inspected,¹² the estimated proportion of

¹⁰ AQIM data for FYs 2005 and 2006.

1 Notes:

2 ^a NA: Information not available or not applicable.

3 ^b There is no citrus production in Germany (Lieberz 2005).

4 ^c There appears to be little or no production of this commodity in Guam (e.g., Morton 1987; NASS 2007).

5 ^d There appears to be little or no banana production in Korea (FAO 2006a).

6 ^e There appears to be little or no apple production in the Philippines (FAO 2006a).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 ^f Records for Hawai'i are considered misidentifications of a related species, *L. langei* Frick (Scheffer and Lewis 2001).

2
3 ^g There appears to be little or no apple production in Singapore (FAO 2006b).

4 ^h Records from the APHIS-PPQ Port Information Network (PIN 309) database. Last access: May 2007.

5

6 **Table B5-6 Plant Pests Intercepted by the Hawai'i Department of Agriculture on the Carry-**
7 **on Baggage of Airline Passengers Coming from the U.S. Mainland, 1995-2006**

Pest Taxon	Scientific Name of Pest	Number of Times Intercepted
Acaridae	<i>Tyrophagus</i> sp.	1
Agromyzidae	<i>Cerodontha dorsalis</i>	1
Aleyrodidae	<i>Bemisia tabaci</i>	1
	<i>Paraleyrodes minei</i>	1
Anthocoridae	<i>Orius insidiosus</i>	1
Anthomyiidae	<i>Delia radicum</i>	2
Anyphaenidae	<i>Anyphaena</i> sp.	1
Anystidae	Unknown sp.	2
Aphelinidae	<i>Aphelinus asychis</i>	1
	<i>Coccophagus</i> sp.	1
Aphididae	<i>Aphis fabae</i>	1
	<i>Aphis</i> sp.	1
	<i>Brachycaudus cardui</i>	2
	<i>Brevicoryne brassicae</i>	1
	<i>Cerataphis orchidearum</i>	1
	<i>Chaetosiphon fragaefolii</i>	2
	<i>Macrosiphum euphorbiae</i>	1
	<i>Melanaphis sorghi</i>	1
	<i>Myzus</i> sp.	1
	<i>Rhopalosiphum maidis</i>	1
	<i>Rhopalosiphum padi</i>	2
	<i>Schizaphis graminum</i>	1
	<i>Sitobion luteum?</i>	1
	Unknown sp.	1
<i>Utamphorophora humboldti ?</i>	1	
<i>Wahlgreniella nervata</i>	1	
Araneidae	Unknown sp.	2
Arctiidae	Unknown sp.	2
Bedellidae	Unknown sp.	2
Berytidae	<i>Acanthophysa</i> sp.	1
Blatellidae	<i>Blatella germanica</i>	1
	<i>Blattella</i> sp.	1
Blattidae	Unknown sp.	2
Braconidae	Unknown sp.	2
Bradybaenidae	<i>Bradybaena similaris</i>	1
	<i>Bradybaena</i> sp.	1
Carcinophoridae	<i>Euborellia annulipes</i>	1
Cerambycidae	<i>Neoclytus acuminatus</i>	1

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

Pest Taxon	Scientific Name of Pest	Number of Times Intercepted
	<i>Plectromerus deutipes</i>	1
Chloropidae	Unknown sp.	1
Chrysomelidae	<i>Diabrotica</i> sp.	1
	<i>Diabrotica u. undecimpunctata</i>	1
	<i>Glyptina</i> sp.	1
	<i>Microtheca ochroloma</i>	1
	Unknown sp.	1
Cicadellidae	Unknown sp.	2
Cimicidae	<i>Cimex lectularius</i>	1
Clubionidae	<i>Clubiona</i> sp.?	1
Coccidae	<i>Coccus hesperidum</i>	4
	<i>Milriscutulus</i> sp.	1
	<i>Saisettia oleae</i>	1
	<i>Saisettia coffeae</i>	5
	<i>Saisettia</i> sp.	1
	Unknown sp.	1
Coccinellidae	<i>Coccinella californica</i>	1
	<i>Hippodamia californica</i>	1
	<i>Hippodamia convergens</i>	3
	<i>Mulsantina picta</i>	1
	<i>Scymnus</i> sp.	1
	Unknown sp.	2
Coreidae	<i>Chelinidea vittiger</i>	1
	Unknown sp.	1
Cucujidae	<i>Ahasversus advena</i>	2
Curculionidae	Brachyderinae	1
	Otidocephalinae	1

1 **A17 CARGO**

2 This chapter summarizes statistics on foreign and domestic imports of fresh agricultural commodities
3 into Hawai'i and discusses them in the context of the associated pest risk. It should be noted that data
4 used to develop this section does not necessarily reflect the current situation. The most recent data
5 sources used for this section are from a 2007 compilation.

6 As Hawai'i is an island state, both international and domestic cargo arrives either by ship or—to a much
7 lesser degree—by aircraft. Approximately 80% of all goods (agricultural and non-agricultural) in Hawai'i
8 have to be imported, and 98% of these arrive in ocean vessels (Figures B6-1 and B6-2) (HDBEDT 2005a;
9 Hawai'iWeb 2007). According to official statistics, Hawai'i received 4.5 million tonnes of sea cargo from
10 domestic trade and 8 million tonnes from foreign trade in 2005 (U.S. Army Corps of Engineers 2005b).
11 However, these numbers do not tell the whole story, as the overwhelming majority of all foreign cargo is
12 not shipped from the exporting country directly to Hawai'i, but makes entry on the U.S. mainland first
13 and is then shipped from there to Hawai'i as domestic cargo (Kosciuk 2007). Information on the true
14 origin of much of this cargo gets lost. Furthermore, on arrival in Hawai'i, it becomes subject to a
15 different set of phytosanitary inspections than directly-shipped foreign cargo. This is because all foreign
16 imports are cleared by the DHS CBP at Honolulu Harbor or HNL on the island of Oahu (Kosciuk 2007),
17 whereas domestic shipments (including shipments of foreign origin arriving from the U.S. mainland) are
18 cleared by the HDOA. HDOA clears cargo at the following locations: Honolulu Harbor and HNL; Hilo
19 Harbor, Kawaihae Harbor, Hilo International Airport, and Kona International Airport at Keahole on the
20 island of Hawai'i; Kahului Harbor and Kahului Airport on the island of Maui; and Nawiliwili Harbor and
21 Lihue Airport on the island of Kauai (HDOA 2007b).

<http://www.hawaii.gov/dot/publicaffairs/index.htm>

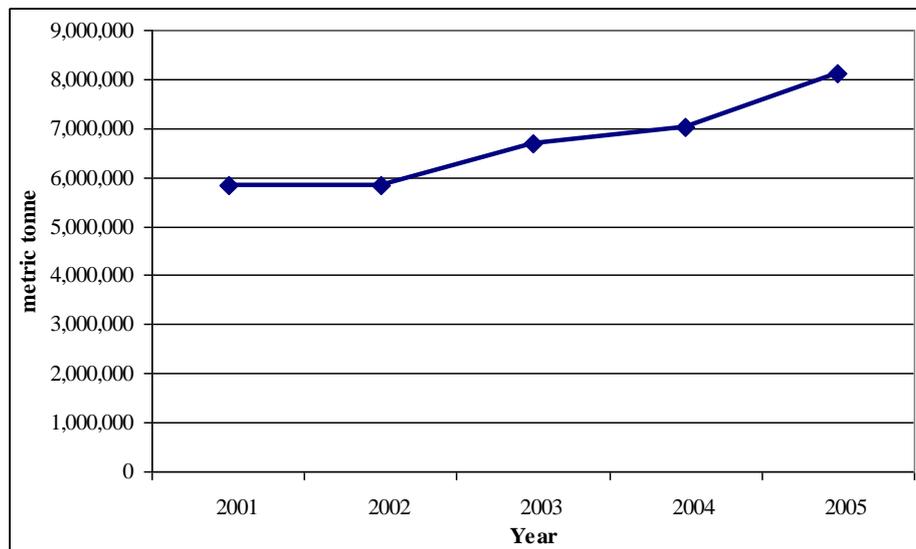

27 The volume of foreign imports to Hawai'i has been increasing over recent years (Figure B6-2) (HDBEDT
28 2005a). The majority of all containerized cargo enters Hawai'i through Honolulu Harbor (Table B6-1)

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 (HDOT 2006), which, in 2005, received 4,395 inbound vessels ranging in draft²³ and type (e.g., dry cargo,
2 tanker, tow or tug). Of these, only 444 were of foreign origin, whereas 3,951 arrived from the U.S.
3 mainland (Table A17-1) (U.S. Army Corps of Engineers 2005a); not all of them were carrying commercial
4 cargo. One source reported that in 2005 the harbor received 1,121 overseas vessels carrying commercial
5 cargo (HDBEDT 2005a).

6 Most of the commercial cargo arriving by aircraft makes entry at HNL (Table A17-2), which receives the
7 bulk of both foreign and domestic air cargo, as well as foreign and domestic air mail (HDBEDT 2005a;
8 Kosciuk 2007). In 2005, over 9,000 international flights carried freight into the state, 94% of which was
9 received at HNL (Bureau of Transportation Statistics 2006); no statistics were available on the number of
10 domestic flights. Of domestic freight arriving in 2005, 94% entered through HNL (Table B6-2) (Bureau of
11 Transportation Statistics 2007).

13 **Maritime Vessels (top) and Aircraft (bottom)**

14

²³ Draft is defined as the depth of water necessary to float a vessel, and is usually measured in feet (U.S. Army Corps of Engineers, Navigation Data Center, U.S. Waterway Data, Data Dictionary, available at <http://www.iwr.usace.army.mil/NDC/data/dictionary.htm>. Last accessed 22 June 2007.)

- 3 NA Information not available.
- 4 ^a Flights into Hickam Air Force Base and Marine Corps Base Hawai’i were excluded. The total number of aircraft
- 5 that carried freight was 9,116, of which 8,912 carried both freight and passengers and 204 carried freight only.
- 6 The number of domestic flights was not available.
- 7 ^b Passengers in transit (100,172 passing through Honolulu International Airport) were excluded.
- 8 ^c Data source: Bureau of Transportation Statistics (2006).
- 9 ^d Data source: Bureau of Transportation Statistics (2007).
- 10 ^e Inter-island aircraft were excluded.
- 11 ^f Cargo includes agricultural and non-agricultural freight. Numbers were rounded.

13 When evaluating the risk of pest introduction through the import of agricultural commodities, it is useful
 14 to know the country of origin and the quantity of arriving commodities, as well as the types of pests
 15 associated with them and the likelihood that these pests are present on them. For this analysis, it was
 16 impossible to obtain much of this information due to a lack of suitable or reliable data.

17 Agricultural commodity imports from foreign origins are recorded by CBP in the USDA-APHIS-PPQ Fruit
 18 and Vegetables database (AQAS 2007). This database contains information on the type of commodity
 19 imported, number of shipments, quantity (with unit of measure), and country of origin. This database
 20 records only imports from foreign countries that have first made entry at a U.S. port; these imports, now
 21 classified as domestic (as mentioned above), fall outside the scope of the database. Beyond its scope are
 22 also all non-agricultural shipments (which nevertheless may present a considerable risk by harboring
 23 hitchhiking pests or pests in WPM; see Chapters B7 and B8). Regarding the quantity of commodity
 24 imports, the unit of measure differs depending on the commodity type. For example, for cut flowers the
 25 unit is usually number of stems, and more rarely kilograms; the unit is also kilograms for fruits and
 26 vegetables, whereas for propagative material, it may be number of plant units, or number of flasks. As
 27 these units are not interconvertible, any quantitative comparison among commodity types becomes
 28 impossible. The situation is even more difficult regarding number, size, and commodity type in domestic
 29 shipments, for which barely any information exists.

30 Although a greater number of shipments of agricultural commodities arrives in Hawai’i by aircraft as
 31 compared to maritime transport, these shipments are typically smaller in volume and weight as
 32 compared to agricultural shipments arriving by sea (discussed in more detail below) (AQAS 2007).
 33 Comparisons among the numbers of shipments from foreign origin entering Hawai’i does not take into
 34 account the size or weight of the shipment. For example, cut flower shipments accounted for about half
 35 of the agricultural shipments entering Hawai’i from foreign origin, yet these shipments are in general

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 smaller (shipments varied from fewer than 100 stems to over 1,000 stems) than fruit and vegetable and
2 propagative plant shipments.

3 For pest interceptions on foreign shipments, a database, Pest ID, is maintained by APHIS-PPQ (USDA
4 2007a). From this database, it is possible to determine the kinds of pests that have been intercepted.
5 However, the information cannot be used for quantitative analysis because only pest interceptions are
6 recorded, leaving the number of inspected units and the inspection procedures unknown. Once a
7 quarantine pest is found in a commodity, the inspection is usually terminated, so that the severity of the
8 infestation, as well as additional pest species that may be present, remain unknown. Of special
9 relevance to this analysis is the fact that foreign shipments undergo phytosanitary inspection at the U.S.
10 port of first entry; this means that pest interceptions on foreign shipments that make entry at a U.S.
11 mainland port before being shipped to Hawai'i are recorded in the database under the name of that
12 port, making it impossible to identify them as ultimately being destined for Hawai'i.

13 Pest interceptions made by HDOA are recorded in one of two databases maintained by the HDOA Plant
14 Quarantine Branch (HDOA 2007c). These interceptions pertain to domestic shipments almost
15 exclusively; however, on occasion, HDOA inspects shipments of foreign origin, and, if interceptions are
16 made, they are recorded in the same databases. One database contains records for pathogens, the
17 other stores records for arthropods (Oishi 2007).

18 **A17.1 FOREIGN IMPORTS**

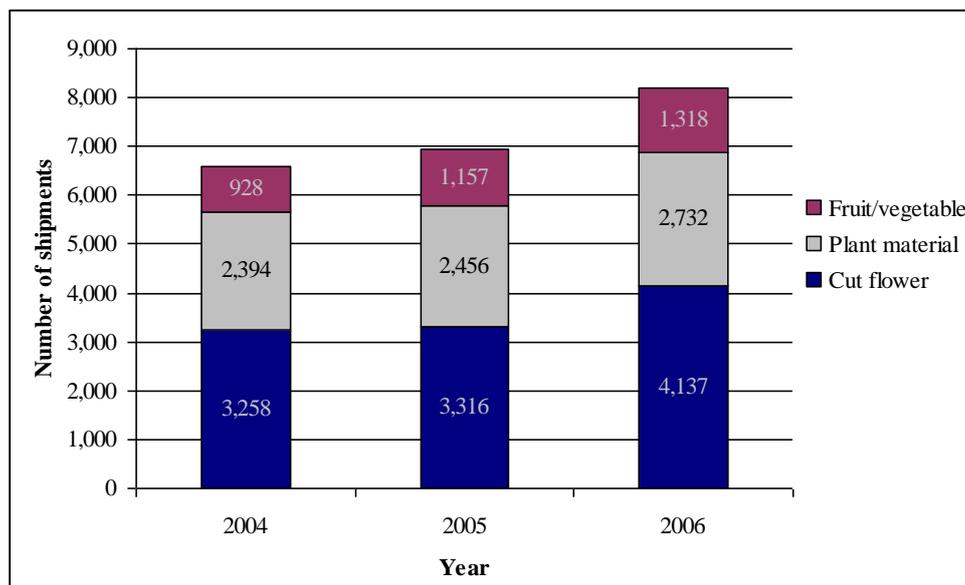

19 This section provides an overview of shipments of fresh agricultural commodities imported into Hawai'i
20 from foreign origins between January 1, 2004 and December 31, 2006. It should be noted that the data
21 presented here are an incomplete reflection of the actual import situation, because foreign imports are
22 commonly cleared at a port-of-entry on the U.S. mainland before proceeding to Hawai'i (Kosciuk 2007).
23 The commodities involved may undergo repackaging, and are often combined with commodities
24 produced in the United States (Kosciuk 2007), making it difficult to determine their true origin.

25 Such practices allow trade to circumvent the commodity risk assessment process (e.g., USDA 2000), the
26 purpose of which is to identify and mitigate pest risks associated with foreign imports. Perhaps for
27 reasons of expedience, Hawai'i is often neglected when risks to the United States associated with
28 importation of foreign commodities are assessed. Any rules or regulations resulting from these
29 assessments are likely not to pertain to Hawai'i, and the commodities are not permitted to be imported
30 directly into the state. However, under current practices, a commodity that was deemed a low pest risk
31 for the U.S. mainland, although representing a high risk for Hawai'i, would be enterable into the
32 mainland without undergoing any phytosanitary treatments, and subsequently could be sent on to
33 Hawai'i as part of a domestic shipment.

34 Between 2004 and 2006, almost 22,000 shipments of fresh agricultural commodities for consumption
35 (an average of approximately 7,000 shipments/year) arrived from 56 different countries at Hawai'ian
36 ports-of-entry (AQAS 2007). During this period, the number of shipments imported increased for each
37 major commodity category (Figure B6-3). Nearly 330 of these consignments were destroyed or re-

1 exported due to the presence of an actionable pest, a contaminant, or a discrepancy with the
2 phytosanitary certificate.

3 **Figure B6-3: Shipments of Fresh Agricultural Commodities Imported into Hawai'i between**
4 **2004 and 2006, by Commodity Type**

5

6 Source: AQAS 2007

7

8 Thailand, Japan, Indonesia, Canada, and Taiwan accounted for 90% of all incoming foreign agricultural
9 shipments (Figure A17-4). In addition to these nations, each of the following countries exported 100 or
10 more agricultural shipments to Hawai'i: Australia, China, the Cook Islands, Fiji, Malaysia, New Zealand,
11 the Philippines, Singapore, and South Korea. This comparison does not take into account the quantities
12 of the commodities received, as an inconsistency of units made a comparison across commodity types
13 impossible (Figure B6-5) (AQAS 2007). Thailand accounted for 54% of the total number of foreign
14 agricultural shipments; Japan, Indonesia, Canada, and Taiwan accounted for approximately 13%, 11%,
15 9%, and 3% of the agricultural shipments, respectively. The other 49 countries or territories exporting to
16 Hawai'i each accounted for less than 1% of the number of agricultural shipments (AQAS 2007).

17 Of the total number of agricultural shipments of foreign origin imported into Hawai'i, about half were
18 cut flowers originating from twelve countries (Figure A17-6). The majority of them (94%) came from
19 Thailand, with Japan and the Cook Islands each accounting for about 2%. The nine other countries, from
20 which cut flowers were imported, each accounted for less than 1% of the shipments. All cut flower
21 shipments arrived by aircraft (AQAS, 2007).

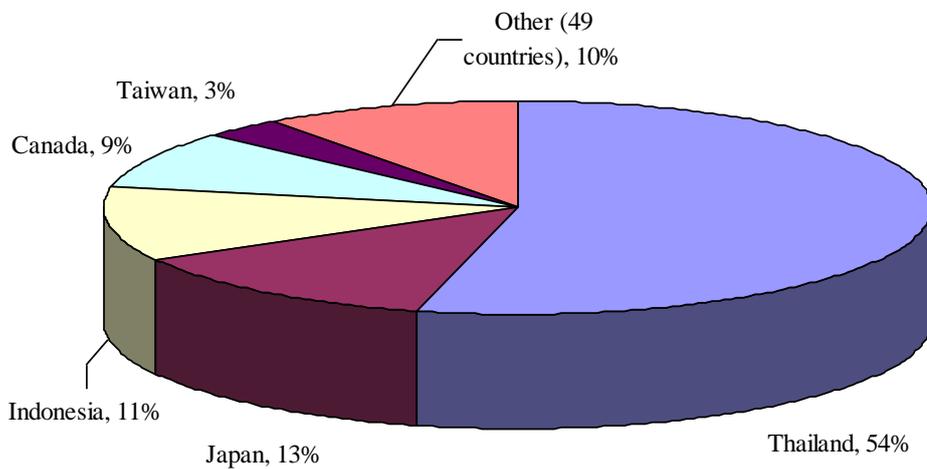

22 Shipments of propagative material, originating in 47 different countries, accounted for 35% of the total
23 number of agricultural shipments imported from foreign origins (Figure A17-6). The majority of these
24 shipments came from Indonesia (about 30%), Canada (about 26%), and Thailand (about 23%), whereas

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Taiwan and Singapore accounted for 6% and 3%, respectively. The other 42 countries and territories
2 each accounted for less than 2% of the total number of shipments. The majority of the propagative
3 material shipments (about 90%) entered Hawai'i by aircraft (AQAS 2007).

4 Shipments of fruits and vegetables, originating in 15 different countries, accounted for about 16% of the
5 agricultural shipments imported from foreign areas (Figure A17-5). The majority of these shipments
6 (about 75%) came from Japan. China, Fiji, New Zealand, South Korea, and Taiwan each contributed
7 between 3% and 7% of the imports. The other nine countries, from which fruit and vegetables were
8 imported, each accounted for less than 1% of the shipments. Most of these shipments (about 84%)
9 arrived via aircraft (AQAS 2007).

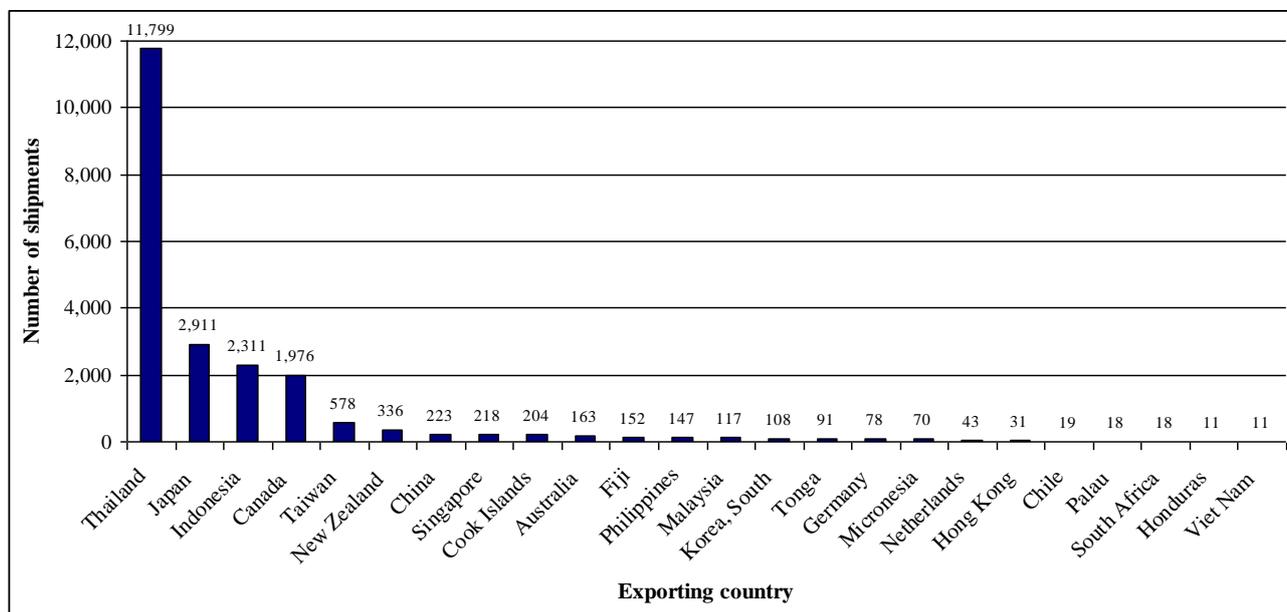

10 **Figure A17-4. Thailand, Japan, Indonesia, Canada, and Taiwan Accounted for 90% of the Fresh**
11 **Agricultural Shipments Entering Hawai'i between 2004 and 2006**

12

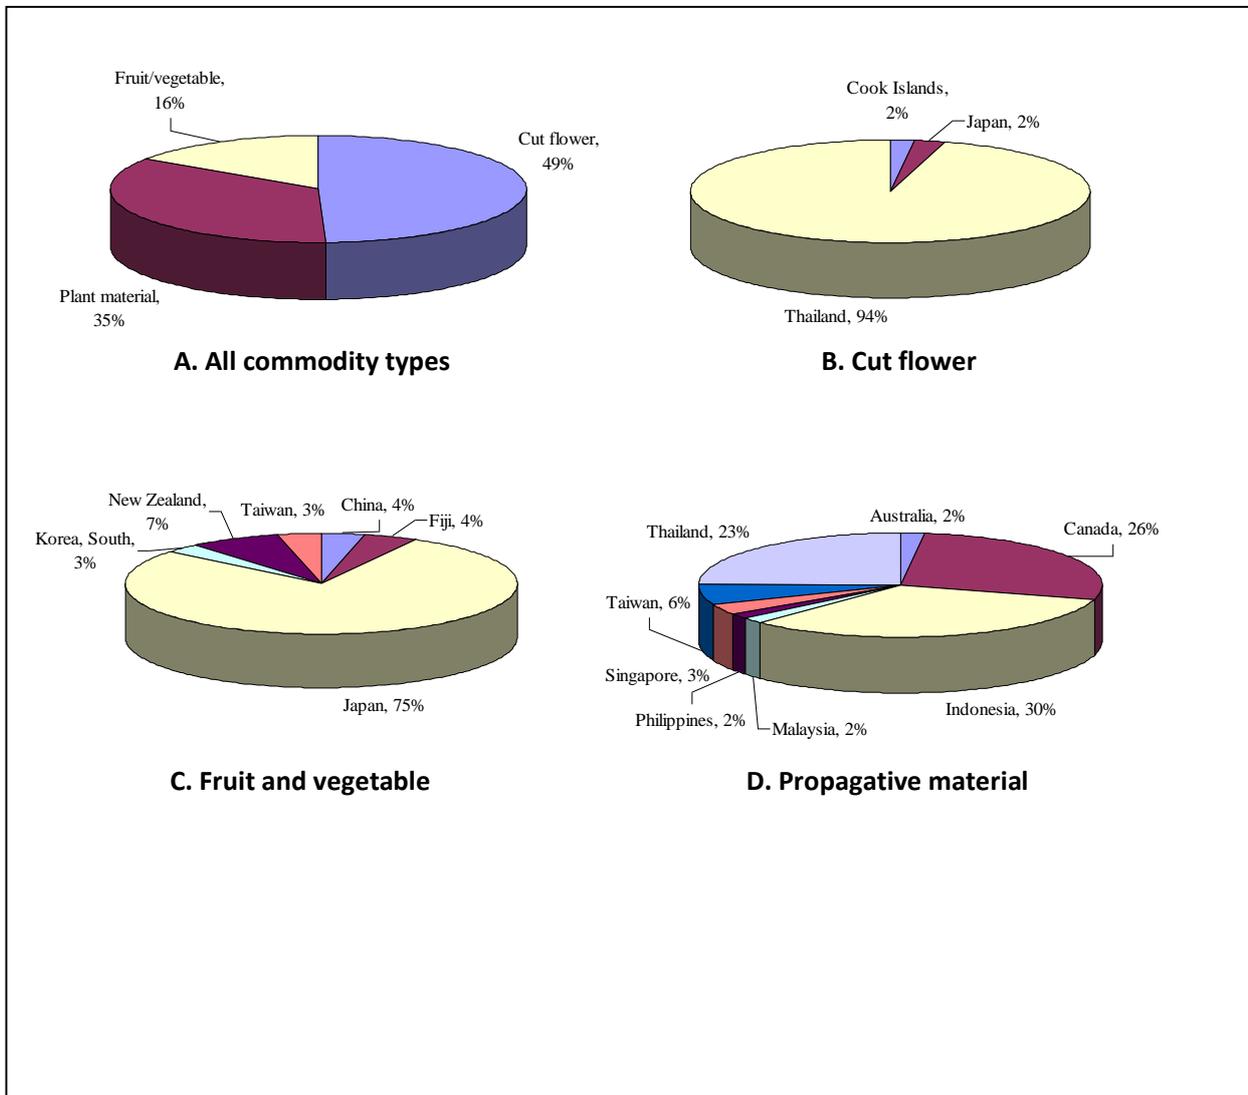

13 Source: AQAS 2007

4 A=Percentage of shipments by commodity type.

5 B=Percentage of cut flower shipments by country of origin.

6 C=Percentage of fruit and vegetable shipments by country of origin.

7 D=Percentage of propagative material shipments by country of origin.

8

9 **A17.1.1 Imports from Thailand**

10 Fifty-four percent (54%) of the agricultural shipments arriving in Hawai'i between 2004 and 2006
 11 originated in Thailand (Figure A17-4). All of these shipments arrived by aircraft (AQAS 2007). Cut
 12 flowers, mostly orchids (*Dendrobium* spp.), accounted for 85% of the shipments from Thailand. Most of

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 the remaining 15% of the shipments contained over 100 different genera of plant propagative material.
2 Fruit and vegetable shipments (mostly fresh mushrooms) accounted for less than 1% of the shipments
3 (See Tables A25-1 and A25-2, at the end of this document).

4 During the same period, 229 reportable²⁴ pests were intercepted by CBP on agricultural commodities
5 from Thailand (Tables A25-1 and A25-2) (USDA 2007a). Of these interceptions, 215 (94%) were on cut
6 flowers, mostly orchids (*Dendrobium* spp.). The mollusc, *Succinea tenella* Morelet (Stylommatophora:
7 Succineidae), was the most commonly intercepted reportable pest from Thailand, entering on cut flower
8 shipments of *Dendrobium* spp. and other species in the orchid family (Orchidaceae). (This snail was also
9 the pest most frequently intercepted on agricultural cargo of foreign origin, in general, entering
10 Hawai'i.) Other reportable or actionable²⁵ pests intercepted included: *Spodoptera litura* (Fabricius)
11 (Lepidoptera: Noctuidae) on cut flowers of *Dendrobium* spp., other species of Orchidaceae, and the
12 lotus, *Nelumbo nucifera* Gaertn.; *Thrips palmi* Karny (Thysanoptera: Thripidae) (which is established in
13 Hawai'i) (Nishida 2002) on cut flowers of *Dendrobium* spp.; and *Sinoxylon conigerum* Gerstaecker
14 (Coleoptera: Bostrichidae) (also established, but actionable, in Hawai'i) on various non-agriculture items.

15 **A17.1.2 Imports from Japan**

16 Thirteen percent (13%) of the agricultural shipments arriving in Hawai'i between 2004 and 2006
17 originated in Japan (Figure A17-4). The majority of the shipments (95%) arrived by aircraft (AQAS 2007).
18 Twenty-six different fruit and vegetable commodities accounted for 88% of the total shipments
19 exported from Japan. Cut flowers of 6 plant genera and other plant material of 40 genera accounted for
20 approximately 9% and 3%, respectively, of the agricultural shipments from Japan (Tables A25-1 and A25-
21 2).

22 All of the 14 reportable insect pests intercepted on agricultural cargo from Japan between 2004 and
23 2006 occurred in air shipments (USDA 2007a). Most of the pests were identified only to the family level.
24 Pests in the orders Lepidoptera and Thysanoptera, the families Aphididae, Plutellidae, Pyralidae
25 (Pyraustinae), Syrphidae, and Tortricidae, and the genera *Delia* and *Listroderes* were intercepted on
26 shipments of *Raphanus* (radish). A species belonging to the Crambidae (Pyralidae auct.) was intercepted
27 on a single shipment of cucumber, *Cucumis sativus*. Consignments of *Solanum* spp. harbored pests in the
28 Aphididae and Thripidae (Tables A25-1 and A25-2).

29 **A17.1.3 Imports from Indonesia**

30 Eleven percent (11%) of the agricultural shipments arriving in Hawai'i between 2004 and 2006
31 originated in Indonesia (Figure A17-4). Almost all of these shipments contained plant material, with over
32 100 genera being represented. Two shipments of lumber products (less than 1% of the total shipments
33 from Indonesia) were exported to Hawai'i (Tables A25-1 and A25-2) (AQAS 2007).

34 All but 1 of the 83 reportable pests intercepted on agricultural shipments from Indonesia were found in
35 air cargo; only *Cryptotermes* sp. (Isoptera: Kalotermitidae) was found in maritime cargo, in a shipment of

²⁴ A reportable pest is one for which USDA–APHIS–PPQ may or may not require a treatment.

²⁵ An actionable pest is one for which PPQ always requires treatment.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 *Tectona grandis* L. f. (teak). Species of Colletotrichum, Phoma, and Cercospora were commonly
2 intercepted fungal pathogens. A majority of the insect pests were not identified to the genus level; they
3 included pests in the Aleyrodidae, Aphididae, Pseudococcidae, other Homoptera, and Tortricidae.
4 *Succinea* sp. and other unidentified molluscs were also intercepted on agricultural shipments from
5 Indonesia (Tables A25-1 and A25-2) (USDA 2007a).

6 **A17.1.4 Imports from Canada**

7 Nine percent (9%) of the agricultural shipments arriving in Hawai'i between 2004 and 2006 originated in
8 Canada (Figure A17-4). These shipments contained mainly plant material (about 100 genera, accounting
9 for 98% of Canada's agricultural shipments), with the remaining 2% being fruit and vegetables (Tables
10 A25-1 and A25-2) (AQAS 2007).

11 No reportable or actionable pests were intercepted on cargo coming from Canada between 2004 and
12 2006 (USDA 2007a).

13 **A17.1.5 Imports from Taiwan**

14 Three percent (3%) of the agricultural shipments arriving in Hawai'i between 2004 and 2006 originated
15 in Taiwan (Figure A17-4). Plant material from approximately 50 genera accounted for about 80% of the
16 exports from Taiwan. The other 20% were fruit and vegetable products, such as bamboo, burdock, and
17 mushrooms (Tables A25-1 and A25-2) (AQAS 2007).

18 No reportable pests were intercepted on commercial cargo from Taiwan between 2004 and 2006 (USDA
19 2007a).

20 **A17.1.6 Pest Approach Rates in Foreign Shipments of Perishable Cargo Arriving by Aircraft**

21 AQIM data collected by CBP and containing records for the period October 2005 to April 2007, were
22 used to estimate the pest approach rate on perishable air. The data were collected at HNL following
23 port-specific standard operating procedures (Area Port of Honolulu 2005; 2006), as well as general
24 instructions in the USDA AQIM handbook (USDA 2006a). Two shipments were inspected per week.
25 During FY 2005, cut flowers were not included in the samples, whereas during FY 2006, cut flowers
26 represented half of the samples. The samples were selected based on a random sampling scheme. Table
27 B6-3 lists the relative frequencies of the countries of origin of the sampled shipments. Japan was the
28 origin of 65% of the shipments. Several other countries contributed small percentages of the shipments.
29 Most shipments were mixed, with several different commodities being listed on the manifests.

30 Of the 165 inspections that were recorded in the AQIM data set, 6 resulted in interceptions of pests
31 (Table B6-4). This yields an estimate of between 1.4% and 7.8% of air cargo shipments arriving at the
32 port of Honolulu accompanied by live pests. With one exception, *Thrips tabaci* Lindeman, which is
33 known to occur in Hawai'i (Nishida 2002), the intercepted pests were not identified to species.

Table A17-3: Countries of Origin of Randomly Selected Samples of Air Cargo Entering Hawai'i, October 2005 to April 2007

Country of Origin	Number of Samples	Percent of Total Samples
Australia	2	1.2
Canada	4	2.4
China	2	1.2
Fiji	3	3.6

7-Nov-06	Japan	Eggplant	Thysanoptera, species of
19-Dec-06	Japan	Strawberry	Lygaeidae, species of; Aphididae, species of

Note: Total sample size: 165.

A17.2 DOMESTIC IMPORTS

A large portion of the shipments of fresh agricultural products entering Hawai'i comes from the U.S. mainland (Table A25-3, at the end of this document). As mentioned previously, foreign shipments may be cleared on the U.S. mainland and then shipped domestically (Kosciuk 2007). These shipments may be repackaged and even mixed with commodities of U.S. origin (Kosciuk 2007). Such practices may compromise Hawai'i's phytosanitary security and increase risks of pest introduction. HDOA has authority to inspect agricultural commodities only, which means that its PQ inspectors are not allowed to hold mixed shipments manifested as "freight of all kinds" for inspection. In the absence of an explicit mention of agricultural commodities on the manifest, PQ inspectors can inspect a shipment only if it is referred to them by other agencies (Oishi 2007). Moreover, PQ does not have authority to hold shipments containing wood packaging material for inspection unless the manifest indicates the presence of agricultural commodities (Oishi 2007). Shipments transported by commercial carriers, such as FedEx and UPS, are often cleared at facilities on the mainland prior to entering Hawai'i (Oishi 2007). Frequently, the U.S. state, from which a commodity originated, is unknown, especially since commodities may be

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 combined at distribution centers. Thus, it is difficult to ascertain the true origin of agricultural
2 shipments.

3 As noted above, PQ maintains two databases, that record arthropods and pathogens, intercepted on
4 commodities arriving from the U.S. mainland (HDOA 2007c). PQ inspectors typically do not inspect
5 agricultural commodities of foreign origin. However, on rare occasions when such inspections are
6 performed on foreign shipments, any pest interceptions made are recorded in the databases (Oishi
7 2007). From these databases, data were extracted only for pests intercepted on or in the following
8 sources: domestic and foreign air cargo, domestic and foreign ship cargo, amnesty programs
9 (commodities surrendered voluntarily upon arrival), baggage from domestic and foreign flights, private
10 ship's stores, air express, military air carriers, FedEx and UPS packages, and U.S. mail or post office
11 facilities. Although the pest status (present or absent) in Hawai'i was provided with each interception
12 record, the status was briefly re-evaluated by consulting databases maintained by the B.P. Bishop
13 Museum in Honolulu (<http://hbs.bishopmuseum.org/hbsdb.html>), other online databases, and the
14 scientific literature, and adjustments were made as needed. The summary of pest interceptions
15 discussed below does not include all of the pests PQ intercepted between 2004 and 2006; rather, only
16 those interception records that pertained to the source categories specified above were used.

17 PQ Specialists intercepted 1,583 specimens of plant pests (arthropods and pathogens), representing at
18 least 140 species not known to occur in Hawai'i, on shipments arriving from the U.S. mainland between
19 2004 and 2006 (Table B6-5, Table A25-3) (HDOA 2007c). Many of the pests intercepted (about 290
20 records) were not identified to genus or species, and it is likely that at least some of them are not
21 present in Hawai'i. Pests were intercepted on agricultural commodities shipped domestically, which
22 actually originated in a foreign country (Table B6-6, Table A25-3). Although their authority to inspect
23 mail facilities is limited (Oishi 2007), between 2004 and 2006, PQ Specialists intercepted 35 pests
24 (identified to species) not yet established in Hawai'i on the mail pathway, which includes the categories
25 FedEx, Air Express, and USPS (Table A17-7, Table A25-3).

26 In order to calculate approach rates of pests associated with commodities or conveyances (e.g., ships,
27 aircraft, containers) from the U.S. mainland, data concerning the total number of conveyances or
28 commodities inspected and the total number contaminated with a pest are needed. These data were
29 not available for the domestic pathways.

30

1 **Table A17-5: Number of Pests Not Known to Occur in Hawai'i Intercepted on Various**
 2 **Pathways by HDOA PQ Specialists between January 1, 2004 and December 31, 2006**

Pathway	Number of Pests ^a Intercepted
Air cargo ^b	1,249
Amnesty bin ^c	2
Baggage ^d	25
Container yard ^e	3
FedEx, Air Express ^f	34
Military air cargo	1
Private ship's stores, domestic	1
Ship's cargo ^g	267
USPS	1
Total	1,583

4 ^a Only records, in which the pest was identified to species, are included in this table. It is possible that some of
 5 the pests not identified to species are not present in Hawai'i; however, since this cannot be verified, those
 6 records were omitted.

7 ^b Air cargo = cargo arriving by aircraft from the U.S. mainland.

8 ^c Amnesty bin = pests found on commodities surrendered voluntarily by aircraft passengers on domestic flights.

9 ^d Baggage = pests found on an agricultural commodity carried in air passenger baggage.

10 ^e Container yard = pests intercepted on agricultural commodities awaiting distribution.

11 ^f FedEx, Air Express = pests intercepted from packages containing agricultural commodities transported by this
 12 commercial carrier.

13 ^g Ship's cargo = pests intercepted on agricultural commodities transported by ship from the U.S. mainland. This
 14 category combines records under the database fields 'ship cargo' and 'routine overtime,' since routine
 15 overtime records are interceptions made on ship's cargo.

3 the pests not identified to species are not present in Hawai'i; however, since this cannot be verified, those
4 records were omitted.

6 **A17.3 SUMMARY**

- 7 • Hawai'i imports approximately 80% of its goods (both agricultural and non-agricultural).
- 8 • Between 2004 and 2006, over 21,000 shipments of fresh agricultural commodities for
9 consumption from 56 countries arrived at ports-of-entry in Hawai'i.
- 10 • Cut flowers accounted for half of the agricultural shipments arriving from foreign areas of
11 origin.
- 12 • Most foreign and domestic shipments of fresh agricultural commodities arrive by aircraft.
- 13 • Consignments of agricultural commodities of foreign origin may be cleared at a port-of-
14 entry on the U.S. mainland then shipped to Hawai'i manifested as domestic cargo.
- 15 • Hawai'i imports many of its fresh agricultural commodities from the U.S. mainland.
- 16 • Quarantine pests are routinely intercepted on foreign imports.
- 17 • HDOA PQ has intercepted pests not known to occur in Hawai'i on domestic shipments of
18 fresh agricultural commodities. Some of these imports were actually of foreign origin.
- 19 • PQ does not have authority to inspect domestic shipments manifested as "freight of all
20 kinds" or WPM accompanying non-agricultural shipments.

1 **A18 “HITCHHIKERS”**

2 In the context of this analysis, a hitchhiker pest is defined as a pest present on a conveyance or shipping
3 container, but not directly associated with a commodity. Hitchhiker pests may have originally entered
4 the conveyance or container on a commodity and remained behind after unloading, or may have
5 entered the cargo hold on their own, e.g., an insect flying in during loading (Caton 2003; Caton et al.
6 2006). Loading at night has been found to lead to higher pest incidence in aircraft cargo holds than
7 loading during daytime, primarily because pests are attracted to lights at night (Caton 2003).

8 The scientific literature mentions numerous cases of hitchhiker pests that have arrived in new areas in
9 cargo holds, aircraft cabins, or shipping containers (e.g., Dale and Maddison 1984; Smith and Carter
10 1984; Takahashi 1984; Gadgil et al. 2000; Gadgil et al. 2002). For example, four species of Noctuidae and
11 several species of Coleoptera and Homoptera are thought to have arrived in Guam in the 1980s as
12 hitchhikers in the holds or cabins of aircraft (Schreiner 1991); the oriental fruit fly is believed to have
13 been brought to Hawai'i in military aircraft from the Mariana Islands during World War II (Swain 1952);
14 and the psyllid, *Heteropsylla cubana* Crawford, was introduced into Hawai'i in the holds of cargo planes
15 (Schreiner 1991).

16 The objective of this chapter is to evaluate the likelihood that exotic hitchhiker pests arrive in Hawai'i on
17 air or maritime cargo conveyances or containers. A lack of suitable data made quantitative analysis
18 difficult; therefore, risk is discussed mainly in qualitative terms.

19 Pest survival in conveyances and containers depends on the combined effects of various conditions,
20 such as temperature, relative humidity, and duration of transport. In modern commercial aircraft, cargo
21 holds are pressurized and heated, generally maintaining a temperature of about 15°C (60°F)
22 (Anonymous airline pilots ("Answerer 8" and "Answerer 11") 2007). Even when not actively heated, hold
23 temperatures after about 8 hours flying at altitude are approximately 7°C in some types of aircraft
24 (Anonymous airline pilots ("Answerer 8" and "Answerer 11") 2007). Similar information for commercial
25 maritime vessels was not available, but in cargo holds that contain fresh fruits or vegetables, or live
26 plants, the temperature would obviously have to be above freezing.

27 Most insect pests would be able to survive these conditions for several hours, as is corroborated by the
28 fact that APHIS-PPQ and CBP have intercepted over 1,000 live reportable pests in aircraft cargo holds or
29 cabins²⁶ at U.S. airports since 1990 (Table A25-4, at the end of the document) (USDA 2007a), and
30 hitchhiker pests intercepted in aircraft cargo holds and stores make up 3% of quarantine-significant
31 pests intercepted on aircraft (including interceptions in cargo and passenger baggage) nationwide
32 (Caton et al. 2006; USDA 2007a). A study by Russell (1987) reported very high survival rates of
33 mosquitoes (*Culex quinquefasciatus* Say), house flies (*Musca domestica* L.), and flour beetles (*Tribolium*
34 *confusum* Jacquelin Du Val) in unpressurized wheel bays of modern Boeing 747B aircraft at altitudes
35 greater than 10,500 meters. The study found that the temperature in the wheel bays ranged from 8°C to
36 25°C, even though the outside temperature was between -42° and -54°C. Aircraft disinfection, while

²⁶ Aircraft may have been passenger aircraft or cargo aircraft, or a combination of the two. Unreliable records and records for military aircraft were excluded.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 employed by some countries to reduce the spread of mosquitoes and other human disease vectors
2 (Centers for Disease Control 2007), is not performed by the United States on arriving flights (Kosciuk
3 2007).

4 At Hawai’ian airports, eight live reportable pests—all adult insects—have been intercepted in aircraft
5 cargo holds or cabins of international flights since 1990 (Table A18-1) (USDA 2007a). Between 2003 and
6 2005, an average of approximately 26 international flights²⁷ arrived in Hawai’i every day (Bureau of
7 Transportation Statistics 2006). However, the proportion of flights, where the cargo holds were
8 thoroughly inspected by APHIS-PPQ or CBP, is unknown. Given the fact that the total sample size for
9 interceptions is unknown, and several other significant data quality problems associated with PPQ/CBP
10 pest interception records, the available information does not lend itself to reliable quantitative analysis.

11 Flights from the mainland carrying cargo of U.S. origin are not pre-cleared by APHIS and are not
12 inspected by CBP upon arrival (Kosciuk 2007). At the same time, HDOA’s PQ does not routinely inspect
13 aircraft cargo holds or cabins (Oishi 2007). Thus, there are no interception records or other data that
14 could help quantify the pest risk posed by this pathway.

15 A number of scientific publications report finds of live quarantine pests in aircraft cabins (e.g., Evans et
16 al. 1963; Goh et al. 1985) and air cargo holds (e.g., Evans et al. 1963; Caton 2003; Dobbs and Brodel
17 2004). Goh et al. (1985) found that 17% of 330 arriving aircraft examined at Changi International Airport,
18 Singapore, harbored mosquitoes and other insects in the cabin. In a 5-year study at the Manila
19 International Airport in the Philippines, Basio et al. (1970) inspected over 14,000 airplanes, detecting
20 more than 700 pests, including live mosquitoes. Evans et al. (1963) found an average of one pest per
21 baggage compartment (cargo hold) and 19 pests per cabin on aircraft arriving in Honolulu, and
22 Rainwater (1963) found live agricultural pests on 16 of 2,662 aircraft arriving in Hawai’i from foreign
23 countries. At the Miami International Airport, Florida (MIA), inspections of the cockpit, galleys, exterior
24 of palletized cargo, and cargo holds of 730 aircraft resulted in the detection of 151 insects from 33
25 families in five orders, along with one plant pathogen (*Xanthomonas axonopodis* pv. *citri* [Hasse]
26 Vauterin et al.) (Dobbs and Brodel 2004). The estimated pest approach rate for foreign cargo aircraft
27 arriving at MIA was 10.4% (Dobbs and Brodel 2004). Caton (2003) reported an average of two flights
28 daily arriving at MIA from Central and South America with quarantine pests in their cargo holds,
29 estimating that one pest species per year would become established in Florida (escape detection and
30 control, find a host plant, and produce offspring) from flights originating from Central America.

31

²⁷ Flights arriving at Hickam Air Force Base and Marine Corps Base Hawai’i were omitted.

4 Note: Unreliable records and records pertaining to military aircraft were omitted.

5
 6 In addition to the conveyances themselves, shipping containers may also harbor hitchhikers. Shipping
 7 containers vary in size and shape, and may be composed of plastic, metal, or other materials (or a
 8 combination of materials) (Figures A18-1 and A18-2). A single container may contain multiple shipments.
 9 Pests, including arthropods, molluscs, and weeds, have been found on the outside, as well as the inside,
 10 of shipping containers.

4 Source: USPS at <http://www.ups.com>
5 Note: Air shipping containers differ in size and shape (left and center), and may not be completely enclosed
6 (right).
7

8 Gadgil et al. (2000) inspected the exterior of 3,681 shipping containers arriving at New Zealand maritime
9 ports and found that approximately 39% were contaminated, with soil on the container bottoms being
10 the most common contaminant (31% of the containers). Fungi of taxa containing plant pathogens were
11 isolated from 83% of the soil samples; species of *Fusarium* were commonly isolated. Nematodes, of
12 which 4% were quarantine organisms for New Zealand, were isolated from 81% of the soil samples.
13 Foliage and woody material were the next common contaminants. Also, egg masses of gypsy moth,
14 *Lymantria dispar* (L.), were found on shipping containers. The authors estimated that containers from
15 South Africa had the highest rate of contamination (50%), followed by the Pacific islands (47.5%).
16 Containers from the Far East (Japan and elsewhere in East Asia) had a contamination rate of 13%. An
17 annual minimum of 36,000 contaminated containers was estimated to be entering New Zealand.

18 In another study, involving sea cargo containers arriving at Australian ports, Stanaway et al. (2001)
19 surveyed wooden components of the containers for pests, in particular, timber-infesting insects. A total
20 of 7,861 arthropods was found on or in the 3,001 containers inspected. Although no live exotic timber-
21 feeding insects were found in the containers' wooden floors, insects with the potential to infest timber
22 were found in 3.5% of the containers. In addition, 11% of the containers had insects considered stored-
23 product pests that were quarantine organisms for Australia. The authors concluded that the risk
24 associated with untreated wooden components of containers is not negligible because of the high
25 volume of container traffic and the frequency with which containers come into contact with timber
26 pests.

27 After inspecting 991 air cargo containers arriving at airports in New Zealand, Gadgil et al. (2002)
28 determined that the exterior, including the bottom, of the containers was generally clean, whereas, on
29 the inside, they found contaminants, mostly fresh leaves and twigs, in 24% of the cases. Fungi were
30 found in soil contaminating 3% of the examined containers. The detection of fresh plant material
31 containing pests, coupled with the fact that newly introduced pests have been found in close vicinity to
32 airports, led the authors to conclude that air cargo containers may provide a pathway by which exotic
33 organisms can become established.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 In 2006, Hawai'i received more than 1.4 million twenty-foot equivalent containers, loaded or empty, at
 2 its maritime ports from foreign or domestic origins (Table A18-2). We do not have any information on
 3 the number of air cargo containers received, which would also include most FedEx and UPS shipments.

4 If we assume a contamination rate of 10%, with 1% of the contaminants being or including quarantine
 5 organisms, and 1% of these organisms being able to establish populations in Hawai'i, we arrive at an
 6 estimate of 13 pest establishments per year from sea cargo containers alone.

7 **Table A18-2: Number of Containers Arriving from Foreign and Domestic Origins at Hawai'i**
 8 **Maritime Ports in 2006**

Port	Number of TEU ^a	Number of Boxes ^b	Containerized Cargo (tonnes)
Hilo	64,499	38,380	424,286
Honolulu	1,113,789	647,755	6,171,258

10 ^a TEU=Twenty-foot equivalent units (loaded and empty).

11 ^b Containers regardless of length.

12

13 **A18.1 SUMMARY**

- 14 • Aircraft cargo holds and cabins, as well as shipping containers, can harbor pests.
- 15 • Aircraft have been implicated in introducing pests into new areas.
- 16 • Inspections of aircraft cargo holds and cabins are not a common practice by either APHIS-
 17 PPQ or HDOA PQ.
- 18 • PQ inspectors do not have authority to inspect containers (neither the container surfaces
 19 nor the shipments within the container) transporting only non-agricultural commodities
 20 unless the presence of BTS is suspected or CBP refers a container to them.
- 21 • Cargo containers used in maritime shipments also are a viable pathway for the introduction
 22 of pests.
- 23 • As many as 13 pest establishments from sea cargo containers alone may occur in Hawai'i
 24 every year.

1 **A19 WOOD PACKAGING MATERIAL**

2 Wood packaging material (also known as solid-wood packing material or WPM), including dunnage,
3 crating, pallets, packing blocks, drums, cases, and skids, is used all over the world in shipments of both
4 agricultural and non-agricultural products. As it is not mandatory for importers to indicate the presence
5 of WPM on shipping manifests, port officers have to rely almost exclusively on their experience and on
6 random checks when selecting shipments, especially of non-agricultural commodities, for WPM
7 inspection (Meissner et al. 2003). Because WPM is routinely re-used and re-conditioned, its origin is not
8 necessarily the same as the origin of the commodity with which it is imported (e.g., WPM in a shipment
9 from Canada could easily have originated in some other country, such as Australia). On September 16,
10 2005, the United States started enforcing the International Plant Protection Convention’s standard ISPM
11 #15, “Guidelines for Regulating Wood Packaging Material in International Trade” (IPPC 2006). This
12 standard requires fumigation or heat treatment for all WPM entering the United States. While it is the
13 purpose of ISPM #15 to reduce the pest risk posed by WPM, there are no conclusive data available
14 showing that this objective is actually being met.

15 Hawai’i receives a variety of imports with WPM from numerous countries. It is difficult to quantify
16 exactly how much WPM is arriving and from where. The only information available for this purpose was
17 an AQIM data set containing records for the period between October of 2005 and April 2007. These data
18 represent the results of WPM inspections in maritime cargo. They were collected at the Honolulu
19 maritime port following port-specific standard operating procedures (Higa 2004) and general
20 instructions in the USDA AQIM Handbook (USDA 2006a). Two shipments were inspected per week. The
21 samples were selected by choosing one container from the first two entries each Monday. Sampling was
22 not limited to agricultural commodities, but included non-agricultural shipments as well. As the
23 selection of samples was thus randomized, the relative frequency of countries of origin (Table A19-1)
24 and commodities (Table A19-2) represented in the AQIM data set should be similar to their relative
25 frequency in the entire population of shipments entering the port of Honolulu. Almost 40% of the
26 shipments with WPM originated in China, and about 20% came from Indonesia. Peru was represented
27 by 8% and Turkey by about 5% of the shipments. A number of other countries contributed small
28 percentages of the shipments. Of the commodities, furniture was the most common with about 15%;
29 most of the other commodities were stone or stone-like products.

3 Of the 166 inspections that were recorded in the AQIM data set, 6 resulted in interceptions of pests.
4 However, it must be noted that port personnel were instructed to “inspect thoroughly at least 50
5 percent of the external surface of the [WPM] for live pests” (Higa 2004). In other words, half of the
6 wood surface may have been left unsearched; inspectors may not have looked for pests hidden inside
7 the wood; and finds of dead pests were not recorded. Further, considering the general difficulty of
8 detecting pests in or on WPM, the true number of infested shipments was almost certainly higher than
9 six. Using 10 as a more realistic number, between 3% and 11% (95% binomial confidence interval) of all
10 shipments with WPM arriving at the port of Honolulu are infested with live pests. This is a disturbingly
11 high number, especially considering that it is occurring in spite of ISPM #15 regulations.

12 Unfortunately, there are no data available to determine how much WPM is entering Hawai’i; therefore,
13 it is not possible to estimate the number of pest species that may have been, and will be, introduced
14 into Hawai’i on this pathway. However, it is certain that this number must be far from negligible.

15 According to the USDA Agricultural Quarantine Activity System Pest ID database (USDA 2007a), APHIS-
16 PPQ or CBP inspectors in Honolulu intercepted 29 pests on wood material associated with maritime
17 cargo during regular phytosanitary inspections (not AQIM data collection) between October 2005 and
18 April 2007. All of these interceptions were insects, and the large majority of them were beetles (Table
19 A19-3). Only nine of the insects were reportable pests. It is interesting to note that the latest
20 interception date recorded was December of 2006, and there are no records for the time between then
21 and April 2007.

22

 4

5 It is more difficult to determine how many WPM-associated pests were intercepted by HDOA inspectors,
 6 because the HDOA database of pest interceptions does not indicate clearly if a pest was associated with
 7 WPM or not. Filtering for the hosts “wood” and “crates” as indicators of an association with WPM, there
 8 were zero interception records for the period between October 2005 and April 2007, whereas for the
 9 entire period between 1990 and 2006, a mere 24 interceptions are listed (out of a total of 17,356
 10 interceptions on any host) (Table A19-4) (HDOA 2007c). Most of the pests intercepted on wood and
 11 crates are already established in Hawai’i. However, some of them (e.g., the odorous house ant,
 12 *Tapinoma sessile* [Say]) do not yet occur in Hawai’i, and have the potential to be aggressive invaders. In
 13 contrast to CBP, HDOA does not have any authority to put on hold non-agricultural shipments for the
 14 purpose of WPM inspection. This means that HDOA can inspect WPM only in agricultural shipments, or
 15 on non-agricultural shipments that have been referred to it by another agency.

1 **Table A19-4: Pests Intercepted on “Wood” or “Crates” during Phytosanitary Inspections by**
 2 **HDOA on any Pathway between January 1990 and October 2006**

Taxon	Family	Country of origin	Number of times intercepted	Status in Hawai'i

Total			20	

3
 4 It is likely that the APHIS-PPQ, CBP, and HDOA interceptions represent only a fraction of the pests that
 5 were actually present. Other studies have estimated that port inspections intercept only 30% or fewer of
 6 the incoming pests (Meissner et al. 2003). A recent HDOA report confirms this: “Even during the Oahu
 7 risk assessment, only about 10% of the volume was inspected, but the numbers of interceptions were
 8 about 10 times greater than the normal inspection of all of the HNL [Honolulu] cargo during that same
 9 period” (HDOA 2007d). WPM is especially difficult to inspect; pests are often hidden inside the wood,
 10 and a large part of the incoming WPM never gets inspected because it is not associated with agricultural
 11 commodities. It is also quite common that port inspectors are not sufficiently trained to detect wood-
 12 boring pests. Training provided to port inspectors along the Mexican border in 2002 made this very
 13 obvious. This training focused on methods for detecting wood-boring beetles of the family Scolytidae,
 14 and resulted in an immediate and dramatic increase in WPM pest interceptions (Table A19-5). For
 15 example, at Pharr and San Diego, the average number of intercepted scolytid specimens increased from
 16 ≤ 1 to over 100 per month as a result of the training, indicating that large numbers of scolytid pests
 17 entering the United States had gone undetected by APHIS-PPQ at these ports. Similar breaches of
 18 quarantine security probably hold true for most U.S. ports-of-entry, including Honolulu, and also apply
 19 to many non-scolytid pests associated with WPM. For example, the Honolulu interceptions do not

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 include any snails (Table A19-4), whereas nationwide, snails represent almost 10% of all WPM
 2 interceptions (Table A19-6), and a snail was found during AQIM data collection in a sample of only 166
 3 (Table A19-7).

4 **Table A19-5: Monthly Average Number of Scolytid Specimens Found on Solid WPM before**
 5 **and after a Scolytid Detection Training at Four Major Southern Border ports in 2002**

Port	Before Training	After Training

9 Note: Not AQIM data collection.

10
 11 Specifically, pest finds recorded in the AQIM data set for Honolulu (Table B8-7) included a member of
 12 the snail family Bradybaenidae, the cerambicid, *Xylotrechus magnicollis* (Fairmaire), an unidentified
 13 member of each of the beetle families Bostrichidae and Cerambycidae, a species of *Cryptotermes*, and
 14 an unidentified noxious weed. No taxonomic information was provided for one of the interceptions. The
 15 pests were intercepted on marble slabs, granite, and stone from China, and on furniture from Indonesia.
 16 Apart from pest interceptions, there were five cases of WPM entering without proof of phytosanitary
 17 treatment (ISPM#), as required by ISPM #15, and one case of contamination with soil.

1 **Table A19-7: Pests on WPM or WPM Lacking Proof of Phytosanitary Treatment Intercepted**
 2 **during AQIM at the Honolulu Maritime Port between October 2005 and April 2007**

Origin	Infested commodity	Interception
China	Marble slab	Bostrichidae
China	Stone statue	WPM no ISPM#
China	Furniture	WPM no ISPM#
China	Slate	Soil
China	Granite	Cerambycidae

Hong Kong	Furniture	WPM no ISPM#
Indonesia	Furniture	<i>Cryptoterme</i> sp.
Indonesia	Furniture	WPM no ISPM#
Indonesia	Furniture	Unidentified noxious weed
Philippines	Stone	WPM no ISPM#
Turkey	Tile, Roof	Unidentified pest

3 Note: Total sample size=166.
 4

5 Table A19-8 lists all pests intercepted on wood at any U.S. port-of-entry since 1985, demonstrating the
 6 great taxonomic variety (Table B8-9) of organisms associated with WPM. Snails were frequently found as
 7 hitchhikers on WPM. Snail invasions may have serious economic and environmental consequences. For
 8 example, *Bradybaena ravida* (Benson), which is not known to occur in Hawai'i, was rated as a high-risk
 9 quarantine pest in a USDA risk assessment for penjing from China (Cave and Redlin 1996).

6

7 Many pests belonging to taxa that have been intercepted on WPM are already established and invasive
 8 in Hawai'i (Nishida 2002), including the following scolytid beetles (CABI 2006). The tropical nut borer,
 9 *Hypothenemus obscurus* (F.), occurs mainly in South and Central America, and attacks eucalyptus,
 10 macadamia, coffee and other hosts. The Asian ambrosia beetle, *Xylosandrus crassiusculus*
 11 (Motschulsky), is native to Asia, and feeds on coffee, sugarcane, litchi, and a large number of other
 12 species. The shot-hole borer, *Xylosandrus compactus* (Eichhoff), is native to Asia, and attacks coffee,
 13 cinnamon, and mango, among other plants. The tea shot-hole borer, *Euwallacea fornicatus* (Eichhoff), is
 14 also native to Asia; it attacks macadamia, avocado, pomegranate, guava, tea, and many other plants.
 15 The island pinhole borer, *Xyleborus perforans* (Wollaston), is native to Asia and Australia, has an
 16 immense host range (Gray and Wylie 1974), and has been intercepted by Japan and other countries
 17 from imported timber of many species and families (Ohno 1990). The brown twig beetle, *Xylosandrus*
 18 *morigerus* (Blandford), is native to Asia, and invasive in large parts of the world; it is highly polyphagous,
 19 feeding on coffee, cocoa, avocado, and teak. Likewise, the bamboo tiger longhorn beetle, *Chlorophorus*
 20 *annularis* (F.) (Cerambycidae), has been introduced and is widespread in Hawai'i (Nishida 2002; CABI
 21 2006).

22 In a recent pest risk assessment (Stanaway et al. 2001), Australian researchers surveyed the wood floors
 23 of empty sea cargo containers for dead and live pests. They found pests in 1,174 out of 3,001 containers,
 24 collecting over 7,400 insects belonging to 18 orders and at least 114 families. Most of the time, a
 25 container harbored only one or two different pest species. Also found were spiders, isopods, mites,

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 millipedes, centipedes, scorpions, and ticks. Among the insect pests collected were Chinese rose beetle,
 2 *Adoretus sinicus* Burmeister, introduced and invasive in Hawai'i, as well as unidentified species of the
 3 genera *Hypothenemus*, *Solenopsis*, and *Vespula*. The study concluded that even though the relative
 4 frequency of sea cargo containers with wood floors infested with exotic pests is very low, this pathway
 5 represents a significant risk due to the immense volume of containers entering ports.

6 A large number of pests potentially associated with WPM have, not surprisingly, already been
 7 introduced into Hawai'i and have established populations there. However, there is still a long list of
 8 species from all over the world that are not yet known to occur in Hawai'i, but have the potential to be
 9 introduced on or in WPM (Table A19-10). This evaluation concludes that, unless more effective
 10 safeguarding measures are introduced, many of these pests may be expected to appear and cause
 11 economic, as well as ecological, damage in Hawai'i over the coming years.

12 **Table A19-10: Examples of Insects with Potential to be Introduced into Hawai'i in WPM**

Order: Family	Species	Distribution ^a	References
Coleoptera: Bostrichidae	<i>Heterobostrychus brunneus</i> (Murray)	sub-Saharan Africa, United States (CA)	Pasek 2000; Haack 2006; Schabel 2006

A19.1 SUMMARY

- Hawai'i receives cargo with WPM from numerous countries all over the world.
- WPM is routinely reused and reconditioned, so that its origin usually cannot be determined.
- The effectiveness of the International Standard, ISPM #15, has not been demonstrated.
- An unfortunate lack of suitable data makes it impossible precisely to quantify the likelihood of introducing exotic pests into Hawai'i on or in WPM. However, it is likely that considerable numbers of pests have been entering Hawai'i in WPM.
- Inspectors at ports-of-entry in Hawai'i intercept only a small fraction of these pests.
- Many exotic species that have been intercepted on WPM have already established populations in Hawai'i, where they attack many economically or ecologically important hosts.
- A significant number of insects worldwide are imminent pests for Hawai'i with a potential for introduction via the WPM pathway.

1 **A20 THE MILITARY**

2 **A20.1 MILITARY PRESENCE IN HAWAI'I**

3 Because of its Central Pacific location, Hawai'i has been of strategic importance for more than half a
4 century, hence the large military presence (Kelly 1998b). Almost 100,000 military personnel and their
5 dependents made up 8% of Hawai'i's population in 1994 (Kelly 1998b), the highest proportion of any
6 state in the country. Military expenditures of \$3.2 billion in 1994 accounted for 9% of the gross state
7 product (Kelly 1998b). In 2004, defense spending was \$4.8 billion (HDBEDT 2007). The military employed
8 17,000 civilians, almost 3% of Hawai'i's workforce, with an annual payroll of \$670 million in 1994. All five
9 services were represented: Army personnel made up 44%, Navy 25%, Marine Corps 16%, Air Force 12%,
10 and Coast Guard 3% of the total. The Hawai'i National Guard accounted for almost 5,000 residents. The
11 military reduced active duty personnel in Hawai'i by 28%, from 61,019 in 1980 to 44,193 in 1994. Most
12 military personnel in Hawai'i are stationed on the island of Oahu, with fewer than 200 active duty
13 personnel assigned to other islands. There are about 100 military installations in the islands. Seventy-
14 eight percent (78%) of personnel are stationed at four: Schofield Barracks, Pearl Harbor, Marine Corps
15 Base Hawai'i (MCBH), and Hickam Air Force Base (AFB), all on Oahu. Seventy-seven percent (77%) of
16 civilian personnel work at Pearl Harbor, Hickam AFB, Tripler Army Hospital, and Fort Shafter Army Base
17 (Kelly 1998b). Approximately 12,000 military members and their families move to and from Hawai'i each
18 year (USPACOM, 1998).

19 In 1998, the United States Pacific Command (USPACOM) reported 57,987 military and 22,984 civilian
20 personnel in Hawai'i (excluding Air Guard) (USPACOM 1998). The 2000 United States Census recorded
21 39,036 military personnel in Hawai'i (Clark and Weismantle 2003). Despite declines in personnel, the
22 military budget in Hawai'i increased from \$862 million in 1977 to \$3.2 billion in 1994 (Kelly 1998b).

23 **A20.1.1 United States Pacific Command**

24 The headquarters for the USPACOM Army, Navy, Air Force, and Marine Corps are located on Oahu.
25 USPACOM's area of responsibility (AOR) extends from the west coast of the continental United States to
26 the eastern shores of Africa, and covers over 700 million km², about half of the Earth's surface. There
27 are 43 countries with over 60% of the world's population in this area. It contains countries with the
28 world's six largest armed forces: People's Republic of China, Russia, United States, India, North Korea,
29 and South Korea. Five of seven U.S. mutual defense treaties are with nations in the AOR. In 1998, the
30 command had about 300,000 military personnel deployed, about one-fifth of the total U.S. active duty
31 military force (USPACOM 1998). Most of the military traffic from the Pacific Region to Hawai'i is from
32 Guam, Japan, and Korea (Simon 2006b).

33 In addition, four sub-unified commands report to USPACOM: U.S. Forces Korea, U.S. Forces Japan,
34 Special Operations Command Pacific at Camp Smith, and the Alaskan Command. USPACOM deploys
35 about 100,000 forward forces in the western Pacific, Japan, Korea, and Guam. A second tier of forward
36 forces is based in Hawai'i and Alaska (USPACOM 1998).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 The U.S. Navy Pacific Fleet, headquartered at Makalapa Crater near Pearl Harbor, is the world's largest
2 naval command, with nearly half of the Navy's total strength. It is active in the Arctic, Indian, and Pacific
3 oceans, and conducts more than 200 peacetime exercises per year. In 1998, the fleet had 190 ships,
4 1,400 Navy and Marine Corps aircraft, 222,000 Navy and Marine Corps personnel, and 38 shore
5 installations. It employed 519 military and 230 civilian personnel in Hawai'i, on a payroll of \$30 million
6 and \$10 million, respectively. The total annual budget in Hawai'i was \$405 million (USPACOM 1998).

7 The U.S. Army Pacific Command (USARPAC) is headquartered at Fort Shafter. It has command and
8 control of U.S. Army forces in the Pacific, except those in Korea. Terrain in the AOR varies from arid
9 deserts and tropical rain forests to arctic tundra. Soldiers are based on the U.S. mainland (including
10 Alaska), Hawai'i, Guam, American Samoa, the CNMI, and Japan (USPACOM 1998).

11 Marine Forces Pacific (MARFORPAC) is the largest field command in the U.S. Marine Corps, deployed
12 both ashore and afloat. It is led by the Marine Force Commander. Combat and support forces were
13 more than 80,000 strong in 1998. There are two major subordinate commands: First Marine
14 Expeditionary Force, headquartered in California, and the Third Marine Expeditionary Force,
15 headquartered in Japan. An air-ground-logistics team, which numbered 6,800 marines and sailors in
16 1998, is also located at MCBH, Kaneohe Bay (USPACOM 1998).

17 Air Force Pacific (PACAF), the air component of USPACOM, is headquartered at Hickam AFB. It is
18 responsible for most Air Force units, bases, and facilities in the Pacific and Alaska. The command
19 employs military and civilian personnel in nine major locations and numerous smaller ones, primarily in
20 Hawai'i, Alaska, Japan, Guam, and South Korea. In 1998, about 300 fighter and attack aircraft were
21 assigned to the command. There were 45,930 personnel, with 32,682 on active duty, 5,051 reserve
22 components, and 8,197 civilians. Flying hours were 10,195 per month (USPACOM, 1998). PACAF has
23 about 100 bases in the Pacific (Spears 2007).

24 **A20.1.2 Military Establishments in Hawai'i**

25 The United States Department of Defense (DoD) listed 63 military installations in Hawai'i in 2004,
26 covering 9,783 hectares and broken down as follows: Army: 20 installations totaling 3,327 hectares; Air
27 Force: 6 installations totaling 1,331 hectares; Marine Corps: 6 installations totaling 1,290 hectares; and
28 Navy: 31 installations totaling 3,835 hectares (DoD 2004). This account contradicts the Hawai'i Military
29 Installation Area Handbook (USPACOM 1998), which listed land controlled by the military in Hawai'i in
30 1998 as 21,230 hectares on Oahu, 34,333 hectares on the island of Hawai'i, 779 hectares on Kauai, 44
31 hectares on Kaula (an islet about 32 km southwest of Niihau), 5 hectares on Molokai, and 2 hectares on
32 Maui, totaling 56,393 hectares and comprising 3.4% of the total land area of the state. The reason for
33 the discrepancy is unknown.

34 **A20.2 REGULATIONS**

35 DoD 4500.9-R, Defense Transportation Regulation Part V, Department of Defense Customs and Border
36 Clearance Policies and Procedures, maintains the integrity of the defense transportation system. It
37 prescribes procedures, defines responsibilities, and identifies agricultural requirements for entry into,

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 and exit from, selected countries of the world in support of U.S. forces (DoD and APHIS, 2006). Chapter
2 505 covers agricultural cleaning and inspection requirements. Chapter 506 includes the DoD pre-
3 clearance program, and Chapter 507 includes the military customs inspector program (USTC 2006a; b;
4 c). The inter-service publication, *Quarantine Regulations of the Armed Forces* (Howard et al. 1992),
5 defines DoD quarantine policies and procedures related to agriculture. In addition, the following
6 combatant commands issue directives outlining customs and border clearance guidance: United States
7 European Command (Directive 30-3); United States Central Command (Regulation 600-10); and
8 USPACOM (Instruction 5840.3, Military Customs Inspection within the USPACOM). These publications
9 establish policy, procedures, and responsibilities for compliance with U.S. and host nation customs laws.
10 The DoD must assist and cooperate with other federal agencies when enforcing U.S. laws, regulations,
11 and agricultural customs requirements without unnecessarily delaying the movement of DoD personnel
12 and material. CBP and APHIS-PPQ are required to report promptly all detections of plant pests, diseases,
13 and soil to DoD's executive agent, the United States Transportation Command (USTRANSCOM), for
14 resolution (DoD and APHIS 2006).

15 The quarantine regulations of the armed forces require the forces to cooperate fully with other agencies
16 and comply with the regulations above. APHIS-PPQ and CBP inspectors are authorized to board ships,
17 aircraft, and other conveyances, and to inspect ports and other facilities. Commanders are required to
18 provide full support for inspections. Cooperation with foreign officials, following applicable host country
19 agreements, is also required. All examinations are subject to necessary restrictions to preserve the
20 security of classified material (Howard et al. 1992).

21 The armed forces must comply with applicable regulations published by other federal agencies
22 governing the movement of pathogens, other pests, wildlife, and arthropod vectors. Commanders of all
23 echelons are responsible within their jurisdictions. They must be cognizant of, and comply with,
24 provisions of the DoD directive 5030.49-R, Customs Inspection, and requirements of the Military
25 Customs Inspection Program. Coordination at the department level is provided by the Armed Forces
26 Pest Management Board (Howard et al. 1992).

27 **A20.3 COOPERATION BETWEEN APHIS-PPQ AND THE DEPARTMENT OF DEFENSE**

28 APHIS-PPQ and DoD have cooperated for over 30 years to safeguard U.S. agriculture and natural
29 resources from plant pests and diseases, invasive species, and noxious weeds that might be harbored
30 aboard returning aircraft and other vessels, both military and civilian (DoD and APHIS 2006). APHIS
31 program duties include facilitating pathway analyses (DoD and APHIS 2006). Appropriate armed forces
32 commanders are required to liaise with local representatives of PPQ (Howard et al. 1992).

33 The two agencies have a MOU, the current version of which was signed on May 5, 2006, and is to
34 continue for 5 years from the date of signing. Concerns include troops, mail, and material, such as rolling
35 stock, aircraft, assault vessels, household goods, ordnance, weapons, containerized cargo, and vehicles
36 in support of contingency or wartime emergencies, the Joint Chiefs of Staff, special operations, and
37 other military-sponsored exercises. More recently, WPM has been targeted for inspection (DoD and
38 APHIS 2006).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 APHIS-PPQ fulfills the objectives of the military agricultural pre-clearance inspection program in
2 cooperation with DoD. PPQ works with DoD to establish permanent pre-clearance positions for
3 combatant commands and, when appropriate, to provide local coordination and services to the
4 military's agricultural pre-clearance inspection program. The MOU requires PPQ and DoD to make
5 military agricultural pre-clearance inspection equivalent at all locations (DoD and APHIS 2006).
6 Permanent PPQ pre-clearance positions are established at two combatant commands: the Central
7 Command and the European Command (DoD and APHIS 2006). Despite having the largest military
8 presence of any of the theaters, the Pacific Command does not have a permanent PPQ pre-clearance
9 position.

10 **A20.4 TRAINING**

11 APHIS-PPQ cooperates with DoD to train military personnel in agricultural inspection procedures and
12 requirements within the United States prior to their deployment overseas. This activity is coordinated
13 with the DoD USTRANSCOM and occurs at the APHIS training facility in Frederick, Maryland, or at other
14 locations as determined mutually by the two agencies (DoD and APHIS, 2006). Manuals and guidelines
15 providing training for military cooperators (USDA 2002; 2003a) and options for soil treatment (USDA
16 2004) have been published.

17 **A20.5 RESEARCH AND DEVELOPMENT**

18 The MOU between DoD and APHIS-PPQ requires cooperation in research and methods development.
19 Efforts include identifying data gaps that hinder effective pest risk and pathway analyses, and perfecting
20 laboratory analysis of soil to detect pests, such as noxious weed seeds, nematodes, pathogens, snails,
21 and insects (DoD and APHIS, 2006).

22 **A20.6 RESPONSIBILITIES OF THE AGENCIES**

23 APHIS-PPQ has general phytosanitary requirements regarding all ships and aircraft, including their cargo,
24 stores, garbage, and baggage arriving in the continental United States from any outside location,
25 including Hawai'i. All are subject to inspection by PPQ. When inspection discloses items prohibited or
26 restricted by quarantine regulations, reveals a plant or animal pest, or when there is reason to presume
27 such a pest is present, an inspector may take one of several actions, such as re-export or destruction of
28 the items (Howard et al. 1992).

29 Air installation commanders or commanding officers of ships must ensure that all actions are taken to
30 comply with PPQ requirements and regulations governing the handling or disposition of baggage, cargo,
31 stores, and garbage. Garbage must be placed in leak-proof, covered containers and disposed of
32 following port procedures authorized by, or under surveillance of, PPQ. Disposal facilities to incinerate
33 or sterilize regulated garbage or other food materials of foreign origin are required (Howard et al. 1992).

34 CBP inspects non-propagative materials arriving from foreign countries, whereas PPQ inspects foreign
35 propagative material. The HDOA PQ inspects foreign trade goods only if referred to them by CBP. HDOA
36 has no authority to inspect mail or foreign goods not referred to it by CBP (Spears 2007). CBP is

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 responsible for clearing aircraft arriving at Hickam AFB and Barber’s Point Naval Air Station. CBP inspects
2 all foreign (including military) traffic, using the Manual for Agricultural Clearance (USDA 2006c).

3 CBP has no jurisdiction in Guam. There is no general pre-clearance for military shipments or personnel
4 leaving Guam. APHIS-WS performs pre-clearance inspections for BTS. All agricultural inspection is done
5 at the first port of arrival in the U.S. mainland or in Hawai’i (Spears 2007).

6 HDOA PQ involvement in military inspection primarily entails the use of dog teams to detect BTS on
7 aircraft arriving from Guam, Saipan, and northern Australia. For other inspections, PQ becomes involved
8 only if requested, usually when prohibited items, such as exotic pets, or pests are detected in military
9 cargo or personal effects.

10 DoD official control of pests in Hawai’i is facilitated through the cooperation of island invasive species
11 committees, which have been formed on Kauai, Oahu, Molokai, Maui, and the Big Island (HEAR 2007).
12 The Coordinating Group for Alien Pest Species governs the invasive species committees. The Hawai’i
13 Invasive Species Council is a government body, at the governor’s cabinet level, established by the
14 Legislature of the State of Hawai’i with authority to provide funding and establish state policy for
15 invasive species.

16 **A20.7 MILITARY PATHWAYS FOR POTENTIAL INVASIVE SPECIES INTRODUCTION**

17 **A20.7.1 Aircraft**

18 All Navy and Marine aircraft in Hawai’i are based at MCBH on Oahu (Simon 2006b). Table A20-1
19 summarizes aircraft arrivals at MCBH in 2006. The majority of aircraft arriving at MCBH (48%) originated
20 on the U.S. mainland. Thirty-four percent (34%) came from locations within Hawai’i, and fewer than 1%
21 from U.S. ships at sea. Only 18% arrived from foreign areas, including U.S. territories. Most of these
22 aircraft came from Guam, Japan, Wake Island, and the Marshall Islands.

23 **Table A20-1: Origin of Aircraft Arrivals at MCBH during Calendar Year 2006**

Origin	Number
Continental United States	255
Hawai’i (other locations)	182
Guam	24
Japan	24
Wake Island	21
Marshall Islands	15
U.S. ships	4
Canada	3
Korea	3
Christmas Island	2
American Samoa	2
Iceland	1
Total	536

24 Source: Dinic 2007

25

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 A total of 536 aircraft carried 7,658 crew members, 10,210 other active duty passengers, and 2,076 non-
 2 duty or retired military members for a total of 19,944 passengers arriving in Hawai'i during 2006. In
 3 total, 298,469 kg of baggage and 1,188,222 kg of cargo were carried by these flights (Dinic 2007).

4 CBP inspects cargo on all military aircraft arriving from foreign areas, including Guam, at MCBH and
 5 Hickam AFB (Simon 2006b). The agency is given as little as 2 hours advance notice of foreign aircraft
 6 arrivals. Of primary concern to the military is the potential for introduction of BTS in flights from Guam;
 7 West Nile virus and coqui frog are also concerns. BTS often is found in the vicinity of military
 8 installations and equipment in Guam. For example, in February 2007, APHIS-WS personnel trapped 272
 9 snakes around the perimeter of the Guam airfield (Salas 2007). All cargo and aircraft destined for
 10 Hawai'i are inspected with the help of specially trained detector dogs. There are 13 dog teams, 10 of
 11 which are at Anderson AFB and 3 at the naval station. Transiting aircraft remaining in Guam longer than
 12 3 hours are inspected (Spears 2007). Further, HDOA inspects every flight arriving in Hawai'i from Guam
 13 for BTS (Simon 2006b; Spears 2007).

14 Personnel arriving from overseas are required to remain aboard aircraft until they are inspected by CBP,
 15 HDOA, and APHIS. Inspection of air crews sometimes is waived by CBP. Passengers arriving from the U.S.
 16 mainland are not inspected, but are required to complete a declaration form (Spears 2007).

17 Table A20-2 presents insect interceptions in military air cargo entering Hawai'i. All are classified as
 18 hitchhikers, since they were found on non-food items.

19 **Table A20-2: Insect Interceptions in Military Air Cargo Entering Hawai'i**

Family	Species	Where Intercepted	Date	Stage	Origin	Known to Occur in Hawai'i
Psychidae	<i>Apterona helix</i> (Siebold)	Private vehicle	03-Jan-99	Larva	California	No
Otitidae	<i>Ceroxys latiusculus</i> (Loew)	Pallet	16-Oct-98	Adult	California	Yes
Carabidae	<i>Gnathaphanus picipes</i> (Macleay)	Crates	03-Apr-97	Adult	Midway Island	Yes
Staphylinidae	<i>Philonthus turbidus</i> Erichson	Crates	03-Apr-97	Adult	Midway Island	Yes
Scarabaeidae	<i>Popillia japonica</i> Newman	Cargo deck	20-Jul-04	Adult	Kadena, Japan	No
Curculionidae	Unknown sp.	Private vehicle	03-Jan-99	Adult	California	No

21
 22 Army air traffic arrives at Wheeler Army Airfield and Schofield Barracks. All arrivals at Wheeler are
 23 domestic, and are primarily transiting to Afghanistan and Iraq. CBP inspects the aircraft arriving from the
 24 U.S. mainland, whereas APHIS-PPQ inspects flights outbound to the mainland. Foreign flights land and
 25 are inspected at Hickam AFB (Spears 2007).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 CBP inspects Navy and Coast Guard aircraft landing at Barber’s Point Naval Air Station (now closed and
 2 returned to the State of Hawai’i). A major concern is the potential for aircraft from carriers arriving from
 3 foreign locations to introduce pests (Spears 2007).

4 No foreign vessels or flights are permitted to arrive at the Pacific Missile Range Facility at Barking Sands
 5 on Kauai. They arrive on Oahu first to be inspected and cleared. Flights that are precleared on the U.S.
 6 mainland may proceed directly to the Pacific Missile Range Facility (Burger 2007).

7 On Guam, military passengers arrive on contract flights at Anderson AFB. Inbound Navy aircraft may not
 8 give advance notification to the Guam Customs and Quarantine Agency, in which case, passengers
 9 disembark without being cleared. There also have been reports of Marine and Navy cargo aircraft
 10 opening holds before being cleared (Spears 2007). This is of significance to Hawai’i because any pests
 11 that become established on Guam are an imminent threat to Hawai’i.

12 **A20.7.2 Ships**

13 Large vessels periodically arrive at Pearl Harbor Naval Base (Simon 2006b). Upon arrival, Form 288, the
 14 ship arrival form, is completed (Spears 2007). Between the beginning of 2003 and May 20, 2007, 122
 15 ships arrived at the base from 14 foreign countries (Table A20-3). The largest proportion of arrivals
 16 (38%) originated in Japan, followed by 16% from Canada, 10% from Australia, 8% from Mexico, and 7%
 17 from South Korea. Ships arriving from other countries comprised 21% (Sloane 2007).

18 **Table A20-3: Origin of Foreign Ship Arrivals at Pearl Harbor Naval Base from January 1, 2003**
 19 **to May 20, 2007**

Year	2003	2004	2005	2006	2007	Total

21
 22 Commanders of fully active foreign military vessels arriving in Hawai’i may be reluctant to permit CBP
 23 inspectors onboard, with the result that these vessels may not always be fully inspected. Ships arriving

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 from the U.S. mainland are not required to disclose any foreign ports-of-call visited earlier. The origin of
2 stores procured for U.S. ships is not always known (Spears 2007).

3 **A20.7.3 Material**

4 Military cargo is difficult to track because of its complex nature, consisting of many types of goods and
5 other materials. Although most items arriving in Hawai'i have been free of foreign contaminants, such as
6 soil (Simon 2006a; b), there remains the potential for contaminated cargo or equipment to enter the
7 state as has occurred elsewhere. For example, there were 984 instances of violations of Air Force
8 quarantine regulations involving cargo shipments arriving at Dover AFB in Delaware and McGuire AFB in
9 New Jersey between 2003 and 2006. Most of the cases involved rolling stock, pallets, and aircraft
10 contaminated with soil. Military transports may carry cargo that is classified as not inspected, also a
11 violation of quarantine regulations (Spears 2007).

12 Vehicles may enter Hawai'i from any of the 43 countries in the Pacific command as well as from the
13 Middle East (Spears 2007). Marine material and vehicles come through Hickam AFB or Pearl Harbor
14 (Bookless 2007).

15 Military cargo arriving in Guam, some of which may be classified, is not subject to inspection. Most
16 rolling stock arrives on naval ships. It occasionally has been contaminated with soil, thus posing a risk of
17 introducing pest organisms. Facilities in Guam for cleaning rolling stock are inadequate. Aircraft arriving
18 in Guam are inspected only if they are carrying food items (Spears 2007).

19 **A20.7.4 Stores and Garbage**

20 The MOU directs APHIS and CBP to prepare and implement compliance agreements with DoD to
21 regulate in-flight meals on air cargo flights (DoD and APHIS 2006). Crew members aboard naval vessels
22 are instructed to consume prohibited products before arrival. Foreign military commanders are
23 informed about the stores and garbage that can be removed from their vessels. Garbage composed of
24 discarded fruit and vegetable material (wet garbage) is considered a high risk (Spears 2007).

25 DoD is responsible for the proper handling of USDA-regulated garbage aboard military conveyances
26 arriving in the United States. Regulated garbage is restricted to prevent the introduction of plant pests
27 and pathogens, and includes plant material that has been aboard any conveyance outside of the United
28 States, except Canada (DoD and APHIS 2006). Special dumpsters are used for the disposal of trash from
29 ships arriving from overseas. Honolulu Disposal, a civilian contractor, handles refuse from Navy ships,
30 and incinerates it at its facility. After use, dumpsters are treated with bleach to sanitize them (Spears
31 2007).

32 Barber's Point Coast Guard Air Station, Hickam AFB, and MCBH have approved facilities for handling
33 garbage arriving on aircraft from foreign points (USDA 2006c). Honolulu Biowaste, a civilian contractor,
34 handles refuse for the Air Force. Garbage from foreign aircraft is double-bagged and steamed-sterilized
35 (Spears 2007).

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Regulated garbage arriving in Guam on military flights from Japan, Taiwan, and the Philippines is
2 collected and deposited in special bins. Food from aircraft is inspected by Guam Customs and
3 Quarantine (Spears 2007).

4 **A20.7.5 Produce and Propagative Materials**

5 Most of the produce destined for military commissaries comes through California; some may originate
6 from foreign sources. HDOA regards this as a deficiency in agricultural safeguarding in Hawai'i, as
7 produce coming through the U.S. mainland from foreign sources may harbor exotic pests. All produce,
8 including that of foreign origin, must be precleared on the mainland (Spears 2007).

9 All produce for military commissaries on Guam originates in the mainland United States. Inspectors in
10 Guam occasionally have detected small insects, such thrips and aphids, in produce shipped from the
11 mainland. Produce of foreign origin found to be harboring pests is destroyed or re-exported (Spears
12 2007).

13 Military transports and cargo transiting Hawai'i en route to other Pacific islands, including Guam, are not
14 inspected or precleared by APHIS-PPQ in Hawai'i (Spears 2007). Military exchanges on Guam import
15 plants for propagation and freshly cut Christmas trees from the U.S. mainland. These practices allow for
16 the potential introduction and establishment of alien species in Guam, which subsequently could enter
17 Hawai'i via the military traffic between the two areas.

18 **A20.7.6 Household Goods**

19 The military customs inspection program for household goods was discontinued in the mid-1990s.
20 Responsibility for inspection of household good was shifted to the owner (Spears 2007). The
21 effectiveness of such self-inspections is unknown (Egan 2007). Household goods of military members are
22 shipped through a commercial port-of-entry, where they are inspected. In Hawai'i, household goods are
23 cleared at Sand Island, Honolulu (Bookless 2007; Spears 2007). The greatest risks associated with
24 household goods, such as those shipped in van-packs, are the potential presence of hitchhiking pests
25 and soil contamination.

26 **A20.8 REDEPLOYMENT AND MILITARY EXERCISES**

27 The frequent redeployment of troops and equipment into the United States from foreign regions
28 potentially creates a major pathway for introduction of alien species. The MOU requires that any aircraft
29 or ocean vessel presented for loading precleared cargo will be clean and substantially free from pests
30 (DoD and APHIS 2006). Military quarantine regulations outline measures, such as surveillance and
31 disinfection, to be used to reduce the risks of pest introduction (Howard et al. 1992).

1 **A21 A SAMPLING OF IMMINENT PEST THREATS TO HAWAI'I**

2 **A21.1 ARTHROPODS**

3 An average of about 20 exotic, terrestrial arthropods becomes established in Hawai'i every year
4 (Beardsley 1979), a rate of introduction matching or exceeding that for the entire continental United
5 States (Beardsley 1962). The latest period reported, July 1, 2005 to June 30, 2006, was typical, and saw
6 the detection of 18 arthropods new to the state (HDOA 2006). Only a small proportion of these
7 immigrants attains pest status in Hawai'i, causing economic harm and necessitating the implementation
8 of control measures. There remain, however, numerous, as-yet unintroduced arthropod species that
9 constitute major threats to the state's economy and natural environment. Some of those regarded as
10 most significant, in terms of potential economic or ecological impact, are discussed below.

11 **A21.1.1 *Aleurodicus pulvinatus* (Maskell) (Homoptera: Aleyrodidae)**

12 This whitefly is known only from the New World tropics (Martin and Watson 1998). Distributional
13 records include Belize, Bolivia, Brazil, Colombia, Costa Rica, Ecuador, El Salvador, Guyana, Honduras,
14 Mexico, Nicaragua, Panama, Peru, Nevis, St. Kitts, Surinam, Trinidad, and Venezuela. The host range of
15 *A. pulvinatus* is quite broad. Hosts include *Cocos nucifera* (Arecaceae), *Psidium guajava* (Myrtaceae),
16 *Coffea canephora* (Rubiaceae), *Coccoloba* spp. (Polygonaceae), *Persea americana* (Lauraceae), *Piper*
17 *nigrum* (Piperaceae), *Hura crepitans* (Euphorbiaceae), *Lacistema* sp. (Lacistemataceae), *Vismia* sp.
18 (Clusiaceae) (Martin and Watson 1998); *Echinodorus* sp. (Alismataceae), *Montrichardia arborescens*
19 (Araceae), *Chrysobalanus icaco* (Chrysobalanaceae), *Terminalia catappa* (Combretaceae), *Ficus* sp.
20 (Moraceae), *Musa* sp. (Musaceae), *Theobroma* sp. (Sterculiaceae), and *Petrea* sp. (Verbenaceae) (Kairo
21 et al. 2001).

22 As an indication of the species' invasiveness, recent surveys suggest that it is expanding its geographical
23 range in the Caribbean, the most likely mode of spread being the movement of nursery plants (Kairo et
24 al. 2001). The whitefly (as *A. iridescens* Cockerell) has been intercepted at U.S. ports on 17 occasions
25 since 1985 on various commodities, including ornamentals, from several countries (PIN 309a). It is a
26 major pest of coconut palm in the West Indies (Martin and Watson 1998). Damage caused by *A.*
27 *pulvinatus* is typical of that caused by whiteflies in general (Mound and Halsey 1978). Feeding by
28 nymphs reduces plant vigor, and the sooty molds that grow in excreted honeydew coating leaf surfaces
29 interfere with photosynthesis, further reducing plant fitness; aesthetic concerns also are raised by the
30 unsightly appearance of infestations on valuable ornamental plants (Kairo et al. 2001). Although no
31 studies have been carried out to quantify losses, the economic impact of this pest is thought potentially
32 to be high. Apart from the loss of plants and costs of their replacement, there have been the high costs
33 of control measures, and potentially adverse effects on the environment and on tourism (Kairo et al.
34 2001). The whitefly also is regarded as a minor pest of guava (Gould and Raga 2002). Given its history as
35 a pest of coconut in the West Indies, and the importance of this palm, as an ornamental plant (Neal
36 1965), to economies dependent on tourism, such as Hawai'i, it poses a significant risk to the state.
37 Introduction of the whitefly could result in the initiation of biological control programs, similar to what
38 has occurred in response to introductions of other whitefly species (e.g., Clausen 1978a). Such programs

1 would have the potential to perturb Hawai'i's native ecosystems by affecting non-target species (e.g.
2 Howarth, 1991).

3 **A21.1.2 *Anastrepha bahiensis* Lima (Diptera: Tephritidae)**

4 The geographic distribution of *A. bahiensis* comprises tropical America. It has been reported from Brazil,
5 Colombia, Panama, Trinidad (White and Elson-Harris 1992); Peru (Korytkowski and Ojeda 1968); and
6 Mexico (Hernández-Ortiz and Pérez-Alonso 1993). Hosts include *Juglans neotropica* and *J. regia*
7 (Juglandaceae), *Coffea arabica* (Rubiaceae) (White and Elson-Harris 1992); *Brosimum alicastrum*,
8 *Pseudolmedia oxyphyllaria*, *Pouroma cecropiaefolia* (Moraceae) (Hernández-Ortiz and Pérez-Alonso
9 1993; Zucchi et al. 1996); *Spondias mombin* (Anacardiaceae), *Psidium guajava* (Myrtaceae) (Sommeijer
10 1975); and *Eugenia variabilis* (Myrtaceae) (Norrbon and Kim 1988).

11 Guava is considered almost a universal host for fruit-infesting Tephritidae (Gould and Raga 2002). The
12 tree is widespread in Hawai'i (Wagner et al. 1999), and could facilitate the spread of this pest
13 throughout the state. Information on the reproductive biology of *A. bahiensis* is unavailable. Fecundity
14 of other species of *Anastrepha* ranges from 200 to about 1,500 eggs per female, and several generations
15 per year are typical (White and Elson-Harris 1992). Adults of *Anastrepha* species may fly as far as 135 km
16 (84 miles); flight thus can be an important means of spread (CABI 2006). The major means of dispersal to
17 previously uninfested areas is the transport, in international trade, of fruit containing larvae. Puparia
18 also may be disseminated, concealed in packing materials accompanying produce. Since 1984,
19 specimens of *Anastrepha* spp. have been intercepted at U.S. ports on well over 38,000 occasions (PIN
20 309a). If the biology of *A. bahiensis* is similar to that of related species, its reproductive and dispersal
21 potentials could be high. The fly represents a potential threat to crops in Hawai'i, such as coffee and
22 guava, and, because it attacks a related species, to the endemic plant, *Eugenia koolauensis* (nioi), listed
23 as Endangered in 50 CFR § 17.12). Introduction of the pest into Hawai'i also could result in the initiation
24 of chemical or biological control programs, with potential ecological consequences. Insecticides for the
25 control of fruit flies, such as *Anastrepha* spp., are used almost everywhere that guavas are grown
26 commercially (Gould and Raga 2002). *Anastrepha* spp. also have been the targets for biological control
27 programs, with some measure of success (Clausen 1978b).

28 **A21.1.3 *Anastrepha fraterculus* Wiedemann (Diptera: Tephritidae)**

29 The name *A. fraterculus* apparently represents a species complex that is as yet little studied (CABI 2006).
30 This group ranges from temporary populations in the south of Texas to Argentina (Foote et al. 1993).
31 *Anastrepha fraterculus* is extremely polyphagous. Preferred hosts are Myrtaceae, including *Eugenia* and
32 *Syzygium* spp. (CABI 2006). A few of the species' many other hosts are *Terminalia catappa*
33 (Combretaceae), *Malus pumila* and *Prunus* spp. (Rosaceae), *Annona* spp. (Annonaceae), *Citrus* spp.
34 (Rutaceae), *Coffea* spp. (Rubiaceae), *Ficus carica* (Moraceae), *Juglans* spp. (Juglandaceae), *Diospyros kaki*
35 (Ebenaceae), *Manilkara zapota* (Sapotaceae), *Persea americana* (Lauraceae), *Solanum quitoense*
36 (Solanaceae), *Theobroma cacao* (Sterculiaceae), *Olea europaea* (Oleaceae), and *Vitis vinifera* (Vitaceae).

37 Guava is listed by Aluja et al. (1987) among natural hosts of the fly. Fecundity ranges from 200 to 400
38 eggs per female (White and Elson-Harris 1992). The species is multivoltine, there being several

1 generations per year (Fletcher 1989a). Long-distance dispersal has not been reported for adults of *A.*
2 *fraterculus*. The major means for introducing the species to previously uninfested areas is the transport,
3 in international trade, of fruit containing larvae; for most regions, the most important fruits likely to be
4 infested by this species are mango and guava (CABI 2006). *Anastrepha fraterculus* is the most
5 economically important species of *Anastrepha* in Brazil and other South American countries because of
6 its broad host range (Foote et al. 1993). In Brazil, where it causes severe yield losses in apple, the pest is
7 of major concern to growers, and represents a significant constraint to fresh fruit export into countries
8 with quarantine barriers (Sugayama et al. 1996). The insect also is an important pest of guava and
9 mango, and to some extent of *Citrus* and *Prunus* spp. (CABI 2006). Even if eggs are not deposited in
10 guava fruit, or do not hatch, the oviposition punctures (stings) may render fruit unmarketable (Gould
11 and Raga 2002). *Anastrepha fraterculus* is a quarantine pest for Chile, Argentina, New Zealand, Turkey,
12 China, and eastern and southern Africa (EPPO 2005a); thus, its introduction could result in a loss of
13 domestic or foreign markets for Hawai'ian-grown commodities, such as citrus, mango, and avocado. In
14 Peru, hot water is used as a quarantine treatment for mango exported to the United States (Sharp and
15 Picho 1990), which increases production costs. *Anastrepha fraterculus* is a potential threat to native
16 plants in Hawai'i listed as threatened or endangered (50 CFR § 17.12), such as *Eugenia koolauensis*,
17 *Solanum incompletum* (popolo ku mai), and *S. sandwicense* (aiakeakua, popo lo). Its introduction into
18 the state likely would lead to the employment of biological or chemical controls, as has occurred
19 elsewhere (Clausen 1978b; Gould and Raga 2002).

20 **A21.1.4 *Anastrepha ludens* (Loew) (Diptera: Tephritidae)**

21 Originally native to Mexico, *A. ludens* presently occurs from southern Texas (temporary populations) to
22 Costa Rica (Foote et al. 1993). This is the only important *Anastrepha* species that ranges more into
23 subtropical regions, occupying the more northern portion of the range of the genus and extending
24 southward only at higher elevations; the fly is said to be able to withstand freezing weather well
25 (Weems 1963). Primary hosts are *Citrus* spp. (Rutaceae), *Mangifera indica* (Anacardiaceae), and *Prunus*
26 *persica* (Rosaceae) (CABI 2006). Other hosts include *Annona* spp. (Annonaceae), *Coffea arabica*
27 (Rubiaceae), *Passiflora edulis* (Passifloraceae), *Carica papaya* (Caricaceae), *Mammea americana*
28 (Clusiaceae), *Musa* sp. (Musaceae), *Opuntia* sp. (Cactaceae), *Persea americana* (Lauraceae), *Pouteria*
29 *sapota* (Sapotaceae), *Psidium guajava* (Myrtaceae), *Cucurbita* sp. (Cucurbitaceae), and *Inga* spp.
30 (Fabaceae) (Norrbon and Kim 1988), several of which are economically or otherwise important in
31 Hawai'i.

32 Fecundity is reported to range between 40 and 1,600 eggs per female (Liedo and Carey 1996). There are
33 four to eight generations per year (Aluja 1993). A flight range of at least 36 km (22 miles) has been
34 reported, and the regular appearance of adults in Texas at least 135 km (84 miles) from known breeding
35 sites in Mexico suggests that the migratory powers of the species are considerably greater (Fletcher
36 1989b). Similar to other *Anastrepha* species, the major means of dispersal to previously uninfested areas
37 is the transport of fruit, such as citrus and mango, and to a lesser extent peaches and guava, containing
38 larvae (CABI 2006). Because of its broad host range, including fruits of considerable economic
39 importance, such as grapefruit and orange, *A. ludens* is considered to be the most economically
40 important *Anastrepha* species threatening the United States (Foote et al. 1993). In an early study,

1 potential production losses caused by this and three other fruit fly species were conservatively
2 estimated to be 26.7 million boxes of citrus at a value of \$70.1 million (1975 farm-level prices) (Andrew
3 et al. 1977); losses at current price levels would be significantly higher. The fly is considered to be a key
4 pest of guava (Gould and Raga 2002). Quarantine treatments, such as hot water (Sharp et al. 1989a) and
5 irradiation (Hallman and Martinez 2001), have been developed to disinfest fruit, potentially increasing
6 production costs. *Anastrepha ludens* is a quarantine pest for Argentina, Brazil, Chile, Paraguay, Uruguay,
7 Turkey, China, and eastern and southern Africa (EPPO 2005a). Its introduction into Hawai'i, therefore,
8 could result in a loss of domestic or foreign markets for various commodities, such as citrus, mango,
9 papaya, and avocado, and could lead to the initiation of biological control programs, as has occurred in
10 response to the introduction of other *Anastrepha* species (Clausen 1978b).

11 **A21.1.5 *Anastrepha obliqua* (Macquart) (Diptera: Tephritidae)**

12 One of the most widespread of *Anastrepha* species (Foote et al. 1993), *A. obliqua*, ranges from Mexico
13 to Argentina and across the Caribbean (CABI 2006). This fruit fly has been recorded on more than 60
14 plant species in 24 families (Foote et al. 1993). The main wild hosts are *Spondias* spp. (Anacardiaceae);
15 *Mangifera indica* (Anacardiaceae) is the major commercial host (CABI 2006). Other hosts include citrus
16 (Rutaceae), *Annona* spp. (Annonaceae), *Carica papaya* (Caricaceae), *Coffea arabica* (Rubiaceae),
17 *Phaseolus* sp. (Fabaceae), *Prunus* spp. (Rosaceae), *Brosimum alicastrum* (Moraceae), *Eugenia* spp.
18 (Myrtaceae), *Diospyros* spp. (Ebenaceae), *Vitis vinifera* (Vitaceae), and *Pouteria* spp. (Sapotaceae)
19 (Norrbon and Kim 1988). Guava is among the natural hosts of the fly (Aluja et al. 1987), which suggests
20 that the plant also is a primary host.

21 Fecundity may exceed 1,300 eggs per female in the laboratory (Liedo and Carey 1996), but 500 to 700 is
22 the normal range under field conditions (Toledo and Lara 1996). There are four to eight generations per
23 year (Aluja, 1993). Similar to other *Anastrepha* species, the major means of dispersal to previously
24 uninfested areas is the transport of fruit, such as mango and, to a lesser extent, citrus and guava,
25 containing larvae. The species has been intercepted in France on mangoes from Mexico (CABI 2006).
26 *Anastrepha obliqua* is one of the most important fruit fly pests of mango (Foote et al. 1993). In Brazil,
27 infestations ranging from 7 to 88% in commercial crops of *Malpighia punicifolia* (Malpighiaceae) were
28 observed, leading to a downgrading of fruit quality (Ohashi et al. 1997). The fly is a major pest of
29 *Eugenia stipitata* in Peru, causing reductions in yield and fruit quality (Couturier et al. 1996), and a major
30 pest of guava (Gould and Raga 2002). Establishment of this pest in Hawai'i could cause a loss of
31 domestic or foreign markets. The species is a quarantine pest for Argentina, Uruguay, China, Taiwan,
32 Indonesia, Korea, New Zealand, Namibia, South Africa, Turkey, eastern and southern Africa, and the
33 European Union (EPPO 2005a; PRF 2007). It also represents a potential threat to native plants in Hawai'i,
34 such as *Eugenia koolauensis*. Its introduction likely would stimulate the initiation of control programs.
35 For example, biological control is employed in Brazil to suppress populations of this species in mango
36 orchards (e.g., Montoya et al. 2000).

37 **A21.1.6 *Anastrepha serpentina* (Wiedemann) (Diptera: Tephritidae)**

38 This fruit fly occurs in most countries of Central America and in South America south to Brazil and
39 Argentina (Foote et al. 1993; CABI 2006). At least 40 species in 13 plant families have been recorded as

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 hosts of *A. serpentina* (Foote et al. 1993). Species of Sapotaceae appear to be the favored hosts. Other
2 hosts include *Citrus* spp. (Rutaceae), *Mammea americana* (Clusiaceae), *Spondias* spp. (Anacardiaceae),
3 *Malus domestica* and *Prunus persica* (Rosaceae), *Solanum lycopersicum* (Solanaceae), *Persea americana*
4 (Lauraceae), *Annona glabra* (Annonaceae), *Ficus* sp. (Moraceae), *Byrsonima crassifolia* (Malpighiaceae),
5 and *Eugenia uniflora* and *Psidium guajava* (Myrtaceae) (Eskafi and Cunningham 1987; Norrbom and Kim
6 1988).

7 Average fecundity ranges from about 80 to 100 eggs per female (CABI 2006), although a maximum of
8 almost 900 eggs per female has been recorded (Liedo and Carey 1996). There are four to eight
9 generations per year (Aluja 1993). Long-distance dispersal is accomplished by the transport of immature
10 stages in fruit or packaging (CABI 2006). *Anastrepha serpentina* is an important pest of sapote
11 (*Calocarpum* spp.), sapodilla (*Manilkara zapota*), *Lucuma salicifolia*, and other fruits in Mexico;
12 infestations in tree-ripened fruit are said frequently to be so high that growers are forced to harvest
13 early and ripen fruit artificially, which lowers its quality (Weems 1969). It also is considered a key pest of
14 guava (Gould and Raga 2002). Hot-water quarantine treatments have been developed for mango
15 infested with this pest (Sharp et al. 1989b), which increase production costs. Establishment of the fly in
16 Hawai'i could lead to the loss of domestic or foreign markets for commodities, such as citrus and
17 avocado. The fly is a quarantine pest for Argentina, Uruguay, New Zealand, Indonesia, and Taiwan (EPPO
18 2005a; PRF 2007). *Anastrepha serpentina* is a potential threat to native plants in Hawai'i listed as
19 threatened or endangered (50 CFR § 17.12), such as *Eugenia koolauensis*, *Solanum incompletum*, and *S.*
20 *sandwicense*. Its introduction into Hawai'i also could stimulate the initiation of biological control
21 programs, as has occurred in response to the introduction of other fruit fly pests (e.g., Clausen 1978b).

22 **A21.1.7 *Anastrepha striata* Schiner (Diptera: Tephritidae)**

23 This species is found throughout Central America, in South America south to Bolivia and Brazil, and in
24 the Netherlands Antilles (CABI 2006). *Psidium guajava* is the primary host (Aluja et al. 1987; CABI 2006).
25 Secondary hosts include *Citrus sinensis* (Rutaceae), *Annona muricata* (Annonaceae), *Chrysophyllum*
26 *cainito* (Sapotaceae), *Prunus persica* (Rosaceae), *Mangifera indica* (Anacardiaceae), *Persea americana*
27 (Lauraceae), *Terminalia catappa* (Combretaceae) (CABI 2006); *Manihot esculenta* (Euphorbiaceae)
28 (White and Elson-Harris 1992); *Solanum macranthum* (Solanaceae), *Eugenia uniflora* (Myrtaceae), and
29 *Passiflora edulis* (Passifloraceae) (Norrbom and Kim 1988).

30 Fecundity ranges from 100 to 800 eggs per female; there are four to eight generations per year (Aluja
31 1993). As in other *Anastrepha* species, long-distance dispersal is accomplished by the movement of
32 immature stages present in consignments of infested fruit (CABI 2006). Little detailed information is
33 available concerning the economic impact of *A. striata*. Although Weems (1982) stated that the species
34 is not considered to be of primary economic importance, it is reported to be an important pest of guava
35 in Venezuela (Marín 1973). It is listed in Gould and Raga (2002) as a key pest of guava. Norrbom (2003)
36 also considered the species to be an important pest of guava and other myrtaceous fruits. Because it is a
37 quarantine pest for New Zealand (EPPO 2005a), establishment of *A. striata* could result in a loss of that
38 market, as well as domestic markets, for Hawai'ian-grown commodities, such as citrus, mango, and
39 avocado. *Anastrepha striata* has the potential to attack federally listed (50 CFR § 17.12) native plants in

1 Hawai'i (e.g., *Eugenia koolauensis*, *Solanum incompletum*, and *S. sandwicense*). Because it represents a
2 potential threat to citrus and other cultivated fruit crops, biological control programs could be initiated
3 against the species, as has occurred in response to the introduction of other fruit fly pests (e.g., Clausen
4 1978b).

5 **A21.1.8 *Bactrocera depressa* (Shiraki) (Diptera: Tephritidae)**

6 The geographic distribution of *B. depressa* is within temperate to tropical East Asia. It ranges from
7 Hokkaido, south through the remaining islands of Japan and the Ryukyu Archipelago, to mainland China
8 (Sichuan) and Taiwan (White and Elson-Harris 1992; Carrol et al. 2002). The species is widely distributed
9 in Korea (Han et al. 1994). Hosts are predominantly Cucurbitaceae. The fly has been recorded on
10 *Cucurbita moschata* and *C. maxima*, *Cucumis metuliferus* and *C. sativus*, *Citrullus lanatus*, *Lagenaria*
11 *siceraria*, and *Trichosanthes kirilowii* (White and Elson-Harris 1992; Mun et al. 2003). Larvae of *B.*
12 *depressa* are reported to infest fruit of tomato (*Solanum lycopersicum* [Solanaceae]) in Korea (Han et al.
13 1994) and Japan (Okadome 1962). Because *B. depressa* has been found in areas (e.g., mountainous
14 regions of the Ryukyu Islands), from which cucurbits are absent, White and Elson-Harris (1992)
15 suggested that the species probably had additional, non-cucurbit hosts.

16 No information is available on reproduction in *B. depressa*. If its biology is similar to that of other
17 *Bactrocera* species (Fletcher 1989a; CABI 2006), a high fecundity (e.g., greater than 1,000 eggs per
18 female) may be indicated, as is typical of the polyphagous dacine Tephritidae (Fletcher 1987). Migratory
19 movements are exhibited by several species of *Bactrocera*, in which flights up to 94 km (58 miles) (*B.*
20 *tryoni* [Froggatt]) have been reported (Fletcher 1989b). However, investigations into the population
21 structure of *B. depressa* by Mun et al. (2003) indicated that the frequency of long-distance dispersal in
22 this species is extremely low. Long-distance dissemination could occur via movement in infested fruit,
23 and the species potentially could be introduced into Hawai'i in commodities, such as cucurbits or
24 tomato. *Bactrocera depressa* is said to be a significant pest of *Cucurbita moschata* (pumpkin or winter
25 squash) and *C. maxima* (Hubbard squash) in Korea and Japan (Mun et al. 2003). In their survey, Han et
26 al. (1994) reported severe damage to *C. moschata* ($\geq 31\%$ of fruits); lesser damage (10 to 30%) to
27 *Citrullus lanatus* (watermelon), *Lagenaria siceraria* (bottle gourd), and ornamental pumpkin (*Cucurbita*
28 spp.); and "mild" damage ($\leq 10\%$) in tomato and melon. Damage is caused by larvae tunneling through
29 and macerating fruit tissue (Fletcher 1987). As *Bactrocera* spp. are quarantine pests for numerous
30 countries, including French Polynesia, New Caledonia, Turkey, Madagascar, Argentina, Brazil, New
31 Zealand, Syria, Uruguay, and Chile (PRF 2007), introduction of *B. depressa* into Hawai'i could result in a
32 loss of foreign, as well as domestic, markets for commodities, such as tomato and cucurbits. As a pest of
33 tomato, the fly represents a potential threat to the endemic *Solanum incompletum* and *S. sandwicense*.
34 Further, its introduction likely would result in the initiation of chemical or biological control programs
35 similar to those targeting other tephritid pests (Roessler 1989; Sivinski 1996).

36 **A21.1.9 *Bactrocera passiflorae* (Froggatt) (Diptera: Tephritidae)**

37 This tephritid is restricted to the tropical South Pacific (Fiji, Niue, Tonga, Wallis and Futuna) (CABI 2006).
38 It has been recorded on at least 55 plant species in 42 genera (SPC 2002a). Hosts include *Artocarpus*
39 *altilis* (Moraceae), *Mangifera indica* (Anacardiaceae), *Passiflora* spp. (Passifloraceae), *Carica papaya*

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 (Caricaceae), *Citrus* spp. (Rutaceae), *Persea americana* (Lauraceae), *Theobroma cacao* (Sterculiaceae),
2 *Ochrosia oppositifolia* (Apocynaceae) (SPC 2002a; CABI 2006); *Eugenia malaccensis*, *Psidium guajava*,
3 and *P. cattleianum* (Myrtaceae), *Coffea liberica* (Rubiaceae), *Pometia pinnata* (Sapindaceae), *Santalum*
4 *yasi* (Santalaceae), *Gossypium barbadense* (Malvaceae), *Inocarpus edulis* (Fabaceae) (Simmonds 1936);
5 and *Chrysobalanus icaco* (Chrysobalanaceae) (Clausen et al. 1965).

6 No information is available on the reproductive or dispersal potentials of *B. passiflorae*. If its biology is
7 similar to that of other *Bactrocera* species (Fletcher 1989a; b), it may exhibit a high degree of fecundity
8 and mobility. The transport of infested fruit would be a major pathway for the pest to be introduced
9 into new regions (CABI 2006). The fly's association with plants, such as common guava and strawberry
10 guava, which are widespread in Hawai'i (Wagner et al. 1999), likely would facilitate its rapid spread
11 throughout the islands. What little information is available concerning the economic impact of this
12 species indicates that its potential impact may be significant. White and Elson-Harris (1992, p. 221)
13 referred to it as a "potential pest," probably because of its restricted distribution. In Fiji, infestation
14 levels have been reported to be as high as 60% in *Fortunella japonica* (kumquat), 40 to 90% in guava,
15 62% in *Syzygium malaccense*, and 20 to 25% in mango (SPC 2002a). Control measures include the
16 bagging of fruit, field sanitation, and trapping (SPC 2002a), which tend to increase production costs. The
17 species is regarded as a serious plant quarantine threat to other Pacific islands (it is a quarantine pest for
18 French Polynesia and New Caledonia [PRF 2007]), and to countries in Australasia and the Asian mainland
19 (CABI 2006). Thus, its introduction into Hawai'i could result in further losses of foreign, as well as
20 domestic, markets for such fruit fly host fruits as mango, citrus, avocado, and papaya. As it attacks
21 closely related host species, its introduction into Hawai'i also could put at risk native plants, such as
22 *Eugenia koolauensis*, *Ochrosia kilaueaensis* (holei), *Santalum freycinetianum* var. *lanaiense* (iliahi), and
23 *Solanum incompletum* and *S. sandwicense*, all listed as endangered in 50 CFR § 17.12. Its introduction
24 also could spur the initiation of biological control programs, as has occurred elsewhere (e.g., Wharton
25 1989).

26 **A21.1.10 *Bactrocera tau* (Walker) (Diptera: Tephritidae)**

27 The geographic distribution of *B. tau* is restricted to temperate to tropical countries of the Oriental
28 Region. The fly occurs in Bangladesh, Bhutan, Brunei, Burma, Cambodia, China, India, Indonesia, Laos,
29 Malaysia, Nepal, the Philippines, Sri Lanka, Taiwan, Thailand, and Vietnam (Narayanan and Batra 1960;
30 White and Elson-Harris 1992; Waterhouse 1993b; Huque 2006). Although preferred hosts appear to be
31 species of *Cucurbitaceae*, such as *Cucumis sativus*, *Luffa acutangula*, *Cucurbita maxima*, *Trichosanthes*
32 *anguina*, *Benincasa hispida*, and *Momordica charantia*, the fly has been recorded on hosts in several
33 other families (Narayanan and Batra 1960; Batra 1968; Syed 1970; White and Elson-Harris 1992; Allwood
34 et al. 1999). These include *Mangifera foetida* and *M. indica* (Anacardiaceae), *Muntingia calabura*
35 (Elaeocarpaceae), *Citrus maxima* (Rutaceae), *Solanum lycopersicum* (Solanaceae), *Borassus flabellifer*
36 (Arecaceae), *Phaseolus vulgaris* (Fabaceae), *Strychnos* spp. (Loganiaceae), *Ficus racemosa* (Moraceae),
37 *Psidium guajava* and *Syzygium samarangense* (Myrtaceae), *Myxopyrum smilacifolium* (Oleaceae),
38 *Manilkara zapota* (Sapotaceae), and *Tetrastigma lanceolarium* (Vitaceae).

1 The fly thus poses a potential threat to several important crops in Hawai'i. Depending on cucurbit host,
2 mean fecundity ranged from 666 to 911 eggs per female (Liu and Lin 2001). The fly is said to exhibit
3 several overlapping generations throughout summer in India; there is no diapause (Batra 1968). Two
4 generations per year in Taiwan are indicated (Chen 2001). The species is reported to make migratory
5 flights (Fletcher 1989b). It has been intercepted in Japan in fresh fruits from Southeast Asia (Takeishi
6 1992), indicating that it is readily transported long distances by human agency. *Bactrocera tau* is an
7 important pest of various fruit crops, such as pumpkin, watermelon, mango, sapodilla, citrus, and
8 tomato, in India (Kapoor 1989) and China (Zhou et al. 1993), presumably causing significant yield losses.
9 In China, insecticides, such as BHC, diazinon, and trichlorfon, are applied to control the pest (Zhou et al.
10 1993; Yang et al. 1994), a practice that increases production costs. As the fly is a quarantine pest for
11 Korea (PRF 2007), its introduction could result in a loss of that market for various Hawai'i fruit crops.
12 *Bactrocera tau* represents a potential threat to native plants in Hawai'i listed as endangered in 50 CFR §
13 17.12, such as *Solanum incompletum* and *S. sandwicense*. As it is a pest of economically important crops
14 (e.g., cucurbits, citrus, mango, guava, tomato), introduction of the fly into Hawai'i likely would result in
15 the initiation of chemical or biological control programs, which have proven to be effective against it and
16 other species of fruit fly elsewhere (Clausen 1978b; Zhou et al. 1993).

17 **A21.1.11 *Bactrocera tryoni* (Froggatt) (Diptera: Tephritidae)**

18 This fruit fly is found throughout the eastern half of Queensland, eastern New South Wales, and the
19 extreme east of Victoria in Australia (CABI 2006). There also have been short-lived outbreaks in South
20 Australia. Adventive populations occur in the Austral and Society Islands and New Caledonia. The fly has
21 been recorded on plants in numerous families (CABI 2006). Hosts include *Mangifera indica*
22 (Anacardiaceae), *Annona* spp. (Annonaceae), *Carica papaya* (Caricaceae), *Terminalia aridicola*
23 (Combretaceae), *Artocarpus odoratissima* (Moraceae), *Coffea arabica* (Rubiaceae), *Eugenia uniflora*,
24 *Psidium guajava*, and *P. cattleianum* (Myrtaceae), *Olea europaea* (Oleaceae), *Nerium oleander*
25 (Apocynaceae), *Averrhoa carambola* (Oxalidaceae), *Passiflora* spp. (Passifloraceae), *Prunus persica*
26 (Rosaceae), *Diospyros kaki* (Ebenaceae), *Dimocarpus longan* and *Litchi chinensis* (Sapindaceae),
27 *Momordica charantia* (Cucurbitaceae), *Musa x paradisiaca* (Musaceae), *Citrus* spp. (Rutaceae), *Persea*
28 *americana* (Lauraceae), *Manilkara zapota* (Sapotaceae), *Solanum* spp. (Solanaceae), and *Vitis* spp.
29 (Vitaceae).

30 An average fecundity of 415 eggs per female has been reported under laboratory conditions;
31 populations under such conditions increased at more than 90% per week (Fitt 1990), indicating a
32 considerable biotic potential. There are four to five generations per year (Hely et al. 1982). The adults
33 are strong fliers. Adult flight and the transport of infested fruit are the major means of long-distance
34 dispersal (CABI 2006). The fly's association with plants, such as common guava, strawberry guava, and
35 bitter melon, which are widespread in Hawai'i (Wagner et al. 1999), likely would facilitate its rapid
36 spread throughout the islands. *Bactrocera tryoni* is the most serious insect pest of fruit and vegetable
37 crops in Australia, infesting all commercial fruit crops other than pineapple and strawberry (CABI 2006).
38 Larvae damage fruit directly by their feeding and indirectly by facilitating entry by organisms of decay. In
39 certain fruits, such as citrus, yield losses are overshadowed by the negative economic impact of lost
40 markets due to quarantine barriers (Hely et al. 1982). In Australia, potential losses to fruit flies in the

1 absence of control measures have been estimated at A\$100 million per year, and most of this is
2 attributable to *B. tryoni* (CABI 2006). As it is known to attack closely related hosts, *B. tryoni* is a potential
3 threat to endangered or threatened native plants in Hawai'i, such as *Eugenia koolauensis*, *Solanum*
4 *incompletum*, and *S. sandwicense*. Because of its status as a pest of a wide variety of crops economically
5 or otherwise important to Hawai'i, including papaya, coffee, eggplant, tomato, mango, lychee, avocado,
6 and citrus (CABI 2006), introduction of *B. tryoni* likely would trigger the initiation of control programs.
7 Biological control has proved to be at least partially effective in suppressing population densities of other
8 dacine fruit flies (Clausen 1978b).

9 **A21.1.12 *Ceratitis rosa* Karsch (Diptera: Tephritidae)**

10 The geographic distribution of *C. rosa* is restricted to subtropical and tropical Africa, the species
11 apparently being less tolerant of cold temperatures than is *Ceratitis capitata* (CABI/EPPO 1997c). It has
12 been reported from Angola, Ethiopia, Kenya, Malawi, Mali, Mauritius, Mozambique, Nigeria, Réunion,
13 Rwanda, South Africa, Swaziland, Tanzania, Uganda, Zaire, Zambia, and Zimbabwe. Hosts include *Prunus*
14 spp. (Rosaceae), *Persea americana* (Lauraceae), *Citrus* spp. (Rutaceae), *Ficus carica* (Moraceae), *Vitis*
15 *vinifera* (Vitaceae), *Litchi chinensis* (Sapindaceae), *Mangifera indica* (Anacardiaceae), *Carica papaya*
16 (Caricaceae) (CABI/EPPO 1997c); *Averrhoa carambola* (Oxalidaceae), *Coffea arabica* (Rubiaceae),
17 *Annona reticulata* (Annonaceae), *Passiflora* sp. (Passifloraceae), *Manilkara zapota* (Sapotaceae), *Eugenia*
18 *uniflora* and *Psidium* spp. (Myrtaceae) (Grové 2001); *Strychnos spinosa* (Loganiaceae) (Weems 1966);
19 *Carissa macrocarpa* (Apocynaceae), *Ziziphus zizyphus* (Rhamnaceae), *Theobroma cacao* (Sterculiaceae),
20 *Garcinia mangostana* (Clusiaceae), *Musa* sp. (Musaceae), *Diospyros virginiana* (Ebenaceae), *Opuntia*
21 spp. (Cactaceae), *Dovyalis caffra* (Flacourtiaceae), *Solanum lycopersicum* and *S. auriculatum*
22 (Solanaceae), Cecropiaceae, Euphorbiaceae, and Podocarpaceae (White and Elson-Harris 1992).

23 In the laboratory, fecundity averaged 520 eggs per female (Monty 1973). Depending on climatic
24 conditions, there may be as many as 12 generations per year (Hill 1983). Adult flight and the transport of
25 infested fruit are the primary means of long-distance dispersal and spread to previously uninfested
26 areas (CABI/EPPO 1997c). *Ceratitis rosa* is a major pest of mango (Joubert et al. 2000) and avocado in
27 South Africa, resulting in a cull rate in the latter of 1.9% (Dennill and Erasmus 1992). Lychee fruit,
28 although a poor host, is damaged by organisms of decay introduced by ovipositing females (de Villiers
29 1990). In South Africa, infestation rates of 50 to 100% have been reported in plum (Weems 1966). After
30 its introduction into Mauritius, *C. rosa* displaced *C. capitata* from many of their shared hosts (Fitt 1989),
31 and a similar phenomenon may have occurred in Zimbabwe (Anonymous 1963), suggesting the potential
32 for *C. rosa* to become as serious a pest as *C. capitata*. Control routinely is achieved by the application of
33 insecticides (de Villiers 1978), which increases production costs. Like *C. capitata*, *C. rosa* is an
34 international quarantine pest with the potential to restrict international trade in fruit (Barnes et al.
35 2000). For example, the fly is an A1 quarantine pest for Europe, and considered by the European and
36 Mediterranean Plant Protection Organization (EPPO) the most important of all *Ceratitis* species
37 (CABI/EPPO 1997c). Its establishment in Hawai'i thus could result in a further loss of domestic or foreign
38 markets for various commodities. *Ceratitis rosa* is a potential threat to plants in Hawai'i listed as
39 threatened or endangered, such as *Eugenia koolauensis*, *Solanum incompletum*, and *S. sandwicense*. Its
40 introduction into Hawai'i likely would result in the initiation of chemical or biological control programs,

1 as has occurred in response to the entry elsewhere of other tephritid species (Roessler 1989; Wharton
2 1989).

3 **A21.1.13 *Ceroplastes japonicus* Green (Homoptera: Coccidae)**

4 This soft scale insect is native to the Old World. It has been reported from Armenia, Azerbaijan, China,
5 Georgia, Japan, Korea, and Nepal in Asia, and, in Europe, England, France, Italy, Russia, Slovakia, and
6 Slovenia (CABI 2003; Ben-Dov et al. 2006). In China, it ranges from the temperate zone to the tropics
7 (Hua 2000). The species has been recorded on plants in at least 26 families (Ben-Dov et al. 2006). Hosts
8 include *Diospyros kaki* (Ebenaceae), *Acer* spp. (Aceraceae), *Nerium oleander* (Apocynaceae), *Ilex* spp.
9 (Aquifoliaceae), *Berberis* sp. (Berberidaceae), *Buxus sempervirens* (Buxaceae), *Cycas revoluta*
10 (Cycadaceae), *Magnolia grandiflora* (Magnoliaceae), *Ficus carica* (Moraceae), *Ziziphus* sp.
11 (Rhamnaceae), *Prunus* spp. (Rosaceae), *Citrus* spp. (Rutaceae), and *Punica granatum* (Punicaceae).
12 Several of these plants are, or are related to economically or aesthetically valuable, or endemic species
13 in Hawai'i, such as *D. kaki* (Japanese persimmon), *N. oleander* (oleander), *Cycas* spp. (cycads, sago-
14 palms), and *Buxus* and *Ziziphus* spp. (Imada et al. 2005; NASS 2006b), and thus are potentially
15 threatened by the introduction of *C. japonicus*.

16 An average fecundity as high as 1,540 eggs per female has been reported for the scale (Jiang and Gu
17 1988). There is one generation per year (CABI 2006). Natural dispersal is accomplished by first-instar
18 nymphs (crawlers), which may be carried on wind or other animals; all stages may be transported long
19 distances in consignments of plant material and produce (CABI 2006). *Ceroplastes japonicus* is reported
20 to be an important pest of several crops, including citrus, mulberry, jujube, pomegranate, tea, apple,
21 and persimmon (Dzhashi 1971; Konstantinova 1976; Luo et al. 1994; Swirski et al. 1997; CABI 2006; Ma
22 and Bai 2004). Konstantinova and Gura (1986) found the scale to infest deciduous fruits, although
23 Pfeiffer (1997) considered it to be only a minor pest in such crops. No information is available specifically
24 on the magnitude of damage (e.g., yield losses) attributed to the pest. Infestation results in reduced
25 vigor and general debility of the host, premature leaf drop and dieback of stems, and the secreted
26 honeydew may serve as a medium for the growth of sooty molds, which interfere with photosynthesis
27 and may lower the market value of fruit (CABI 2006). The species is a quarantine pest for Belarus,
28 Ukraine, New Zealand, and Peru (EPPO 2005a; PRF 2007), suggesting that its introduction could result in
29 a loss of domestic or foreign markets for Hawai'i-grown commodities. Its introduction into Hawai'i could
30 result in the initiation of chemical or biological control programs, as has occurred elsewhere (e.g., Xia et
31 al, 1985; Swirski et al. 1997; Zhou et al. 2003), thus potentially impacting native ecosystems.

31

1 **A21.1.14 *Conogethes punctiferalis* (Guenée) (Lepidoptera: Pyralidae)**

2 The geographic distribution of *C. punctiferalis* extends from temperate to tropical Asia and into
3 Australasia (Australia, Papua New Guinea) (CABI 2006). This polyphagous species has been recorded on
4 plants in at least 20 families (CABI 2006). Hosts include *Carica papaya* (Caricaceae), *Gossypium*
5 *herbaceum* (Malvaceae), *Helianthus annuus* (Asteraceae), *Prunus persica* (Rosaceae), *Zea mays*
6 (Poaceae), *Citrus nobilis* (Rutaceae), *Punica granatum* (Punicaceae), *Vitis vinifera* (Vitaceae), *Zingiber*
7 *officinale* (Zingiberaceae), *Ricinus communis* (Euphorbiaceae), *Morus alba* (Moraceae), *Psidium guajava*
8 (Myrtaceae), *Macadamia integrifolia* (Proteaceae) (CABI 2006); *Diospyros kaki* (Ebenaceae) (Umeya and
9 Okada 2003); *Quercus* spp. (Fagaceae) (Park et al. 1998b); *Mangifera indica* (Anacardiaceae) (Nair 1975);
10 *Dimocarpus longan* (Sapindaceae) (Huang et al. 2000); *Pinus massoniana* (Pinaceae) (Hua 2005); and
11 *Durio zibethinus* (Bombacaceae) (Brown 1997). Several of these (e.g., papaya, guava, macadamia,
12 mango, and Japanese persimmon) are economically important crops in Hawai'i (NASS 2006b).

13 Female *C. punctiferalis* lay an average of 20 to 30 eggs on the surface of fruits or on the ear silk and
14 tassels of corn (CABI 2006). Five generations per year have been reported (Wang and Cai 1997).
15 Demographic studies indicated that, under ideal conditions, populations may increase by a factor of
16 almost 21 times per generation (Bilapate 1977). Long distance dispersal may be effected via the
17 transport of commercial consignments of fruit. For example, pear fruits from Korea were found to be
18 infested with larvae of *C. punctiferalis* at a Canadian port-of-entry (Lee et al, 2000). Since 1984, the moth
19 has been intercepted at U.S. ports on at least 79 occasions (PIN 309a). *Conogethes punctiferalis* is one of
20 the most destructive pests of peach in China and of cotton and grain sorghum in Australia, in which
21 latter country infestations of 27% of bolls and 100% of seed heads, respectively, have been reported
22 (Anonymous 1957). In grains, stems bored by the moth are easily broken down by the wind and farming
23 practices, resulting in decreased yields (CABI 2006). Yield losses were as high as 42% in castor bean
24 (Kapadia 1996), 49% in plum (Wang and Cai 1997), and 50% in grape (Ram et al, 1997). In persimmon,
25 the pest may be present as eggs and larvae on or in fruit at harvest (Tomomatsu et al. 1995). Losses in
26 persimmon crops of almost 2% have been reported, and may continue until harvest (Kim et al. 1997).
27 Annual losses in chestnut crops in parts of Zhejiang Province, China, have been estimated at 120 tonnes
28 at a value of almost \$121,000 (Xu et al. 2001). In fruit crops, injury generally occurs when fruit is nearly
29 ripe (Hely et al. 1982). Larval tunneling and attack by secondary organisms of decay may render fruit
30 valueless (Clausen 1931). As the species is a quarantine pest for countries, such as Canada, Chile, New
31 Zealand, and Peru (EPPO 2005a; PRF 2007), its introduction could result in a loss of domestic or foreign
32 markets for various agricultural commodities grown in Hawai'i. Introduction of the pest into the state
33 likely would result in the initiation of chemical or biological control programs similar to those carried out
34 in other countries (e.g., Choo et al. 1995; Wang et al. 2002), again potentially putting native Hawai'ian
35 ecosystems further at risk.

36 **A21.1.15 *Copitarsia decolora* (Guenée) (Lepidoptera: Noctuidae)**

37 This moth is reported to occur in Mexico, Guatemala, Costa Rica, Venezuela, Uruguay, Peru, Colombia,
38 Ecuador, Chile, Argentina, and Bolivia (Liberman 1986; Angulo and Olivares 2003). It has been recorded
39 on *Medicago sativa* (Fabaceae), *Capsicum frutescens* and *Solanum tuberosum* (Solanaceae), *Cynara*

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 *scolymus* and *Helianthus* sp. (Asteraceae), *Allium* spp. (Liliaceae), *Fragaria ananassa*, *Malus pumila*, and
2 *Rubus* sp. (Rosaceae), *Simmondsia chinensis* (Simmondsiaceae), *Zea mays* and *Triticum* sp. (Poaceae),
3 *Pistacia vera* (Anacardiaceae), *Beta vulgaris* (Chenopodiaceae), *Brassica oleracea* (Brassicaceae),
4 *Dianthus caryophyllus* (Caryophyllaceae), *Feijoa sellowiana* (Myrtaceae), *Actinidia deliciosa*
5 (Actinidiaceae), *Vitis vinifera* (Vitaceae) (Angulo and Olivares 2003); and *Amaranthus cruentus*
6 (Amaranthaceae) (Guerrero et al. 2000).

7 *Copitarsia decolora* exhibited an average fecundity of 1,038 eggs per female under laboratory conditions
8 (Larraín 1996). At least four generations per year have been reported (Urra and Apablaza 2005). Long-
9 distance spread of the moth is accomplished via the movement of infested plant materials in commerce.
10 *Copitarsia* spp. frequently are intercepted on produce and cut flowers at U.S. ports (Venette and Gould
11 2006). *Copitarsia decolora* has been intercepted at U.S. ports on grape and apple from Chile (Santacroce
12 1993). In Peru, *C. decolora* is a major pest of potato (Alcala 1978), and is one of a complex of pests
13 (including *Spodoptera eridania* Stoll and agromyzid leafminers) of broad bean (*Vicia faba*), which
14 reduces yield by 50 to 60% (Gomez 1972). Defoliation on the order of 60% has been reported in rape
15 (*Brassica napus* var. *napus*), although with no appreciable effect on yield (Larraín 1996). The noctuid
16 may also constitute a significant pest of quinoa (*Chenopodium quinoa*) in Chile (Lamborot et al. 1999).
17 Gonzalez (1983) identified the moth (as *C. consueta* [Walker]) as an occasional pest in vineyards. It
18 occasionally is found on fruit trees, and the larvae may bore into immature fruits (Santacroce 1993).
19 *Copitarsia decolora* poses a potential threat to listed (50 CFR § 17.12) native plant species in Hawai'i,
20 such as *Solanum incompletum* and *S. sandwicense*. As it is known to attack cultivated crops that are
21 valuable in Hawai'i, such as brassicas and grape, its introduction could result in the initiation of chemical
22 control programs, as have targeted the pest elsewhere (e.g., Gonzalez 1983).

23 **A21.1.16 *Cryptophlebia leucotreta* (Meyrick) (Lepidoptera: Tortricidae)**

24 The distribution of *C. leucotreta* is restricted to subtropical and tropical Africa, where it is widespread
25 (CABI 2006). This pest attacks host plants in numerous families, including *Ananas comosus*
26 (Bromeliaceae), *Camellia sinensis* (Theaceae), *Citrus* spp. (Rutaceae), *Annona muricata* (Annonaceae),
27 *Averrhoa carambola* (Oxalidaceae), *Ceiba pentandra* (Bombacaceae), *Coffea arabica* (Rubiaceae), *Litchi*
28 *chinensis* (Sapindaceae), *Mangifera indica* (Anacardiaceae), *Olea europaea* (Oleaceae), *Persea*
29 *americana* (Lauraceae), *Punica granatum* (Punicaceae), *Ricinus communis* (Euphorbiaceae), *Zea mays*
30 (Poaceae) (CABI 2006); *Prunus* spp. (Rosaceae), *Quercus* sp. (Fagaceae), *Juglans* sp. (Juglandaceae),
31 *Macadamia integrifolia* (Proteaceae), *Vitis vinifera* (Vitaceae) (Annecke and Moran 1982);
32 *Bequaertiodendron magalismontanum* (Sapotaceae), *Calotropis procera* (Asclepiadaceae), *Capparis*
33 *tomentosa* (Capparaceae), *Catha edulis* (Celastraceae), *Cola nitida* (Sterculiaceae), *Combretum* spp.
34 (Combretaceae), *Diospyros* spp. (Ebenaceae), *Eugenia uniflora* and *Psidium guajava* (Myrtaceae), *Ficus*
35 *capensis* (Moraceae), *Garcinia mangostana* (Clusiaceae), *Abutilon* spp. and *Hibiscus* spp. (Malvaceae),
36 *Musa x paradisiaca* (Musaceae), *Phaseolus* spp. (Fabaceae), *Podocarpus falcatus* (Podocarpaceae),
37 *Schotia afra* (Caesalpiniaceae), *Triumfetta* spp. (Tiliaceae), *Ximenia caffra* (Olacaceae), and *Ziziphus* spp.
38 (Rhamnaceae) (Whittle 1984). Many of these are economically or otherwise important in Hawai'i.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Depending on temperature, average fecundity was reported to range from 87 to 456 eggs per female
2 (Daiber 1980). There may be as many as five generations per year (van den Berg 2001). The capacity for
3 long-distance flight by adults is indicated by records of migrants found in Sweden, thousands of
4 kilometers beyond the natural range of the species (Svensson 2002). Dispersal over long distances also
5 may be facilitated by the transport of fruit infested with larvae (CABI 2006). The species has been
6 intercepted at U.S. ports in various fruits on more than 166 occasions (Whittle 1984; PIN 309a). In South
7 Africa, *C. leucotreta* is a major pest of citrus, guava, lychee, and avocado, in which crop losses may reach
8 80% (van den Berg 2001). The moth occasionally is an important pest of cotton (Whittle 1984), causing
9 yield losses as high as 90% (CABI 2006). Losses of up to 28% in peach crops also have been reported
10 (CABI 2006). Primary damage is caused by larvae boring into fruits (Hill, 1983). Opportunistic secondary
11 fungal and bacterial rots may cause further damage to fruits or bolls (van der Geest et al. 1991). Larvae
12 attacking the young, green fruits of guava, although unable to penetrate the skin, produce blemishes
13 (van den Berg 2001), which likely lowers market price. The moth is a quarantine pest for Korea,
14 Paraguay, Uruguay, Argentina, Brazil, Chile, New Zealand, and Indonesia (PRF 2007), suggesting that its
15 introduction could result in a loss of domestic or foreign markets for various Hawai'iian-grown
16 commodities, such as citrus, pineapple, mango, mangosteen, macadamia, lychee, and avocado.
17 Introduction of this pest into Hawai'i also poses a potential threat to native plants listed as threatened
18 or endangered, such as *Eugenia koolauensis*, *Abutilon eremitopetalum*, *A. menziesii* (kooloaula), and *A.*
19 *sandwicense*, and *Hibiscus arnottianus* ssp. *immaculatus* (kokio keokeo), *H. brackenridgei* (mao hau
20 hele), *H. clayi*, and *H. waimeae* ssp. *hannerae* (kokio keokeo).

21 **A21.1.17 *Eotetranychus cendanai* Rimando (Acari: Tetranychidae)**

22 Except for an adventive population in Guam (Nafus and Schreiner 1999), *E. cendanai* is restricted to East
23 and Southeast Asia. It occurs in Cambodia, the Philippines, Taiwan, and Thailand (Bolland et al. 1998). In
24 addition to various *Citrus* species, the mite has been recorded on *Sesbania grandiflora* (Fabaceae) and
25 *Zoysia japonica* (Poaceae) (Bolland et al. 1998).

26 Thongtab et al. (2002) studied the reproductive biology of the mite in the laboratory. Fecundity on *C.*
27 *maxima* averaged 26 eggs per female; population densities tended to increase rapidly. The calculated
28 intrinsic rate of natural increase was 0.156, indicating that the average population was growing at
29 almost 16% per day. Several generations per year are indicated (Barrion and Corpuz-Raros 1975;
30 Thongtab et al. 2002). Tetranychid mites may disperse over considerable distances naturally by
31 "ballooning" on air currents (Jeppson et al. 1975). The disjunct distribution of *E. cendanai*, with a
32 population established in Guam far from the presumed Asian center of origin of the species, suggests
33 that it has significant spread potential. The mite is listed in Waterhouse (1993b) as a widespread and
34 important pest in Thailand; although, because of its limited distribution, Gerson (2003) considered its
35 overall, global pest status to be minor. On citrus, feeding injury results in leaf and fruit drop, and fruit
36 russetting, resulting in a downgrading of its quality (Thongtab et al, 2002). The mite thus is a potential
37 threat to *Citrus* spp. in Hawai'i, which not only are commercially important (NASS 2006a), but are
38 popular as ornamental and fruit trees in residential plantings (Neal 1965). *Eotetranychus cendanai* poses
39 a potential threat to *Sesbania tomentosa*, listed in 50 CFR § 17.12 as endangered in Hawai'i. Its

1 introduction into the islands could spur the initiation of biological control programs of the kind presently
2 being considered elsewhere (e.g., Thongtab et al. 2001).

3 **A21.1.18 *Gymnandrosoma aurantianum* Lima (Lepidoptera: Tortricidae)**

4 This tortricid is known from the American tropics. It has been reported from Argentina, Brazil, Peru,
5 Ecuador, Venezuela, Colombia, French Guiana, and Surinam in South America, throughout Central
6 America, Mexico, and from Cuba, Dominica, Puerto Rico, and Trinidad and Tobago in the Caribbean
7 (White 1999; Adamski and Brown 2001). Hosts include *Cupania vernalis* and *Litchi chinensis*
8 (Sapindaceae), *Cojoba arborea* (Fabaceae), *Theobroma cacao* (Sterculiaceae), *Citrus* spp. (Rutaceae),
9 *Macadamia integrifolia* (Proteaceae), *Prunus persica* (Rosaceae), *Punica* sp. (Punicaceae), *Psidium*
10 *guajava* (Myrtaceae) (Adamski and Brown 2001); *Simarouba amara* (Simaroubaceae) (White and Tuck
11 1993); *Cocos nucifera* (Arecaceae), *Musa acuminata* (Musaceae), and *Annona* spp. (Annonaceae) (Bento
12 et al. 2001).

13 Fecundity ranges from about 150 to 200 eggs per female (Bento et al. 2001); eggs apparently are
14 deposited on mature fruit (White and Tuck 1993). The life cycle may be completed within 36 days
15 (Blanco et al. 1993). Field data indicate at least three generations per year (White 1999). Rapid, long-
16 distance dispersal probably is accomplished by larvae within fruit transported in commerce, as is
17 suggested by the record of species of *Gymnandrosoma* or *Ecdytolopha* (a closely related genus)
18 intercepted at U.S. and foreign ports in cargo or baggage (Adamski and Brown 2001; PIN 309a).
19 *Gymnandrosoma aurantianum* is an important pest of citrus in Brazil (Bento et al. 2001). Yield losses
20 have been estimated to be as high as 50% in infested areas, and total losses to the industry may reach
21 \$50 million per year. The moth also is considered to be a major pest of macadamia in Costa Rica, causing
22 reductions in yield and nut quality (Coto 1999). Damage is caused by caterpillars boring through fruits
23 and consuming seeds (Adamski and Brown 2001). Control measures typically consist of insecticidal
24 treatments (e.g., Scarpellini and dos Santos 1997), which increase costs of production. Because this pest
25 reportedly is difficult to control (Faria et al. 1998; Bento et al. 2001), its introduction could cause a loss
26 of domestic or foreign markets for Hawai'ian-produced citrus, macadamia, or lychee. *Gymnandrosoma*
27 spp. are quarantine pests for New Zealand and Venezuela (PRF 2007). *Gymnandrosoma aurantianum*
28 also has the potential to attack plants in Hawai'i of considerable aesthetic value, such as coconut (Neal
29 1965). As it represents a potential threat to citrus and macadamia production, its introduction could
30 stimulate the initiation of control programs. The pest is a candidate for biological control in Brazil
31 (Molina et al. 2005).

32 **A21.1.19 *Helicoverpa assulta* (Guenée) (Lepidoptera: Noctuidae)**

33 This moth is distributed from the temperate zone to the tropics of the Old World (CABI 2006). It occurs
34 in sub-Saharan Africa, throughout South, Southeast, and East Asia, and ranges south through Oceania to
35 Australasia. *Helicoverpa assulta* appears mainly to attack members of the Solanaceae, including
36 *Nicotiana* spp., *Datura stramonium*, *Solanum lycopersicum*, *S. melongena*, *Capsicum annum*, and
37 *Physalis* spp.; other hosts are *Cucurbita moschata* (Cucurbitaceae), *Zea mays* (Poaceae), *Crocasmia* sp.
38 (Iridaceae), *Perilla* sp. (Labiatae), *Vigna unguiculata* and *Pisum sativum* (Fabaceae), and *Piper* sp.
39 (Piperaceae) (Zhang 1994; Robinson et al. 2001; CABI 2006).

1 Fecundity ranging from 423 to 505 eggs per female has been reported, and may be influenced by host
2 plant (Nandihalli and Lee 1995a). Up to three generations per year have been reported in Japan (CABI
3 2006). *Helicoverpa* spp. (e.g., *H. zea*) are strong fliers, and may disperse long distances (Metcalf and
4 Metcalf 1993). Larvae of *H. assulta* may be moved internationally in infested commodities. The pest has
5 been intercepted at U.S. ports on at least 21 occasions, most commonly on cut flowers (PIN 309a).
6 Damage is caused by larvae boring into the fruits of hosts, which not only causes direct damage, but also
7 may facilitate the entry of bacteria causing soft rots (Park et al. 1998a). In Korea, the moth is the most
8 serious insect pest of *Capsicum annuum* (Kim et al. 2002). Yields of *C. frutescens* were reduced 10 to
9 15% in the absence of control measures (Wei 1987). Rates of damage in unprotected tobacco crops
10 exceeded 23% (Nandihalli and Lee 1995b). The species also is reported to be a major pest of corn in
11 Indonesia (Chu 1979). Insecticidal applications are a prevalent control tactic (Yang et al. 2004), which
12 raises production costs and may impact non-target arthropods. The insect represents a potential threat
13 to crops in Hawai'i, such as cucurbits, eggplant, tomato, peppers, and corn. It is a quarantine pest for
14 New Zealand (PRF 2007), suggesting that its introduction could result in the loss of that market, as well
15 as domestic markets, for Hawai'ian agricultural products. Outbreaks on crops in Hawai'i could trigger
16 biological or chemical control programs, similar to those that have been initiated against the pest
17 elsewhere (e.g., Hirai et al. 1996; Yang et al. 2004). *Helicoverpa assulta* also represents a potential threat
18 to the endangered, native Hawai'ian plants, *Vigna o-wahuensis*, *Solanum incompletum*, and *S.*
19 *sandwicense*.

20 **A21.1.20 *Hemiberlesia diffinis* (Newstead) (Homoptera: Diaspididae)**

21 This is a tropical species, known from Central and South America, and the Caribbean (Miller and
22 Davidson 1998). Plants in at least 20 families have been recorded as hosts of *H. diffinis*, including
23 *Psidium guajava* (Myrtaceae), *Persea* sp. (Lauraceae), *Prunus domestica* (Rosaceae), *Cocos* sp.
24 (Arecaceae), *Hibiscus* sp. (Malvaceae), *Manihot* sp. (Euphorbiaceae), *Theobroma* sp. (Sterculiaceae),
25 *Nerium oleander* (Apocynaceae), *Ficus* sp. (Moraceae), and *Punica* sp. (Punicaceae) (Miller and Davidson
26 1998; Ben-Dov et al. 2006). At least some hosts recorded in the United States (e.g., Nakahara 1982)
27 apparently should be considered those of a closely related species, *H. neodiffinis* Miller and Davidson,
28 which is strictly temperate in distribution and with which *H. diffinis* has long been confused (Miller and
29 Davidson 1998).

30 No information is available concerning the biology or ecology of *H. diffinis*. The reproductive potentials
31 of related species, such as *H. rapax* (Comstock), *H. lataniae* (Signoret), and *H. pitysophila* Takagi, vary,
32 with fecundities ranging between 6 and 30 to 50 eggs per female with generations numbering from 2 to
33 6 or more per year, depending on latitude (Kosztarab 1996; CABI 2006). If the reproductive biology of *H.*
34 *diffinis* is similar, a high reproductive potential for this species may be indicated. Long-distance dispersal
35 may be accomplished on plant materials transported in trade, as evidenced by several interceptions of
36 *Hemiberlesia* spp., including *H. diffinis*, on various fruits in cargo (PIN 309a). *Hemiberlesia diffinis* is
37 considered a minor pest of guava (Gould and Raga 2002). The scale is a potential threat to avocado and
38 guava production in Hawai'i, and has the potential to attack plants of aesthetic value, such as coconut
39 and oleander (Neal 1965), as well as the endemics, *Hibiscus arnottianus* ssp. *immaculatus*, *H.*
40 *brackenridgei*, *H. clayi*, and *H. waimeae* ssp. *hannerae*, listed as endangered in 50 CFR § 17.12. Its

1 introduction also could stimulate the initiation of biological control programs, similar to what has
2 occurred in response to the introduction of numerous other invasive diaspidid scales (e.g., Rosen and
3 DeBach 1978).

4 **A21.1.21 *Icerya aegyptiaca* (Douglas) (Homoptera: Margarodidae)**

5 The geographic distribution of *I. aegyptiaca* is tropical to subtropical. Its range extends from Africa
6 (Egypt, Kenya, Zanzibar), eastward through the Middle East (Israel, Yemen), South, Southeast, and East
7 Asia (China, Japan, Taiwan), and south through the Pacific to Australia (Ben-Dov et al. 2006). This species
8 is highly polyphagous. Hosts include *Artocarpus* spp. and *Ficus* spp. (Moraceae), *Annona* spp.
9 (Annonaceae), *Citrus* spp. (Rutaceae), *Cocos nucifera* and *Phoenix dactylifera* (Arecaceae), *Pandanus*
10 *odoratissimus* (Pandanaeae), *Mangifera indica* (Anacardiaceae), *Achras sapota* (Sapotaceae), *Eugenia*
11 spp., *Psidium guajava*, and *P. cattleianum* (Myrtaceae), *Solanum* spp. (Solanaceae), *Acacia* spp. and
12 *Vigna marina* (Fabaceae), *Euphorbia* sp. (Euphorbiaceae), *Hibiscus* sp. (Malvaceae), *Ochrosia* spp.
13 (Apocynaceae), *Casuarina equisetifolia* (Casuarinaceae), *Carica papaya* (Caricaceae), *Punica granatum*
14 (Punicaceae), *Zea mays* (Poaceae), *Musa* spp. (Musaceae), *Scaevola* spp. (Goodeniaceae), *Bidens pilosa*
15 (Asteraceae), *Malus pumila* (Rosaceae), *Dodonaea viscosa* (Sapindaceae), *Plumbago capensis*
16 (Plumbaginaceae), *Tectona grandis* (Verbenaceae), *Vitis vinifera* (Vitaceae) (Ben-Dov et al. 2006); *Piper*
17 *nigrum* (Piperaceae), *Persea americana* (Lauraceae), *Coffea* spp. (Rubiaceae), *Colocasia esculenta*
18 (Araceae) (CABI 2006); *Ipomoea tuba* (Convolvulaceae) (Williams and Watson 1990); and *Camellia*
19 *sinensis* (Theaceae) (Gentry 1965).

20 Depending on temperature, mean fecundity has been reported to range from 70 to 143 (maximum: 247)
21 eggs per female; there are at least two generations per year (Azab et al. 1968). Females are largely
22 sedentary, moving only when disturbed; long distance dispersal is accomplished on infested fruit,
23 cuttings, and leaves of hosts (CABI 2006). *Icerya aegyptiaca* has been reported to be a serious pest of
24 citrus, fig, and shade trees in Egypt, although it is now largely controlled by natural enemies (CABI 2006).
25 It also is a pest of breadfruit, avocado, banana, citrus, and ornamentals in the South Pacific; annona,
26 jackfruit, sapote (*Pouteria sapota*), mulberry, and guava in India; and breadfruit in the Maldives Islands.
27 Its status in relation to these hosts in Hawai'i likely would be the same. Damage to the plant is caused by
28 sap depletion; shoots dry up and die, and defoliation occurs (Waterhouse 1993a). In addition, copious
29 quantities of honeydew are produced by the scales, which may foster the growth of sooty molds over
30 the surfaces of leaves, reducing photosynthesis. Heavy infestations of breadfruit on Pacific atolls have
31 been reported to kill even mature trees, but, more often, trees are partially defoliated, reducing crop
32 yields, sometimes by 50 to 100%. Introduction of *I. aegyptiaca* could result in a loss of foreign, as well as
33 domestic, markets for Hawai'ian-grown agricultural commodities. The scale is a quarantine pest for
34 several countries other than the United States, including Syria, French Polynesia, Chile, and Korea (PRF
35 2007). As it represents a potential threat to several plants that are culturally or economically important
36 to Hawai'i, including *Pandanus tectorius* (hala), taro, citrus, mango, papaya, breadfruit, palms, koa,
37 avocado, and banana, its introduction could result in the initiation of biological control programs, which
38 have proved successful against it elsewhere (Waterhouse 1993a). The scale also poses a threat to listed
39 (50 CFR § 17.12) endemic plants in Hawai'i, such as *Scaevola coriacea* (dwarf naupaka), *Eugenia*
40 *koolauensis*, *Solanum incompletum* and *S. sandwicense*, *Vigna o-wahuensis*, *Euphorbia haeleleana*

1 (akoko), *Ochrosia kilaueaensis*, *Bidens micrantha* ssp. kalealaha (kookoolau) and *B. wiebkei* (kookoolau),
2 and *Hibiscus arnottianus* ssp. immaculatus, *H. brackenridgei*, *H. clayi*, and *H. waimeae* ssp. hanneriae.

3 **A21.1.22 *Lobesia aeolopa* Meyrick (Lepidoptera: Tortricidae)**

4 The geographic distribution of this widespread species extends across four biogeographic regions: the
5 Ethiopian, Palearctic, Oriental (Razowski 2000), and Australasian (Robinson et al. 2007), from the cold
6 temperate zone to the tropics. Countries where it is reported to occur include: in Africa–Kenya,
7 Madagascar, Uganda, and Zimbabwe; in Asia–China, India, Indonesia, Japan, Korea, Malaysia, Sri Lanka,
8 Taiwan, and Thailand; and in Australasia–New Guinea and Norfolk Island (Zhang 1994; Smithers 1998;
9 Hua 2005; Robinson et al. 2007). *Lobesia aeolopa* has been recorded on a wide range of plants in several
10 families, among which are some of economic and ecological importance to Hawai'i. Hosts include
11 *Diospyros kaki* (Ebenaceae), *Hibiscus* sp. (Malvaceae), *Quercus acutissima* (Fagaceae), *Prunus yedoensis*
12 (Rosaceae), *Solidago canadensis* and *Vernonia* sp. (Asteraceae), *Caesalpinia* sp. (Fabaceae), *Actinidia*
13 *chinensis* (Actinidiaceae), *Citrus* sp. (Rutaceae), *Camellia sinensis* and *Ternstroemia gymnanthera*
14 (Theaceae), *Coffea arabica* (Rubiaceae), *Ilex integerrima* (Aquifoliaceae), *Litchi chinensis* (Sapindaceae),
15 *Mangifera indica* (Anacardiaceae), *Melochia* spp. (Sterculiaceae), *Lantana camara* (Verbenaceae),
16 *Ricinus communis* (Euphorbiaceae), *Lindera* sp. (Lauraceae), *Ulmus parvifolia* (Ulmaceae), *Vitis* spp.
17 (Vitaceae), *Zea mays* (Poaceae) (Robinson et al. 2007); and *Eucalyptus* spp. (Myrtaceae) (Nasu et al.
18 2004).

19 No information is available on the reproductive biology of *L. aeolopa*. In the related species, *L. botrana*
20 (Denis and Schiffermüller), fecundity may exceed 300 eggs per female; there may be four generations
21 per year (Avidov and Harpaz 1969). If reproduction in *L. aeolopa* is similar, its biotic potential could be
22 high. The occurrence of the species in remote areas, such as Norfolk Island (Smithers 1998),
23 demonstrates its capacity to disperse over long distances. Little information is available on the economic
24 impact of *L. aeolopa*. It is reported to be a pest of eucalyptus (Nasu et al. 2004) and tea (Sonan 1939) in
25 Japan; although, in the latter case, damage was said to be slight. Plant reproductive organs, as well as
26 leaves, are attacked. Larvae have been found in fruit of *Leucas cephalotes*, *Lantana camara*, and coffee
27 (van der Geest et al. 1991; Robinson et al. 2001), which would lower yields. As the species is a
28 quarantine pest for South Africa (DEAT 2005), its introduction could result in a loss of that market for
29 Hawai'ian-grown commodities, such as lychee, mango, and corn. *Lobesia aeolopa* has the potential to
30 attack endemic plants in Hawai'i listed as endangered or threatened (50 CFR § 17.12), and which are
31 close relatives of its known hosts, such as *Hibiscus arnottianus* ssp. immaculatus, *H. brackenridgei*, *H.*
32 *clayi*, and *H. waimeae* ssp. hanneriae, and *Caesalpinia kavaiense* (uhiuhi). As a potential pest of corn, its
33 introduction could result in the initiation of chemical control programs; insecticidal use is common in
34 that crop throughout the United States (Wright and Van Duyn 1999). Other management options might
35 include biological control programs, which have proven effective against other tortricid pests in the
36 United States and elsewhere (Clausen 1978c).

37 **A21.1.23 *Lobesia botrana* (Denis & Schiffermüller) (Lepidoptera: Tortricidae)**

38 This moth is widespread in Europe (ranging as far north as Germany), occurs in Africa as far south as
39 Kenya, and ranges through the Near East into central Asia; its distribution in East Asia is restricted to

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 Japan, where it occurs on all of the main islands (Whittle 1985). Disjunct populations have been
2 reported from the south Pacific (Samoa and Tuvalu; Hopkins 1927). Although polyphagous, *L. botrana*
3 prefers *Vitis* spp. (Vitaceae) (Whittle 1985; CABI 2006). Other hosts include *Berberis vulgaris*
4 (Berberidaceae), *Clematis vitalba* (Ranunculaceae), *Galium mollugo* (Rubiaceae), *Olea europaea*
5 (Oleaceae), *Prunus* and *Rubus* spp. (Rosaceae), *Rhus glabra* (Anacardiaceae), *Ribes* spp.
6 (Grossulariaceae), *Silene vulgaris* (Caryophyllaceae), *Solanum tuberosum* (Solanaceae), *Medicago sativa*
7 and *Trifolium pratense* (Fabaceae), *Ziziphus jujuba* (Rhamnaceae) (Whittle 1985); *Actinidia chinensis*
8 (Actinidiaceae), *Dianthus* sp. (Asteraceae), *Diospyros kaki* (Ebenaceae) (CABI 2006); *Hypericum*
9 *calycinum* (Hypericaceae), and *Punica granatum* (Punicaceae) (Robinson et al. 2001).

10 Fecundity may exceed 300 eggs per female; a maximum of four generations per year has been recorded
11 (Avidov and Harpaz 1969). Mobility of adults apparently is limited. Schmitz et al. (1996) found dispersal
12 of virgin females within vineyards rarely to exceed 80 meters. However, larvae may be moved long
13 distances within fruit in baggage or cargo; the moth has been intercepted at U.S. ports-of-entry more
14 than 80 times since 1975 (Whittle 1985; PIN 309a). *Lobesia botrana* is an important pest of grape, in
15 which losses of 80% have been reported (Whittle 1985). Apart from the direct impact of larval feeding or
16 tunneling, a major contributor to yield loss is infection of damaged berries by opportunistic saprophytes
17 or pathogens, particularly *Botrytis cinerea* (Roehrich and Boller 1991; CABI 2006). Further losses stem
18 from the time and labor spent in cleaning grape bunches of the silk webbing and feces deposited by
19 larvae, which may account for 30 to 40% of the harvesting effort (Avidov and Harpaz 1969). In
20 viticulture, the damage caused, particularly fungal contamination, interferes with the wine-making
21 process and may result in a product of low quality (Rousseau et al. 2005). *Lobesia botrana* thus
22 represents a potential threat to Hawai'i's growing winemaking industry (e.g., Shimabukuro 2004).
23 Damage to other fruit crops, such as persimmon and pome and stone fruit, may be significant (Ben-
24 Yehuda et al. 1999), and may result from larvae feeding and developing within fruit (e.g., Maison and
25 Pargade 1967). The species is a quarantine pest for South Africa, Brazil, China, Egypt, Jordan, Paraguay,
26 Uruguay, Argentina, Canada, and Chile (EPPO 2005a; PRF 2007), suggesting that its introduction could
27 result in a loss of domestic or foreign markets for Hawai'ian-grown fruits. Because it is known to feed on
28 close relatives of plants listed as threatened or endangered in Hawai'i, *L. botrana* represents a potential
29 threat to *Silene alexandri*, *S. hawaiiensis*, *S. lanceolata*, and *S. perlmanii*, and *Solanum incompletum* and
30 *S. sandwicense*. As the moth is a pest of grape and other fruit crops, its introduction could result in the
31 inauguration of biological control programs, which have proven effective against other tortricid pests in
32 the United States and elsewhere (Clausen 1978c).

33 **A21.1.24 *Mamestra brassicae* (L.) (Lepidoptera: Noctuidae)**

34 This species occurs throughout Europe, ranging into temperate and subtropical Asia, and northern Africa
35 (Carter 1984). *Mamestra brassicae* is highly polyphagous, attacking crops in several families, including
36 Brassicaceae (particularly varieties of *Brassica oleracea*), Asteraceae (*Lactuca sativa*, *Chrysanthemum*
37 sp.), Chenopodiaceae (*Beta vulgaris*), Fabaceae (*Pisum sativum*, *Phaseolus vulgaris*), Liliaceae (*Allium*
38 *sativum*), Solanaceae (*Solanum lycopersicum*, *S. tuberosum*, *Nicotiana tabacum*), Rosaceae (*Prunus*
39 *persica*), Caryophyllaceae (*Dianthus caryophyllus*), Poaceae (*Zea mays*), Vitaceae (*Vitis vinifera*),
40 Fagaceae (*Quercus* sp.), and Polygonaceae (*Rheum* sp.) (Carter 1984; Zhang 1994; CABI 2006). Although

1 brassicas are said to be the most preferred hosts (CABI 2006), Rojas et al. (2001) found no significant
2 difference in the mean number of eggs deposited on cabbage and tomato by females in choice tests.

3 Fecundity averages 500 to 1,500 eggs per female; there may be three generations per year (CABI, 2006).
4 Adults are said to be “sedentary” (Bues et al. 1988) and “non-migratory” (Poitout and Bues 1976),
5 indicating a low natural potential for long-distance dispersal. However, the pest has been intercepted at
6 U.S. ports on more than 1,100 occasions on various commodities in cargo (PIN 309a), indicating its
7 potential to move long distances rapidly by human agency. *Mamestra brassicae* is considered to be a
8 serious pest of many crops, in which even small larval populations may be quite damaging (Hill 1987).
9 Damage is caused by larvae defoliating and tunneling into the interiors of plants or plant organs,
10 including fruits, such as apple and tomato (Carter 1984; CABI 2006). Feeding damage of 50% has been
11 recorded in sugar beet (Onodera 1998). Cabbage crops may suffer losses of up to 80% (CABI 2006).
12 Under certain cropping systems, damage may be too great to produce a commercially viable cabbage
13 crop (Brandsaeter et al. 1998). Control typically involves the application of insecticides (Steene 1995;
14 Beltrami et al. 2004), which increases costs of production. As the moth is a quarantine pest for New
15 Zealand, the former states of Yugoslavia, and Southern Africa (EPPO 2005a; PRF 2007), its introduction
16 could result in a loss of foreign, as well as domestic, markets for Hawai’i agricultural commodities, such
17 as tomato, cabbage, and corn. Introduction into Hawai’i also could result in the initiation of biological
18 control programs, as has occurred elsewhere (e.g., Rost 1997), and could put at risk endangered, native
19 plants, such as *Solanum incompletum* and *S. sandwicense*.

20 **A21.1.25 *Parlatoria blanchardi* (Targioni Tozzetti) (Homoptera: Diaspididae)**

21 This scale is widespread in tropical and subtropical areas of Europe, Asia, and Africa (Watson 2005; Ben-
22 Dov et al. 2006). It also occurs in South America (Argentina, Bolivia, Brazil), parts of the Caribbean, and
23 Australia. Hosts are predominantly species of palms (Arecaceae), such as *Hyphaene thebiaca*, *Latania*
24 *sp.*, *Neowashingtonia sp.*, *Phoenix spp.*, *Pritchardia filifera*, and *Washingtonia filifera*, but the insect has
25 been recorded on plants in other families, such as *Vinca major* (Apocynaceae), *Jasminum spp.*
26 (Oleaceae), and *Ziziphus mauritiana* (Rhamnaceae) (Ben-Dov et al. 2006).

27 Fecundity averages about 10 eggs per female, with a maximum of 29 recorded (Howard 2001). There are
28 three to five overlapping generations annually (Watson 2005). Dispersal of this species may occur locally
29 via wind, birds, or insects, or long distances in the transport of infested plants. High scale densities
30 towards the end of the season may result in infestation of fruit just prior to harvest (Howard 2001), also
31 facilitating spread. The scale was introduced into the United States in 1890 on date palm offshoots from
32 Algeria and Egypt, but later eradicated (Carpenter and Elmer 1978). Since 1984, it has been intercepted
33 at U.S. ports on more than 1,300 occasions (PIN 309a). Howard (2001) and Watson (2005) summarized
34 the damage caused by this pest. Heavy infestations weaken the tree by increasing transpiration,
35 depleting nutrients and destroying chlorophyll, thus impairing photosynthesis and productivity. Feeding
36 on fronds causes necrosis of tissues and dieback. Heavily infested offshoots become stunted; attacked
37 fruit shrivels, resulting in downgrading or rejection. Yield losses as high as 70 to 80% have been
38 reported. Palms 5 to 10 years of age may be killed outright. *Parlatoria blanchardi* is the most serious
39 insect pest of date palm, *Phoenix dactylifera*, in Australia, and has been a factor in hindering the

1 development of a significant date industry in that country (Knihinicki and Flechtmann 1999). The scale
2 poses a threat to various ornamental palms in Hawai'i, which are important aesthetically and otherwise
3 to the state (Neal 1965). It also represents a potential threat to Hawai'i's endangered (50 CFR § 17.12),
4 native *Pritchardia palms* (loulou, wahane). Its introduction could spur the initiation of chemical or
5 biological control programs, as has occurred elsewhere (Carpenter and Elmer 1978).

6 **A21.1.26 *Planococcus lilacinus* (Cockerell) (Homoptera: Pseudococcidae)**

7 This tropical species ranges from South Asia through Southeast and East Asia into Melanesia and some
8 of the other island groups (Marianas, Carolines) of the Pacific. It occurs in East Africa, and has a limited
9 distribution in the Americas (CABI 1995; Ben-Dov et al. 2006). It is reported from Fujian and Guangxi in
10 China, and is established in Taiwan (Hua 2000). The host range of *P. lilacinus* includes species in at least
11 35 families, including *Mangifera indica* (Anacardiaceae), *Annona* spp. (Annonaceae), *Cordia myxa*
12 (Boraginaceae), *Rhododendron* sp. (Ericaceae), *Euphorbia pyriformis* (Euphorbiaceae), *Arachis hypogaea*
13 and *Erythrina* spp. (Fabaceae), *Artocarpus* spp. (Moraceae), *Psidium guajava* and *Eugenia* spp.
14 (Myrtaceae), *Citrus* spp. (Rutaceae), *Pandanus* sp. (Pandanaeae), *Cocos nucifera* (Arecaceae), *Gardenia*
15 *jasminoides* (Rubiaceae), *Litchi* sp. (Sapindaceae), *Punica granatum* (Punicaceae), *Zizyphus jujuba*
16 (Rhamnaceae), *Manilkara zapota* (Sapotaceae), *Solanum* spp. (Solanaceae), *Theobroma cacao*
17 (Sterculiaceae), *Vitis vinifera* (Vitaceae) (Ben-Dov et al. 2006); and *Santalum album* (Santalaceae)
18 (Rostaman 1997).

19 Fecundity has been reported to range from 55 to 152 eggs per female (Loganathan and Suresh 2001).
20 Two or three generations per year have been suggested (Ooi et al. 2002). Similar to other species of
21 Coccoidea (scale insects) (Gullan and Kosztarab 1997), local dispersal would be accomplished by newly
22 emerged crawlers. Longer-distance movement would be effected via the transport of infested plant
23 materials. The mealybug has been introduced accidentally into continental Africa within the past three
24 decades (Williams et al. 2001). Since 1984, *P. lilacinus* has been intercepted on various commodities at
25 U.S. ports on almost 1,700 occasions (PIN 309a). *Planococcus lilacinus* is a serious pest of various fruit
26 and other crops in Asia, including guava, lemon, ber, pomegranate, lychee, coffee, and cocoa (Williams
27 2004). Infestations in citrus and coffee result in premature fruit drop and heavy losses in the latter crop.
28 Feeding in coconut palm results in drying of the inflorescence and button shedding (Moore 2001). The
29 mealybug also transmits a cocoa virus in Sri Lanka (Schmutterer 1977). It has been reported to infest
30 fruit for sale in southern Asia (Williams et al. 2001). Infested fruit may be downgraded in quality or
31 become unmarketable (Ooi et al. 2002). In India, insecticides are applied to control the mealybug in
32 coffee (Williams 2004), a practice that increases production costs. Miller et al. (2002) considered the
33 species to be a major threat to U.S. agriculture. As it is a quarantine pest for Paraguay, Uruguay,
34 Argentina, Brazil, Korea, and southern Africa (EPPO 2005a; PRF 2007), its introduction could result in a
35 loss of domestic or foreign markets for Hawai'i crops, such as mango, eggplant, *Annona* spp., and lychee.
36 Other valued plants, such as hala, coconut, and *Erythrina sandwicensis* (wiliwili) (Neal 1965), potentially
37 could be at risk. This pest poses a potential threat to listed native plants in Hawai'i, such as *Eugenia*
38 *koolauensis*, *Euphorbia haeleleana*, *Gardenia brighamii* (nau) and *G. mannii* (nanu), *Santalum*
39 *freycinetianum* var. *lanaiense*, and *Solanum incompletum* and *S. sandwicense*. Its introduction could

1 result in the initiation of biological control programs, similar to what has occurred elsewhere (e.g., India;
2 Reddy et al. 1992).

3 **A21.1.27 *Planococcus minor* (Maskell) (Homoptera: Pseudococcidae)**

4 This mealybug ranges from South Asia, through parts of Southeast and East Asia (Taiwan), and into
5 several island groups of the South Pacific to Australia (Ben-Dov et al. 2006). It also is widespread in
6 South America (from southern Argentina to Guyana), southern North America (Costa Rica, Guatemala,
7 Honduras, Mexico), and the Caribbean. The species is extremely polyphagous, having been recorded on
8 plants in at least 69 families (Ben-Dov et al. 2006). Hosts include *Colocasia esculenta* (Araceae), *Abutilon*
9 sp. and *Hibiscus* spp. (Malvaceae), *Solanum* spp. (Solanaceae), *Harrisia portoricensis* (Cactaceae),
10 *Theobroma cacao* (Sterculiaceae), *Citrus* spp. (Rutaceae), *Coffea* spp. and *Gardenia jasminoides*
11 (Rubiaceae), *Mangifera indica* (Anacardiaceae), *Musa* spp. (Musaceae), *Cyperus rotundus* (Cyperaceae),
12 *Cordia alliodora* (Boraginaceae), *Eugenia* spp. and *Psidium guajava* (Myrtaceae), *Vitis vinifera* (Vitaceae),
13 *Ziziphus* sp. (Rhamnaceae), *Amaranthus* sp. (Amaranthaceae), *Annona* spp. (Annonaceae), *Helianthus* sp.
14 and *Bidens pilosa* (Asteraceae), *Euphorbia* spp. and *Manihot esculenta* (Euphorbiaceae), *Persea*
15 *americana* (Lauraceae), *Ipomoea* spp. (Convolvulaceae), *Brassica* spp. (Brassicaceae), *Cucurbita* spp.
16 (Cucurbitaceae), *Zea mays* (Poaceae), *Arachis hypogaea* and *Erythrina* sp. (Fabaceae), *Artocarpus* spp.
17 (Moraceae), *Cocos nucifera* (Arecaceae), *Pandanus* spp. (Pandanaceae), *Pyrus pyrifolia* (Rosaceae), and
18 *Asparagus plumosus* (Liliaceae).

19 Reported fecundity ranges from about 200 to over 500 eggs per female, depending on host plant; there
20 may be as many as 10 generations per year (Maity et al. 1998; Martinez and Suris, 1998; Sahoo et al.,
21 1999). As in other species of Coccoidea (Gullan and Kosztarab 1997), local dispersal would be
22 accomplished by newly emerged crawlers. Longer-distance movement would be effected via the
23 transport of infested plant materials. The mealybug has been intercepted in Japan in shipments of
24 banana fruit from the Philippines (Sugimoto 1994). It has been intercepted at U.S. ports on more than
25 4,400 occasions on commodities from various countries (PIN 309a). *Planococcus minor* is an important
26 pest of coffee in India (Reddy et al. 1997). It is a pest of durian (*Durio zibethinus*) in Thailand, causing
27 loss of yield and reduction in market value (Anonymous 2003). Infestations in other fruits may result in a
28 downgrading of quality or unmarketable fruit (Ooi et al. 2002). The mealybug is a vector of banana
29 streak virus in Cuba (González et al. 2002). Insecticidal applications provide good control of the
30 mealybug (e.g., Shukla and Tandon 1984), but increase crop production costs. Miller et al. (2002)
31 considered the species to be a major threat to U.S. agriculture. As it is a quarantine pest for Korea (PRF
32 2007), introduction of *P. minor* into Hawai'i could result in the loss of that market for important crops,
33 such as mango, avocado, banana, and cucurbits. Because it is known to feed on closely related hosts, the
34 mealybug is a potential threat to listed native plants in Hawai'i, such as *Amaranthus brownii*, *Hibiscus*
35 *arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *H. clayi*, and *H. waimeae* ssp. *hanneriae*, *Solanum*
36 *incompletum* and *S. sandwicense*, *Bidens micrantha* ssp. *kalealaha* and *B. wiebkei*, *Abutilon*
37 *eremitopetalum*, *A. menziesii*, and *A. sandwicense*, *Eugenia koolauensis*, *Euphorbia haeleleana*,
38 *Gardenia brighamii* and *G. mannii*, and *Cyperus trachysanthos* (puukaa). Because it represents a
39 potentially serious threat to economically or aesthetically valuable crops (e.g., avocado, banana, citrus,
40 coffee, mango, guava, hala, wiliwili, coconut, corn, brassicas, cucurbits), its introduction likely would

1 spur the initiation of control programs. It has been the target of a biological control program in India
2 (Reddy et al, 1997); other species of *Planococcus* have been targeted for biological control in the United
3 States and elsewhere (Bartlett 1978).

4 **A21.1.28 *Pseudaonidia trilobitiformis* (Green) (Hemiptera: Diaspididae)**

5 This scale occurs primarily in subtropical and tropical regions of Australasia, the Orient, Africa, Central
6 and South America, the Caribbean, and Florida in the United States, but also has been reported from
7 more temperate areas, such as the Republic of Georgia and Japan (Ben-Dov et al. 2006). It is extremely
8 polyphagous, having been recorded on plants in at least 47 families (Ben-Dov et al. 2006). Hosts include
9 *Agave mexicana* (Agavaceae), *Mangifera indica* (Anacardiaceae), *Carica papaya* (Caricaceae), *Diospyros*
10 *kaki* (Ebenaceae), *Quercus* sp. (Fagaceae), *Persea americana* (Lauraceae), *Hibiscus* sp. (Malvaceae),
11 *Artocarpus* spp. (Moraceae), *Punica granatum* (Punicaceae), *Coffea* spp. (Rubiaceae), *Litchi sinensis*
12 (Sapindaceae), *Psidium guajava* and *Eugenia* spp. (Myrtaceae), *Cocos nucifera* (Arecaceae), *Ziziphus*
13 *spina-christi* (Rhamnaceae), *Citrus* spp. (Rutaceae), *Santalum austro-caledonicum* (Santalaceae),
14 *Capsicum* spp. (Solanaceae), *Prunus domestica* (Rosaceae), and *Vitis vinifera* (Vitaceae).

15 No information is available on the biology of the scale. A related species, *P. duplex* (Cockerell), exhibits
16 three generations per year in Louisiana; fecundity of *P. paeoniae* (Cockerell), also known from the
17 southern United States, ranges from 30 to 50 eggs per female (Kosztarab 1996). If the biology of *P.*
18 *trilobitiformis* is similar, its reproductive potential could be high. Long-distance dispersal of *P.*
19 *trilobitiformis* likely is accomplished by transport on infested plant materials, as evidenced by numerous
20 interceptions of the species at U.S. ports (PIN 309a). *Pseudaonidia trilobitiformis* is regarded as a minor
21 pest of avocado, cacao, citrus, coconut, coffee, mango, and passion fruit (Hill 1983). The scale is a pest of
22 cashew in Brazil, requiring treatment with insecticides for its control (Silva et al. 1977), which increases
23 costs of production and may impact non-target species. It is a quarantine pest for Korea and New
24 Zealand (PRF 2007), suggesting that its introduction into Hawai'i could result in a loss of domestic or
25 foreign markets for commodities, such as mango, papaya, avocado, and lychee. *Pseudaonidia*
26 *trilobitiformis* has the potential to attack plants listed as endangered or threatened in Hawai'i, such as
27 *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *H. clayi*, and *H. waimeae* ssp. *hannerae*, and
28 *Eugenia koolauensis*. Since it poses a potential threat to citrus and other economically important crops,
29 its introduction into Hawai'i could stimulate the initiation of biological control programs, similar to those
30 that have occurred in response to the introduction of other diaspidid scales (e.g., Rosen and DeBach
31 1978).

32 **A21.1.29 *Tetranychus lambi* Pritchard & Baker (Acari: Tetranychidae)**

33 With the exception of two disjunct populations reported from Asia (Iran and Taiwan), the geographic
34 range of *T. lambi* is restricted to islands of the South Pacific, Australia, and New Zealand (Bolland et al.
35 1998). This polyphagous species has been recorded on plants in several families. Hosts include *Abutilon*
36 *tubulosum* (Malvaceae), *Acaena* sp. and *Prunus persica* (Rosaceae), *Euphorbia* sp. and *Manihot esculenta*
37 (Euphorbiaceae), *Arenga engleri* (Arecaceae), *Aspidistra* sp. (Liliaceae), *Calathea crocata* (Marantaceae),
38 *Carica papaya* (Caricaceae), *Galactia tenuiflora* (Fabaceae), *Colocasia esculenta* (Araceae), *Cucurbita*
39 spp. (Cucurbitaceae), *Goodenia ovata* (Goodeniaceae), *Homalocladium platycladum* (Polygonaceae),

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 *Lobelia heterophylla* (Campanulaceae), *Morus alba* (Moraceae), *Musa* spp. (Musaceae), *Solanum*
2 *melongena* (Solanaceae), *Oxalis* spp. (Oxalidaceae), *Panicum maximum* (Poaceae), *Poncirus trifoliata*
3 (*Rutaceae*), *Quercus alba* (Fagaceae), and *Stephania japonica* (Menispermaceae) (Bolland et al. 1998).

4 Bonato and Gutierrez (1999) reported mean fecundity in a population reared on green bean, *Phaseolus*
5 *vulgaris*, to be approximately 134 eggs per female. The calculated net replacement rate (the number of
6 times a population increases in a generation) was 69.5, indicating considerable biotic potential. In
7 Australia, there are said to be many overlapping generations annually (Pinese and Elder 2004). As in all
8 spider mites (Tetranychidae), long-distance dispersal occurs by wind-borne individuals and in the
9 movement of infested plant materials (Jeppson et al. 1975). Little information is available on the
10 economic importance of *T. lambi*. It is considered a major pest of agriculture in much of the southern
11 and western Pacific (Waterhouse 1997). It is one of three spider mites that are significant pests of cotton
12 in Australia, causing bronzing and desiccation of leaves (OGTR 2002). In banana, attack is concentrated
13 on leaves, although, in severe outbreaks, mites may move to the fruit (Gold et al. 2002). Feeding
14 produces areas of discoloration on the fruit surface that may later dry out and crack. As indicated by its
15 reported host range, *T. lambi* is a potential threat to economically or culturally important plants in
16 Hawai'i, such as papaya, taro, cucurbits, banana, and eggplant. The mite also is a potential threat to
17 endemic Hawai'ian plants, such as *Abutilon eremitopetalum*, *A. menziesii*, and *A. sandwicense*, *Acaena*
18 *exigua* (liliwai), *Euphorbia haeleeeleana*, *Lobelia gaudichaudii* ssp. *koolauensis*, *L. monostachya*, *L.*
19 *niihauensis*, and *L. oahuensis*, *Panicum fauriei* var. *carteri* and *P. niihauense* (lauehu), and *Solanum*
20 *incompletum* and *S. sandwicense*, all listed as endangered (50 CFR § 17.12). Its introduction into Hawai'i
21 could result in the initiation of biological control programs. Natural enemies of the pest are known (e.g.,
22 Chazeau 1983), and could prove effective at regulating its numbers.

23 **A21.1.30 *Unaspis yanonensis* (Kuwana) (Homoptera: Diaspididae)**

24 This armored scale is widespread in East and Southeast Asia, from Pakistan to Japan and south to
25 Indonesia (Ben-Dov et al. 2006). Adventive populations also occur in Armenia, Australia, Fiji, France, and
26 Italy. Hosts are predominantly Rutaceae, in particular, species of *Citrus* (e.g., *C. aurantium*, *C. deliciosa*,
27 *C. maxima*, *C. medica*, *C. natsudaidai*, *C. nobilis*), *Fortunella japonica*, and *Poncirus trifoliata*, but also
28 include *Damnacanthus* sp. (*Rubiaceae*) (Ben-Dov et al, 2006).

29 Fecundity averages 177 to 196 eggs per female; there are as many as three generations per year
30 (Blackburn and Miller 1984). Although *U. yanonensis* is said to have a low inherent dispersal potential
31 (CABI/EPPO 1997j), it has spread over long distances in the international movement of plant materials
32 (e.g., to southern France; Burger and Ulenberg 1990). The scale also has been intercepted at U.S. ports
33 on more than 2,800 occasions since 1984, mainly on citrus fruit (PIN 309a). *Unaspis yanonensis* is said to
34 do more damage to citrus crops in Japan than any other pest (Kukhtina 1970). Twigs, leaves, and fruits
35 may be heavily attacked, and severe infestations often result in the death of trees (Rosen and DeBach
36 1978). An inordinate amount of damage seems to be caused relative to the numbers of scales feeding
37 (Clausen, 1933). Feeding causes circular, yellowish blotches on leaves, eventually resulting in almost
38 total necrosis, and severe distortion of fruit (Blackburn and Miller 1984). Affected fruits lose their
39 commercial value (CABI/EPPO 1997j). *Unaspis yanonensis* is said to replace the closely related *U. citri* as

1 an important citrus pest in China, Taiwan, and Japan (Smith and Peña 2002). It thus is a potential threat
2 to *Citrus* spp. in Hawai'i, which not only are commercially important (NASS 2006a), but are valued as
3 ornamental and fruit trees in residential plantings (Neal 1965). The scale is a quarantine pest for Turkey,
4 Syria, Tunisia, Peru, Belarus, and East and southern Africa (EPPO 2005a; PRF 2007), suggesting that its
5 introduction could result in the loss of domestic or foreign markets for Hawai'ian-grown citrus. As *U.*
6 *yanonensis* represents a significant threat to citrus production, its introduction likely would result in the
7 initiation of chemical or biological control programs, similar to those that have occurred elsewhere. For
8 example, routine insecticidal applications have been required to control the pest in Japan and France
9 (Blackburn and Miller 1984). The scale is under apparently successful biological control in Japan (Rosen
10 1990).

11 **A21.2 PLANT PATHOGENS**

12 As indicated by the recent detection of the fungus, *Puccinia psidii* Winter (Urediniomycetes: Uredinales),
13 which produces a rust disease in the native myrtaceous plants, *Metrosideros polymorpha* (ohia lehua)
14 and the federally listed (50 CFR § 17.12) *Eugenia koolauensis* (Uchida et al. 2006), Hawai'i is vulnerable
15 to the introduction of potentially devastating invasive plant pathogens. The fungus causing ohia rust has
16 been established in Florida for many years (Burnett and Schubert 1985), and possibly entered Hawai'i on
17 plant material imported from that state. A sampling of pathogens that represent potential threats to
18 Hawai'i's plant resources is discussed below.

19 **A21.2.1 "Candidatus *Liberobacter asiaticum*" Jagoueix et al. (Alphaproteobacteria: 20 Rhizobiales)**

21 This bacterium exhibits a primarily Asian distribution, ranging from Saudi Arabia and Yemen in the west
22 to Taiwan and Japan (Ryukyu Islands) in the east (EPPO 2005d). It also occurs in Mauritius and Réunion
23 in Africa. Recently, it has been introduced into Florida (EPPO 2005b) and New Guinea (Davis et al. 2005).
24 Hosts are restricted to Rutaceae, and include *Citrus* spp. and *Fortunella* spp. (CABI/EPPO 1997d). Natural
25 infection of plants in other rutaceous genera (e.g., *Severinia*, *Feronia*) is said to be possible (Timmer et
26 al. 2000). *Liberobacter asiaticum* is spread from host to host by grafting or by an insect vector, the
27 psyllid, *Diaphorina citri* Kuwayama (Timmer et al. 2000; CABI 2006), which now occurs in Hawai'i (HDOA
28 2006). However, both graft- and insect-transmission apparently are not highly efficient. Graft-
29 transmission rates are variable because of the irregular distribution of the bacterium within hosts; most
30 vector-aided spread occurs when psyllid population densities are high and succulent growth is present
31 on both donor and receptor plants (Timmer et al. 2000). Moreover, some hosts may be more resistant
32 to the bacterium than others. For example, Schwartz et al. (1973) found that, even in areas of high
33 disease incidence, pummelo, lemon, and lime (*C. aurantiifolia*) crops maintained acceptable fruit yields
34 despite infection. Pummelo and lime are said to show some of the weakest symptoms among *Citrus* spp.
35 (CABI/EPPO 1997d). Rapid, long-distance dispersal would be facilitated most likely by the movement of
36 infected plant propagative material (CABI/EPPO 1997d). Its introduction into Florida and New Guinea
37 (where infected planting material was found; Davis et al. 2005) suggests that it is spread widely by
38 human agency.

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 This bacterium causes the disease known as greening or Huanglongbing (Timmer et al. 2000), which is
2 one of the most devastating diseases of citrus (Garnsey 1999). According to Garnsey, no other disease so
3 completely limits citrus production or is so difficult to control. Yield losses of 30 to 100% have been
4 reported, and the impact of the disease may be so severe that large areas of citrus cultivation must be
5 abandoned (CABI/EPPO 1997d). Chronically infected trees show extensive defoliation and twig dieback;
6 fruits tend to be undersized, misshapen, and poorly colored, often with a bitter taste (Timmer et al.
7 2000), and thus are likely to be of below-market quality. In South Africa, citrus trees routinely are
8 treated with antibiotics (CABI/EPPO 1997d), which increases production costs. As the pathogen is a
9 quarantine pest for countries, such as Argentina, Brazil, Chile, Jamaica, Korea, Paraguay, Uruguay, and
10 the European Union (EPPO 2005a; PRF 2007), its introduction could result in a loss of foreign, as well as
11 domestic, markets for Hawai’ian-grown citrus. Citrus also is valued in Hawai’i as an ornamental and fruit
12 tree in residential plantings (Neal 1965). Spread of the bacterium from Florida or Asia to Hawai’i could
13 have an indirect environmental impact, spurring the initiation of chemical or biological control programs
14 targeting its vector, *D. citri*, similar to what has occurred elsewhere (CABI 2006). The survival of Hawai’i’s
15 endemic *Trioza psyllids* (Zimmerman 1948) could thereby be jeopardized.

16 **A21.2.2 *Xanthomonas axonopodis* pv. *citri* (Hasse) Vauterin et al. (Gammaproteobacteria:
17 *Xanthomonadales*)**

18 This bacterium is widespread in tropical and subtropical Asia, ranging from Saudi Arabia in the west to
19 Taiwan and Japan in the east, and south to Indonesia (EPPO 2005e). It also occurs in New Guinea and
20 Australia, parts of Oceania, Africa, and South America, and in Florida, where it is under official control (7
21 CFR § 301.75-1). Natural hosts are species of Rutaceae, and include *Citrus* spp., *Poncirus trifoliata*,
22 *Fortunella* spp., *Severinia buxifolia*, and *Swinglea glutinosa* (Bradbury 1986; CABI/EPPO 1997k).

23 Of the several forms of the bacterium, the Asian strain (A strain) is the most virulent and polyphagous
24 (CABI/EPPO 1997k). Evidence suggests a high reproductive rate for the species. For example, following
25 initial infection and multiplication, bacteria may emerge from leaf stomatal openings in as few as 5 days
26 to provide inoculum for further disease development (Graham et al. 2004). In experimental citrus plots,
27 Gottwald et al. (1988) found infection to increase as much as 0.9% per day, suggesting a rather high
28 biotic potential. Natural spread of the pathogen is achieved locally through the transport of propagules
29 in rain splash and on the wind; longer-distance dispersal may be effected by severe storms, such as
30 tornadoes and hurricanes (Gottwald et al., 1997). The calculated maximal distance of natural spread
31 ranged from 12 m (39 feet) to 3.5 km (2 miles) over a 4-month period (Gottwald et al. 2002b).
32 Dissemination also may occur via the movement of infected propagative material and planting stock,
33 such as budwood and rootstock seedlings (CABI/EPPO 1997k), and probably has been the predominant
34 means of spread to other continents from the species’ presumed center of origin in tropical Asia (Das
35 2003). The pathogen has been intercepted at U.S. ports on more than 60 occasions since 1988 (PIN
36 309a).

37 Citrus canker, the disease caused by this pathogen, is considered one of the most damaging to
38 commercial citrus crops, affecting both the appearance and flavor of fruits (Anonymous 1982b).
39 Infection causes necrotic lesions on leaves, stems, and fruit; trees may suffer defoliation, badly

1 blemished fruit, secondary fruit rots, premature fruit drop, twig dieback, and general decline
2 (CABI/EPPO 1997k; Schubert and Sun 2003). For example, 83 to 97% of diseased fruit in grapefruit crops
3 has been reported; canker lesions may make fresh fruit unmarketable (Das 2003). In less severe cases,
4 lesions on fruit may reduce its market value (Timmer et al. 2000; Wang et al. 2004). Control measures
5 commonly include the application of copper-based bactericides (e.g., Graham et al., 2004), which may
6 significantly increase production costs. For example, Gottwald et al. (2002a) predicted that, should the
7 disease become endemic in Florida, the high costs of chemical and other controls might make
8 impossible the profitable cultivation of some of the more susceptible citrus species, such as grapefruit.
9 These authors also estimated that establishment of the pathogen would result in severe curtailment of
10 interstate and international trade in fresh fruit, which currently represents approximately 20% of the
11 state's \$9-billion commercial citrus industry. As the bacterium is a quarantine pest for numerous
12 countries, including Argentina, Ukraine, New Zealand, Peru, Chile, Turkey, Uruguay, Thailand, and the
13 European Union (EPPO 2005a; PRF 2007), Hawai'i's citrus exports could be similarly affected. Given the
14 importance of *Citrus* spp. as fruit and ornamental trees, the spread of *X. axonopodis* pv. *citri* to Hawai'i
15 could result in initiation or expansion of chemical control programs employing the copper-based
16 compounds typically used against crop-infecting bacteria (Timmer et al. 2000). Long-term use of these
17 bactericides may result in accumulation of high levels of copper in soils, with potential phytotoxic and
18 other environmental consequences (Graham et al. 2004). Although research is still in a preliminary
19 stage, the efficacy of biological control of citrus canker, involving the release of strains of bacterial
20 species antagonistic to *X. axonopodis* pv. *citri*, also has been considered (Das 2003).

21 **A21.2.3 *Guignardia citricarpa* Kiely (Ascomycetes: Dothideales)**

22 This fungus is thought to have originated in Southeast Asia, subsequently spreading to other tropical and
23 subtropical regions, including Australia, Africa, and South America (CABI/EPPO 1997f). In East Asia, the
24 fungus ranges from Zhejiang Province in China to Taiwan (EPPO 2005c). Potential global distribution
25 apparently is limited by cold and dry conditions (Paul et al. 2005). Hosts are principally or exclusively
26 species of *Citrus* (Rutaceae), including *C. maxima*, *C. sinensis*, *C. paradisi*, *C. limon*, *C. aurantiifolia*, and *C.*
27 *reticulata*; records of the fungus on non-citrus plants are considered doubtful, and may involve other
28 *Guignardia* species (CABI/EPPO 1997f; Farr et al. 2006). *Guignardia citricarpa* may be established in an
29 area for many years before symptoms of disease appear, and a further 5 to 30 years may pass until the
30 disease reaches epidemic proportions (Anonymous 1982a). Local spread within orchards occurs
31 primarily through the dissemination of ascospores in water and on the wind, whereas long-distance
32 dispersal is achieved by the movement of infected plant materials or nursery stock (CABI/EPPO 1997f).
33 The broad distribution of the fungus, showing establishment on four continents (EPPO 2005c), suggests
34 that it is readily dispersed via the international transport of citrus propagative material. It has been
35 intercepted on more than 6,300 occasions at U.S. ports on various citrus organs, including living plants,
36 from numerous countries (PIN 309a). Disease is caused by the anamorphic form of the fungus,
37 *Phyllosticta citricarpa* (McAlpine) van der Aa, which invades the fruit rind without harming the pulp
38 (Timmer et al. 2000). Characteristic symptoms involve the appearance of black spots on the fruit
39 surface, which range from 1 to 25 mm in diameter and may number more than 1,000; spots may
40 coalesce to affect most of the surface (Anonymous 1982a; Seymour and Burnett 1982). Severe infection
41 often causes premature fruit drop (Timmer et al. 2000). Losses exceeding 80% have been reported

1 (Seymour and Burnett 1982; CABI/EPPO 1997f). Affected fruits that mature to harvest-stage are
2 unmarketable as fresh fruit, and suitable only for lower value end uses, such as processing (Anonymous
3 1982a; Timmer et al. 2000). Ironically, although infection renders fruits unmarketable for cosmetic
4 reasons, it may improve their eating quality by making them sweeter (Anonymous 1988). The pathogen
5 is a quarantine pest for several countries, including Turkey, Peru, Uruguay, Chile, New Zealand, and the
6 European Union (PRF 2007), suggesting that its introduction could result in a loss of foreign, as well as
7 domestic, markets for Hawai'ian-grown citrus fruit.

8 **A21.2.4 *Helicobasidium mompa* Tanaka (Urediniomycetes)**

9 This fungus occurs in Asia (China, India, Indonesia, Japan, Korea, Malaysia, Taiwan) and Africa (Malawi,
10 South Africa, Uganda) (CABI 2006; Farr et al, 2006). It is known to attack at least 104 plant species in 44
11 families (Uetake et al. 2001). Hosts include *Asparagus officinalis* (Liliaceae), *Beta vulgaris*
12 (Chenopodiaceae), *Brassica oleracea* (Brassicaceae), *Citrus* sp. (Rutaceae), *Daucus carota* (Apiaceae),
13 *Diospyros kaki* (Ebenaceae), *Ficus* spp. (Moraceae), *Ipomoea batatas* (Convolvulaceae), *Glycine max*
14 (Fabaceae), *Pyrus* sp. (Rosaceae), *Sesamum orientale* (Pedaliaceae), *Solanum tuberosum* (Solanaceae),
15 *Gossypium* sp. (Malvaceae), *Camellia sinensis* (Theaceae) (Farr et al. 2006); *Vitis* sp. (Vitaceae) (Clark and
16 Moyer, 1988); and *Medicago sativa* (Fabaceae) (Sakuma et al. 1984).

17 This pathogen is dispersed in irrigation water and in infested manure, and, more commonly, by the
18 movement of infested soil, such as that eroded by heavy rains or adhering to transplants from infested
19 nurseries (Clark and Moyer 1988). Although it is primarily soilborne, infecting plants in the field, it also
20 causes a rot that continues to develop on the roots in storage, and, thus, could be transported rapidly in
21 the international root crop trade. The fungus is said to be highly virulent, exhibiting an infection rate in
22 apple of greater than 33% within 6 months in experimental field tests (Uetake et al. 2001). This fungus,
23 the causal agent of violet root rot, is known to cause serious losses in sweetpotato crops in Asia during
24 years that favor disease development (Clark and Moyer 1988). Decay of the fibrous roots progresses
25 from the tips, and may destroy the entire root system. Foliage of severely infected plants becomes
26 chlorotic; older leaves may fall prematurely. In Korea, infection rates in apple were somewhat greater
27 than 5% (Lee et al. 1995). Mortality of apple stocks in Japan was reported to be about 8% under
28 experimental conditions (Uetake et al, 2001). Soil fumigation is one means employed for control (e.g.,
29 Sakuma et al. 1984), which increases production costs. Establishment of the pathogen in Hawai'i could
30 cause a loss of foreign or domestic markets for root crops, such as sweetpotato. It is a quarantine pest
31 for New Zealand (PRF 2007). *Helicobasidium mompa* also poses a potential threat to endemic Hawai'ian
32 plants listed as threatened or endangered, such as *Solanum incompletum* and *S. sandwicense*.

33 **A21.2.5 *Scutellonema bradys* (Steiner & Le Hew) Andrásy (Tylenchida: Hoplolaimidae)**

34 This nematode is native to West Africa, but has spread to other regions of the world (CABI 2006). It has a
35 scattered distribution in the New World between the southern United States (Arkansas, Florida,
36 Louisiana) and Brazil, and in parts of the Caribbean (including Puerto Rico) (CABI 2006; Handoo 2007). In
37 Asia, it occurs in India, Pakistan, and Korea; and possibly Taiwan (Tsay 1997). Primary hosts are species
38 of *Dioscorea* (Dioscoreaceae); other hosts include *Hibiscus* spp. (Malvaceae), *Cucurbita melo*
39 (Cucurbitaceae), *Sesamum indicum* (Pedaliaceae), *Sorghum bicolor* (Poaceae), *Manihot esculenta*

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 (Euphorbiaceae), *Cocos nucifera* (Arecaceae), *Corchorus olitorius* (Tiliaceae), *Solanum lycopersicum*
2 (Solanaceae), *Synedrella nodiflora* (Asteraceae), *Pachyrhizus erosus* (yam bean; Fabaceae) (CABI 2006);
3 *Citrus sinensis* (Rutaceae) (Mead 1987); and Convolvulaceae (Kermarrec et al. 1987). Jatala and Bridge
4 (1990) listed *Scutellonema* spp. among nematode pests of sweetpotato.

5 *Scutellonema bradys* exhibits high reproductive and dispersal potentials. In stored tubers of *Dioscorea*
6 spp. (yam), populations may increase as much as 14-fold in a 5 to 6-month period (Jatala and Bridge
7 1990). The nematode is a migratory endoparasite of roots and tubers, and may also be present in soils
8 around host plants (CABI 2006). In Florida, *Scutellonema* spp. are widespread in field and greenhouse
9 soils (O'Bannon and Duncan 1990). Imported nursery stock thus is a potential pathway for entry of *S.*
10 *bradys* into Hawai'i. Infested tubers also are known to be a major means of long-range dispersal of the
11 pest. It has moved among the islands of the Caribbean in recent decades (e.g., Degras and Kermarrec
12 1976; Kermarrec et al. 1987), and has been intercepted at U.S. ports (PIN 309²⁸) in yam tubers.
13 *Scutellonema bradys* causes a decay of yam known as "dry rot disease," resulting in blackening and
14 cracking of the skin of the tuber (Jatala and Bridge 1990). This condition causes a significant reduction in
15 the quality and marketable value of tubers. Preharvest damage to yams by *S. bradys* was as high as 40%
16 in Nigeria; losses in storage may run 80 to 100%. The nematode is a quarantine pest for French Polynesia
17 and Thailand (PRF 2007), and an A2 quarantine pest for the Caribbean Plant Protection Commission
18 (EPPO 2005a). Its introduction into Hawai'i, therefore, could result in a loss of foreign, as well as
19 domestic, markets for commodities, such as sweetpotato. As it represents a potential threat to plants,
20 such as citrus, sweetpotato, cucurbits, tomato, and coconut, its introduction also could result in the
21 increased use of nematicides, which are employed for the control of *Scutellonema* spp. elsewhere (e.g.,
22 Ogbuji 1983). Because it is known to attack related hosts, *S. bradys* represents a potential threat to
23 native plants in Hawai'i, such as *Hibiscus arnottianus* ssp. *immaculatus*, *H. brackenridgei*, *H. clayi*, and *H.*
24 *waimeae* ssp. *hanneriae*, and *Solanum incompletum* and *S. sandwicense*, all listed as endangered in 50
25 CFR § 17.12.

²⁸ Records from the USDA-APHIS-PPQ Port Information Network (PIN 309). Last accessed February 2007.

1 **A22 ACKNOWLEDGMENTS**

2 This report was the result of a team effort, and could not have been completed without the kindly
3 assistance and cooperation of the following individuals:

4 **USDA-APHIS-PPQ:** D. Alontaga, D. Berringer, V. Harrington, A. Nakamura, N. Nakamura, J. Pasek, T.
5 Richardson, M. Simon, M. Tanner, C. Toguchi

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 **A23 AUTHORS**

2 This pathway analysis was conducted by:

3 **Thomas W. Culliney**

4 Entomologist, USDA-APHIS-PPQ, Center for Plant Health Science & Technology (CPHST), Plant
5 Epidemiology & Risk Analysis Laboratory (PERAL)

6 **Heike E. Meissner**

7 Entomologist, USDA-APHIS-PPQ, CPHST, PERAL

8 **Andrea V. Lemay**

9 Plant Pathologist, USDA-APHIS, Planning & Policy Development, Risk Analysis Systems

10 **Alison D. Neeley**

11 Entomologist, USDA-APHIS-PPQ, CPHST, PERAL

12 **Lynn J. Garrett**

13 Agricultural Economist, USDA-APHIS-PPQ, CPHST, Director's Office

14 **Brian M. Spears**

15 Entomologist, USDA-APHIS-PPQ, CPHST, PERAL

16 **Nicanor J. Liquido**

17 Entomologist, USDA-APHIS-PPQ, CPHST, PERAL

2 ^a CType: CF = cut flowers; FV = fruit or vegetable; PM = plant material

3 ^b # of ship. = total number of shipments regardless of weight or amount.

4 ^c Reportable pests intercepted are pests that were intercepted on plant hosts entering Hawai'i between 2004
5 and 2006 that match plant hosts that were imported into Hawai'i during those years. Only pests reported as
6 being intercepted on permit or general cargo were affiliated with commodity imports. This is not a
7 comprehensive list of reportable pests intercepted, e.g., pests intercepted only in baggage, ship's stores,
8 quarters, or other situations are not included.

9

10

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

1 **Table A25-2: Reportable Pests Intercepted on the Commodities Entering as Permit or**
 2 **General Cargo**

Country	Commodity	Where Intercepted	Reportable Pest
Australia	<i>Rhopalobaste</i> sp.	Permit cargo	<i>Palmicultor browni</i> (arthropod)
	<i>Pinus</i> sp.	Permit cargo	species of Pseudococcidae (arthropod)
Fiji	<i>Colocasia esculenta</i>	Permit cargo	<i>Paraputo leveri</i> (arthropod), species of Pseudococcidae (arthropod)
		Baggage	species of Pseudococcidae (arthropod)
Malaysia	<i>Exocaria</i> sp.	Permit cargo	<i>Conchaspis</i> sp. (arthropod)
Thailand	Orchidaceae	Permit cargo	<i>Cladosporium</i> sp. (pathogen), <i>Succinea tenella</i> (mollusc), species of Lepidoptera (arthropod), species of Noctuidae (arthropod)
		General cargo	<i>Fromundus pygmaeus</i> (arthropod), <i>Spodoptera litura</i> (arthropod), <i>Succinea tenella</i> (mollusc)

3 Source: USDA 2007a

4 Note: The commodities were not listed in the PPQ280 database (possibly not entered into the database or listed
 5 under a different host name).

Table A25-3: Fresh Fruits and Vegetables, with Accompanying Pests, from the U.S. Mainland Entered Hawai'i during the Period January 1, 2004 to December 31, 2006

Commodity	Shipments (lbs) in 2004	Shipments (lbs) in 2005	Shipments (lbs) in 2006	Pests not known to occur in Hawai'i that were intercepted on shipments of the commodity ^a

Sources for produce shipments and intercepted pests: Vierra 2007 and HDOA 2007c, respectively. Data for exact origins of the commodities are not available.

^a Limited verification of pest status in Hawai'i was conducted using online databases, such as the Bishop Museum's Hawai'i Biological Survey Databases and the Crop Protection Compendium (CABI 2006), and scientific literature.

Table A25-4: Reportable Pests Intercepted for Hawai'i in Aircraft Cargo Holds and Cabins between January 1, 1990 and June 16, 2007

Reportable Pest ^a	Number Intercepted
Acrididae, species of	6
<i>Acroleucus vicinalis</i> (Lygaeidae)	1
Acrolophidae, species of	1
<i>Adoretus sinicus</i> (Scarabaeidae)	1
<i>Aeolus nigromaculatus</i> (Elateridae)	1
<i>Agrius</i> sp. (Sphingidae)	1
Agromyzidae, species of	1
<i>Agrotis</i> sp. (Noctuidae)	1
Aleyrodidae, species of	1
<i>Allonemobius</i> sp. (Gryllidae)	1
<i>Altica</i> sp. (Chrysomelidae)	1
Alticinae, species of (Chrysomelidae)	2
<i>Amphimallon solstitialis</i> (Scarabaeidae)	1
<i>Amphimallon</i> sp. (Scarabaeidae)	1
<i>Anastrepha</i> sp. (Tephritidae)	2
<i>Anaxipha</i> sp. (Gryllidae)	6
<i>Ancognatha scarabaeoides</i> (Scarabaeidae)	6
<i>Ancognatha</i> sp. (Scarabaeidae)	49
<i>Ancognatha ustulata</i> (Scarabaeidae)	9
<i>Anomala</i> sp. (Scarabaeidae)	21
Aphididae, species of	2
Apioninae, species of (Curculionidae)	3
<i>Archophileurus</i> sp. (Scarabaeidae)	1
<i>Arcte coerulea</i> (Noctuidae)	1
Arctiidae, species of	15
<i>Athlia rustica</i> (Scarabaeidae)	1
<i>Atractomorpha</i> sp. (Pyrgomorphidae)	1
<i>Atta sexdens</i> (Formicidae)	3
<i>Atta</i> sp. (Formicidae)	6
<i>Aulacaspis tubercularis</i> (Diaspididae)	1
<i>Aulacophora indica</i> (Chrysomelidae)	1
<i>Aulacophora nigripennis</i> (Chrysomelidae)	1
<i>Banasa</i> sp. (Pentatomidae)	1
<i>Barybas</i> sp. (Scarabaeidae)	1
<i>Berecynthus hastator</i> (Pentatomidae)	1
<i>Blapstinus</i> sp. (Tenebrionidae)	7
<i>Blissus</i> sp. (Blissidae)	1

Reportable Pest ^a	Number Intercepted
<i>Blitopertha</i> sp. (Scarabaeidae)	1
Bostrichidae, species of	3
<i>Calligrapha</i> sp. (Chrysomelidae)	1
<i>Calloplistria</i> sp. (Noctuidae)	1
Cassidinae, species of (Chrysomelidae)	1
<i>Caulopsis microprora</i> (Tettigoniidae)	1
<i>Caulopsis</i> sp. (Tettigoniidae)	1
Cerambycidae, species of	4
<i>Ceraspis centralis</i> (Scarabaeidae)	1
<i>Ceratitis capitata</i> (Tephritidae)	1
Cercopidae, species of	1
<i>Chlorotettix</i> sp. (Cicadellidae)	3
Chrysomelidae, species of	6
Cicadellidae, species of	14
Cicadidae, species of	2
Cixiidae, species of	3
<i>Cleogonus</i> sp. (Curculionidae)	1
<i>Colaspis</i> sp. (Chrysomelidae)	9
<i>Conocephalus saltator</i> (Tettigoniidae)	1
<i>Conocephalus</i> sp. (Tettigoniidae)	11
<i>Conoderus pictus</i> (Elateridae)	2
<i>Conoderus</i> sp. (Elateridae)	3
<i>Conotrachelus</i> sp. (Curculionidae)	3
<i>Cornu aspersum</i> (Helicidae)	1
Crambidae, species of	3
Crambinae, species of (Crambidae)	1
Ctenuchidae, species of	3
Curculionidae, species of	12
<i>Cyclocephala mafaffa</i> (Scarabaeidae)	1
<i>Cyclocephala</i> sp. (Scarabaeidae)	28
Cydnidae, species of	14
<i>Dallasiellus bacchinus</i> (Cydnidae)	6
Delphacidae, species of	6
Deltocephalinae, species of (Cicadellidae)	1
<i>Dichromorpha</i> sp. (Acrididae)	1
<i>Diplotaxis</i> sp. (Scarabaeidae)	8
<i>Draeculacephala clypeata</i> (Cicadellidae)	1
Dynastinae, species of	16

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

Reportable Pest ^a	Number Intercepted
(Scarabaeidae)	
<i>Dyscinetus</i> sp. (Scarabaeidae)	1
<i>Earias insulana</i> (Noctuidae)	1
<i>Ecpantheria</i> sp. (Arctiidae)	1
Elateridae, species of	6
<i>Endotracha</i> sp. (Pyralidae)	1
Eneopterinae, species of (Gryllidae)	1
<i>Epitragus</i> sp. (Tenebrionidae)	3
<i>Epitrix</i> sp. (Chrysomelidae)	1
<i>Erinnyis</i> sp. (Sphingidae)	1
<i>Euconocephalus</i> sp. (Tettigoniidae)	2
<i>Eutheola</i> sp. (Scarabaeidae)	4
<i>Eulepidotis guttata</i> (Noctuidae)	3
Eumolpinae, species of (Chrysomelidae)	2
<i>Euphoria</i> sp. (Scarabaeidae)	4
<i>Eurychilella</i> sp. (Miridae)	1
<i>Euschistus</i> sp. (Pentatomidae)	2
<i>Exitianus</i> sp. (Cicadellidae)	1
<i>Exophthalmus</i> sp. (Curculionidae)	1
Flatidae, species of	1
Formicidae, species of	1
Galerucinae, species of (Chrysomelidae)	4
Gelechiidae, species of	16
<i>Geniates</i> sp. (Scarabaeidae)	3
Geometridae, species of	7
<i>Gonodonta</i> sp. (Noctuidae)	3
Gryllidae, species of	4
Gryllinae, species of (Gryllidae)	1
<i>Gryllodes</i> sp. (Gryllidae)	1
<i>Gryllotalpa</i> sp. (Gryllotalpidae)	2
<i>Gryllus capitatus</i> (Gryllidae)	1
<i>Gryllus</i> sp. (Gryllidae)	85
Herminiinae, species of (Noctuidae)	1
<i>Herpetogramma</i> sp. (Crambidae)	1
<i>Horistonotus</i> sp. (Elateridae)	1
Lagriinae, species of (Tenebrionidae)	1
Lepidoptera, species of	9
<i>Leucania inconspicua</i> (Noctuidae)	1
<i>Leucothyreus</i> sp. (Scarabaeidae)	2
<i>Ligyris</i> sp. (Scarabaeidae)	9
Limacodidae, species of	1
<i>Liogenys macropelma</i> (Scarabaeidae)	2
<i>Liogenys quadridens</i> (Scarabaeidae)	1
<i>Liogenys</i> sp. (Scarabaeidae)	6
Lycaenidae, species of	1

Reportable Pest ^a	Number Intercepted
Lygaeidae, species of	9
<i>Macropygium</i> sp. (Pentatomidae)	1
<i>Malacorhinus irregularis</i> (Chrysomelidae)	1
<i>Maladera</i> sp. (Scarabaeidae)	1
<i>Manopus</i> sp. (Scarabaeidae)	3
<i>Melanaethus spinolai</i> (Cydniidae)	2
<i>Melipotis</i> sp. (Noctuidae)	3
Meloidae, species of	1
<i>Melolontha</i> sp. (Scarabaeidae)	1
Melolonthinae, species of (Scarabaeidae)	13
Membracidae, species of	2
<i>Messor</i> sp. (Formicidae)	1
<i>Metaleptea brevicornis</i> (Acrididae)	1
<i>Metamasius hemipterus</i> (Dryophthoridae)	2
<i>Miogryllus convolutus</i> (Gryllidae)	1
Miridae, species of	11
Myrmicinae, species of (Formicidae)	6
<i>Neochetina eichhorniae</i> (Eirrhinidae)	1
<i>Neoconocephalus punctipes</i> (Tettigoniidae)	3
<i>Neoconocephalus</i> sp. (Tettigoniidae)	28
Noctuidae, species of	236
Nymphalidae, species of	1
<i>Nysius</i> sp. (Lygaeidae)	5
Oecophoridae, species of	1
Olethreutinae, species of (Tortricidae)	1
<i>Oncometopia</i> sp. (Cicadellidae)	1
<i>Orphulella punctata</i> (Acrididae)	1
Orthoptera, species of	1

Risk Analysis and Management Recommendations for the Prevention and Mitigation of Terrestrial Invasive Species in the Micronesia Region

Source: USDA 2007a

- ^a Records exclude pest interceptions made on military aircraft and those for which discrepancies in the data are suspected (i.e., in cases in which it is questionable that the pest was actually intercepted in an aircraft cargo hold or cabin).
