Figure 5.37. A) Number of commercial and fishing vessel and B) MSC vessel entries to HI from 2006-2011 that had traded with specific bioregions Last Port of Call during the evaluation period. Note that vessels may have multiple entries (Lloyds MIU and DoD datasets). Note that vessels arriving from Guam are also represented in Bioregion 14 South Pacific Ocean.

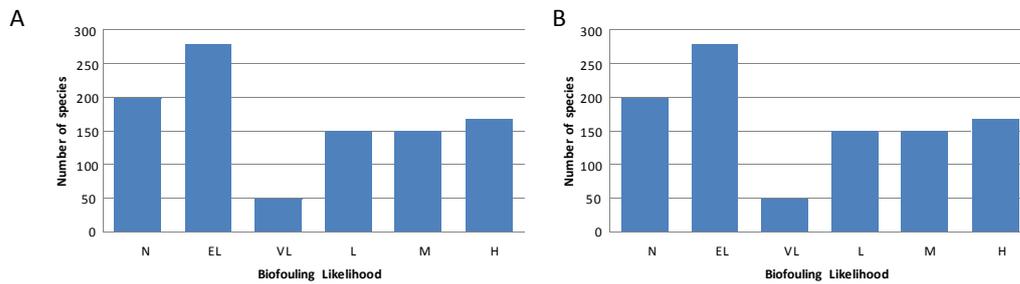

Figure 5.38. Number of Species for Biofouling related Inoculation Likelihood Ranks to HI based on LPOC arrivals. A) commercial vessels and fishing alone, B) commercial, fishing and MSC vessels. Where N = negligible, EL = extremely low; VL = very low, L = low, M = moderate, and H = high. Data from Lloyds MIU and DoD datasets.

Table 5.9. Biofouling species with a “High” (n=167) and “Medium” (n=150) likelihood of arrival in HI associated with all vessel traffic.

5.5 Summary of Spread from Guam to other jurisdictions of Micronesia and Hawai'i

The jurisdictions of Micronesia are variously exposed to the global suite of non-native marine and estuarine species through commercial and MSC vessel traffic, as discussed above. This exposure has been used to identify the suites of species with “High” likelihoods of arrival. MSC vessels demonstrably increase the exposure of various jurisdictions of Micronesia to novel bioregions, and therefore suites of non-native marine and estuarine species (Table 5.10). For example, MSC vessels increased the exposure of Guam to the Arabian Seas by 2.85 times, which would mean that species found in the Arabian Seas would have a 2.85 times greater likelihood of arrival in Guam when MSC vessels are counted. In contrast, the MSC vessels have no detectable effect on Hawai'i.

A comparison of “High” and “Medium” likelihood of inoculation species identified for various jurisdictions of Micronesia with those identified for Guam (Table 5.11) indicates a significant overlap. A total of 270 species are identified as having “High” or “Medium” likelihoods of arrival in at least one location in Micronesia, with 56 (21%) identified for a single Micronesian

jurisdiction, 24 of which were restricted to Guam. Only four species determined to be of “High” likelihood in another jurisdiction of Micronesia were not identified as a “High” likelihood for Guam. This suggests that similar factors influencing arrival to Guam are acting in other jurisdictions of Micronesia, rather than a formal “hub and spoke” model, as has been previously suggested.

Table 5.10. Increase in exposure to IUCN Bioregions (and Guam) for the jurisdictions of Micronesia and Hawai’i attributed to MSC vessels (1.00 = no increase).

20. Guam	N/A	2.44	1.00	4.25	1.55	54.00	1.00

In contrast, the pattern for Hawai’i is substantially different from Micronesia with 318 species identified as having “High” or “Medium” likelihoods of arrival, of which 158 are unique to Hawai’i, with only 9 species ranked as “High” in both Guam and Hawai’i. This infers that invasion risk to Hawai’i is driven by factors independent of Guam or other jurisdictions of Micronesia.

Table 5.11. Comparison of “High” and “Medium” likelihood of inoculation species in all jurisdictions of Micronesia and Hawai’i.

5.6 Discussion and Conclusions

This study clearly demonstrates that a number of non-native species associated with biofouling represent a risk to Micronesia. Out of the global suite of 2,365 marine species identified with a recognized invasion history, 136 were considered native to Micronesia and 109 species have been previously introduced to Guam (but may or may not also be present in one or more of the other jurisdictions of Micronesia), leaving 2,120 species from our database with an invasion history that represent a novel risk of invasion to Guam (Table 5.1). Of these 2,120 species, 1,241 were deemed to have some likely association with biofouling of vessels. Micronesia has a relatively poor taxonomic knowledge base despite high endemism and high levels of interest, and has not invested in significant evaluations of its current state of marine introductions, although Guam has had investigation of its non-native marine biota through literature and museum collection evaluations and a baseline survey of Apra Harbor (Paulay et al 2002). In contrast, the knowledge base for biological introductions is perhaps greatest in Guam relative to the other jurisdictions of Micronesia (but see Campbell et al 2007).

In order to advance the understanding of risk exposure it is imperative that a greater knowledge base is developed. Targeted field surveys are especially critical to determine the current levels of introductions, particularly in high risk areas (e.g., ports, marinas, aquaculture facilities) using a consistent suite of protocols and a shared taxonomic dataset. At a more fundamental level, studies on the alpha taxonomy of species with potential for invasiveness need to be undertaken, in order to better understand the diversity, ecology, and current geographic ranges of invasive species. A DNA barcoding study would help provide an indication of the unaccounted 'cryptic' species-level diversity present in the Micronesian region.

For the biofouling species assessed in this report, an evaluation of transport pressure was based on global distribution of the species (in native, cryptogenic and introduced bioregions). This enabled identification of the number of arriving vessels into Micronesia that **could have transported** the species to Micronesian waters. This required a number of critical assumptions:

- that a species presence in a bioregion represents an established population **throughout** the bioregion,
- that all vessel categories are equally able to transport all species and
- that all trade routes from bioregions to Micronesia are equally 'stressful'.

These assumptions represent conservative approaches to the information available. The ability to discern a non-native marine species presence in overseas ports has been demonstrated to be problematic (e.g., Hayes and Hewitt 1998, 2000; Hewitt and Hayes 2001, 2002; Barry et al. 2008). While there have been numerous efforts to provide up-to-date information on invasions into various global regions (see review by Campbell et al. 2007), the information is typically out-of-date by the time it is in the peer reviewed literature. Assuming that a report for a species in a bioregion represents an established population in that bioregion allows a risk manager to use the information in making an assessment. Similarly, assuming that a species is spread throughout the bioregion, when it may have only been reported from one location, may assist in addressing the

significant lag time between incursion, detection and reporting. During this period, which can encompass more than a decade, the opportunity for the species to have spread through natural and human-mediated means creates the high likelihood that nearby regions and ports will have been infected. It is worth noting though that assuming a species is spread through a region based on detections in one or several places within that region may be an erroneous conclusion and when considering how best to increase biosecurity for Micronesia and Hawaii, such assumptions should not be readily applied.

Differences among vessel categories (types) can clearly influence inoculation pressure elsewhere (e.g., Carlton 1985, 2001; Carlton and Hodder 1995; Coutts 1999; Wonham et al. 2000; Floerl 2002; Coutts and Dodgshun 2007; Piola et al. 2008). Vessel behaviors differ significantly both individually and across vessel categories. These behavioral differences include, but are not limited to, vessel speed, time spent in port, and maintenance history.

An evaluation of vessel speed based on the Lloyds MIU dataset indicated that at the gross scale of vessel categories used here, no clear differentiation could be discerned. Clearly, some vessel types move at much slower speeds than others, and recent reports suggest that these slower moving and sedentary vessels, including barges, dredges, drilling rigs and floating production, storage and offloading units (FPSOs), may harbor larger quantities and diversity of species than other vessels (e.g., Coutts 2002; Floerl 2002; Floerl and Inglis 2005; Davidson et al. 2009; Coutts et al. 2009, 2010a, b). The relationship, however, between a vessel's maximum, or even mean, speed (representing sheer forces) and the successful transport of species to new regions remains unclear.

The presence of hydrodynamically protected areas on a vessel's hull, such as sea-chests, rudders, and propeller shafts (e.g., Gollasch 2002; Hayes 2002; Coutts et al. 2003; Coutts and Taylor 2004; Hayes et al. 2004b; Coutts and Dodgshun 2007) nevertheless suggests that speed alone will not preclude a species presence on a vessel but may significantly reduce the abundance of a species. Coutts (1999) evaluated commercial (merchant) vessels entering Bell Bay in Tasmania, Australia and found that speed was a good correlate of species abundance and a moderate correlate for diversity. However, this study concentrated on the uniform areas of the hull surface and did not explore niche or protected areas of a ship's hull.

A time in port analysis was not undertaken in this study due to the limitations on data availability, particularly for military vessels. In previous studies (Hewitt et al. 2009e, 2010) differences between time spent in port for the various vessel categories provided a clear indication of differences in opportunity for species to settle on the vessel (assumed to correlate with time in port). This factor was used in previous studies as a multiplier of vessel visits from a bioregion to account for the increased likelihood that a species would be transported. However, the accumulation of biofouling in a small area of a vessel is unlikely to be a linear process. Indeed the accumulation of species onto settlement panels often follows an exponential increase in diversity as the habitat, increases in complexity (Sutherland and Karlson 1978). At some point however, an asymptote (a leveling off) of the species accumulation is expected to occur in the local patch, or more broadly once the community accumulates the entire species pool from a bioregion (Rosenzweig 2001). How rapidly the community is assembled varies widely across regions and time of year (Sutherland and Karlson 1978; Lewis 2002; Lewis et al. 2004; Dunstan and Johnson 2006).

As voyage duration increases, the number of bioregions visited by vessels entering Guam was found to encompass 12 bioregions after 30 days, reaching saturation (all 18 bioregions) after 183 days. Taking into account the expected operational cycle of vessels between dry-docking and antifouling paint applications, coupled with the restrictions placed on in-water cleaning in many jurisdictions, most vessels will be expected to have significant communities of species drawn from a wide suite of bioregions. Based on the assessment of voyage duration, multiple bioregions are visited by half of the vessels travelling for periods of less than one year. This in turn increases the opportunity for species from disparate regions to attach to the hull and also increases the total opportunity for individual species to be transported.

A number of vessel characteristics could not be evaluated and did not contribute to the final evaluation. As noted above, vessel speed did not appear to differentiate between vessel categories but varied widely within several categories. The implications that hydrodynamically protected areas may continue to harbor communities of biofouling associated species make this variable unlikely to fully eliminate any species from a vessel. Similarly, antifouling paint has been deemed to provide prophylactic protection, however the incomplete and often inappropriate applications of antifouling paints are unlikely to result in the complete elimination of a species from a vessel. While antifouling paint history coupled with more generic hull husbandry information could potentially provide significant information on the likely state of biofouling, this information could not be obtained at the scale required, and therefore could not be included in this assessment.

Biosecurity risk is typically derived from assessing both the arrival likelihood and the species consequence (impact). In this evaluation, a species' successful inoculation has been deemed to have an unacceptable consequence in keeping with a quarantine endpoint. A quarantine consideration, where the arrival of a new species is deemed to represent an unacceptable impact, is frequently employed where the desire is to prevent new invasions. In this report, the desire was to identify the species most likely to be introduced without differentiation with regard to the potential impacts they might cause. Consequently, the predictions made in this report necessarily relied on the most probable arrivals into Guam and subsequent transfer to other jurisdictions of Micronesia.

This assessment has concentrated on the likelihood of transport and inoculation, however not all species will have the physiological tolerances to establish and survive the environmental conditions found in nearshore waters of Micronesia. Establishment represents the survival and development of a self-sustaining population once a species has been inoculated into a new (receiving) environment (e.g., Occipinti-Ambrogi and Galil 2004). The likelihood of establishment has been theorized to relate to characteristics of the invading species (and its inoculation) as well as characteristics of the receiving environment (e.g., Carlton 1985; Lodge 1993; Ruiz et al. 2000; Hewitt and Huxel 2002; Lockwood et al. 2007).

Species characteristics which influence establishment likelihood include the physiological tolerance to the new (receiving) environment sufficient for reproduction to occur and all life history stages to survive. These are typically based on empirical evaluations of species' tolerances to a suite of environmental factors, such as temperature, salinity, light, dissolved oxygen, however these empirical evaluations have been carried out for a relatively small number of species (e.g., Hayes and Hewitt 1998, 2000; Campbell 2009).

Given these constraints, a second method of estimating probable survival in a new region is to

match the environmental characteristics of the donor region where a species is known to exist, with a recipient region – environmental matching (e.g., Hilliard and Raaymakers 1997; Kilroy et al. 2008; see also Hewitt and Hayes 2001, 2002). As Barry et al. (2008) suggest, evidence to support the utility of environmental matching in the marine environment is limited, largely due to the inappropriate selection of environmental characteristics and scale by various authors. The ability for environmental matching to provide realistic risk evaluations becomes increasingly limited as nonsensical or irrelevant environmental factors are included in the analysis (Barry et al. 2008).

One of the greatest errors in environmental matching assessments is the inappropriate use of scale. As Hewitt and Hayes (2002) demonstrate, environmental matching is meant to create a surrogate measure for the species of concern's tolerances. This is done by selecting a location where a species is known to exist (the donor location), and using the range of environmental values to compare with a potential recipient location. If the donor location is restricted to a port, rather than the entire province or bioregion in which the species resides, then an artificial limit to the range of environmental values will be derived. To illustrate this, Hewitt and Hayes (2002) demonstrated that the temperature ranges of the Port of Sydney and the Port of Hobart do not overlap and hence, based on a simple environmental match, species would not be expected to survive in both. Regardless, Sydney and Hobart reside within a single large scale province and share many species. For example, when their temperature ranges are compared with the temperature tolerances of the non-native seastar, *Asterias amurensis*, they both fall well within the range of its survival (Hewitt and Hayes 2002).

Non-native marine species have been shown to fully realize their fundamental niche (*sensu* Hutchinson 1957), suggesting that their physiological tolerances are conservatively represented by the wide ranging environmental conditions in their native distribution (e.g., salinities and water temperatures). In a previous evaluation (Campbell and Hewitt 2011), the known temperature tolerances of several non-native marine species in Australian waters were compared with the sea surface temperature maxima and minima (over a ten year period) for their native provinces (Figure 5.37A). The environmental range of temperatures in a species' native provinces conservatively describes the temperature tolerances of the species in most cases, suggesting that the environmental ranges of provinces can be used as conservative surrogates of species' tolerances.

As a consequence, the environmental overlaps of different provinces may indicate the likelihood of species' survival in various regions. Significant provincial overlap occurs from the Arctic to the Antarctic along the eastern Pacific basin (Figure 5.37B), suggesting that many species could survive within a wide range of provinces across the eastern basin, and that their restricted distributions may be constrained more by other factors (e.g., transport opportunity, receiving community resistance including predation and competition) than significant physiological 'resistance'. The northern and southern distribution of the large brown kelp, *Macrocystis integrifolia* is a case in point (Graham et al. 2007).

Undertaking an assessment of the physiological constraints of the risk species identified here would require a significant effort and result in a large amount of remaining unknowns, given existing data limitations for many marine and estuarine species. Similarly, developing an understanding of the environmental constraints of Guam and other Micronesian environments to challenge species is beyond the scope of the current assessment.

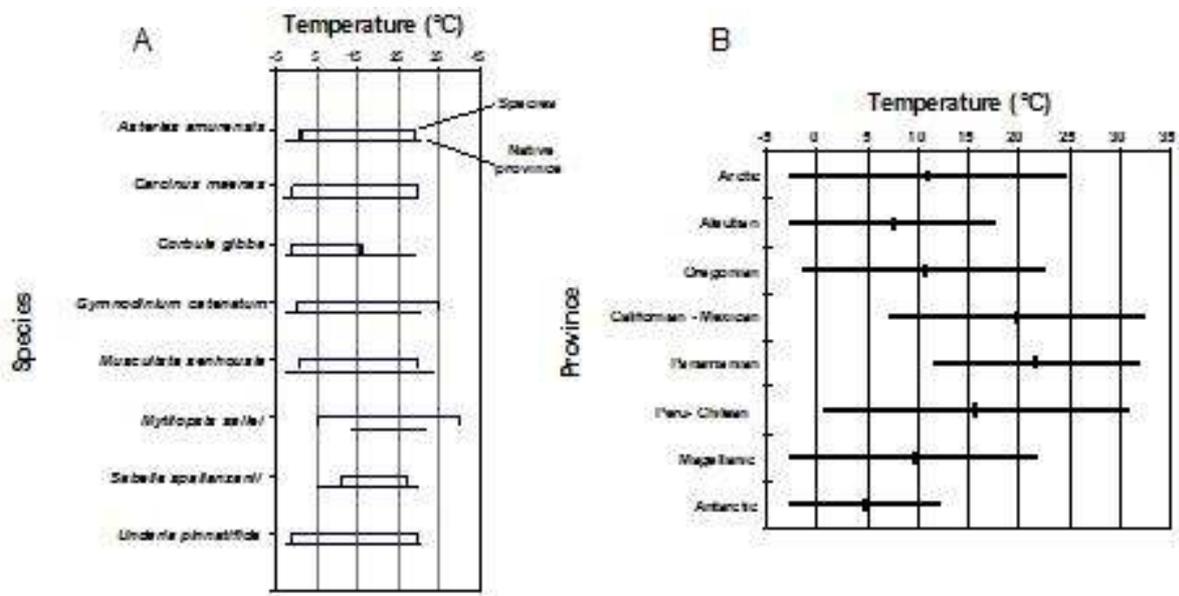

Figure 5.37. A) comparison of species' physiological tolerances (top line) versus native province Sea Surface Temperature range (bottom line); B) Comparison of Sea Surface Temperature for the eastern Pacific provinces (from Hewitt and Campbell unpublished data).

A posthoc assessment of species impact could lead to a greater refinement of the lists provided here, identifying those species which once inoculated and established could result in unacceptable impacts to economic, environmental, social or cultural values. Predicting impact (or consequence) of potential non-native marine species is problematic. In previous work, Hewitt et al. (2009e) evaluated the biofouling species risks to Australia and determined that of 657 species which were deemed to pose a threat to Australia, impact information could only be derived for 162 (24.7%). This information included both demonstrated impacts (or lack of impact) based on scientific assessment, as well as inferred impact based on expert opinion. For the remaining approximately 75% of species, no inferred or demonstrated impacts could be derived from the literature.

More recently, Dahlstrom (2012) evaluated the ability of biosecurity impact studies to detect an impact where the outcomes were non-significant. Dahlstrom focused on 31 algal and crustacean evaluations that have been cited to support an assessment of “no threat” by managers. Dahlstrom found consistently low power which led to an acceptance of Type II (false positive) errors at rates 5 to 19 times greater than acceptance of Type I (false negative) errors. These results suggest that for the suite of studied species for which no impact was discerned, 95% were unlikely to detect an impact due to poor design, and these species may have large impacts that have been missed due to high variation or small sample sizes.

These two examples suggest that researchers have no ability at the present time to assign consequence (impact) scores for between 75% and 90% of known invading species due to either a lack of scientific investigation, or poor implementation of impact studies leading to false conclusions. As a result, this study has focused on the quarantine endpoint to aid determination of species which require further study.

This study has identified 243 species which have a “High” likelihood of inoculation into at least one Micronesian jurisdiction or Hawai’i, with 85 species presenting a “High” likelihood of inoculation in at least one Micronesian jurisdiction, and an additional 168 species in Hawai’i. The 85 species representing an increased risk to Micronesia appear to be heavily influenced by traffic activities associated with Guam and with MSC vessels. These species include species that may impact aquaculture activities, coastal industries, wild fisheries and other living marine resources, protected and habitat-forming species, social/cultural values and human health.

PART III.
Marine Biosecurity Plan

Chapter 6: Marine Biosecurity Plan Recommendations for Micronesia

by Gregory M. Ruiz and Chela J. Zabin

6.1 Introduction

The purpose of this chapter is to outline key elements of a regional marine biosecurity plan for Micronesia. This begins with a brief review of the types of biosecurity plans that have been developed or proposed within the region. Next, a conceptual framework is outlined for vector management, serving as an operational structure to develop and advance biosecurity. Within this framework, specific recommendations are made for management practices, actions, and focused research and analyses needed to respond effectively to the threat of marine biological invasions. Finally, the structural (institutional) components necessary to meet these recommendations are considered. Throughout this approach, we draw upon information presented in the preceding chapters on (a) existing knowledge about marine invasion processes throughout the world, (b) the operation and management practices for vectors that transfer non-native marine species in Micronesia, (c) some critical gaps in baseline knowledge about regional vectors and invasions, and (d) the state of existing infrastructure (programs and capacity) for marine biosecurity.

While we identify critical components and actions for the regional biosecurity plan, a detailed implementation plan to achieve these goals is not presented here. The latter is clearly beyond the scope of the current project and represents a next step in the process. Pragmatically, it is important to recognize that any implementation plan is a political process, which requires (a) direct engagement and participation of the parties — countries, organizations, and people — involved in Micronesia, (b) consideration of possible legal instruments and approaches (i.e., regulations, agreements, partnerships, policies), and (c) assessment of available resources and institutional capacities to meet specific goals and timelines. In September 2011, the U.S. Navy entered into an agreement with the University of Guam to create a strategic implementation plan. The goal of this chapter, and indeed the entire report, is therefore to set the stage for this process, providing the necessary framework, activities, and actions.

The major impetus for this report is the current DoD Buildup in Guam, and associated activities, but the biosecurity plan recommendations are intended to be broader in spatial and temporal extent. For this reason, we have considered activities throughout Micronesia, as well as the linkage between Micronesia and Hawai'i. In addition, we have included consideration of some activities that may change through time. For example, it is clear that the magnitude and type of construction and vessel activities will change throughout the Buildup, and some transport mechanisms for marine species that are currently rare (or not in operation) in Micronesia may become important in the future. While we have attempted to capture this broad spatial and temporal scope, it is also important to acknowledge that our treatment cannot be comprehensive and anticipate all possibilities in this respect, especially given the time provided for this analysis. Nonetheless, we hope that the conceptual framework and rationale developed here can be applied broadly to any omissions or unanticipated future concerns.

In this chapter, as elsewhere in the report, the terms “non-native species” and “invasive species” are used unavoidably as synonyms. The term “invasive species” is variously and often vaguely defined throughout the literature (Ruiz and Carlton 2003). In general, it is meant to refer to species that have a negative or undesirable impact, but the effects of most non-native marine species have never been assessed in this regard (see Chapter 1, Section 1.4). The term “invasive” is used commonly in legislation, guidelines and management plans (see next section), and we refer to “invasive species” where it is used in this way. Elsewhere, we use the term “non- native species”.

6.2 Existing Plans and Recommendations for the Region

6.2.1 Ship-Mediated Invasions: Secretariat of the Pacific Regional Environment Program and The International Maritime Organization

A strategy for addressing shipping-related marine invasions in the region (SRIMP-PAC) was developed by the Secretariat of the Pacific Regional Environment Program (SPREP) in cooperation with the IMO (South Pacific Regional Environment Programme 2006). The SRIMP-PAC strategy takes a broad view, aiming to reduce the spread of marine invasive species to all Pacific Island countries and territories (PICTs). It emphasizes “pre-border” controls, or regulations, inspections and management actions in Pacific Rim countries to reduce biofouling on vessels and the uptake of organisms in ballast tanks before vessels leave port, as the most effective and cost-efficient approach. Such measures would also be taken in PICTs, along with at-border strategies to assess risk of incoming vessels and management strategies for reducing release of non-native species in ports and coastal waters. The plan also recommends the development of “post-border” strategies, such as early detection through monitoring, rapid- response plans, and eradication and control measures, while acknowledging that these are more costly and less-effective than prevention measures.

Other components of the SRIMP-PAC plan include structural and political components such as building an organization to carry out the plan (with SPREP/IMO as leads); mounting a major awareness campaign in all Pacific Rim countries; working to implement laws, regulations, and standards for ballast water and hull fouling; and building capacity for participating countries to carry out the plan elements. The strategy calls for a formal overall risk assessment for the region, with the intention of identifying high-, medium- and low-risk ports, as well as identifying risks posed by specific vessel types or voyages. The risk assessment would be used to guide the further development of management plans. In addition, the plan calls for a formal risk assessment for transiting vessels in the region, specifically for an analysis of regions where ballast water is discharged and a determination as to whether these pose a risk to PICTs.

Acknowledging the lack of baseline information about non-native species already present in the Pacific, the plan calls for initial surveys, along with three levels of ongoing monitoring for new invaders: comprehensive surveys at high-risk ports (based on the protocol developed by the Australian Centre for Research on Introduced Marine Pests); reduced scale surveys at medium risk ports (based on methods developed by Hawai’i’s Bishop Museum); passive settling plates at low-risk ports (based on methods developed by the Smithsonian Environmental Research Center). The document also notes the lack of taxonomic expertise in the region, and recommends coordination

between countries in the region and scientific experts elsewhere, as well as the need for a coordinated database for information on species, ship movements and ballast water and hull fouling management issues. Taxonomic and DNA barcoding studies on invasive species may also be considered.

The SRIMP-PAC strategy includes a work plan which outlines what is to be done, when, by whom, as well as potential funding sources and existing models to follow. It does not specifically address military vessels.

6.2.2 Aquaculture Imports and Quarantine: Secretariat of the Pacific Community

SPC has developed quarantine guidelines for aquatic species introduced to the region for aquaculture (Humphries 1995). A draft version of these guidelines and recommendations was adopted by SPC in 1994. Essentially, the guidelines provide minimum standards for quarantine, including the following:

- Evaluating each proposed introduction on a case-by-case basis
- Risk assessment to assign risk categories for proposed introductions
- Health certification as well as pre- and post-entry examination for disease
- Secure quarantine facilities (including consideration of site of facility to minimize accidental releases due to natural disasters, e.g. floods and tsunamis) and training to improve ability to test for disease
- Preparation of a regional strategy on aquatic biosecurity
- Development of a regional disease database

6.2.3 General Invasive Species Plans: Secretariat of the Pacific Regional Environment

Program

Guidelines for the development of national invasive species management plans (across all habitat types) for Pacific Island countries were drafted by the Secretariat of the Pacific Regional Environment Program, following a series of meetings and discussions with various agencies in the region (Tye 2009). The document advocates use of the precautionary principle in the management of invasive species, assuming, in the absence of information to the contrary, that any non-native species will become problematic and should be prevented from spreading and/or becoming established. As does the SRIMP-PAC document, it emphasizes a hierarchical approach to dealing with invasive species, i.e., prioritizing prevention, which is less costly and more effective than managing invasive species post-establishment, and advocating eradication where possible rather than long-term management. Biological control, using host-specific species, is recommended as a potential management strategy where eradication is not possible; with containment and long-term management by chemical or physical methods as last-resort actions.

The document addresses non-native species across all habitat types and presents an excellent

overall framework for the development of invasive-species management plans. Unlike SRIMP-PAC, it focuses on species entering the country via imports; ballast water and hull fouling are not mentioned in the document. It contains guidelines broadly organized into three major thematic areas, which are further broken down into nine sub-themes as follows:

I. Foundations

A. Generating support for actions to manage and prevent invasions

B. Building capacity

C. Legislation, policy and protocols

II. Problem definition, prioritization and decision-making

A. Baseline and monitoring, specifically the development of baseline information on the abundance and distribution of invasive species

1) Prioritization of management activities

2) Research on priority species

III. Management Action

A. Biosecurity, defined as prevention of the spread of invasive species

B. Management of established invasive species

C. Restoration of native species

These thematic areas are further developed in the document, with steps and actions to be taken toward specific goals, but the SPREP plan does not provide specific strategies or methods. For example, the plan advocates the development of monitoring programs for invasive species but offers no details of best approaches for monitoring. Best management practices for different vectors or pathways are also not detailed.

6.2.4 Pacific Invasives Initiative

The Pacific Invasives Initiative reviewed national biosecurity/biodiversity plans and invasive species management activities (Pacific Invasives Initiative 2010) for 12 Pacific Island countries, to assess alignment with the SPREP document and to identify existing gaps in the plans. The countries reviewed in the Micronesian region were the RMI, FSM, and Palau. The review found that all countries except for RMI had addressed invasive species in their national biodiversity strategy and action plans (a biosecurity plan for RMI is currently in draft form; see next section). RMI, FSM (Pohnpei, Kosrae and Yap) and Palau had also completed invasive species action plans (Chuuk now has a draft plan; see Section 6.2.5 below). The review found that while all countries had taken some steps to address the issue of invasive species, major gaps existed in invasive species plans and activities.

In general, countries had done well in recognizing the need for public education and outreach and had engaged in such activities (Pacific Invasives Initiative 2010). Most countries recognized the

need to build capacity of local agencies to address invasive species. Most also had management plans for some species and/or were already engaged in invasive-species management; most acknowledged the need for increasing capacity for invasive-species detection at ports of entry and for revising, coordinating, and streamlining legislation and policy related to invasive species.

Major gaps existed on several fronts: few of the countries recognized the need or had taken steps to gather baseline data on the abundance and distribution of non-native species already present; approximately half of the countries had not recognized the need for or taken action to prioritize which species should be targeted for management or to carry out research necessary for building a best approach to management of priority species. Countries in general had also done poorly in terms of garnering political support, developing pre-export protections (to reduce spread from a country), and including restoration of native species into invasive-eradication projects. Overall, the report concluded that most of the countries did not know how to plan an effective invasive species management program or how to identify and incorporate best-management practices into their programs (Pacific Invasives Initiative 2010).

6.2.5 Local Area Plans in Micronesia

Most of the countries in the region are addressing invasive species either in biosecurity legislation or invasive species plans or both. However, efforts to date have been limited and are mostly focused on terrestrial and to some extent freshwater species. Palau seems to have advanced the furthest in addressing invasive species in general and marine species in particular.

6.2.5.1 Palau.

Palau's National Invasive Species Strategy (2004) includes consideration of marine species and outlines a number of action items:

- 1) periodic review of the country's legal and regulatory framework with regards to invasive species, and the revision and adoption of updates to these as needed;
- 2) preparation of a National Invasive Species Strategy (below), which was drafted nearly simultaneously with the National Invasive Species Policy;
- 3) thorough initial surveys in terrestrial and marine environments to identify and quantify invasive species;
- 4) identification of priority species for management actions, and the identification of areas at greatest risk for entry and establishment of invasive species
- 5) prevention of new invasions, detection through regular monitoring, and management/eradication of established species;
- 6) restoration and re-establishment of native species to be included as part of management activities; and
- 7) cooperation between various local, regional and international agencies working on invasive species.

Many of these items have since moved forward.

Palau's National Invasive Species Strategy (2004), or NISS, acknowledges explicitly the potential importance of marine invasions in a country that depends heavily on a healthy marine

environment. The NISS was written by the country's National Invasive Species Committee, after a review of relevant documents from Australia, SPREP, the Global Invasive Species Programme, the Convention on Biological Diversity, and the Bahamas National Invasive Species Strategy. The NISS lays out a series of objectives to meet four major goals:

- 1) the provision of a national framework for dealing with invasive species;
 - 2) the prevention of new invasions;
 - 3) management of invasive species already in Palau; and
 - 4) coordination with other regional and international organizations dealing with invasive species.
- Additionally, the document details the roles and responsibilities for dealing with invasive species for the national and state governments, traditional leaders and community members.

The NISS was formed after a SPREP-led workshop in 2003, and recommendations from this workshop appear as an appendix to the strategy document. Two specific recommendations for dealing with aquatic/marine species in Palau came out of this workshop: 1) immediate action to eradicate tilapia and 2) working with dive operators to involve recreational divers in hull inspections of yachts and commercial vessels. In addition, the appendices include voluntary codes of conduct for many sectors (vectors), including aquaculture. It was agreed that use of non-native species for aquaculture ought to be discouraged generally, and, wherever used, the species should be contained in secure facilities.

In 2006, the Palau National Invasive Species Committee reviewed the NISS. The committee modified language for clarity and to make several of the major goals and objectives more comprehensive (Palau Invasive Species Committee 2006a, 2006b). The NISS added a fifth major goal, that of increasing public awareness and support for invasive species prevention and management.

Following its review of the NISS, Palau's National Invasive Species Council developed an Action Plan (Palau National Invasive Species Committee 2007). The Action Plan follows the structure of the NISS closely, laying out specific actions to be taken to achieve the goals and objectives of the NISS as well as time frames for these.

Palau took some initial steps to gather baseline data on invasive marine species within its borders. With help from Australian scientists, the NISC and other agencies carried out a training workshop and a baseline survey of its major port in 2007. Several new non-native species were found as a result of this survey and a manual removal of some of these was attempted. In addition, a public awareness campaign was carried out by Koror state on an invasive anemone in Jellyfish Lake (Palau National Invasive Species Committee 2007). To the best of our knowledge, however, there have been no follow-up marine surveys, nor is it clear that any actions are being taken to prevent further introductions to Jellyfish Lake.

Palau also launched major campaigns to eradicate tilapia that involved the assistance and support of many agencies and community members (reviewed by Walsh et al. 2010). Tilapia was also added to the list of species prohibited for import into Palau, although the government is now

reconsidering this (as noted in Chapter 4).

In 2010, during the present analysis, Palau was considering the adoption of a biosecurity bill. The bill would create a Division of Biosecurity, increasing the ability of biosecurity agents to inspect incoming vessels and goods and to act to control or eradicate pest or disease outbreaks. The bill would specifically prohibit the release of bilge or ballast water in Palauan ports (draft version February 2010), but otherwise would not address ship-mediated invasions. Many of its provisions, such as requiring an incoming vessel to submit voyage records prior to arrival, and granting biosecurity agents the power to sample vessels or parts of vessels, would create an initial framework to reduce ship-mediated invasions associated with ballast water and hull biofouling .

6.2.5.2 Republic of the Marshall Islands

At the time of our analysis, the Republic of the Marshall Islands (RMI) was also considering a biosecurity bill, which was nearly identical to Palau's (based on a draft version as of September 2010). In this bill, discharge of ballast or bilge water is prohibited "at sea" in the Marshall Islands rather than specifically in port and the maximum fine for such discharge is \$100,000 (no specific fine is listed in the Palauan bill). This is the only specific reference to marine species and their vectors.

6.2.5.3 Federated States of Micronesia

Chuuk State's Invasive Species Taskforce has developed a draft strategic action plan (Chuuk Invasive Species Task Force Strategic Action Plan, draft version November 2010). The plan focuses on programmatic development, including finding funding and resources, building capacity, increasing coordination between agencies, and generating public awareness. However, it also (a) includes eradication/control measures for two terrestrial plants on the island of Weno, (b) identifies one marine species – the crown-of-thorns sea star (*Acanthaster planci*), a native species which can severely impact coral reefs -- for control measures in Chuuk Lagoon as well as some of the outer islands and (c) calls for 10 surveys in the Chuuk Lagoon and six on outer islands to identify other invasive marine species. No measures for preventing non-native species transfers are addressed.

Kosrae's Invasive Species Action Plan is modeled on the SPREP plan, based on that plan's three major theme areas and nine sub-themes (Section 6.1.3). The Kosrae plan lists specific objectives to achieve the more general objectives suggested by SPREP, however the proposed activities do not appear to meet objectives in many instances. For example, the general Objective 2 in Table B1.2 is "Monitoring invasive species movement on island, and between countries and territories." The matching proposed specific objective is to "review existing port and border surveillance and rapid response arrangements" and the proposed activity is "quarterly visits to Quarantine for bio-security updates." It is not evident how this would result in species-level monitoring information. Although marine species are mentioned in the Kosrae plan, no specific vectors are addressed nor are any actions proposed to deal with marine species.

6.2.5.3 Individual U.S. Military Bases

A publication that reviews 12 case studies of invasive species on military bases and lays out some basic recommendations for the military was prepared for the DoD by the National Wildlife Federation (Westbrook et al. 2005). Among the recommendations is the inclusion of an invasive

species management plan in a base's Integrated Natural Resource Management Plan. The document states such plans ought to emphasize prevention and rapid response and identify target species for which management actions should be detailed. The authors emphasized the importance of education and outreach and coordinating efforts with civilian groups and agencies already working on invasive species. Additionally, they called for specific funding for invasive- species management on bases and for bases to support research on prevention and control techniques. Marine species were not addressed specifically in the plan, either in the case studies or recommendations. As far as we can determine, the report's recommendations have not been officially adopted by the DoD.

6.3 Conceptual Framework for Vector Management

In marine ecosystems, invasions have often resulted from the broad scale transfers of entire species assemblages or communities, such as those associated with ships' ballast water or hull fouling communities. These are relatively non-selective mechanisms and literally thousands, if not tens of thousands, of species may be entrained by them. It is difficult to predict which organisms will be associated with any particular transfer (vessel), let alone estimate with any confidence which of these may cause severe ecological or economic impact. Neither is it easy to predict the next 'new' invasive species, particularly in the tropics. While targeted movement of individual marine species also occurs (as noted in Chapter 4), and some of these species have invaded new regions with negative effects, the fact remains that most invasions are attributed to the above "bulk" transfers.

As a result of this history, marine invasion management and policy has focused strongly on treating the vector, rather than taking a species-specific approach. This is particularly evident in the evolution of ballast water treatment (see Chapter 2 for review). This led Ruiz & Carlton (2003) to outline a conceptual framework for vector management, highlighting the interplay of research, management, and policy. Although motivated by a particular vector, they also considered the general principles and approach to have broad application to other vectors and ecosystems, and even to management of single species.

Figure 6.1 illustrates the four core components of vector management. First, vector analysis (research) characterizes the propagule supply, or species composition and abundance, associated with a particular vector, including the operation of the vector and factors that affect the supply of organisms delivered. Second, vector strength assesses the number or proportion of invasions attributed to the vector. Third, vector interruption (or disruption) represents management action or treatment to reduce the likelihood of transfers and invasions. And fourth, efficacy of vector interruption measures the effectiveness of the action on (a) reducing or interrupting organism transfers and (b) decreasing the establishment of new invasions.

Vector management can be characterized as a stepwise and interactive process within this framework (Ruiz & Carlton 2003). Information about transfers and invasions of species associated with a vector (components 1 and 2, Figure 6.1) form the basis for management action (component 3) to interrupt the invasion process. Following management action(s), it is also important to evaluate the efficacy of this action (component 4), in terms of its intended effect on reducing transfers (4a) and also subsequent invasions (4b). The two types of efficacy measures are complementary and necessary. The former measures the short-term proximate effects of

management on species during the transfer process, and the latter assesses whether the ultimate goal of reducing invasions is achieved.

While each of these components plays a clear and important role in vector management, it is important to recognize that it is the interaction among components that plays a vital role in creating an effective program and desired outcomes for biosecurity. This interaction or relationship among the components forms the basis for adaptive management, whereby initial management actions (component 3) are evaluated (component 4), providing feedback about whether these have been sufficiently effective or whether further actions are required.

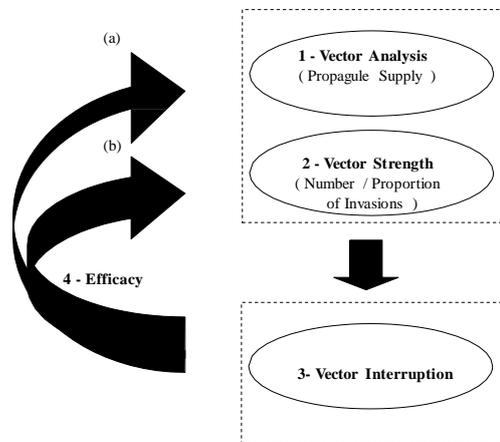

Figure 6.1. Framework for vector management. Vector management consists of four components and the interactions among them: (1) Vector analysis – characterization of vector operation, including organisms transferred by the vector; (2) Vector strength – assessment of the number or percent of invasions attributed to a particular vector; (3) Vector interruption (disruption) – actions taken to reduce the transfer of organisms and likelihood of invasions; (4) Efficacy – measurement of the effect of vector interruption on the transfer of organisms (4a) and number or rate of invasions (4b). [From Ruiz and Carlton 2003, Figure 18.3]

Such a feedback loop is a vital part of biosecurity, as in other areas of environmental management for multiple reasons. First, science often cannot predict the exact quantitative response of actions, due to uncertainties in the available data or sometimes complex mechanisms. Second, management is often based on historical patterns of invasion, which may not anticipate changes that will affect underlying processes and dynamics, such as global trade patterns or climate change (in the case of invasions).

We consider this a useful framework to use in evaluating the operational structure and present gaps for vector management in Micronesia. A successful biosecurity program requires that each of these components, operating together to provide the necessary policy framework, management actions, and directed research for successful management. Moreover, vectors are the functional units that move species, and each vector often involves a specific set of operating requirements, organizations and people, regulations, and information resources. Thus, evaluating biosecurity from a vector management perspective, may more effectively target and transfer specific recommendations to the appropriate user groups.

In the section below, a vector management framework is used to evaluate the existing biosecurity program by vector in Micronesia. This summarizes some information presented previously in the report and uses this background to advance recommendations to address specific gaps for prevention of coastal marine invasions. Additional aspects of biosecurity, beyond those aimed at

prevention, are considered in subsequent sections.

Although the current focus of this analysis is on Micronesia and Hawai'i, many of the same issues and recommendations are relevant to other global regions. This biosecurity plan therefore provides a model to consider for potential broader application, especially for DoD activities, where biosecurity practices are established globally by one entity; in contrast, practices for commercial and other non-DoD activities are highly variable around the world and governed by many different jurisdictions.

6.4 Prevention of Marine Invasions: Vector Management Recommendations

The primary objective of biosecurity is to minimize the likelihood of new invasions and associated undesirable impacts. While biosecurity can include post-border responses to new incursions, such as eradication, containment, and control, a premium is usually placed on pre-border efforts that aim to prevent invasions from occurring in the first place. Prevention, or minimizing the probability and number of new invasions, is usually viewed as the most cost-effective and desirable strategy to pursue, because it can be extremely difficult to eradicate or control species once they have colonized a region (Wittenberg and Cock 2005).

Prevention measures are directed usually at specific vectors and aim to reduce the magnitude (concentration or abundance) and frequency of species transfers to a target area. Such measures may be aimed at entire communities (e.g., ballast water of ships, as discussed in Chapter 2) or particular species of concern, and vectors are an explicit focal point for evaluation and management action(s) in most cases. Thus, vector management is a central aspect of most efforts to prevent invasions, whether on land or in water.

Here, the management of specific vectors is addressed to prevent or minimize marine invasions in Micronesia, considering current efforts and providing recommendations. This is organized by vector, treating separately DoD versus civilian activities, although we recognize that the level of DoD activities (and personnel) in the region also affects commercial and private activities. Our goal is to evaluate and consider three components of vector management (vector analysis, disruption, and efficacy; Section 6.3) in this treatment, focusing on the specific vector itself. This analysis does not yet consider broader issues, such as cross-vector management opportunities, institutional and political frameworks, or coordination and capacity within (and outside of) Micronesia, or post-border management of marine invasions. These other dimensions of biosecurity are discussed in subsequent sections.

In the treatment below, it is assumed that the transfer of non-native species to Guam presents some risk of invasion and impact, as outlined in previous chapters. Controlling for other factors, it is also assumed that the likelihood of establishment increases with (a) increased number of individuals, or propagule supply, of a single species and (b) the number of species. There is strong empirical and theoretical support for these assumptions. While not all species have the same probability of establishment or would result in the same impact(s), both of which would also vary geographically, the information needed to make such distinctions is extensive and simply not available; this limitation results from both a general lack of necessary data and also time. Thus, the evaluation that follows (a) takes a precautionary approach that assumes invasion risk is positively related to magnitude of organism delivery and (b) assumes the goal of vector management is to

reduce the unintentional or unwanted transfer of species and associated probability of invasions; we recognize that the desired level of protection (or acceptable risk) depends upon values, requiring political and social decisions. This approach is consistent with that used to develop existing regulations and guidelines for ballast water management and which is also being used to advance recommendations for management of biofouling on vessels (see Chapter 2).

6.4.1 Military Vessels: (A) Ballast Water

6.4.1.1 Vector Analysis. There have been a few previous studies of organisms in ballast water of U.S. Navy vessels (Holm et al. 2005; Ruiz and Smith 2011), but we could find no such data for vessels arriving to Guam, other parts of Micronesia, or Hawai'i. It is clear from studies of ballast water, that geographic source(s), age, and environmental conditions affect biological contents in ballast water, such that extrapolation from other studies may not be representative of vessels arriving to Micronesia (Verling et al. 2005, National Research Council 2011).

More surprising, there is a conspicuous lack of available information on ballast water discharge and management for most U.S. Navy vessels, or any other military vessels, arriving to Micronesia or Hawai'i. While the Navy has a requirement to record ballast management information in ships' logs, these data are simply not available for analysis. It is not evident that any record keeping is required currently for other DoD vessels. For both U.S. Navy and other DoD vessels, no studies were found that characterize ballast delivery and management patterns in the region.

The lack of data on ballast water discharge and management represents a fundamental gap for effective vector management. Without access to simple reporting data it is not possible to assess the flux (quantity or quality) of ballast, the level of implementation with specific guidelines (see 6.4.1.3), and any gaps in current management practices, as is now undertaken for commercial ships (see Chapter 2).

As noted previously in Chapter 2, there is uncertainty about whether vessels operating under MSC are expected to follow ballast water practices required for U.S. Navy vessels under OPNAVINST 5090.1C, or whether these vessels are expected to follow USCG ballast water regulations for commercial ships when arriving to Guam, CNMI, and Hawai'i. At present, relatively few follow the latter, and most ballast water management and discharge practices are not known for these vessels.

To assess the potential transfers of organisms associated with ships' ballast water, in order to inform appropriate management responses, we recommend that the following minimum steps be adopted by DoD:

- 1. Implement a system for U.S. Navy ships to report ballast water discharge per port arrival in Micronesia and Hawai'i, modeled after that used by USCG, such that the data are compiled electronically at a centralized database.** This should include key information on volumes, sources, and management (treatment). The data are not restricted to port activities but intended to include all ballast operations in Micronesia and Hawai'i. Although the U.S. Navy is required to log these data, none of this information is available, nor has it been examined or evaluated, to our knowledge.
- 2. Extend a ballast water reporting requirement and reporting system to all military vessels operating in Micronesia and Hawai'i, including those operating under MSC and other branches of the military.** This could be the same reporting system outlined in Recommendation #1, to avoid redundancy. If multiple reporting systems, however, they should be designed to assure the same data are collected across vessels, using the same data fields and units of measure.

3. Conduct an initial comprehensive analysis of current ballast water discharge and management patterns by U.S. military vessels, including those operated under MSC and all branches of the DoD, for Micronesia and Hawai'i. This should be part of a report on the current operation of this vector, and it may be repeated at some regular interval, as part of assessing program efficacy (see Section 6.4.1.3).

We note that the number of vessels arriving to these regions is relatively small, compared to similar nationwide and continuous analyses of commercial vessels by USCG. Thus, implementation of these recommendations is not expected to require a large effort, especially as good models for these activities already exist, in the U.S. and other countries, and can serve as blueprints to minimize time and expense in system design.

A reporting and analysis program is a logical and necessary first step in evaluating current marine invasions risks associated with ballast water by military vessels in Micronesia and Hawai'i. Depending on the outcome, an analysis of associated biota may also be needed, as discussed further below.

It is also useful to recognize that such a program for ballast water analysis of DoD vessels in Micronesia could serve as a pilot project for possible broader application. First, this program could be applied to other geographic regions, and perhaps to all regions, because the same issues and information gaps outlined previously apply broadly. Second, an initial analysis would provide a useful baseline, against which ongoing or future data collection and analysis could examine effects or changes in ballast water management and risks (see Section 6.4.1.3).

6.4.1.2 Vector Disruption.

Although the U.S. Navy has requirements for ballast water exchange, these are not as stringent as those for commercial vessels, because the exchange is allowed to occur much closer to shore (see Chapter 2). In addition, the treatment requirements are changing for commercial ships, under pending U.S. regulations and IMO requirements, to the use of technologies to achieve particular concentration-based discharge standards. Although military vessels are not required to comply with the regulations for commercial vessels, it is evident that they frequently will exceed the commercial vessel standards in the future. No plans have been identified or stated by the U.S. Navy to address this disparity.

More broadly, specific guidelines or requirements do not appear to exist for ballast water treatment of vessels operated under other branches of the U.S. military. Under the U.S. Clean Water Act, discharges by military vessels must comply with UNDS. Since 1999, ballast water has been designated as one of the discharges for which standards are being developed, but specific UNDS requirements have not been provided to date (United States Environmental Protection Agency 1999).

Despite the U.S. Navy requirements for ballast water exchange, it is not clear whether vessels operating under MSC — especially those operated under contract that are not Navy-owned must follow Navy requirements for ballast water treatment (as noted above). Moreover, it does not

appear that there are requirements for ballast water treatment by other vessels (e.g., barges and supply vessels) under contract to DoD, including those during the Buildup, other than those that may apply to commercial vessels. As with MSC vessels, however, we believe it is ambiguous to contractors and vessel operators as to which requirements may apply to them, and there are currently no requirements for private or commercial vessels arriving to Micronesia, outside of those in Guam and CNMI (see Chapter 2).

To reduce organisms transferred in ballast water and the associated invasion risks, we recommend the following steps by DoD:

4. Revise and upgrade current treatment requirements for U.S. Navy vessels to converge on those for commercial vessels. The goal should be to (a) increase the distance from shore for ballast water exchange in the immediate and short term and (b) plan for ballast treatment technologies to further reduce the concentrations of coastal organisms in ballast tanks.

5. Clarify explicitly whether current U.S. Navy regulations apply to all MSC vessels. We further recommend that the Navy inform all vessels (including contractors) operating under MSC whether they are subject to U.S. Navy or USCG requirements of ballast water treatment.

6. Establish ballast water treatment requirements for vessels operating under all branches of the U.S. military. We suggest a similar treatment approach to that recommended for U.S. Navy vessels (above), and this could perhaps be accomplished by UNDS. However, there is a premium on timeliness, especially with respect to the Guam Buildup.

7. Establish ballast water treatment requirements for vessels operating under contract to any branch of the U.S. military to include barges, supply vessels, or any other vessel type capable of carrying ballast water. This could include clarification that all U.S. federal regulations apply to these vessels, as well as separate requirements for other countries in Micronesia. We further suggest separate outreach and implementation tools should be considered for contract vessels and contractors, compared to those military- owned or operated vessels (see 6.4.1.3). As above, there is a premium on timeliness, to coincide with the context of expected increases of activity during the Guam Buildup construction phase.

6.4.1.3 Efficacy.

Previous work measures the efficacy of ballast water exchange aboard MSC vessels (Chapter 2), suggesting a greater distance from shore is desirable to minimize transfers of coastal organisms, as recommended above. While these experimental measures or assessments of efficacy are highly informative, there are two other dimensions of efficacy that require additional consideration and attention.

First, it is not clear the extent to which the current U.S. Navy policy is implemented. As discussed above, there has been no evaluation or analysis to verify the frequency of compliance with U.S. Navy requirements. This is perhaps most striking for MSC vessels (as above) and also likely most important here, because these vessels tend to carry and discharge more ballast than surface combatants (United States Environmental Protection Agency 1999). However, we have

highlighted the lack of sufficient data and analyses to assess the performance (compliance) of all U.S. Navy vessels. This is largely an issue of short-term efficacy, evaluating whether the treatment is implemented properly to achieve the desired reduction in abundances of organisms in ballast water (component 4a of vector management; Figure 6.1).

Second, the extent to which new invasions by non-native marine species are accumulating in Guam or other areas is largely undefined. Past surveys indicate invasions are occurring, but the scope and timing of these is poorly resolved, because there are no consistent or long-term programs that exist in Micronesia with this purpose. This data gap presents a challenge for evaluating the long-term efficacy of management for ballast water, as well as all other vectors, to prevent invasions (component 4b of vector management; Figure 6.1). Although such data limitations are not unique to Micronesia (National Research Council 2011), they are more pronounced here than in some other global regions, where (a) more research has been conducted, (b) the biota is less diverse, and (c) the biogeography of organisms is better understood.

While field-based surveys of marine organisms are the only way to address this second measure of efficacy, it is important to also consider briefly the application and interpretation of field survey data. Although this section focuses on ballast water, surveys would in fact have application for other vectors as well. While surveys to test for invasions due to ballast water may focus on particular types of organisms (i.e., those transferred in ballast water), some organisms are specific to ballast water (holoplankton) and others are possibly transferred by ballast and hulls of ships (e.g., many benthic invertebrates with plankton larvae); the potential vectors associated with invasions can be ascribed based upon life-history information of the species (see Chapters 1 and 5). Importantly, for those species invasions attributed to ships, it is usually not possible to know which specific ship(s) caused an invasion, or in many cases whether it was military or commercial. Thus, field surveys provide critical information to know whether particular vectors are allowing invasions to occur, but they usually cannot pinpoint the exact, specific vessel or event responsible. In this sense, such field measures provide a broad indicator of status and trends of invasions, and the extent to which particular vectors continue to result in new invasions, in response to current management practices (vector disruption; Figure 6.1).

Another important application for field surveys is in creating the potential to respond to new incursions, when they occur. There is considerable literature and interest in “Early Detection and Rapid Response” (EDRR) to invasions, which obviously requires a system for detection of new non-native species as they arrive and establish new populations (Wittenberg and Cock 2001; McNeely et al. 2004). Thus, depending on the particular goals for field surveys, they have application for both assessing vector management (invasion prevention) and triggering invasion response (e.g., control, eradication, or containment).

To assess and improve efficacy of ballast water treatment, we recommend that DoD take the following steps:

8. Assess the extent of ballast water treatment (both in terms of percentage of vessel arrivals and discharge volumes) prior to discharge by U.S. Navy and other military vessels arriving to Micronesia. The data for this, as well as the analysis could be a component of Recommendation #3 (above), if implemented. This may need to be done at regular intervals,

especially if and when (a) compliance with existing requirements is low or (b) requirements for ballast water treatment change.

9. Establish a program that implements targeted outreach and administrative tools to increase compliance with ballast water treatment requirements (see Recommendations #4-7) for military and non-military vessels associated with the DoD. This applies to commercial and contracted vessels (including barges and cargo vessels) that operate under contract to the Navy, or MSC, as well as all other vessels that arrive to U.S. Navy or other DoD facilities. For example, requirements could be explained in educational materials and also could be specified in contract agreements. No requirements are specified currently by DoD for many vessel types, and there is uncertainty about what requirements exist (as discussed above). Such a program would apply to U.S. Navy vessels only as needed, if compliance is low or requirements change (see Recommendation #8).

10. Implement a program of field-based surveys in Micronesia, including but not limited to Apra Harbor, to (a) assess efficacy of vector management practices to prevent invasions and (b) provide detection capability for response(s) to new incursions that occur. While this need exists throughout Micronesia, Apra Harbor is a high priority, given the high level of shipping and other vector activities that already exist and are expected to increase as a result of the Guam Buildup (See Chapter 3). This program should involve DoD working in partnership with other federal and local agencies throughout Micronesia. The use of these survey data are not restricted to management of the ballast water vector, but have broad applications. Further aspects of survey design and goals are discussed in Section 6.5.

6.4.2 Military Vessels: (B) Compensating Fuel Tanks

Although the discharge of seawater from compensating fuel tanks by DoD vessels has been suggested to be an activity with a “low risk” of transferring non-native marine species, we were unable to locate any analysis that characterized and evaluated the locations, volumes, and biological content of marine organisms being discharged from these tanks. The classification of “low risk” comes from the Phase I assessment review to develop UNDS, and it results because ships do not generally take on seawater in compensating fuel tanks within ports (United States Environmental Protection Agency 1999). However, vessels do discharge in coastal water or ports, and the sources of seawater in fuel tanks may be near to shore, depending on the particular mode of operations (i.e., where fuel is used and where seawater compensation occurs). Thus, despite the previous assessment, it does appear that transfers of organisms can occur with discharge of seawater from compensating fuel tanks, and that some of these organisms can be coastal species that are non-native at the discharge location.

The extent to which coastal organisms are transferred from one location to another will depend greatly upon the source locations of the seawater used in tanks. Although invasions can occur at many depths and distances offshore, most marine invasions are known from bays or ports, and some are known from adjacent coastal habitats (Chapter 1). Thus, minimizing transfers of coastal organisms, either directly between bays or in close proximity to bays (where adjacent coastal waters be a source or recipient of non-native organisms that can reach suitable habitat for

colonization), has been the main focus of prevention for ballast water management, and a similar rationale would apply to compensating fuel tanks. To our knowledge, the extent (including frequency and volume) with which such transfers occur from discharge of compensating fuel tanks has not been characterized for DoD vessels operating in Micronesia or elsewhere.

Although we recognize many vessels are expected to carry seawater from open ocean sources in their compensating fuel tanks, low frequency discharges of water from coastal sources may pose an elevated risk of invasion. The key question that should be addressed is whether and the extent to which this occurs. To answer this question, and evaluate whether further management is desirable, we recommend that DoD take the following step:

11. Evaluate the locations and volumes of seawater operations (including both uptake and discharge) for compensating fuel tanks discharged in Micronesia. If uptake occurs close to shore, review and revise current practices to achieve one or more of the following outcomes: (a) prevent uptake close to shore, setting specific minimum distance requirements; (b) prevent discharge close to shore, setting a minimum distance requirement, for seawater from coastal sources (as outlined in “a”).

6.4.3 Military Vessels: (C) Biofouling

The U.S. Navy has focused considerable attention and resources in analysis and prevention of biofouling on vessels, as well as the development of methods for hull husbandry. Indeed, it is recognized as a world leader in advancing basic and applied research for this area. However, the primary focus of this effort has been on maintaining operational performance, efficiency, and readiness of the vessel, and not prevention of non-native species transfers and invasions.

As outlined in Chapter 2, a program for maintaining operational performance does not necessarily meet criteria for preventing invasions, as these are two very different objectives that strive for distinctly different outcomes. A vessel can operate within an acceptable range of performance, and still transfer significant numbers of organisms associated with the hull and underwater surfaces, especially in niche areas (e.g., rudders, intakes, thrusters). In the sections that follow immediately, existing practices are evaluated from a biosecurity and vector management perspective.

6.4.3.1 Vector Analysis.

Although the U.S. Navy has specific policies and protocols for assessing biofouling on its vessels (Naval Ships Technical Manual 2006), and collects a significant amount of data in the process, it appears that these have not been used to estimate the extent (including abundance and species composition) of living organisms that arrive on vessels to Guam, other parts of Micronesia, Hawai'i, or other global regions. We did not have access to these data to evaluate their scope and potential application for this purpose.

While the current U.S. Navy program for biofouling assessments applies to Navy-owned vessels, it appears that privately owned vessels under contract to the Navy generally do not participate in this program, including many vessels that operate under MSC. A limited survey of some of the latter vessels, upon arrival to Guam, indicated that the extent of biofouling can be relatively high (Chapter 2).

We are not aware of past analyses or existing programs that are designed to evaluate biofouling associated with amphibious vessels or other DoD vessels that arrive to Guam or other parts of Micronesia.

To assess the potential transfer of non-native species by ship biofouling, we recommend DoD take the following steps:

12. Evaluate the extent (including especially total abundance and species composition) of biofouling on all types of DoD and U.S. Navy vessels operating in Micronesia, including amphibious vessels and vessels operated under MSC. This requires in-water surveys of vessels at multiple time intervals, since biofouling changes through time. Particular attention should be given to “niche” areas (such as sea chests, rudder hinges, intakes, propeller, bilge keels, thrusters, and dry-dock block areas), as these are known to be areas of high-density and diversity. It is also important to include in this evaluation the different types of vessels, operating modes, routes and tempos; all of these characteristics affect biofouling. It may be possible to utilize existing U.S. Navy protocols, or augment these in some fashion, but this should be evaluated to confirm resulting data can address biosecurity dimensions. It should be noted that a small percent cover over much of the vessel can result in a large total number of organisms for the entire vessels, and especially if high-density niche areas are present.

13. Track and evaluate changes in vessel traffic patterns and operations (including vessel types, geographic regions visited, port residence times, and speed) for all types of DoD and U.S. Navy vessels operating in Micronesia, including amphibious vessels and vessels operated under MSC. Variation in vessel traffic patterns and operations affects the quantity and species composition of biofouling organisms and therefore invasion risks (Chapters 2 and 5). While the U.S. Navy collects some of this information on vessel movements and tempo, this is used for a different purpose than biosecurity assessment, and some of these data have not been accessible for this report. An analysis of biofouling on current vessels is proposed in Recommendation # 12 for current military vessel traffic, but this does not evaluate potential future changes in vessel types and behaviors. A system for anticipating and tracking shifts in traffic could serve as an “early-warning” mechanism and trigger an explicit evaluation (as outlined in Recommendation #12; see also next section) for novel types of vessels or vessel operations for the Micronesia region.

Although the DoD must know the voyage histories and other operational details of its vessels, we were not given this information (except for MSC records) and therefore cannot evaluate what exists. However, it appears that a mechanism for ready access and integration of these data across different commands may not exist. Even within a command, there may be missing data for voyage histories, as was found for vessels under MSC. Having an efficient system for access to vessel data, both within and across commands, is necessary to implement Recommendations #12 and #13.

Although we are considering the use of these data for marine biosecurity purposes, such an information resource would no doubt have many other applications within DoD.

It should be noted throughout this discussion on vessel traffic data that no assumptions are made about who would have access to this information. It is understood that security concerns exist for some types of vessels. However, this does not preclude developing an efficient system for vessel information key to biosecurity analysis, and implementation of such an analysis, by DoD or its designees that avoids disclosure of sensitive information.

6.4.3.2 Vector Disruption.

The U.S. Navy has guidelines for management of biofouling to sustain operational performance of vessels (Naval Ships Technical Manual 2006), but it does not have specific guidelines or standards that aim to address the separate biosecurity concerns with biofouling. As noted previously, existing guidelines for both inspections and hull husbandry apply clearly to vessels owned by the U.S. Navy, but there appears to be uncertainty or ambiguity about their application to private vessels operated under MSC, including some prepositioned ships (Chapter 2). In addition, it appears that specific husbandry guidelines or requirements may not exist for the movement of decommissioned DoD vessels or the operation of vessels by DoD contractors (e.g., movement of barges and dredges).

Biosecurity standards for biofouling on commercial vessels are now emerging at the state, country, and international levels (Chapter 2). There is still some uncertainty about acceptable levels of biofouling and also the application of tools (e.g., in-water cleaning and various coatings) to achieve particular standards. Despite some uncertainty about the specific standards, there is nonetheless broad consensus (both in the scientific literature and among advancing standards) that heavily fouled vessels represent a high and undesirable level of marine invasion risk. Thus, a clear priority for vector disruption is in preventing the movement of heavily fouled ships, which carry high abundances of organisms and possibly high diversity.

To reduce the transfer and invasion risk of organisms associated with ship biofouling, we recommend DoD take the following steps:

14. Establish specific biosecurity criteria (requirements) for acceptable levels of hull biofouling for all types of DoD and U.S. Navy vessels, including amphibious vessels and vessels operated under MSC. These criteria should consider and draw upon existing guidelines that have emerged recently in other regions (see Chapter 2). In addition, the biosecurity criteria for biofouling should be included in the Naval Ships Technical Manual (2006) or similar document for application within the U.S. Navy and other branches of the military.

15. Extend DoD biosecurity requirements for acceptable levels of hull biofouling (Recommendation #14) to include vessels under contract to any branch of the U.S. military, such as barges, dredges, and other vessels. Separate outreach and implementation tools should be considered for contract vessels and contractors, compared to those military-owned or operated vessels (see 6.4.3.3).

16. As the highest priority: Implement (a) inspection of vessels operated under DoD with high biofouling potential, due to extended periods of lay ups or port residence times, and (b) cleaning for those that are heavily fouled prior to their movement into, out of, or within Micronesia. This is singled out as the highest priority for immediate action for both military and non-military vessels, as components of Recommendations #14 and #15, because movements of these vessels pose a high risk of invasions. Of great concern are prepositioned ships, barges, dredges, decommissioned vessels, and any other vessels that have extended residence times. To implement this recommendation, residence time (weeks to months) in a port or location should serve as the trigger for such action. While we do not provide a specific model of implementation we note that several options could be considered. The U.S. Navy has an existing program for inspection of vessels, which may serve this purpose for Navy-owned and operated vessels. In addition, the state of California is proposing that commercial operators provide documentation of hull biofouling surveys and cleaning (if needed), at regular intervals and more frequently for vessels with extended residence times; some variation of this approach could also be used for DoD vessels.

17. Review and establish criteria for in-water cleaning methods that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters. The results of this effort should be included in the Naval Ships Technical Manual (2006) or similar document for application within the U.S. Navy and other branches of the military.

6.4.3.3 Efficacy.

As outlined for ballast water in a previous section (6.4.1.3), assessing short-term efficacy of management (prevention) for biofouling transfers focuses on the extent to which biosecurity measures are met. To assess and improve efficacy, we recommend that DoD take the following steps:

18. Assess the extent to which vessels operating in Micronesia under DoD achieve acceptable levels of biofouling, as outlined in Recommendations #14-16. This assessment should include estimates (of percent vessels that meet desired biofouling criteria, as above) according to vessel type, allowing adaptive management to be targeted to address specific issues. The data for this analysis could be a component of Recommendation #12 and #16 (above), if implemented. Additional inspections may be desired, especially where data are insufficient and to ground-truth data for commercial operators. The assessment for this recommendation may need to be done at regular intervals, especially if and when (a) compliance with existing requirements is low, (b) biofouling levels change through time on each vessel, and (c) traffic patterns, vessel types, or vessel behaviors change.

19. Implement targeted outreach and administrative tools to increase compliance with biofouling requirements in Micronesia (see Recommendations #12-16) for military and non-military vessels associated with DoD. This applies primarily to commercial and contracted vessels (including barges, MSC, and other cargo vessels) that operate under contract to the Navy, or MSC, as well as all other vessels that arrive to U.S. Navy or other DoD facilities. For example, requirements could be explained in educational materials and also could be specified in contract

agreements. Such a program would apply to U.S. Navy vessels only as needed, if compliance is low or requirements change (see Recommendation #8).

In addition to these short-term measures of efficacy, there is also a need to assess the extent to which new invasions continue to occur, for which biofouling is a possible vector. The recommended action for this was outlined previously, as Recommendation #10, which was intended to encompass and serve equally to the needs for ballast water, hull biofouling, and many other vectors.

Another potential longer-term approach to assess efficacy (and invasion risk) is in modeling the capacity of organisms associated with biofouling (or other vectors) to colonize environmental conditions present in Micronesia. Since it is likely that some organisms that arrive to Micronesia are not able to survive local conditions, such an approach could refine a risk analysis, removing from further consideration those species that are not able to colonize. Although this is theoretically possible, the necessary data to construct these models are very limited for many species (see Chapter 5), although such studies may be feasible for better-documented taxa, such as marine macroalgae. Perhaps more problematic, the potential number of species being moved on ships in particular is vast, and any modeling would require an extensive program of sampling and taxonomic identification, in addition to knowledge about the organisms' tolerances. This approach certainly has some merits, especially for targeted and limited groups of species, but it also has clear constraints in the scope and speed with which it could be applied from a vector management perspective.

Finally, any specific responses to low compliance or performance of vessels to meet specific criteria for husbandry have not been addressed here, as this is beyond the scope of our analysis and requires consideration of the various institutional tools and approaches available to DoD. However, two different types of responses may be considered here. The first is approaches and tools to increase compliance in the future. The second is a short-term response plan to a breach in biosecurity. For example, if a vessel arrives that is heavily fouled, and may even intend to stay in port for a prolonged period of time, what is the response by DoD? The same question is relevant for vessels expected to discharge untreated ballast water. We recommend that DoD develop a response plan for such breaches in biosecurity, and this may benefit from coordination with other federal and state agencies; this recommendation for such a coordinated response plan is included in a subsequent section.

6.4.4 Commercial Vessels: (A) Ballast Water

Outside of U.S. jurisdictions, there are no existing requirements for ballast water management or reporting by commercial vessels that apply broadly to Micronesia. While a few countries have considered or developed guidelines, it is not clear the extent to which industry (a) knows these exist or (b) follows them. In general, there is a paucity of regional data for vector analysis or to evaluate the extent of vector disruption (ballast water treatment).

While it appears likely that the international treaty (convention) passed by the IMO will come into force in the near future, requiring the global fleet of commercial ships to treat their ballast water before discharge, it is also the case that most countries in Micronesia do not have a program to assess compliance with such ballast water treatment requirements. Thus, outside of U.S.

jurisdictions (which fall under USCG and the Environmental Protection Agency oversight), there is presently no mechanism to enforce or measure efficacy of any international standards for countries throughout the entire region of Micronesia. This gap is largely a lack of capacity, in terms of personnel, training, and supporting data infrastructure. In addition, even if the capacity were to exist, there may also be the need in some countries to legally authorize a lead agency to implement oversight of ballast water management for arriving vessels.

We recommend the following steps for ballast water management of commercial vessels arriving to countries throughout Micronesia:

20. Establish ballast water management and reporting requirements for all commercial vessels (including cargo ships, cruise ships, passenger ships, barges, and any other vessel that can carry ballast water) that operate in Micronesia. While international requirements for ballast management may occur if the IMO requirements are imposed on global shipping, separate regional action may also have advantages, in timeliness or addressing gaps that may exist regionally with IMO requirements. Regardless of the specific requirements implemented, there are currently no reporting systems in place for ballast water management in Micronesia, outside of U.S. jurisdictions, limiting any ability to assess compliance or efficacy of management for this vector. While individual countries could implement this recommendation, a coordinated and consistent regional approach is most desirable, for consistency and efficiency. It may also make sense to establish one regional program for implementation (see Recommendation #21), with participation from member countries.

21. Develop the capacity (personnel, training, and data management infrastructure) to evaluate ballast water management reporting and compliance by commercial vessels that operate in Micronesia. Ideally, this would be an integrated regional program with participation from member countries, because this approach would provide consistency and also economy of scale, especially for data management and analysis. There are many models for structure of such a program, including central coordination and distributed agents in member countries, and participating countries should agree on most desirable and functional model.

22. Review and revise (as needed) legal authority to implement ballast water management program for commercial ships operating in Micronesia, as outlined in Recommendations #20-21. This review should address authority to require reporting, implement inspections of vessels, and any enforcement tools desired in Micronesia.

23. Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of ballast water management requirements (see Recommendations #20) for commercial ships operating in Micronesia. As outlined in previous recommendations, a key component of outreach is regional coordination across the participating countries to provide a concerted and consistent message. A regional program for outreach should be considered, to achieve this outcome as well as economy of scale. If ballast water reporting is required (see Recommendation #20), this could use a web-based reporting system, which could also include a web-based information system on ballast water management requirements for the region.

6.4.5 Commercial Vessels (B) Biofouling

There are presently no requirements for management of biofouling on commercial vessels for biosecurity purposes in Micronesia. When considering a vector management framework, little information is presently available to assess hull husbandry practices or associated biota for vessels that operate in Micronesia. Yet, biofouling is responsible for a relatively large proportion of invasions on a global scale, and it appears to pose significant invasion risks to Micronesia (see Chapters 2 and 5).

Several jurisdictions around the world have voluntary guidelines for hull fouling management, and some of these are moving toward regulations to establish minimum frequency of hull inspection and treatment (e.g., dry-docking, coatings, cleaning). For example, California now requires commercial vessels operating in state waters to submit a Hull Husbandry Reporting Form once a year, as one step to assess potential biofouling based on hull husbandry and operations (especially extended residence periods in port), and has proposed regulations for permissible levels of biofouling.

For some regions, the types of approaches being considered or advanced to identify and treat vessels with potentially high biofouling levels include:

1. Ships agents/captains of vessels must maintain and submit records of anti-fouling measures and recent lay-ups to the harbor staff prior to arrival.
2. Vessels with extended lay-ups must provide evidence of inspection and (if necessary) hull cleaning, to meet acceptable levels of biofouling.
3. Any vessel which cannot present such records must remain in a quarantine area in water greater than 200 meters, in which remote video inspections could be done on the hull of vessels before entry into port is allowed.
4. Harbor staff or other designated enforcement agency staff have the authority to inspect vessels and require out of water cleaning (where possible) and/or refuse entry to heavily fouled vessels.
5. The harbor or other designated enforcement agency retains the right to clean the vessel at the owner's expense (either in dry-dock or with methods that minimize release of organisms to local waters) if it is heavily fouled and/or fouled with species determined to be potentially detrimental to the region.

In general, we recommend that the region develop a similar approach and take the following steps:

24. Establish biosecurity criteria (requirements) for acceptable levels of hull biofouling for all commercial vessels (including cargo ships, cruise ships, passenger ships, barges, dredges, fishing vessels, and other vessel types) that operate in Micronesia. These criteria should consider and draw upon existing guidelines that have emerged recently in other regions (as above; see also Chapter 2).

25. Establish reporting requirements on hull husbandry practices and operational characteristics for commercial vessels (including cargo ships, cruise ships, passenger ships, barges, dredges, fishing vessels, and other vessel types) that operate in Micronesia. Vessels should submit husbandry and operational profile in advance of arrival, and at a minimum frequency (e.g., annually) if in routine operation. If a vessel has a long port residence time or lay up (weeks to months), a new submission should be required.

26. Establish requirements for routine inspection and certification of biofouling levels for any commercial vessel that operates in Micronesia with a long port residence time or lay-up.

Of great concern are barges, dredges, decommissioned vessels, and any other vessels that have extended residence times, because these are prone to heavy biofouling levels. To implement this recommendation, residence time (weeks to months) in a port or location should serve as the trigger for such action. As one model to consider, the state of California is proposing that commercial operators provide documentation of hull biofouling surveys and cleaning (if needed to meet acceptable levels of biofouling).

27. Review and establish criteria for in-water cleaning methods for commercial vessels that do not pose a risk of spreading or releasing non-native organisms (which do not presently occur) in surrounding waters.

In-water cleaning is currently used and is likely to continue as an important management strategy to reduce biofouling on vessels, and there is a need for specific guidelines and protocols aimed specifically at reducing the associated invasion risks. Such guidance is not available in Micronesia.

28. Develop the capacity to (a) assess the extent to which commercial vessels operating in Micronesia achieve acceptable levels of biofouling (see Recommendations #24), and (b) respond to high-risk commercial vessels (i.e., those with high biofouling) that arrive to a port in Micronesia.

The first component requires establishing methods (i.e., protocols for hull biofouling assessment), training, personnel, and data management infrastructure to conduct an independent assessment of vector management efficacy at some interval and stratifies (distributes) measures according to vessel type. This may be repeated if and when traffic patterns, vessel types, or vessel behaviors change. The second component requires development of a response plan to unexpected events, in terms of who responds and the specific details or options for response; the need for response plans has broader application across many vectors, as well as response to new invasions, and is discussed in a subsequent section.

29. Review and revise (as needed) legal authority to implement biofouling management program for commercial ships operating in Micronesia (see Recommendation #24-

26). This review should address authority to require reporting, implement inspections of vessels, and any enforcement tools desired in Micronesia.

30. Implement targeted outreach to inform the shipping industry, ports, and resource management agencies of biofouling management requirements (see Recommendations #24-

26) for commercial ships operating in Micronesia. As outlined in previous recommendations, a key component of outreach is regional coordination across the participating countries to provide a concerted and consistent message.

In addition to measures focusing on incoming vessels, we agree with the recommendations of SRIMP-PAC (South Pacific Regional Environment Programme 2006) that countries should act to ensure that outgoing vessels, particularly those that have been in port for longer than a few days, are not departing with high levels of biofouling. Thus, the above recommendations focus on all operating vessels and are not restricted to just arriving vessels. In this context, relevant authorities may assess vessels prior to arrival or departure and determine that particular actions are required. An ideal long-term goal may be for increasingly broad-based programs, where countries in Micronesia work with SRIMP-PAC and SPREP to encourage Pacific Rim and other importing

countries to develop uniform clean hull standards.

6.4.6 Fishing Vessels

As with other types of commercial and private vessels, there are no marine biosecurity requirements for fishing vessels that operate in Micronesia, except those that may apply to ballast water discharge (see above and Chapter 2). Fishing vessels vary in size, type, and operations, including the extent to which they visit ports. While this may present some challenges in implementation of vector management (including reporting, assessment, and outreach) for these vessels, they are considered here as a type of commercial vessel. **The same recommendations for biosecurity practices on commercial ships, above, apply to commercial fishing vessels that operate in Micronesia.** Those recommendations that focus on biofouling have the most relevance in this regard, as many fishing vessels do not carry ballast water.

In addition to movement of organisms on ships' hulls and ballast water, fishing vessels may transfer live marine organisms in storage tanks (live tanks, storage holds, and wells) and on fishing nets and gear. In many cases, these may not be the fisheries species but incidental associated organisms, which can be small in size and not immediately evident. The extent to which this occurs in Micronesia is not clear, as detailed information is currently not available for the region.

Finally, fishing vessels that are seized and held in port (due to fishing or other violations) may pose an added risk of species introductions, if they are heavily fouled (see Chapter 3). Although a biosecurity program should reduce the occurrence of heavily fouled vessels in the region, it is nonetheless imperative to treat impounded vessels with an added level of scrutiny.

For fishing vessels, we recommend application of the previously outlined recommendations for commercial ships as well as the following:

31. Establish biosecurity practices and requirements for fishing vessels that operate in Micronesia to prevent the release of viable organisms associated with flushing of tanks (live tanks, storage holds, and wells) or cleaning of fishing gear. This should consider (a) the potential use of on-shore facilities for disposal of biological waste and (b) distance from shore (or ports) as a strategy to reduce likelihood of invasions.

32. Implement inspections of any impounded vessel in Micronesia to (a) assess level of hull biofouling and (b) treat vessels (if needed) to reduce biofouling to acceptable level. This recommendation requires specific protocols and capacity, which are addressed in Recommendations #24-29.

33. Implement targeted outreach to inform the fishing industry, ports, and resource management agencies of biofouling management requirements for fishing vessels operating in Micronesia. While this may overlap somewhat with previous outreach recommendations for other types of commercial vessels, it is also important to recognize that this is a unique segment of the vessel traffic. Moreover, outreach for other vessels would not include guidelines for impounded vessels, fishing gear, or unique holding tanks on fishing vessels. Making outreach materials available in multiple languages may be especially important for this segment of the vessel traffic.

6.4.7 Recreational Boats and Yachts

There are no biosecurity guidelines or requirements for hull biofouling associated with recreational vessels that arrive to or operate in Micronesia. Even though some recreational vessels can be heavily fouled, including transient vessels that travel great distances, a lack of biosecurity measures is not unusual for most global regions. However, some programs do exist in some countries to address this gap.

New Zealand has voluntary guidelines for recreational boaters, which are expected to become mandatory shortly. Boaters arriving to New Zealand are asked to arrive with clean hulls, having applied antifouling paint within 1 year of arrival, and to keep logs and records of anti-fouling measures to present to biosecurity agents. These agents inspect a boat's records and carry out hull inspections at ports of first entry into the country. They can also direct boat owners of heavily fouled boats to cleaning facilities where boats are cleaned at the owner's expense.

In Australia's Northern Territory, concern for marine pests (invasions) has led to requirements for recreational vessels entering ports in the Darwin area. Boat owners are being asked to either 1) demonstrate that their boats have been cleaned or painted with antifouling paint in Australia, or 2) undergo a hull inspection and cleaning of internal seawater systems. The cost of inspection and seawater-system cleaning is borne by local government. Both overseas arrivals and boats that have visited other ports in Australia are subject to these inspections.

To reduce risks of species transfers associated with recreational vessels and yachts, we recommend the following steps:

34. Establish biosecurity practices and requirements for recreational vessels that operate in Micronesia to reduce the transfer of biofouling organisms. As the number of recreational vessel arrivals to ports in Micronesia is relatively low, it is feasible to require that all arriving boaters present evidence of anti-fouling measures to port authorities and customs. This paperwork should be reviewed by harbor staff or other management agency prior to a boat's arrival and assessment made of whether a hull inspection is appropriate.

35. Establish the capacity to inspect and treat (if necessary) recreational vessels that operate in Micronesia to reduce associated biofouling to an acceptable level. This recommendation requires identification of acceptable levels of biofouling, methods of assessment (inspection) and treatment, and personnel (with training and authority) to implement. Several risk matrices exist for recreational boats. The matrix developed for the state of Hawai'i (Leonard 2009) should be reviewed and considered for application in Micronesia.

Finally, the Port of Guam master plan suggests that the haul out facility at Perez Marina might not be needed and recommends instead building an inspection, maintenance and repair facility at the Harbor of Refuge. If this occurs, it may have relevance and potential application for biosecurity measures outlined above.

6.4.8 Kayaks, Outriggers and Personal Watercraft

The use of small, personal watercraft can potentially result in transfers of marine organisms. Although the potential magnitude (numbers) of organisms moved may be relatively small via this vector, such transfers can result in new invasions and spread of organisms. Although the current analysis focuses on marine organisms, the potential importance of this mechanism is demonstrated by overland transport of zebra mussels on small craft in North America.

We recommend that the following step be taken:

36. Implement a targeted outreach program for DoD and civilian populations with specific guidelines on methods to minimize species transfers associated with small boats, jet skis, and other water sports gear being moved into or within Micronesia. DoD, Customs, and other agencies could provide DoD personnel, visitors, marinas, and sports shops with a checklist of gear/equipment for use in water that outlines simple, appropriate biosecurity practices. This could be extended to include SCUBA diving, snorkeling, and recreational fishing (see Recommendation # 42).

6.4.9 Amphibious Vehicles

Although protocols exist for removing biota from amphibious vehicles, we were not able to obtain data or locate any reports that assess the efficacy of current protocols in Micronesia, including (a) the extent to which protocols are implemented, (b) the efficacy in removing marine biota, and (c) what residual organisms may exist.

We recommend that DoD take the following approach for biosecurity surrounding amphibious vessels:

37. Assess efficacy of biosecurity protocols and revise (as needed) for DoD amphibious vehicles operating in Micronesia. In general, amphibious vehicles and any in-water gear and equipment that is moved into or within Micronesia should be decontaminated before departure from a location or before redeployment in water elsewhere. If the latter, vehicles and gear should be cleaned onshore, such that all biological material, sediment and wastewater is retained and disposed of properly, to prevent release of biota (including small organisms and resting stages) to waterways in the country or state of entry.

6.4.10 Grounded Vessels

As with impounded vessels, invasion risks may increase for grounded vessels, due to increased residence time for any organisms associated with the vessels' hulls and underwater surfaces. Based on Harbor Rules and Regulations of the Port Authority of Guam (2000), it would appear that the Guam Port Authority has the authority to remove sunken or abandoned vessels on Guam at the owner's expense. However, jurisdiction, response plans, and mechanisms for implementation of desired actions surrounding grounded or abandoned vessels are not so clear in many parts of Micronesia.

From a biosecurity perspective, any response plan should include an assessment of possible biofouling organisms and whether this poses particular risks of invasion, in addition to any

concerns about other impact to the local environment and navigation.

We recommend the following step be taken:

38. Clarify and establish for grounded and abandoned vessels in the various jurisdictions of Micronesia: (a) which agency has the legal authority for removal of grounded and/or abandoned vessels, (b) a response plan that includes assessment and removal of non-native species present, and (c) mechanisms (including funding and training) for implementation.

6.4.11 Other In-Water Structures, Equipment, or Gear

Any objects or surfaces exposed to marine waters can be colonized by marine (biofouling) organisms, and their movement from one location to another poses a risk of non-native species transfer and invasion. In addition to vessels, examples of other in-water structures, equipment, and gear that are moved commonly among locations include:

- Fish aggregating devices (FADs), which are objects deployed for long periods of time to attract fish, including vessels, buoys, and other floating objects.
- Dry-docks.
- Floating docks or pontoons, such as those in marinas.
- Fixed maritime structures, which are sometimes constructed elsewhere from new material or refurbished materials, are held in-water at other locations (including overseas) before transport and deployment.
- Mobile platforms, drilling rigs, and related equipment, such as used for oil and natural gas drilling/exploration.
- Buoys and channel markers.
- Scientific equipment.

All of these particular structures often have extended in-water residence times in one location before movement (if it occurs) to another location. In fact, many of these structures are known to accumulate dense aggregations of biofouling organisms, and examples exist in the published literature that document the movement of these structures (and sometimes very dense biofouling) among locations without any treatment. Importantly, this movement can occur across large geographic distances, introducing novel non-native biota.

At the present time, there are no biosecurity requirements for the movement of these and other similar structures into or within Micronesia. This represents an important gap in preventing non-native species transfers. Even though the frequency of moving these structures may be low, such

rare events have the potential to represent high-density inoculations of marine organisms in the absence of any assessment and management action (where needed to reduce such transfers).

We recommend the following steps be taken:

39. Establish biosecurity practices and requirements for the movement of any in-water structure (including FADs, dry-docks, floating docks, fixed structures, mobile platforms and drilling rigs, buoys and channel markers) to reduce the transfer of biofouling organisms into or within Micronesia. This recommendation includes establishment of acceptable levels of biofouling and also the legal authority to implement these practices in the various jurisdictions.

40. Establish the capacity to inspect and treat (if necessary) in-water structures that are being moved into or within Micronesia to reduce associated biofouling to an acceptable level. This recommendation requires specifying methods of assessment (inspection) and treatment, a lead agency with authority, and personnel (with appropriate training) to implement.

Because the movement of some types of in-water structures by DoD has occurred historically, and may occur in the future, this recommendation applies to both DoD and the various countries of Micronesia, understanding that the particular assets or structures may differ among jurisdictions.

6.4.12 Construction Materials

Movement of construction materials can transfer associated marine organisms, especially when materials are moved directly from one in-water or shore location to another. Examples of construction materials that are commonly moved from one geographic source location for application or disposal at another, which can transfer organisms, include: sand, gravel, rock, coral rubble, and dredge spoils. Even a brief holding period (days to weeks) out of water may not prevent biotic transfers associated with construction materials, because some organisms (and their resting stages) can persist out of water for long periods, especially under damp conditions. We recommend the following biosecurity measure:

41. Establish biosecurity practices and requirements for the movement of any construction materials that are sourced from marine waters and shores (including sand, gravel, rock, coral rubble, and dredge spoils) to reduce the transfer of marine organisms into or within Micronesia. This should include consideration of sources, treatment (including extended holding periods on land), and certification or inspection to confirm implementation.

This recommendation applies to both DoD and the various countries of Micronesia, as construction and construction materials are used by all entities.

6.4.13 Diving and Recreational Fishing Gear

Movement of diving gear and recreational fishing gear has the potential to transfer non-native marine organisms among locations, even though in-water exposure is episodic relative to structures and vessels (above). Invasions appear to have resulted from this mechanism, including invasions by zebra mussels in isolated quarries used for diving in the eastern U.S.

(<http://www.dgif.virginia.gov/wildlife/zebramussels.asp>).

To minimize the transfer of organisms, we recommend the following step:

42. Implement a targeted outreach program for DoD and civilian populations with specific guidelines on methods to minimize species transfers associated with diving gear (whether work or recreational) and fishing gear being moved into or within Micronesia. DoD, Customs, and other agencies could provide DoD personnel, visitors, sports shops, and marinas with a checklist of gear/equipment for use in water that outlines simple, appropriate biosecurity practices. This could be extended to and coordinated with a similar effort for recreational small water craft (see Recommendation # 36).

6.4.14 Live Trade of Marine Organisms

It is evident that live trade, or the moving of live marine organisms, is common practice around the world, especially associated with aquaculture, food, bait, and pets (aquaria). Micronesia is no different in this regard. While there are some current biosecurity measures focused on live imports and aquaculture throughout the region, there are also inconsistencies and some gaps, and no overarching framework has emerged to date.

The International Council for the Exploration of the Sea (ICES), established in 1973, has developed a code of practice for reducing the negative impacts of non-native species associated with aquaculture and fisheries enhancement. This code, which is being promoted by the Food and Agriculture Organization (FAO), the IUCN, the Convention on Biological Diversity (CBD), and other international organizations, has since been revised several times. The current version (International Council for the Exploration of the Sea 2005) also covers organisms imported live for other purposes, such as food and bait, and includes practices to reduce the spread of disease and exotic genetic material.

ICES asks member countries considering new introductions to submit a detailed prospectus, including a risk assessment, to ICES for comment. Following an approval, countries are asked to adhere to a set of management guidelines for that species and to submit follow up reports to ICES. This process is largely advisory in nature, with implementation up to the countries involved, as ICES does not have regulatory oversight for participating countries.

Detailed guidelines for implementing the code are provided in three ICES documents (International Council for the Exploration of the Sea 1984, 1988, 2005). Appendices in these documents detail the preparation of the prospectus, risk assessment, quarantine procedures and monitoring.

Guidelines for species introductions for aquaculture were also developed and adopted by the FAO. These are outlined in two technical reports (Food and Agriculture Organization 1995,1996). The FAO advocates for the use of local species when production strategies are known and feasible; and it recommends the introduction of exotic species when the positive benefits are higher than possible negative impacts, always applying the precautionary approach when there are big information gaps. Taking the stance that all imported species will eventually escape the confines of their facility, the FAO recommends that risk assessments should be based on the assumption that these constitute introductions into the wild. Thus, the guidelines recommend that if a species is

approved for importation, a contingency plan for dealing with escape and mitigation of impacts ought to also be in place, and that the importing country should establish the legal framework for funding for such plans (Food and Agriculture Organization 1995).

The Secretariat for the Convention on Biological Diversity (CBD, 2004) has also published a series of recommendations for the development of sustainable mariculture. Like the FAO, the CBD recommends the use of endemic or native species in mariculture, and whenever possible, of culturing in contained facilities, rather than in open pens.

Finally, as noted previously, guidelines for evaluation of diseases and quarantine measures of aquaculture species have been recommended by SPC (Humphries 1995; see Section 6.2.2 above).

In general, we recommend that Micronesian countries and territories adopt the protocols and approaches outlined by ICES, FAO, CBD, and SPC. While some of these protocols are for a particular segment of live trade (e.g., aquaculture), their application should be considered more broadly to include all movement of all live marine organisms intended for the aquarium or pet trade, bait, scientific research or any other purpose that could result in the organism being released into the environment.

We recommend that the following steps to taken:

43. Establish explicit aquaculture biosecurity practices for Micronesia. This includes identification and adoption of specific protocols for risk assessment (see Recommendation #44, below), screening of pathogens, quarantine, inspection, and regional program oversight or assessment. A key dimension requires coordination and active involvement of relevant agencies and groups such as resources development, community colleges and invasive species management organizations. National, state, local/traditional governing bodies need to specify (and perhaps authorize) lead agencies and also oversight authority.

44. Establish a formal risk assessment process for all marine organisms used or proposed for live trade in Micronesia. The risk assessment should be science-based and applied consistently; the precautionary principle should be applied in cases where data are absent. Many references and toolkits for the development of risk assessment are available (i.e., International Council for the Exploration of the Sea 2005; Secretariat of the Convention on Biological Diversity 2010). Forums for sharing data relevant to risk assessment across the region should be developed. Risk assessments should be carried out for species already in trade or on already-developed “white lists.”

45. Create quarantine facilities for marine organisms for use in Micronesia. This may be a single regional facility or multiple facilities; if the latter, consideration should be given to having at least one facility with high-level technical capability and infrastructure. The facilities should follow specific, accepted protocols (see Recommendation # 43). The facility must have trained staff to carry out protocols, and must be sited in a secure location to minimize risks of accidental releases due to natural disasters such as typhoons, tsunamis, and floods.

46. Improve reporting and screening systems for import of live marine organisms in Micronesia. Ideally, prior to import, organisms would be identified to species and certified as free

of disease or associated by-catch organisms (such as additional species of invertebrates). Reporting or labeling for shipments would facilitate and improve biosecurity screening and reduce unwanted imports.

47. Provide quarantine agents in Micronesia with the necessary legal authority, training, and support to enforce requirements at border entry and post-border locations (e.g., aquaculture facilities and sales outlets). Capacity building and institutional strengthening of quarantine officers and agencies on aquatic biosecurity measures and aquatic animal health will be crucial for biosecurity management. There is currently a large knowledge gap on aquatic biosecurity within the agencies that will be tasked with implementing biosecurity measures.

Although Micronesia is a large and diverse region, with many cultures and jurisdictions, the recommendations for biosecurity practices of live trade apply throughout the region. Advancing a uniform and consistent approach to biosecurity throughout the region is most desirable, because it would likely reduce the effort and cost and would serve to increase clarity and possibly compliance, compared to an uneven patchwork of requirements and guidelines. Thus, communication, coordination, and participation among all member countries and jurisdictions in Micronesia is a critical approach toward this outcome.

6.5 Detection of Marine Invasions: Recommendations

Detection plays a vital role in implementing an effective biosecurity program. First, detection is used in vector management to assess (a) the extent to which new invasions are occurring and (b) the vector(s) responsible for these invasions. Repeated measures over time assess the efficacy of vector management to prevent new invasions, providing a core component of the vector management framework discussed above (Section 6.3; see also Figure 6.1). Second, the detection or occurrence of non-native species, and their geographic distribution, forms the basis for responses to new incursions, including eradication, control, or containment. Put simply, without knowledge of existing invasions no such post-border responses are possible.

Field-based surveys are required for both applications of detection. Moreover, it is critical that surveys are conducted using standardized and quantitative measurements that are repeated over time, if a goal is to understand temporal changes in non-native species diversity (number) at a site associated with particular vectors. It is clearly possible to detect species occurrences with many methods, but we suggest that assessing differences in time or space requires a formal, statistical approach (Ruiz and Hewitt 2002; Ruiz and Carlton 2003).

The design of field-based surveys should be driven by the particular objectives. Some of the key variables to consider include taxonomic focus, habitat focus, frequency, geographic scope, and specific methods. Methods include not only those surrounding the collection and analysis of biotic samples, but also issues of data and sample management or continuity (see Ruiz and Hewitt 2002 for discussion), especially if an objective is to provide comparisons with long-term measures, which engage different people (with staff turnover) through time. In addition, the use of genetic tools is a valuable component of surveys, providing (a) independent verification of taxonomic identification and (b) new methods to efficiently screen large numbers of species, using next generation sequencing /NGS (Hayes et al. 2005; Darling and Blum 2007; see National Research Council 2011 for brief discussion). However, prior to embarking on massive environmental

sequencing using NGS technologies, it will be necessary to build a DNA barcode library for the fauna and flora of the region. This will allow identification of environmental sequences obtained through NGS. One way to achieve this may be to undertake molecular-assisted alpha taxonomic studies (i.e., DNA barcoding-assisted taxonomic studies), which would provide rapid, standardized, quantitative, and reproducible results, particularly for insufficiently studied biota characterized by cryptic species (which is the case for almost all marine benthic taxa). The costs of DNA sequencing are rapidly going down, so in the near future this may be the most cost-efficient, as well as time-efficient, manner to undertake field-based surveys.

We recommended previously that a program of field based surveys be implemented in Micronesia, in part to assess vector management by DoD associated with vessels' ballast water and hull biofouling. Recommendation #10 states: "**Implement a program of field-based surveys in Micronesia, including but not limited to Apra Harbor, to (a) assess efficacy of vector management practices to prevent invasions and (b) provide detection capability for response(s) to new incursions that occur.**"

Here, further detail is provided to design and implement such a program, with a particular focus on these shipping vectors. While this is relevant to DoD activities and associated biosecurity, such a program also has relevance to commercial shipping in Guam and other regions of Micronesia.

We recommend the following steps be taken to advance a program of field-based surveys in Recommendation #10:

48. Develop a specific design for standardized, quantitative, and repeated field-based surveys for detection of non-native marine species in Apra Harbor, Guam, especially to examine species invasions through time associated with DoD and commercial vessels. We recommend that DoD assume a lead role in developing the design of these surveys, as well as their implementation (Recommendation #10), working in close partnership with (a) other federal and local agencies in Guam and (b) other countries and jurisdictions in Micronesia (see below). Surveys should focus on invasions due to shipping, because it is a dominant vector for marine invasions. In addition, an initial focus should be on Guam, because it is a regional hub for shipping in Micronesia (see Chapter 3). The design should explicitly define the taxonomic focus, habitat focus, methods for collection and analysis, frequency of sampling, and study duration to detect changes in non-native species diversity (i.e., new invasions) attributed to ships ballast water and biofouling through time. As noted above, these data examine the efficacy of vector management to prevent new invasions.

49. Develop a specific design for standardized and quantitative field-based surveys to compare non-native marine species present in Apra Harbor to other bays and ports in Micronesia, focusing particular attention to species invasions associated with vessels. We recommend that DoD also assume a lead role in developing and implementing these surveys. This is intended to examine geographic distribution of non- native species present in Guam (that resulted from transport by ships) and the extent of spread to other locations in the region. These data examine the efficacy of vector management to prevent the spread of invasions from Guam to other regions. Ideally, these surveys would be repeated over time, although perhaps at less frequent intervals than above (Recommendation #48). In addition to the broad-based surveys, a more focused and intensive approach could also be advanced for a few species, serving

as important model systems or indicators to understand spread dynamics (risk) in the region.

The above recommendations address the need to rigorously assess the pattern and rate of invasions to support vector management, including especially efficacy of current prevention measures, but do not provide a mechanism for early detection. New invasions may certainly be detected at an early stage in such surveys, but these are not designed explicitly for the purpose of early detection. To implement early detection capability, there are two general types of approaches that are used:

- First, field-based measures are explicitly designed and used to detect selected species of concern, focusing on sites where incursions are likely. These are usually focused efforts for known species, allowing tailored protocols (such as those implemented for brown tree snakes) at key points of entry; the goal here is intensive and efficient measures, instead of broadly trying to achieve early detection for many species at once.
- Second, a public outreach effort and reporting system is established to encourage any new or suspected non-native species to be detected. These can be either focused efforts (and complementary to the first method) for particular species of concern, or very broad-based efforts to include many species, taxonomic groups, and habitats. This approach obviously benefits from many potential observers who may encounter non-native species, either due to search or accident, and it is clear that many new marine invasions are first detected by the public (e.g., Chinese mitten crabs along the eastern U.S., Ruiz et al. 2006).

To be useful and effective at early detection, both approaches require personnel time and resources. This is most obvious in the first approach. For the second approach, the actual detection effort is distributed broadly, which has clear advantages and perhaps little direct cost, but it is also important to recognize that personnel are required for coordination (including communication and outreach) as well as verification and tracking of reported sightings.

To develop early-detection capacity for marine invasions, we recommend the following step:

50. Design and implement a public reporting system for new or suspected non-native marine species in Micronesia, as a component of education and outreach efforts in the region. This system could be designed for focus on particular species of concern (see next section) or provide broad-based early detection capability. This system should include a permanent hotline number and website, allowing the general public to report suspected non-native species and also provide a portal for additional information on non-native marine species, current policies, and actions throughout Micronesia. This contact information should be included in public outreach/education materials. A specific lead agency should be designated and provided sufficient trained personnel to respond to inquiries from the public, as part of the overall biosecurity program infrastructure for Micronesia (see Section 6.7.3). This reporting system, and overall program, must obviously be designed and implemented as a partnership between DoD and other agencies and jurisdictions throughout Micronesia. Some information is already shared within and among countries on an informal basis, and this reporting system would serve to (a) build upon current efforts, (b) establish a stronger framework, and (c) contribute to a regional database on non-native species records.

Focused early detection efforts, using the first approach above with field surveys to detect target species of concern, are considered further as possible responses in the next section.

6.6 Response to Marine Invasions: Recommendations

Throughout this chapter, a premium is placed on steps to prevent new invasions, as the highest priority for marine biosecurity, but we also recognize that there will be breaches of this security, occurring either as (a) the delivery of non-native organisms associated with a particular vector or (b) the establishment, colonization, or occurrence of non-native organisms in the natural environment. In each case, it is appropriate and desirable to consider a response plan to limit undesired impacts or outcomes associated with a breach or incursion. Part of this plan is a clear decision process about when and how to respond, as well as who should respond.

In Section 6.4 on vector management, specific recommendations were outlined for assessing and detecting breaches in biosecurity, during the transfer (vector) stage. For a breach at the vector stage, such as the arrival of a vessel that exceeds an acceptable level of biofouling, these previous recommendations included the development of a response plan; this is intended to define specific response actions, how and when to implement them, who would implement them, and the necessary resources to implement them.

A similar response plan is needed for a new incursion and breach at the invasion (colonization) stage, serving to define first if a response is triggered and then the nature of the response. The decision of whether to respond to a new invasion is a complex one, as it depends upon many factors, including: (1) the potential consequences or impacts of the invasion; (2) the chances of success or feasibility of achieving a desired outcome; and (3) the capacity and available resources needed for action.

In recent years, several non-native marine species have been the focus of successful eradications, demonstrating the feasibility of such efforts to achieve the desired outcome (Culver and Kuris 2000; Bax et al. 2002; Miller et al. 2004; Anderson 2005; Hopkins et al. 2011). However, not all invasions are conducive to eradication (or control and containment), as the effort and likelihood of success depends greatly upon the organism, its areal extent and abundance, and particular treatment options (Myers et al. 2000; Crombie et al. 2008; Edwards and Leung 2009). Furthermore, the consequences of invasions will differ among species and locations, reflecting the type and magnitude of effects as well as the social values in a region (see Appendix A).

Ideally, a response plan for new incursions would begin with an analysis of costs, benefits, and feasibility of achieving a particular outcome or objective, before proceeding to implement specific actions. The initial part of this two-step process is important for setting priorities, because (a) it is simply not possible to implement actions for all invasions with limited resources and (b) only a subset of non-native species will have high impacts. Unfortunately, the initial analysis step often requires data on the impacts of a species and the value assigned to those consequences (in addition to feasibility), which may not yet exist. Furthermore, where data on potential impacts are available, it is important to consider the level of uncertainty about how robust or relevant the data are for the region (Micronesia). Evaluating this information is thus central to establish an efficient response capability, and may guide the design of detection efforts (see Recommendation #50).

To develop a response plan for marine invasions, we recommend the following steps be taken:

51. Evaluate social, cultural, economic, and ecological values in Micronesian countries that may be impacted by invasions by non-native marine species. This follows and expands directly upon the pilot project (Appendix A) to adequately characterize core values at risk to invasions in the region, for inclusion broadly in decisions about management and response. The new survey must be statistically adequate, in order to begin to answer some of the questions raised in Appendix A.

52. Establish a watchlist of high-risk non-native marine species that are known or thought to pose significant ecological, economic, social, or cultural impacts to Micronesia, focusing on species that are not established or widely distributed in the region. This list should be developed by experts based upon evaluation of those species that (a) have known invasion histories (or unusual potential for invasion), (b) are thought to pose a high risk to core values, (c) are likely to survive regional environmental conditions, and (d) are likely to be transported by known vectors in operation in Micronesia. We recognize various methods could be used to evaluate these four criteria, from quantitative to qualitative, and given existing data limitations for all criteria and species, this is not a precise process. The resulting list is not intended to be comprehensive but serves to identify a list of potential high-impact species for possible management action, including detection (see previous section) and response. Although there is no specific target number of species for this list, limiting this to a small and manageable number has clear advantages for some applications, such as detection.

53. Develop a detection program and response plan for new incursions by a few focal non-native marine species on the watchlist of high-risk non-native marine species for Micronesia (see Recommendation #52). Species should be selected from the watchlist, based upon detection ability (due to size, morphological uniqueness, habitat distribution) and perceived severity of invasion consequences. The goal of this recommendation is to establish a demonstration project, using a few high-impact species to develop this response capacity and experience, instead of a program with comprehensive coverage. Ideally, the detection program would include focused surveys and a public reporting system (Recommendations #49-50), using these focal species as model system to develop these capabilities.

6.7 Implementation and Capacity: Priorities and Recommendations

This chapter is intended to provide recommendations for marine biosecurity and best management practices in Micronesia, addressing current gaps that exist across all sectors of activity (military, commercial, and private). This is a large scope for even one country, let alone for many countries that span such a broad range of cultures, activities, and geography. While we have addressed key areas of marine biosecurity in the region, there are no doubt some omissions, due to the scope of the endeavor and available time.

The effort to implement all of the proposed recommendations for Micronesia is extensive and may appear daunting, requiring considerable capacity that does not now exist. Although development of these recommendations is linked to the Guam Buildup, it is important to recognize that (a) these are core elements and objectives for a regional biosecurity plan and (b) the timeline for implementation of each recommendation is not yet specified. As indicated elsewhere in this report, the specific timeline and extent of implementation is obviously contingent upon available

resources for this purpose. Defining the specific timeline, resources, and responsibilities for implementation is beyond the scope of this report, requiring a detailed implementation plan produced by DoD in partnership with other parties (i.e., agencies, jurisdictions, organizations, and groups) in Micronesia to address these elements.

From the onset of our analyses, an implementation plan was specified as the next stage in the process, for which this report would provide necessary background and recommendations. In an effort to help advance an implementation plan, however, we provide some priorities and also discuss possible approaches and structural aspects for implementation in the sections below.

6.7.1 Initial Priorities for Implementation

A clear priority is the prevention (reduction) of marine species transfers associated with the movement of vessels and in-water structures. This applies to any movements to Guam, other parts of Micronesia, and Hawai'i. This applies to DoD activities, including: (a) the movement of any vessels, whether owned by the DoD, operated by MSC, or operated by a contractor (either under MSC or for another purpose); and (b) the movement of any in-water structures such as dry-docks, piers, dredges, and platforms. This applies equally to movement of any vessels or in-water structures for commercial or private use.

This area is emphasized as a priority for multiple reasons. First, the movement of vessels and in-water structures is a dominant source of non-native species transfers and invasions on a global scale. Second, it is clear that there are critical gaps, and a lack of clarity, in biosecurity in Micronesia for management of these vectors, leaving the door open for species transfers to occur by such movements (Section 6.4; see also Chapter 2). Third, there is a high level of regional connectivity of vessel movements in Micronesia, creating the opportunity for spread of associated non-native organisms (Chapter 3). Fourth, some vessels are known to arrive to Guam with high levels of biofouling (Chapter 2). Fifth, increased movement of vessels into Guam is expected during the Buildup, including those types of vessels (e.g., barges) prone to high biofouling, creating an additional sense of urgency.

While many specific recommendations have been made in this chapter to establish a broad-based biosecurity approach surrounding movement of vessels and in-water structures (and materials), we also have underscored throughout the **critical need to address vessels and structures that have high levels of biofouling.** The movements of such in-water assets (with high biofouling) pose relatively high risks of invasion and spread of non-native marine species in Micronesia, but specific biosecurity requirements on acceptable levels (or management) of biofouling do not exist for movement of these assets, either within or outside DoD.

Thus, **one of the highest priorities for rapid implementation are the specific steps to identify, assess, and treat (if necessary) vessels or structures that have propensity for the highest biofouling accumulations.** Specifically relevant to DoD activities in this regard are steps outlined in Recommendations #14-19, 39, and 40; a parallel set of recommendations are provided for commercial and private activities. In addition, we recommend that any vessel or structure with a long residence time (weeks to months) in a location or uncertain hull husbandry should receive an explicit, high level of scrutiny before movement among locations. While long residence time can occur for any vessel, certain vessel types are particularly prone to experience long residence times,

including:

- Preposition ships operated under DoD;
- Mothballed or decommissioned vessels (either military or commercial);
- Barges and dredges (used in support of military or commercial activities);
- Any laid-up vessel.

The planned, predicted, or observed arrival of any vessel or structure with history of long residence times in a location should trigger an assessment and response, to achieve effective vector management. While establishment of a reporting (detection) system was recommended to identify vessels with potential high biofouling levels (see Section 6.4), a critical aspect is training for assessment and response. Thus, we emphasize the need to implement an education and training program in order to identify and respond to vessels (and structures) with high biofouling levels. Ideally, such training would be done as a single program, together for DoD and commercial activities, including the various countries and responsible agencies throughout Micronesia (see also next Section). This approach would serve to provide a consistent approach and avoid redundant efforts, and also address the full spectrum of commercial and military assets that may operate under the DoD, especially when considering activities by contractors.

The movement of vessels and in-water structures are identified as a high priority for rapid implementation, providing the rationale for this selection, but we do not imply that other recommendations are low priority. Movement of organisms with live trade (such as aquaculture) or other vectors also poses significant risks, which should be mitigated and reduced. Indeed, invasions that result from any vector have the potential to cause severe impacts, even if they occur at low frequency. Vessels and in-water structures were selected merely as a dominant vector and starting point to advance regional biosecurity in marine ecosystems.

6.7.2 Approaches to Implementation

We have attempted to provide a strong conceptual framework as the basis or set of organizing principles for our recommendations, which are presented and organized by vector in this chapter. As a result, many of these recommendations are closely related, with strong parallels (by design) across vectors. The intention in creating these separate recommendations (#1-53) was to identify explicit needs and steps for a marine biosecurity plan. However, implementation should be advanced as a coordinated and integrated approach, organizing according to the parallel themes and objectives.

An integrated approach would serve to streamline the overall effort and resources required for implementation. This is perhaps best exemplified by considering vector management for ballast water and biofouling of vessels, including both DoD and commercial vessels across Micronesia:

- First, approaching recommendations for the entire Micronesia region, with full participation of member countries, offers clear economy of scale. There are relatively few vessel visits in Micronesia overall, compared to some global regions. Most vessels visit

Guam, and many of these vessels visit multiple countries (instead of completely novel vessels to each country). This suggests that some data collection and assessment needs can be combined efficiently on a regional scale, rather than conducting completely separate programs.

- Second, there is strong overlap between activities recommended for DoD and commercial vessels, such that there is excellent opportunity to jointly develop and implement some activities, especially in establishing uniform methods, criteria, response plans, and outreach components.
- Third, although recommendations were developed for ballast water and hull fouling as separate vectors, some of the reporting, training, infrastructure, and legal framework components can be combined effectively.
- Fourth, a regional approach to implementation (with similar standards and approaches) also serves to simplify and create a consistent, uniform message for outreach and implementation by the diverse sectors involved in operating and managing vessels.

An integrated approach does not require any specific assumptions about authority or oversight for implementation of specific components, as no recommendations were made in this regard. Instead, an implementation planning process is suggested that seeks simply to integrate activities in order to enhance coordination, efficiency, and consistency.

One approach and a logical next step to advance an implementation plan would be to create a matrix (table) of recommendations that is used to characterize the scope and possible integration of specific actions. For each recommendation, the initial goal would be to develop a matrix that lists of the following information:

- 1) Specific vector (e.g., all cargo ships, barges, fishing vessels, live food, pet import).
- 2) Specific type of actions required by category (e.g., recording, inspection, treatment, outreach, training, protocol development, criteria for acceptable level of vector operation).
- 3) Current agency responsible for each type of action (if one exists) by each jurisdiction in Micronesia. [Note: this does not imply responsibility for funding or capacity to implement.]
- 4) Likely responsible agency in each type of action by jurisdiction in Micronesia. [Note: this does not imply responsibility for funding or capacity to implement.]
- 5) Estimated cost associated for each type of action, including that for each jurisdiction and for Micronesia overall.
- 6) Estimated time required to implement each type of action (assuming available resources exist), including that for each jurisdiction and for Micronesia overall.
- 7) Estimated recurring cost (if one exists) for each type of action, including that for each jurisdiction and for Micronesia overall.
- 8) Possible sources and amounts of funding to implement each action, including that for each jurisdiction and for Micronesia overall.
- 9) Priority for each action according to jurisdiction and overall.

This information serves to outline the operational details for implementation and could be used to evaluate feasibility, timeline, cost, responsibilities, coordination and integration for the specific

actions. It would be useful to consider various levels of effort for each of the cost estimates (e-g, above). This overall approach would provide a solid basis developing an implementation plan. By necessity, collecting this information would require involvement, participation, and partnership among the various jurisdictions in Micronesia.

Although this treatment is focused on biosecurity for marine habitats, coordination and integration of activities with those in terrestrial and freshwater environments should also be evaluated. This may be especially relevant and useful for overall program structure, communication, and outreach activities. In addition, we recognize that border control, customs, and other agencies within Micronesia likely operate across these boundaries already.

6.7.3 Structural Aspects of Implementation

Many of the specific recommendations made in this document cannot be put into place without some institutional and structural changes, which require the cooperation and coordination of agencies throughout Micronesia. There is also a need for increased communication and integration in activities, if the goal of implementing a truly regional plan is to be realized.

To provide some of the structural capacity of the Micronesian region to deal with marine invasive species, we recommend the following:

54. Create a single program, the Micronesian Marine Biosecurity Facility (MMBF), to serve as a focal point, coordinating body, communication and information center, and training resource for marine biosecurity activities throughout Micronesia. The MMBF would not replace the need for biosecurity activities within the individual countries but instead would serve as a resource center for the Micronesian countries, agencies, industry, and the public to (a) provide training and advice, (b) develop protocols and methods, (c) help establish detection and response capability, (d) implement education and outreach campaigns on a regional scale, (e) characterize current regulations and guidelines that exist, and (e) seek and coordinate regional funding. The MMBF could also serve as a central data center for reporting, analysis, screening, and maintaining records for vector activities or non-native species information (see Section 6.4). The MMBF should be formed as a formal partnership among the countries of Micronesia.

55. Establish a Memorandum of Understanding (MOU) among government agencies and the DoD departments establishing a response plan and command structure in cases where urgent action by multiple agencies is needed to respond to marine biosecurity. Responses to non-native species are often delayed when such a response plan and structure are not in place, especially when multiple agencies or jurisdictions are involved (Anderson 2005). Moreover, this MOU would allow joint action across countries within Micronesia, rather than requiring independent capacity be developed in each country. If it is not possible to have such a MOU across government and military jurisdictions, then we recommend the development of parallel command structures with an agreement to coordinate efforts through joint activities of the commanding officers.

56. Identify and establish a source of dedicated, long-term funding to implement marine biosecurity recommendations outlined in this chapter. While the type of analysis discussed in section 6.7.2 provides one approach to identify funding needs and possible sources, the most likely

outcome will be a combination of funding sources to achieve the desired objectives. Funding sources, amounts, and durations certainly will vary for the different activities recommended in this report. However, in addition to advancing individual objectives, there is a critical need to sustain marine biosecurity as a long-term and vital activity, just as customs and border security (for goods and people) is an ongoing activity. To sustain marine biosecurity and provide long-term continuity requires some core level of activities, personnel, and coordination, which will require dedicated funding.

57. Define management and oversight for implementation of regional marine biosecurity activities in Micronesia. Defining management and oversight is a critical part of implementation planning and the overall function of biosecurity efforts in Micronesia. The MMBF could serve or assist in a management and oversight role. However, if this is not done, another administrative structure should be arrived upon to provide necessary oversight, evaluation, and management. In particular, the current capacity that exists in Micronesia is dispersed across countries, and it is possible that a broad range of people and organizations around the globe may participate in various aspects of implementation. Thus, management and oversight is required to assure that work and directed research addresses specific objectives, and also to provide continuity among countries and over time.

Finally, education and outreach are considered an integral tool for marine biosecurity and for implementation of a programmatic approach to fall under the umbrella of the MMBF. Moreover, we note that many of our recommendations include specific and targeted outreach or training components, in order to advance specific objectives in vector management.

6.8 Summary

The overall goals of this report were to (a) evaluate current activities that pose a risk of marine invasions to Micronesia and (b) provide recommendations for management practices to minimize the likelihood of invasions and associated negative impacts. We have identified specific gaps in marine biosecurity, resulting from current practices, critical information gaps, and lack of capacity (which includes infrastructure, people, and resources). To address these gaps, we have presented 58 separate recommendations, which outline particular steps that could be taken. This analysis and information is intended as input for development of a detailed implementation plan, as the next step to be undertaken. Importantly, some recommendations and approaches were identified as high priorities for implementation. It is also evident that implementation planning also requires evaluation of available resources (which determine the scale or rate of implementation) and involvement of agencies and jurisdictions in Micronesia (i.e., those engaged and affected by implementation activities), which are beyond the scope of this report.

Although the Guam Buildup was the primary for advancing this analysis and a biosecurity plan, the approach undertaken is visionary in its scope. Guam is clearly a hub for military and commercial activities and therefore the potential transfer of non-native species into Micronesia. The analysis and recommendations for biosecurity were funded due to proposed DoD activities in the Mariana Islands but extend throughout Micronesia and include linkages (indirect effects) for Hawai'i. The spatial scale examined is very broad. Moreover, similar analyses have been undertaken for marine, freshwater, and terrestrial components at this scale. The overall approach is unusual for its broad geographic and taxonomic scope, as well as including many countries and

cultures.

In many respects, advancing the regional biosecurity plan for Micronesia provides an important model for many reasons:

- First, the approach explicitly considers multiple vectors and environments (marine, freshwater, and terrestrial systems) together, using an appropriate spatial scale at which invasions operate.
- Second, implementing a large-scale, integrative, and cross-cutting plan should result in improved biosecurity protection, efficiency, and consistency, compared to advancing many individual activities in isolation.
- Third, this plan seeks to establish a coordinated and consistent strategy that operates internationally, across many different countries and cultures.
- Fourth, most understanding and management of marine invasions come from temperate latitudes and continents, and this plan aims to address invasions on tropical islands ecosystems, having high relevance on a global scale.

Even though Micronesia is a large area and spans many countries, current levels of trade and the number of points of entry are small relative to many other global regions. This suggests that understanding transfers of vessels and goods is more feasible here than many areas, even for Guam, and should make biosecurity more feasible than in many regions. In short, this underscores the value of Micronesia as a model. It is important to recognize that current capacity and resources limit current biosecurity activities in Guam, and Micronesia more broadly, and this must be considered a major focus of any implementation plan for the region.

By implementing a cohesive regional plan and key protocols to address marine invasions, DoD and its partners across Micronesia would become world leaders in advancing marine biosecurity, especially in tropical ecosystems. Such a program could effectively become a global model and training center, providing benefits to Micronesia and many other regions.

Appendix A: Perceptions of Impact of Non-Native Marine Species

By Marnie Campbell & Chad Hewitt

A.1 Background

This research forms a component of a risk assessment undertaken for the U.S. Defense forces transfer of U.S. troops (and associated infrastructure) from Okinawa, Japan, to Guam. It is expected that this relocation to Guam will inadvertently result in a transfer of non-native species to Guam that may subsequently spread throughout Micronesia. A component of this work was to determine the risk (the combination of likelihood that a species will be transferred to Guam and other Micronesian countries and the consequence [impacts of these transferred species]) to the marine environment of Guam and Micronesia.

This research targets Guam, Palau and Saipan, using questionnaires and interviews to collect information about environment, economic, social and cultural core values that people in these locations hold and how they perceive that non-native species will affect these values. It was planned initially that this information would be used as a component of the consequence analysis for the overall risk assessment (see Chapter 5). However, the risk assessment used a quarantine end point and hence all consequences were considered significant. As such, this Appendix now represents a measure of the values that would be affected and provides a values mapping for a risk assessment that would have an impact end point. Typically, environmental risk assessments ignore social and cultural impacts and thus we are ensuring that this aspect is not lost, to provide a voice to the local and indigenous people in this region.

The importance of recognizing valid risk perceptions has been identified and studied for a number of years with the main insight for this study being the ability to understand and anticipate people's responses to a hazard [non-native marine species] (Slovic 1987, 2000; Sheeran and Orbell 1999) and hence managing this response within a holistic risk management framework.

By ascertaining people's motivations, actions and beliefs the driving factors associated with intentional and unintentional introductions and further spread (secondary transfers) can be effectively managed. This is pertinent for this risk assessment, as the public are potentially hostile to changes that they are seeing as being foisted upon them (such as the increase in military presence in Guam and subsequent exposure to shipping).

A.2 Aims

This research had two specific aims:

1. Identify known and perceived values that may be impacted by non-native marine species and
2. Assess the perception of changed values if non-native species occur in the region.

This research is preliminary (a pilot study), focusing on Guam as the primary site of impact, with a further assessment of two trading partners within Micronesia (Palau and Saipan). The results and trends seen are country relevant and cannot be extrapolated to other countries within or across Micronesia.

A.3 Determining Consequence – Values

Within this appendix, the use of the terminology “value” refers to things and/or notions/beliefs that people feel are important to them. Although the inclusion of economic, social and cultural values is beyond the initial scope of the project, the research team was approached by the NISC project coordinator to include this aspect within this report. This has occurred, but the report is limited due to the methods that could be utilized. Thus, what is presented in this appendix is a very preliminary assessment of all values (the assessment is limited in its scope) that provides some insights, and there are a number of important caveats (see next section). It is recommended that further investigation of these preliminary findings is necessary to truly elucidate the social, economic and cultural aspects.

A.4 Caveats

A number of caveats are important to note for this aspect of the consequence data:

1. This work was not a component of the original tender and thus it was not budgeted for.

Instead, it was fit into the study as possible while undertaking the major component of work (as presented in Chapters 1-6). But this meant that data was collected in a manner that is acceptable in western style questionnaire surveys (i.e., responses were elicited via an electronic survey by emailing the survey to people that were able to send the email onto others [referred to as snowballing]) but is of less use for studies wishing to collect data from cultural or social groups. Thus the data presented for the values has limited scope. An improved collection method (such as a temporal ethnographic study that incorporates participant observation and immersion in local culture) would see a better outcome for this data.

2. When working with cultural and social groups a better technique to collect data is via a series of meetings, informal chats, focus group interviews, and observations via immersion within difficult cultural contexts. This type of work is more field intensive and unfortunately could not be undertaken in this situation. The research presented in this chapter has identified a number of values through our initial face-to-face interviews and meetings and further reading, but often these values may have represented a miniscule aspect of cultural identity, which is difficult to ascertain and to value as a whole.

3. Values are based on a person’s heuristics, which are influenced by aspects such as their cultural background and identity, age, gender, and income level. Because of the manner in which the questionnaires were administered (see caveat 1), it was unlikely that indigenous cultural or social groups would respond. Thus, the data received is more likely to be influenced by ‘outsider’ opinions and under-represents Chamorro and Carolinian culture. This is particularly true for the analysis of change in value.

4. It is recognized that respondents may potentially overvalue aspects of their culture as a sense of cultural pride, when in reality that particular aspect is neither practiced or has been forgotten by most of the population. The same can be said for activities that respondents may be involved with or an area that they may wish not to have affected. The researchers do not judge these aspects and

believe that all aspects are worth consideration and assessment. Thus, the research as used all data as presented on face-value.

The response rates for our electronic questionnaires were relatively low and typically limited to expatriate American citizens, with few indigenous respondents.

What was achieved was a number of meetings (interviews) that elucidated values based on face-to-face interviews (see Table B.1) and the identification and support of values via reading the published literature, informal discussions, and visiting museums. This information was used to develop a questionnaire to ascertain the validity of these values, to collect further values that may have been missed and to see if people felt that a value would change if a non-native marine species entered a region. This means that the results under-represent the indigenous population and the general public.

A.5 Methods

A.5.1 Data Collection

A three-staged approach was used to collect values and then to investigate whether respondents perceived if values would change once a non-native marine species arrived in their region (Guam, Palau and Saipan). Ethics approval was provided for this research (H11233) by the Tasmanian Social Science Human Research Ethics Committee. In all instances researchers followed the ethics approved sampling methods and met the Australian National Statement standards. Data was collected using interviews and three questionnaires that were distinct for Guam, Palau and Saipan. Non-random purposive sampling (e.g., Babbie 2007; Walter 2010), with additional snowballing, was used given that this was a preliminary assessment. The sampling frame was restricted to scientists, environmental managers, industry (shipping and tourism related), government officials, and the public that had declared an interest in non-native marine species risk associated with the potential alterations in Guam vessel traffic associated with the U.S. Defense Force redeployment of troops to Guam. The sampling frame⁶ was restricted in that other participants were identified as sampling progressed and hence the frame could not be fully identified. As such, snowballing (the description of this method is provided below) was also used.

Stage 1: Identification of values. A triangulation process (e.g., Esterberg 2002) was used to identify and clarify values. The initial step in the triangulation was to hold face-to-face meetings

⁶ “Sampling frame: the listing of all units in the population from which the sample will be selected” (Bryman 2012).

and focus group interviews. These occurred from 31st March 2010 until 24th April 2010. These meetings and interviews elucidated people's values and served to direct us to further individuals to meet/interview. The second step of the triangulation involved researching the literature and/or materials that could help substantiate the values that were identified. A bibliography of the literature that was reviewed is provided (see References) to give insight into the literature that was assessed with regards to this study. The outcomes of this were the creation of a draft list of values that were relevant to Guam, Palau and Saipan.

Interviews occurred in Guam (31 March – 9th April 2010), Palau (10 April – 18th April 2010) and Saipan (19th April – 24 April 2010) and occurred on an individual basis or via group discussions. Discussions (in the form of semi-informal interviews) were held by introducing the topic and providing a background on the research that was occurring. Participants were encouraged to express their opinions and ideas related to the research topic. As such, the participants were involved in the construction of meaningful results related to the topic (i.e., they could drive the interview direction within the bounds of the research topic). Although the agenda for discussions/interviews was restricted to the research topic, the direction of the discussions was guided by the participants and hence participants were able to articulate what was important to them, to have more 'power' in the discussions and subsequently influence the results by choosing what they would and would not discuss.

Stage 2: Alteration of values. Based on the values identified at stage 1, a questionnaire was developed that asked respondents to: (a) rate each provided value on a scale of worth (1 = low, 5 = high); (b) add additional values that may have been missed; and (c) rate these new values on the same scale of worth.

Stage 3: Change in value. Based on the values identified at stages 1 and 2, respondents were asked if a non-native species arrived in their region could they state whether this would change their view on the value. If they answered "yes" then they were asked to rate how the value had changed (i.e., a decrease in value is now worth less or an increase results in the value being worth more). Please note that "worth" does not have a dollar value, but instead its used to infer an importance to someone – this importance can be intrinsic (i.e. hold importance merely for being) or utilitarian (i.e. holds an importance because it can be used by humans [provides a service]), or a combination.

A.5.2 Bias in Data Collection

A non-random purposive sampling method was used with a restricted sampling frame (scientists, environmental managers, industry, government officials and the public that had stated an interest in non-native marine species risk associated with the potential alterations in Guam vessel traffic), which under-represents the actual population. Thus, the results do not reflect the population in each country but rather reflects people that might be affected by the changing vessels movements into and out of Guam or have to manage these altered vessel movements or potential increases in non-native marine species. In this situation, under-representation of the sample is not a major concern because this is a preliminary study that is highlighting trends (Walters 2010). In essence, the sampling was guided by a theoretical sampling plan that would enable the problem of non- native marine species to be explored.

A snowballing technique was implemented (e.g., Bryman 2012). This method targeted people that work in areas relevant to non-native marine species and marine species and then used these people to establish contacts with others. This technique was used as the ability to establish a sampling frame given the short time frame for the research, was not possible.

To overcome recall bias (Szklo and Nieto 2007), each participant in meetings, interviews and questionnaires were briefed on the issues being investigated prior to beginning the questionnaire. Briefing all participants ensured that everyone involved was exposed to the same data pertaining to non-native marine species and the redeployment of U.S. Defense Forces.

To ensure that leading questions were not used and to identify any wording issues within the questionnaire, a pilot group of individuals was used as a trial. Two interviewers were used, with each having been trained to standard protocols (to ensure replicability; Stewart and Cash 2008), and one interviewer being in charge of quality control and quality assurance of interview techniques.

A.5.3 Data Analysis

Due to the preliminary nature of this research quantitative analyses are not possible. Instead descriptive statistics were used to describe the trends, with value network maps being used to explore the strength of linkages across and between values.

A.6 Results

A.6.1 Identified Values

A total of 337 values, from 61 participants, were identified across environment, economic, social, cultural values and combinations of these values (Figure A.1). We identified 140 values for Palau, 105 for Guam, and 92 for Saipan.

Guam identified the most environmental values, followed by Palau and then Saipan (Figure A.1). Palau, closely followed by Guam identified the highest amount of economic values, with a similar trend for the social values. Palau, followed by Saipan identified the most cultural values, with a large reduction in the identification of cultural values occurring in Guam.

In Saipan, the following additional values were identified:

- Coastal protection from reef
- Coastal protection provided by seagrasses
- Water quality improvement (filtering) provided by seagrasses

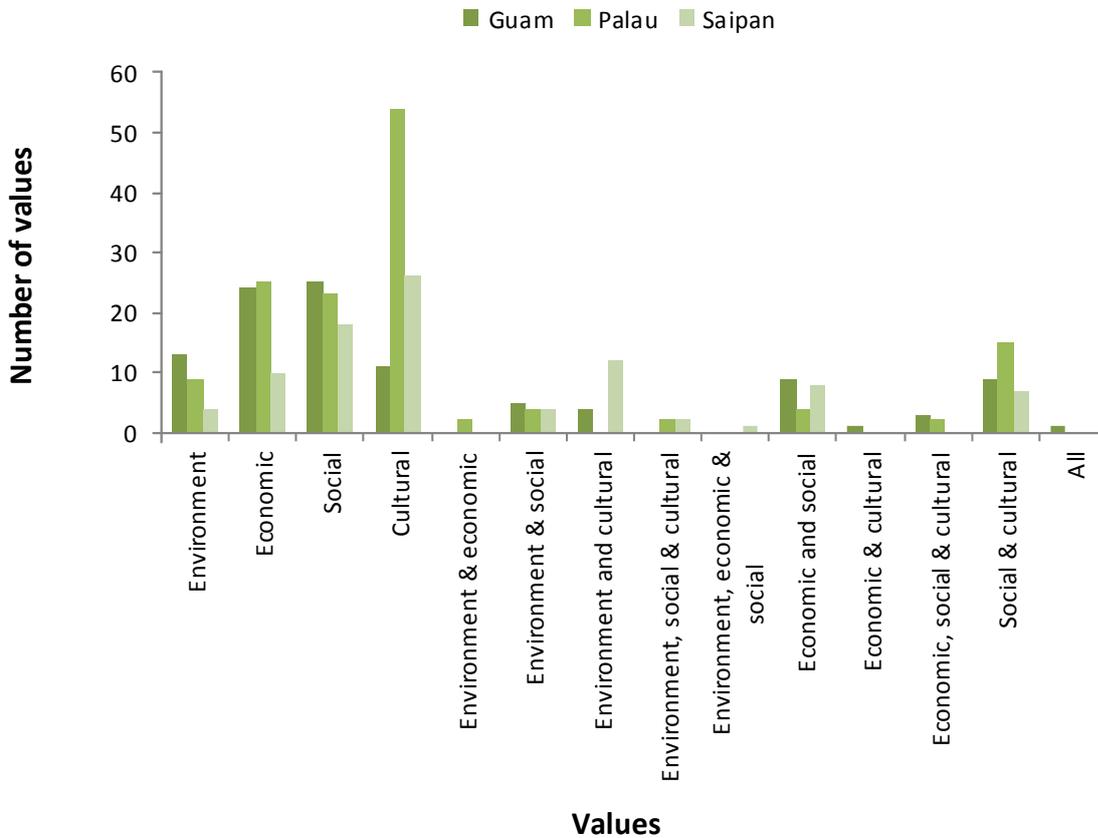

Figure A.1. Total numbers of values within each presented category for Guam, Palau and Saipan. The category “All” represents the identified value(s) that spanned across the environment, economic, social and cultural aspects.

A.6.2 Value Networks

Value networks (Figure A.2) were then used to illustrate the strength of connection across and between the core values (environment, economics, social and cultural). Each value had a number of identified ‘subcomponents’ (an element of a core value that with other subcomponents forms the entire core value) that represented a single core value (circles in Figure A.2), or could represent multiple values (lines connecting two, three, or four core values). Within Guam, there was minimal overlap or sharing of values, with most subcomponent values representing just one value and relatively little cross-over of values or participant perceptions that values crossed over (Figures A.1 and A.2). The values identified in Guam had a stronger social and economic focus compared to the other two regions. In Palau, there was a stronger network of subcomponents shared across core values, with social and cultural values sharing the strongest linkages (Figures A.1 and A.2). A similar trend was evident for Saipan (Figures A.1 and A.2).

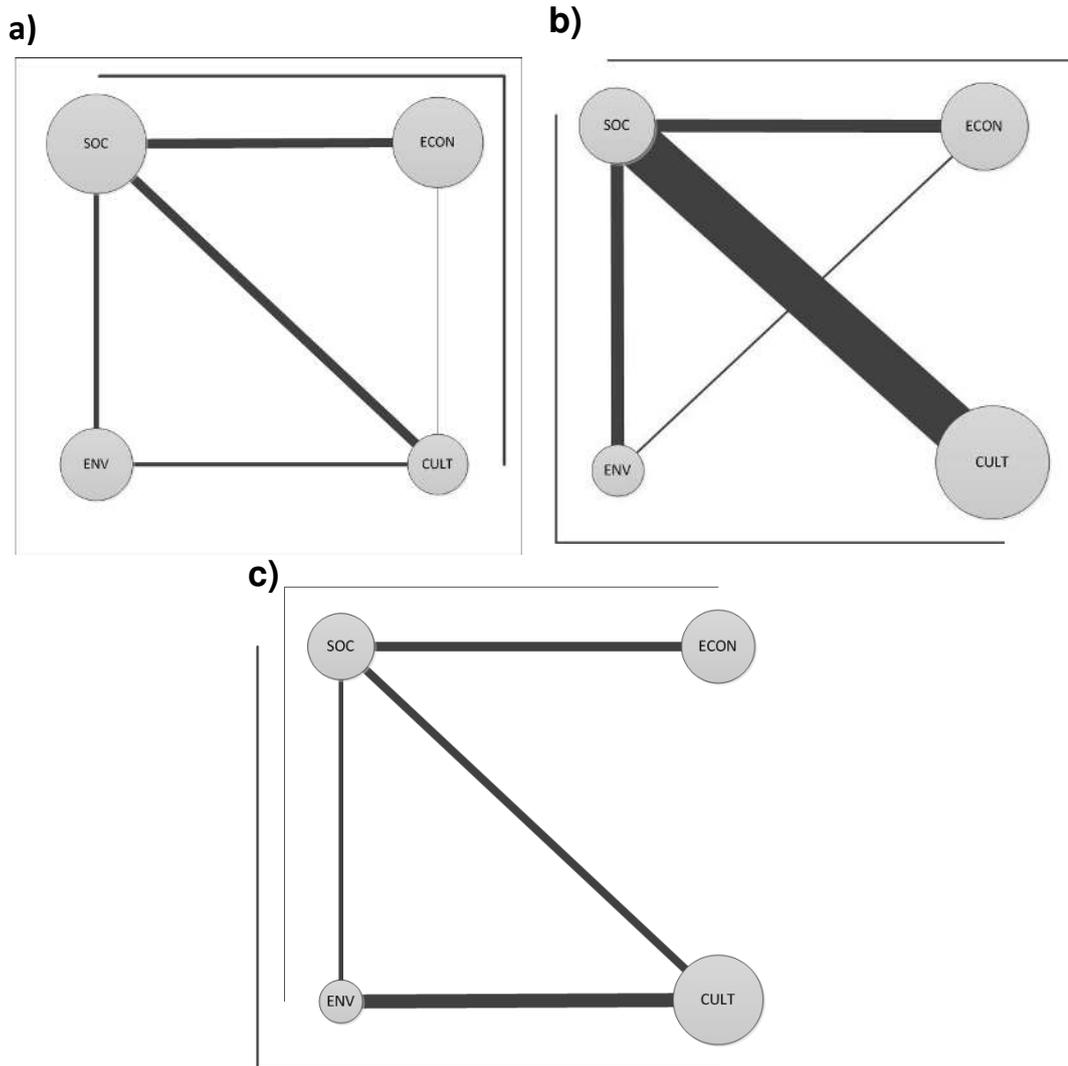

Figure A.2. Value networks illustrating the proportion of core values for each region and the strength of linkages between core values for: a) Guam; b) Palau; and c) Saipan. Core values are denoted by SOC = social; ECON = economic; ENV = environment; and CULT = cultural. The number of identified subcomponents in each category (one, two, three, four core values) is represented graphically by the size of the circle or thickness of the lines (networks).

A.6.3 Worth of Values

No responses were received from Palau and hence they are excluded from this portion of the analysis. It is recommended that further investigations are undertaken to elucidate the patterns and to better engage with the Palauan population to provide reliable outcomes concerning their perceptions about the identified values, the identified values worth and change in identified values worth.

The survey (questionnaire) results are preliminary, with low response rates; hence questionnaire findings discussed below need to be taken in the context that reliability is low. The data indicate some preliminary trends that need further investigation. In Guam, survey participants rated 63% of identified values as high value, with 21% having a neutral value (neither high nor low), and the remaining 16% having a low value. This differentiation between value worth can be further categorised based on each of the core values: 74% of the identified environmental values were rated as a high value, followed by 64% of social values, 57% of economic and 54% of cultural values (Figure A.3a).

In Saipan, 52% of the identified values were rated as having high value, with 44% having a neutral value and 4% having a low value. On a core value basis, 64% of environmental values were rated as high, with 59% of economic, 72% of social and 21% of cultural values being rated as high. Saipan participants rated the majority (73%) of cultural values as having a neutral value (Figure A.3b). This may reflect an inability to properly assess the value and hence a choice to select the middle option (i.e., to fence sit or to remain undecided).

A.6.4 Change in Value Worth

The participant's perceived change in worth of the core values due to a non-native species varied across the countries. Within Guam, 57% of the values remained unchanged, 39% of values would decrease in worth and 4% would increase in worth (Figure A.4a). A small number of social (Education – University of Guam, and education Schools) and cultural values (Seasonal fisheries: impediment to equipment; and food gathering) were perceived as potentially increasing in worth if an introduction occurred. The largest impact (decrease in core value worth) occurred for the cultural values (72% of values would decrease in worth), followed by social (44%), environment (43%) and economic (21%).

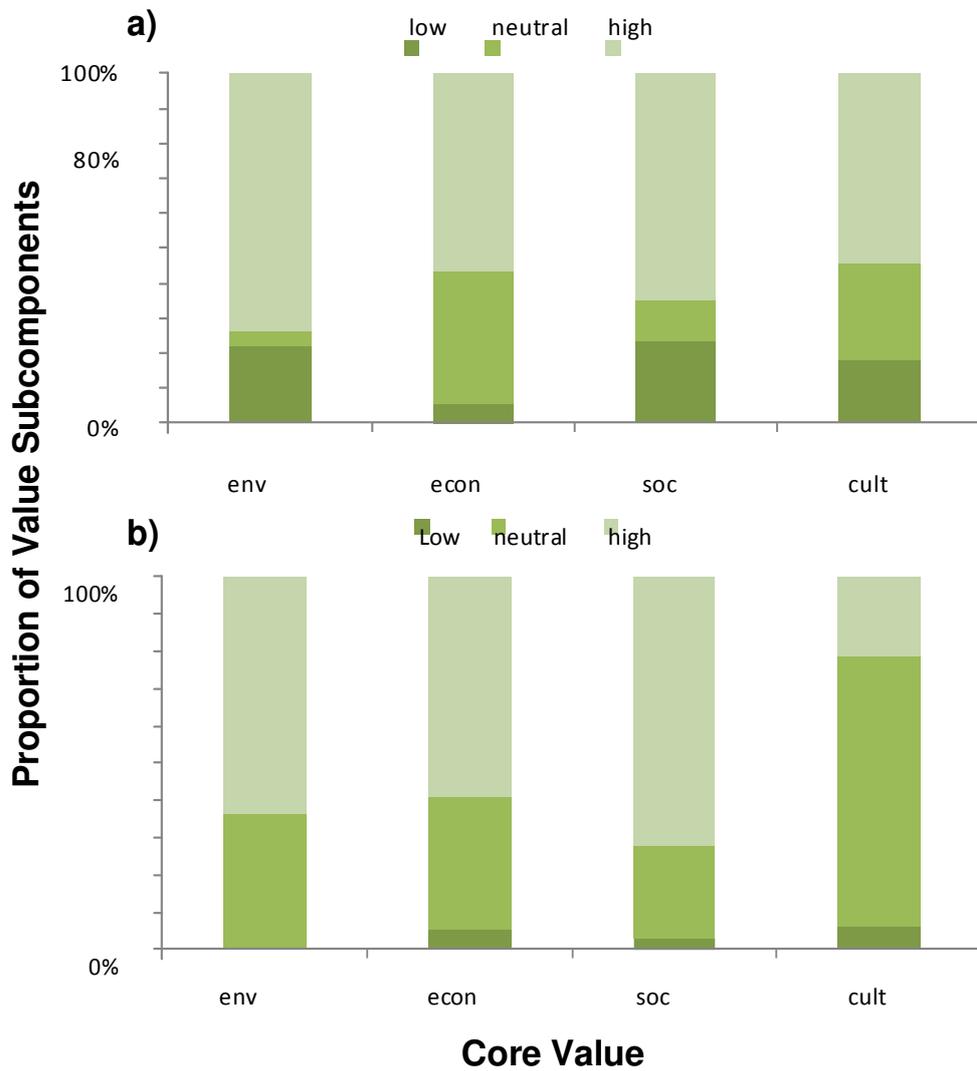

Figure A.3. Proportion of each core value subcomponent that was rated as having a high, neutral or low value by survey respondents for a) Guam; and b) Saipan. Where values are denoted as env = environment; econ = economic; soc = social; and cult = cultural.

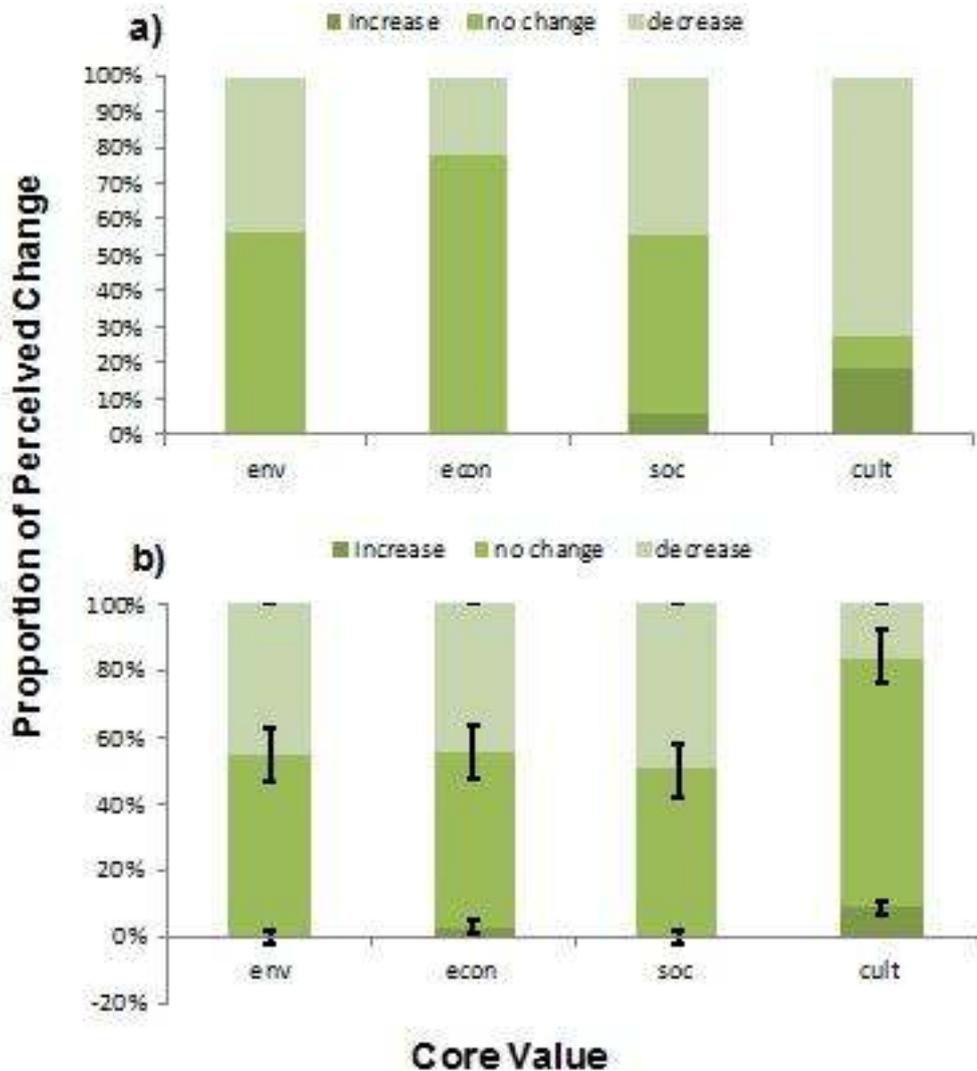

Figure A.4. Participant's perceived change in core value worth after an non-native species enters a countries water for: a) Guam; and b) Saipan (with standard error bars). Where values are denoted as env = environment; econ = economic; soc = social; and cult = cultural.

Within Saipan, the change in value was variable. Fifty-nine percent of the values did not change worth. Yet, there was a decrease in perceived value for 37.5% of the values with a small (3%) increase in value worth. At the scale of the core value, 54.5% of environmental values remained unchanged, and a further 45.5% of environmental values decreased in perceived worth (Figure A.4b). Economic values had a similar trend, with 53% remaining unchanged, 44% decreasing in perceived worth, and 3% increasing in worth. Social values were divided equally (50:50) between worth remaining unchanged or worth decreasing. Cultural values had the largest dichotomy, with 75% of values remaining unchanged, 16% decreasing in worth and 9% increasing in perceived worth.

A.6.5 Participant Feedback and Comments Received to Date

An opportunity for participants to provide feedback and make comments about the discussions and interviews and the questionnaires was provided. Further feedback will be collected after the report is released. Feedback and comments collected to date is summarized in Table A.1. A number of participants wished to remain anonymous and provided verbal information but requested that this information not be repeated within the report. The authors have respected these wishes and have used these data to inform the report in a manner that maintains anonymity (and these are not listed in Table A.1).

Table A.1. Participant’s initial feedback

Feedback and comments	Country relevance		
	Guam	Palau	Saipan
The marine environment is intrinsic to our life and lifestyle.	✓	✓	✓
We rely heavily on marine resources (food and tourism)		✓	
Loss or impacts on marine resources will increase poverty		✓	
Attempting to place a value on single aspects of cultural identity is difficult (if not impossible) because the real value, in many cases, is with the whole and not the individual parts. This could also be said for ecological systems	✓	✓	✓

Table A.1. Continued

Feedback and comments	Country relevance		
	Guam	Palau	Saipan
The assessed values may be dependent (auto-correlated) upon the cultural background of the recipient and their time spent in Micronesia (level of exposure to the culture and environment)	✓	✓	✓
Most of your respondents in the CNMI will most likely be outsiders. Consequently, their answers may reflect their impression of what others may have on certain issues or be biased by their own cultural identity.			✓
Indigenous respondents may overvalue aspects of their culture as a sense of cultural pride - when in reality, that particular cultural aspect is neither practiced or has been forgotten by most of the population.	✓	✓	✓
Some cultural values may be rooted in the marine environment but unaffected by change in this area.	✓	✓	✓
Biggest risk (from non-native species) is that we are not prepared.		✓	
Developing countries have a goal to support their economies and therefore sometimes things are lost	✓	✓	✓
An important part of our culture is the community projects that are organized by Chiefs.		✓	
Traditionally always people saved for tomorrow. This sustainability has been lost. A breakdown of traditions is occurring.	✓	✓	✓

Table A.1. Continued

Feedback and comments	Country relevance		
	Guam	Palau	Saipan
Buul (traditional management of resources in Palau) is managed by the Chiefs, with the community providing enforcement. Buul is now also used to manage behaviors. Fishing seasons and techniques were originally managed by Buul's, but now these are managed by legislation.		✓	
There needs to be an improved flow of information so the community knows what's happening with non-native marine species.		✓	
There is no important social/cultural importance of the sea, except when people want to use this resource			✓

A.7 Discussion and Conclusions

This research set out to identify known and perceived values that could be impacted by non- native marine species and to determine if perceptions of these values may be altered if a non- native marine species incursion occurred. The research successfully identified a large number of values (n = 337: Guam 105; Palau 140; and Saipan 92; Supplemental Tables 1-3) for the three different countries assessed. These values ranged across environment, economic, social, and cultural, with combinations thereof. Values vary from place to place, with place-culture being the greatest influence for the spatial and temporal patterns that can be detected (e.g., Williams 1981).

Although cultural and environmental values were kept as separate core values, it is noted that these values are often categorized together because philosophically environmental values themselves are considered to be embedded within culture (i.e., culture is a whole way of life), making it difficult to separate the two effectively. Thus, in some instances within this research, there was a downgrading of environment values (i.e., fewer environmental values may have been identified) that does not truly reflect the realized value or its worth. It is also noted that U.S. imperialism (i.e., Zimmerman 1998) has potentially influenced the values identified and reported for Guam and Saipan. Yet, the U.S. influence in Palau is less intense (Palau remains a Republic that was once a U.S. Protectorate but has now attained its own freedom), which is reflected in Palau by the higher number of identified cultural values and the strength of network connections between cultural and other values. This topic is discussed further below, noting however that the authors of this work are not sociologists and therefore the interpretation is limited and potentially naïve from a social science perspective.

A.7.1 Value Networks

A.7.1.1 Guam

Environmental and cultural values exist in Guam but were not valued as highly as economic and social values. Also, from a network perspective, Guam had little connection between core values (Figure A.2a). This lack of connection may be related to the history of this region. Guam has had a long history of being occupied by foreign nations, including occupation by the Spanish, Japanese and the U.S., which has resulted in the loss of the Chamorro culture (Jennison-Nolan et al. 1979a, 1979b; Diaz 1994; Rogers 1995; Zimmerman 1998).

The stronger social and economic focus of the identified values in this study may be related to the utilitarian societal norms witnessed in this region. Guam is heavily influenced by the U.S. (it is a U.S. Territory) and the resource conservation ethic (i.e., natural resources abound in nature and should be used, with conservation standing for development: "...the greatest good of the greatest number for the longest time...") (Pinchot 1947, 1968; Callicott 1990). The resource conservation ethic is strongly enshrined in the U.S. legislation and government management of resources (Callicott 1990; Groom et al. 2006). As a U.S. Territory in the Pacific Rim, a perception exists that local norms and beliefs are often diluted as the country is forced to adopt U.S. laws and practices (i.e., 'peripheralization'⁷; Wilson 2000a; Perez 2002).

Within this research, there was a strong indication that participants felt that Guam was disenfranchised, resulting in a loss of culture through 'Americanization' (e.g., Barusch and Spaulding 1989; Diaz 1994; Perez 2002). This was reinforced by participants indicating that they did not want more U.S. Defense Forces in Guam. This opinion was further reinforced by street protests that occurred during the survey work and subsequent protests that have occurred (e.g., <http://ww4report.com/node/8160>; <http://links.org.au/node/1547>; <http://reefrescue.wordpress.com/2010/02/26/guam-protests-navys-plan-to-dredge-coral-reef/>; http://www.horseopera.org/Insular_Empire_2010/?page_id=564).

There was also a general perception amongst some survey (Guam and Saipan) participants that cultural values are no longer authentic because they are not practiced by the majority of the population or that modernization of society has no room for these outdated concepts. However, typically these sentiments were provided by Caucasians expatriate Americans, not Chamorro or Carolinian participants.

⁷ Peripheralization refers to the "differential distribution of power, interest, labor, and capital across space, and the domination of local spaces and cultures by the mandates of military-industrial time" (Wilson 2000a).

A.7.1.2 Palau

Cultural values, followed by economic, social and then environmental values were identified in Palau (Figure A.2b). The strongest of connections occurred between social and cultural values, probably related to the strong community and cultural identity that still remains in this country. Palau also has a strong cultural law that governs usage of species (Buil 8-tiered system and fishing grounds; e.g., Johannes 1978, 2002) and influences lifestyles, including environmental goals aligned with conservation (D Olkeriil pers. comm.). The parliament is currently working on translating traditional stewardship into legislation that will simplify the three tiered system that currently exists (N Idechong and D Alexander pers. comm.). Marine protection has a strong focus within Palau (e.g., Gilman 1997a), especially within tourist focal areas such as the Rock Islands and Koror or on specific species that have a cultural value (e.g., Campbell 2003; I Olkeriil pers. comm.). This protection stance is often linked with customary management of marine resources (Gilman 1997a; Johannes 2002; D Olkeriil and I Olkeriil pers. comm.), which has been degraded in the past but is being rebuilt at present (N Idechong and D Alexander pers. comm.).

A.7.1.3 Saipan

The number of values identified for Saipan was similar to Palau, with a large number of cultural values, followed by an equal weighting of social and economic values, with fewer environmental values (Figure A.2c). Although, within Saipan, the importance of the sea turtle has been used to express and maintain Carolinian culture (Kolinski et al 2001). This value was identified, and its subsequent worth was identified as high, by survey participants. Much like Guam, the connections between values were relatively weak, with the strongest connection existing between the environment and culture. Again, the history of Saipan may have an influence on the identified values and assessed worth/changes in worth. Saipan has had five centuries of colonial rule, seen four empires and accommodates two indigenous cultures (Rios-Martinez 2000). Chamorros were forcibly removed from Saipan for a significant portion of the islands history, with the Carolinian culture becoming dominant during this period. When the Chamorro people returned to Saipan a disjunction in their Saipan culture had been created (R Hunter pers. comm.).

Saipan is within the U.S. CNMI (became a Commonwealth of the U.S. in 1986; Gilman 1997b; Rios-Martinez 2000) and is subsequently heavily influenced by the U.S. (Rios-Martinez 2000; Warheit 2010). Saipan constitutes part of the U.S. colonialism where a number of ‘insular areas’ are occupied by the U.S., where they are provided with some political willpower, but have fewer rights (King 1991; Rios-Martinez 2000; Warheit 2010). For example, a number of elements of sovereignty were surrendered when Saipan and the U.S. formed the Commonwealth (King 1991; Rios-Martinez 2000; Warheit 2010), with a major issue being the loss of the Islands rights to self-governance. This loss of power has caused some issues through time.

A.7.2 Worth and Changing Values

Although this information was collected, the low response rate to the survey tools leaves little that can be accurately stated about these data. In general, there are a multitude of ways to identify values (e.g., Corraliza and Berenguer 2000; Kalof and Satterfield 2005; Fraj and Martinez 2006)

and to determine a value's worth (e.g., Knetsch 1994; Satterfield 2001; Emerton and Bos 2004; IUCN/The Nature Conservancy/The World Bank 2004; Pagiola et al. 2004; The World Bank 2004; Kalof and Satterfield 2005). Recently there has been a move away from Willingness to Pay (WTP) and Willingness to Accept (WTA) style assessment of a value's worth, because of fundamental flaws in these processes (Kalof and Satterfield 2005). The result has seen the development (or further development) of axiomatic traditions that capture 'non-cost' and 'non-utilitarian' values. These methods are 'divorced' from the market and recognize that the environment (or at least many components of the environment) is a limited resource (Satterfield 2001; Kalof and Satterfield 2005).

The methods that were employed for this research, although in hindsight were not effective at collecting values from indigenous groups, did not use WTP/WTA style methods and did not rely on a dollar based system. Instead, the elicitation techniques attempted to use a narrative style (via interviews, group discussions, and surveys) to collect or identify values for each country and gauge worth and change in worth. The central question that was investigated was what were the values that would be impacted from an introduction of a marine species? This method was separated from the Guam Buildup research so that values, worth, and change in worth could be identified and driven by participants that are local to the countries being examined (i.e., not influenced by outside observer preferences). This method has been suggested as ideal for identifying and capturing the worth of values when non-market based values are explored (Satterfield 2001). Thus, the elicitation method was sound, but it required more time in country to fully explore the values in a face-to-face method that was more suitable to the countries sampled.

What this research has managed to achieve is some insight into the potential value worth and changes to worth that may be perceived of as occurring if a non-native marine species was to arrive in Guam or Saipan (Palau is excluded here due to a no response rate to the questionnaire). In general, participants from Guam and Saipan indicated that few values would benefit from a non-native marine species arriving in the country. A non-native marine species incursion would decrease the worth of a number of values, with more than 50% of values (summed across all core values) being negatively impacted (Figure A.4). Although the study needs further validation, in a management context the 'no change in worth' values would be excluded from further assessment as the perception is that these values are not deleteriously impacted by an incursion. It is the values that have decreasing worth that have a high management potential. Again, the authors reiterate that our findings are preliminary and hence no action should be taken until further exploration of these values is conducted.

One obvious missing link in the data that was collected is the 0% (i.e., no response) questionnaire response rate from Palau. This poor buy-in of participants to the questionnaire was not reflected within the interviews and discussions that had elicited keen interest, with people expressing a desire for inclusion. The poor survey response rate in Palau might be due to the cultural implication where freedom of enquiry is restricted in some instances. For example, Kesolei (1977) discusses the concept that Palauans believe that there is a hierarchy to data availability. Full information disclosure to the public is rare. In a social context, the more you know in Palauan society the more credibility that person is afforded, with information flow (or the right to know) being based on an individual's social status, age, or lineage (Gilman 1997b).

A.7.3 Future Research Needs and Recommendations

The preliminary research indicates that there is some concern over the impacts that non-native marine species will have in Guam, Palau and Saipan. Hence, it is strongly recommended that a full-scale perceptions study be undertaken in the Micronesian region to determine the perceptions of impact (involving the identification of values, identifying each value's worth and identifying potential changes in value). The collection of information needs to be done in a format that would feed into a non-native marine species risk assessment framework to enable social and cultural values to be assessed equally with economic and biological values.

The authors note however, that because of the preliminary (pilot) nature of this research it is necessary to re-iterate that the outcomes are descriptive, they under represent the population (small and non-random sample size), and hence have a low reliability. Further exploration of the perceived worth and impacts (change in worth), especially to the core values assessed here, is required. The authors urge that this further research follow an ethnographic design that enables the researchers to spend more time with the populations within Micronesia, to truly gauge the level of worth and potential change to values with the perceived potential introduction of marine species. To this effect, it will be valuable to include an expert with non-native marine species expertise and risk assessment to be involved in these studies to help guide the work to ensure that useful data for a risk assessment can be obtained.

Data collection methods need to be refined to meet each country's needs and cultural requirements and to allow face-to-face interviews with a greater sample size of people. Questionnaires were not an effective tool in this instance and the reliability of the data could easily be improved via the running of a number of stakeholder workshops, group interviews, and single interviews. In general, interviews (individual or group) provided the most valuable data, but workshops facilitated by local or a regional agency with expert input, may provide more effective to gauge, especially with regards to the social and cultural elements of impact from non-native species. In societies where information flow is select or restricted (e.g., Palau) the need to more fully engage with government agencies is required. This could be achieved via the use of more intensive one-on-one interviews that collected the questionnaire information directly.

Supplemental Data Tables for Appendix A

Table S.1 Guam values defined where grey shading denotes an identified value. Where -1 denotes a perceived decrease (loss) of worth for the identified value; 0 denotes a perception of no change in worth for the identified value; and 1 = a perceived increase in the worth of an identified value.

Value	Environment	Economic	Social	Cultural	Change in Value*
Catchment effects					0
Harmful algae blooms and nuisance species: health					0
Habitat forming areas: mangroves					-1
Habitat forming areas: coral					-1
Disease					0
Natural authenticity					-1

Supplement to the Regional Biosecurity Plan for Micronesia and Hawaii Marine Risk Assessment

**Based on comments received from various reviewers of the Micronesia Biosecurity
Plan Marine Risk Assessment**

**Edited by members of the University of Guam Micronesia Biosecurity Plan
Development Team**

August 2013

Critique of Chapter 5 of the Marine MBP

Many of the sections of the marine MBP report provided a solid and reliable overview of biosecurity issues in Micronesia, as well as offered useful implementing suggestions. Part I provides a good background on the history, mechanisms, and the impacts of marine invasions. In addition, the political, economic, and legal framework important to the development of risk assessment and biosecurity plans were outlined, and the vectors and human activities conducive to the introduction of non-native species in Micronesia were reviewed. Part III presented an exhaustive and thoughtful list of recommendations to develop a successful marine biosecurity plan tailor-made to the region. However, several of the marine experts contacted to review the draft marine MBP had serious concerns with the quality of Part II/Chapter 5 of the report (the Risk Assessment). A detailed critique of these sections follows, based on the reviewers' comments.

Chapter 5 suffers from erroneous assumptions, gross simplifications, wrong metrics, and a failure to include environmental and ecological data. This assessment should serve as a guideline to develop management strategies and assessment protocols specific to Micronesia. As presented, however, the risk assessment is not credible and does not provide any guidance for the implementation of a marine biosecurity plan because of:

- the non-transparent methodology employed (analyses based on a proprietary and incomplete database)
- the grouping of donor regions into unacceptably large geographical units
- the disregard of environmental and ecological data
- the lack of a thoughtful and informed review of taxonomic query results
- the masking of raw data which prevents an evaluation of the presented results, and
- the flawed likelihood-metric used to evaluate arrival/inoculation risks.

Many of these issues can be traced back to the proprietary database on which the risk analysis is based. This database consists of a limited number of potentially invasive species. Most of the analyzed species are considered to pose an invasion threat to Micronesia, as ship traffic to the region originates from many of the 18 large bioregions (apparently the basic units to document distribution ranges in the database). For this reason the taxon lists in tables 5.3 - 5.8 are almost exact copies of each other. Therefore, the risk assessment is not tailor-made to Micronesia but is in fact a generic one. If – for example – this risk assessment approach was applied to a location in the Arctic that received vessels from some of the 18 large IUCN bioregions, most of medium to high risk invasive species listed for Micronesia would also appear in the "risk assessment analysis" of this Arctic locality because these species (i) are absent from the Arctic and (ii) have a broad distribution range (overlapping with many of the vast bioregions ships originate from). This underscores the necessity to include environmental and ecological variables in the analysis. Furthermore, the taxonomic identity of many of the listed invasive species is questionable. As a result, many of the medium to high risk invasive species listed for Micronesia can be rejected because:

- (i) they already occur in the region (many being natives)
- (ii) many are temperate (to subtropical) species that are highly unlikely to survive in tropical waters, and
- (iii) many are bulk container taxa that from a practical perspective represent a large proportion of the species diversity in their respective genera.

It is difficult to imagine the utility of the Chapter 5 Risk Assessment given that the so-called "invasive species watch lists" (a) fail to list many of the important potentially invasive species, (b) are riddled by species that pose no threat (native species and non-natives restricted to other climate regions), and (c) list a number of species for which correct identifications are next to impossible.

To expand on point (c), although difficult to include in the risk assessment, one must keep in mind that cryptic diversity abounds in many groups of marine organisms (as is alluded to in part 3 of the report). Therefore simple "species watch lists" fail to capture the true extent of the potential marine invasive species in the region.

The most vocal critic among the marine experts ends with the following statement: "Lastly, please realize that you are writing a very important document that will steer future development, management, and conservation efforts in a highly biodiverse region, which is often considered to be one of the last strongholds of relatively pristine tropical reef systems. To do justice to the people and the natural heritage of the region, I sincerely hope that the authors consider improving the risk assessment analysis specifically focusing on non-native species (not just "databased" invasive species) that can realistically invade the tropical waters of Micronesia."

More specific criticisms of Chapter 5 have been grouped into 5 categories:

1. On the accessibility of the species dataset:

The Risk Assessment depends on a listing of non-native marine and estuarine species that have "demonstrated or inferred potential to cause impact". Species listed in this database were compiled from many literature sources (over 1,000 data sources, according to the report) from both peer reviewed publications and grey literature. The authors of Chapter 5 did not see fit to release the full database they used, nor did they list their literature sources. This is very unfortunate as it precludes independent analysis of the adequacy of the available data. For instance, were there species of potentially high concern that were missed in the risk analysis? How were the species lists compiled? Are newest reports of invasive species included in the listings? Are there taxonomic issues with any of the listed species? Aside from allowing independent review of the Chapter 5 risk analysis, access to this database would be particularly useful to develop and optimize management strategies concerning invasive species in the region (that is, be able to rank which taxa are of highest priority for invasive species managers).

It is assumed that the database is based on research supported by public funds, and that the development of the species database itself was likewise supported by public funds. Therefore it seems reasonable to suppose that the species database should be available to the public. It seems, however, that this database is proprietary. A clarification seems necessary – is the database indeed proprietary? If so, what are the reasons for protecting it?

2. On the species included in the likelihood/watch lists:

As mentioned above, there are five main problems with the list of non-native marine species used in the risk analysis:

a. Assumption that only species known to be invasive pose any risk:

The literature is loaded with new records of hitherto unknown invasive species, which certainly does not support the hypothesis that a complete compilation of all invasive species is possible at this stage nor that all currently known invasive species have been archived. Moreover, little work on invasive species in the tropics has been done in comparison to the less species-rich temperate regions. Therefore the species lists are biased towards temperate species (many of which might not be able to establish populations in the tropics), and fail to take into account emergent invasive species from the tropics. It is important to acknowledge the possibility that a species which is not catalogued in the database and which does not occur in Guam can be introduced (for example, any species that belongs to a genus of which invasive representatives are known).

b. Problems with geographic range designations:

There seem to be numerous errors in the listed geographic ranges of species. Many species presumed native to Guam are nonetheless listed as having medium or high likelihood of arrival. Among the marine macroalgae, *Bryopsis pennata*, *Caulerpa mexicana*, *C. racemosa* var. *lamourouxii*, *Dictyosphaeria cavernosa*, *Neomeris annulata*, *Ulva clathrata*, *Valonia fastigiata*, *Chnoospora minima*, *Padina boryana*, *Acanthophora spicifera*, *Asparagopsis taxiformis*, *Centroceras clavulatum*, and *Hypnea spinella* already occur in (are native to?) Guam.

The red alga *Acanthophora spicifera*, a very aggressive tropical invasive, is listed as a "Medium" likelihood of arrival for Guam, the CNMI, and FSM (see table 5.11) – yet it is actually believed to be native in these areas. However, it has been reported that this species successfully invaded the RMI and UMI (Line Islands) (Tsuda et al. 2008, Knapp et al. 2011). Table 5.11 fails to list *A. spicifera* invasion likelihood risk for either RMI or UMI. *Acanthophora spicifera* might be the best-documented and fiercest "red algal invader" in the region and is recorded as such in the following publications:

Tsuda R.T., Coles S.L., Guinther E.B., Finlay A.O. & Harriss F.L. 2008. *Acanthophora spicifera* (Rhodophyta: Rhodomelaceae) in the Marshall Islands. *Micronesica* 40: 245-252.

Knapp I.S., Godwin L.S., Smith J.E., Williams C.J. & Bell J.J. 2011. Records of non-indigenous marine species at Palmyra Atoll in the US Line Islands. *Marine Biodiversity Records* 4: e30.

c. Known invasive species omitted from database:

Several known invasive species that should be included in the watch lists are inexplicably not listed in the database. These include the macroalga *Spyridia*, and 3 species of marine fish reported from Apra Harbor (Smith et al. 2009). Given the methodology used in the risk analysis, one would expect to see the infamous invasive strain of *Caulerpa taxifolia* to be listed in the tables, but it is not listed. It is unclear why this species did not make the watch list. Perhaps it is considered by the authors to be the same taxon as the native *C. taxifolia*? However, from a biological perspective, the reviewer who raised this concern is fine with it not being listed on the watch list. This brings up the next point (d).

Based on the fact that many of the listed species (natively) occur in the recipient region, it seems that this analysis does not focus on non-native species but all species that are likely to be transported (which differs from the methodology description). Are the authors concerned with genetic exchange between donor and recipient regions even if the (morpho-)species already occurs in the recipient region? If so, this should be clearly stated in the report.

Smith, B.D., T.J. Donaldson, T. Schils, A. Reyes, K. Chop, and K. Dugger. 2009. Marine Biological Survey of Inner Apra Harbor, Guam. University of Guam Technical Report No. 126.

d. Inclusion of species from temperate and colder waters (non-consideration of environmental parameters and ecology):

Plenty of temperate species are considered to have a medium or high risk to be introduced, despite biologically low likelihood for establishment. Case in point: the giant kelp *Macrocystis pyrifera* almost certainly would not survive in the tropics. In fact, a recent post on the algae-I list inquired about intentional introductions of this species in France and China, where it apparently wasn't able to survive. Here it is listed as a medium risk invader in the tropics. On p. 312, the chapter authors cite Graham et al. (2007) in support of their inclusion of *Macrocystis* in their species list. However, Graham et al. (2007) mention that the alga occurs over a wide temperature gradient from boreal to warm temperate waters. Why would you then consider this species to be an invasive outside of this wide temperature range (i.e., in tropical Micronesian waters)?

Other temperate algal species that are deemed unlikely to be established in Micronesia and Hawaii include *Sargassum muticum*, *Pylaiella*, *Bangia*, *Caulacanthus*, and *Corallina officinalis*.

Graham, M. H., J. A. Vásquez, and A. H. Buschmann. 2007. Global ecology of the giant kelp *Macrocystis*: From ecotypes to ecosystems. *Oceanography and Marine Biology* 45: 39-88.

e. Problems with cryptic species:

A large proportion of some of the groups included in this report are in fact cryptic species (currently lumped in species complexes). The marine MBP categorizes them as cryptogenetic species (=species of uncertain geographic origin), but this is not exactly correct. Many of these species can reasonably be assumed to be native to Micronesia, but their identification to species-level is dependent on a molecular-assisted alpha taxonomy approach and has not been conducted on most of the considered taxa. Some of these groups in which cryptic diversity abound include textbook examples of invasive species in the region.

For example, the *Ulva* species listed in the tables are bulk container taxa that include a diversity of species throughout their distribution range. The listed names have often been used out of convenience because morphological characteristics to identify *Ulva* species are limited. Indicating that "just" these *Ulva* "species" have a high likelihood to spread shows the shortcomings of the methodology based on a preconceived list of invasive species. The same is basically true for all the other listed green algae in this and subsequent tables. Among the red algae, *Laurencia brongniartii* (an often misapplied name) and *Hildenbrandia rubra* also stand out. Inclusion of *Hildenbrandia rubra* shows that the data was analyzed without much knowledge about phycology. Records for *Hildenbrandia* are scarce in the region & this particular species identification has often been one of convenience – it is unlikely that this is the same species throughout its huge distribution range. The type locality of this species is in Norway. It's unrealistic to assume that this species can grow in Micronesian waters.

3. On the bioregions used in the risk assessments:

Geographic distributions of the species used in the Chapter 5 risk assessments were delineated based on 18 large scale IUCN marine bioregions (see figure 5.3). These bioregions are too broad to be useful for risk assessments. The entire area covered by the Micronesian Biosecurity Plan falls within one vast bioregion (bioregion #14) that stretches from the Marianas in the west to Hawai'i and the Tuamotus in the east (N.B., the placement of Palau is not clear from figure 5.3 – it could be in bioregion #14 or #13). Bioregion #14 straddles a large portion of the well known “mega-transect” of declining marine biodiversity from the western to the central Pacific (driven largely by processes such as isolation and dispersal limitation). For example, there are marine species native to the Solomon Islands that are not present in Guam, and there are native species in Guam that are not found in Fiji, much less Hawai'i (which is very depauperate and has proportionally higher marine endemism than other areas of the Western Pacific). Therefore, placing a species of interest as belonging to bioregion 14 is not at all useful, as it will tend to erroneously designate introduced species as native. Consider the impact of the assumed size of bioregion 14 on Hawai'i: the assumption used in this analysis disregards risks of exchanging invasive species between Micronesia and Hawai'i. This doesn't seem logical and it invalidates the risk assessment. The prime objective of the MBP is to prevent arrival and establishment of invasive species in Micronesia and Hawai'i, and Micronesia is undoubtedly a major source of invasive species for Hawai'i (and vice versa).

The authors of Chapter 5 imply that they do not only rely on the 18 regions designated by IUCN. They state that the IUCN bioregions have overlapping boundaries, resulting in a sequence of ‘core’ and ‘transitional’ areas that are roughly equivalent to a newer, finer-scale, and more widely-accepted biogeographic analysis by Spalding et al. (2007). However, it is difficult to comprehend how the bioregion overlaps can be equivalent to Spalding et al.'s approach, given that Spalding et al. (2007) identified a total of 62 marine provinces and 232 ecoregions. Logically, some of this geographic detail must be lost in an analysis based on only 18 bioregions.

The ‘conservative approach’ to estimating species distributions favored by the chapter authors simply does not result in a useful risk assessment, when the geographic scale employed is so large that there is virtually no difference between a region-specific risk assessment (what the authors set out to do) and a global analysis (what actually resulted from their work). While it is true that fine-scale geographic distribution data are not available for many taxonomic groups, there are some better studied groups for which such data are readily available (e.g., marine macroalgae, fish, etc.). Why not work on a finer geographical scale when possible? A finer geographic grain could have been applied for those taxa for which data are available, and a coarser-grained analysis could still have been done for taxa that lack such resolution.

Spalding, M. D., H. E. Fox, G. R. Allen, N. Davidson, Z. A. Ferdana, M. Finlayson, B. S. Halpern, M. A. Jorge, A. Lombana, S. A. Lourie, K.D. Martin, E. McManus, J. Molnar, C. A. Recchia, and J. Robertson. 2007. www.nature.org/MEOW. Accessed May 2008.

4. On environmental & ecological parameters, and niche modeling:

This has already been referred to in point 2, but it is important to stress that the inclusion of ecological data and environmental parameters (especially temperature data) is essential to produce a tailor-made invasive risk assessment plan for a specific region, i.e. the goal of this

report. Given that that very little biological information was included in the risk analysis, this chapter is essentially an extension of chapter 3, and should be included there as a subsection.

On page 311 of the original document, the chapter authors reject the use of “environmental matching” studies (more popularly known as environmental niche modeling), which is employed to model species distributions (including predicting potential species invasions). They cite Hewitt and Hayes (2002) in support of their arguments; however their 2002 paper does not represent the current state-of-the-art of remote sensing products. It is suggested that they have a look at Verbruggen et al. (2009) and Tyberghein et al. (2012) on niche modeling of marine species using environmental data. The reviewer in this case disagrees with the rejection of environmental matching/niche modeling, arguing that this is currently the only realistic method to conduct a risk analysis of a large suite of invasive taxa incorporating environmental conditions. If the distribution ranges of the taxa of interest are of high resolution, most of the environmental data will be too. Also, with the availability of increasingly better satellite imagery products, this is the only option if one wants to include the temporal variability in environmental variables (seasonality) to model invasive risks on a global scale (consistent use of a single product of the same resolution and similar error margins). This approach is the norm and - although not perfect - a great improvement on analyses that ignore environmental parameters completely (like the here-presented analysis).

Also (still on p. 311), the environmental match between the Port of Sydney and the Port of Hobart based on an IUCN bioregion approach indicates the weakness of the methodology used in this report. If the authors opt for a very coarse-scale biogeographic concept (as commented on before), indeed little environmental variability is to be expected. If, however, they used the widely accepted and most current biogeographic concept of Spalding et al. (2007), the authors would have noticed that both ports are two ecoregions apart (Sydney: marine ecoregion 203; Hobart: marine ecoregion 205). Furthermore since the authors are from Australia they should be aware that the IMCRA bioregion model is at an even finer scale than Spalding's marine ecoregion model and is completely compatible with the latter. So, if one conducts an invasive species risk analysis confined to a specific region, why not use the best biogeographic concept available for that region? Both harbors are 4 meso-scale IMCRA bioregions apart, which clearly indicates that these regions differ environmentally. The reason for the failure of niche modeling to accurately predict the species distribution of *Asterias amurensis* is not because of a fundamental flaw with niche modeling studies, but rather because the biogeographic region used in the analysis was too large. Inaccurate prediction of the range of the seastar does not justify the exclusion of environmental data in the marine MBP risk assessment.

5. On assumptions in the analyses:

To determine the risk of introduction of a potentially invasive species, Chapter 5 authors equated likelihood of introduction with the proportion of vessel arrivals originating from different global bioregions. Given the acknowledged incompleteness and inaccuracy in the available vessel traffic data, it would have been better to concentrate on environmental/ecological factors that determine the establishment, survival, and spread of potentially invasive species in tropical waters. An inoculation only needs to occur once to be successful, probabilities of how many times such introductions can occur are rather irrelevant for a good biosecurity plan. If species X has the physiological capability to invade Micronesia (for instance, if it is a habitat generalist and only occurs in a geographically confined tropical location), then the inoculation only has to happen once for a successful establishment. On the other hand if species X only occurs in temperate waters then the likelihood of inoculation in Micronesia is practically zero (contradicting the unrealistic likelihoods calculated in the risk assessment). Chapter 5 does not assess the risk of species invasions; rather it estimates the probability of an invasion from a generic representative of a bioregional fauna/flora.

Table 5.2 presents a likelihood matrix that defines probability of inoculations based on proportion of vessel traffic from different bioregions. There are two major problems with this likelihood matrix:

- a) the levels are arbitrarily defined (e.g., what is the real-life difference between 1-10% probability – “extremely low” – and 10-25% probability – very low? And as mentioned above, wouldn't a single successful inoculation be sufficient to establish a species in a new locality?
- b) flawed use of the *proportion* of vessel traffic, rather than the actual number of vessels. The problem with this method is illustrated in the following example:

Say, you have two regions for which you do a risk assessment (R1 and R2).

For R1 you have 500 ship arrivals from Bioregion A, 100 from Bioregion B, and 50 from Bioregion C.

For R2 you have 5 ship arrivals from Bioregion A, 10 from Bioregion B, and 50 from Bioregion C.

This translates into the following percentages of total arrivals:

R1: 77% from A, 15% from B, and 8% from C

R2: 8% from A, 15% from B, and 77% from C

So, you conclude that the risk of an invasion in R1 is highest from A (once again incorrectly ignoring environmental/ecological variables), then B, and then C.

For R2 you find the reverse.

However, when you look at the real risk, you see that both regions are similarly connected to

bioregion C (equal risk, both have 50 ship arrivals from this region). Yet, in your risk analysis you conclude that the likelihood of a non-native species arrival from Bioregion C at R1 (based on 50 ship arrivals) is "extremely low" whereas this likelihood is regarded to be high at R2 (based on the same number of ship arrivals: 50). Similarly, you find an equal risk (77%) of a species from Bioregion A arriving at R1 as one from Bioregion C arriving at R2, whereas R1 receives 500 ship arrivals from Bioregion A and R2 "only" 50 from Bioregion C.

It could be argued that you could conduct this likelihood for the two regions combined (which is not done in this report), but the essence remains the same: where do these proportional cut-off margins come from and how were they arbitrarily defined? The arrival of a single heavily fouled barge from an unlikely tropical donor region is a much greater risk than hundreds of clean Navy vessels from San Diego.

The errors of this approach are well illustrated in the results of the risk analyses for the FSM and RMI. For the FSM, the total number of vessel arrivals was 811 while for the Marshall Islands, there were 1170 arrivals. So, if a non-native species X could be "imported" on 615 vessel entries in the FSM, this would be regarded as a high risk likelihood (76%). The same number of potential arrivals of this species (bioregion in fact) in the Marshall Islands (615), would suddenly become a medium (almost a low risk: 53%) for the Marshall Islands. This "proportional" risk assessment approach is wrong, in the above scenario species X poses an equal invasion threat to the FSM and the Marshall Islands.

Because the total number of arrivals is higher and because of the limited number of "predetermined" potentially invasive species in the data set, it is mathematically obvious that the Marshall Islands have a lower number of species that meet the proportional thresholds that determines the "high risk category" when compared to the FSM.

Recommendations:

The inclusion of an analysis that pinpoints/ranks the last ports of call that pose the greatest threat to import viable non-native species to Micronesia would be of great benefit to the development of a biosecurity plan.

Also, on p. 318 there is mention of ranking ports of inoculation into high-risk, medium-risk, and low-risk – such a ranking would be extremely useful for invasive species managers.

Likewise, a ranking of species from those of negligible concern to species of serious concern (=high likelihood of introduction coupled with large potential ecological impacts) would be a very important contribution to the risk assessment and biosecurity plan. This would require consideration of environmental parameters (of the receiving environment) and ecological data (of the potential invasive species) to derive better predictions of which species are physiologically capable of establishing themselves in Micronesia and Hawai'i (i.e., environmental niche modeling).

A comprehensive marine risk assessment would not focus solely on biofoulers on commercial and MSC vessels, but also consider:

- (a) biofouling communities brought in by recreational vessels and barges (both are less maintained than commercial vessels, therefore have higher risks of transporting invasive species), and
- (b) other vectors, most importantly introductions from the live trade and from ballast water.

Consider expanding risk analyses beyond the known invasive species, by including species that are likely to exhibit invasive characteristics – for instance, including all species in genera that include invasive representatives.

Consider gathering new (primary) data on tropical marine invasive species in Micronesia. Chapter 6 of the marine MBP already recommends baseline surveys and periodic monitoring of port areas, and the development of a coordinated database on information on species, vessel traffic, and ballast water (section 6.2.1, p. 318). To these very timely recommendations, one could add alpha-taxonomic studies on species complexes that include invasive members. Such studies should include a molecular/ DNA barcoding component, which would provide rapid and inexpensive determinations of taxa.

Lastly, to improve the quality of the existing analyses as they stand, the following are recommended:

- release of the full species database, including references used, mention of availability of ecological, environmental, and distributional data (or lack thereof), and an assessment of the reliability / accuracy of the data provided
- assembly of more data (and better data) on the distribution of species
- improvement of species lists (acknowledgement of cryptic species/ species complexes, known invasive species not currently in database)
- geographically finer-scale analyses for those groups where available data permits more detailed analyses (e.g., marine macroalgae, which have a good database on species' biology and geographic distributions).

4 Volume IV - Terrestrial Systems

**Regional
Biosecurity Plan
for Micronesia and
Hawaii**

Volume IV

Prepared by:

University of Guam and the Secretariat of the Pacific Community 2014

This plan was prepared in conjunction with representatives from various countries at various levels including federal/national, state/territory/commonwealth, industry, and non-governmental organizations and was generously funded and supported by the Commander, Navy Installations Command (CNIC) and Headquarters, Marine Corps.

Terrestrial Risk Assessment of Alien Invasive Species for Micronesia and Hawai'i

**Edited version of an original document
produced by USDA**

2013

The original document, from which this edited version was produced, was prepared by United States Department of Agriculture (USDA), Animal and Plant Health Inspection Service (APHIS). A team from the USDA APHIS Plant Protection and Quarantine (PPQ), Plant Health Programs–Quarantine Policy Analysis and Support staff and Veterinary Regulatory Support staff compiled this document from Terrestrial Risk Assessments that were prepared by risk assessment teams from the USDA-APHIS Plant Protection and Quarantine, Center for Plant Health and Technology, Raleigh, North Carolina, the USDA-APHIS Wildlife Services, National Wildlife Research Center, Hilo, Hawai'i, the USDA-APHIS Wildlife Services, National Wildlife Research Center, Fort Collins, Colorado, the USDA-APHIS Veterinary Services Centers for Epidemiology and Animal Health, Fort Collins, Colorado, and the USDA-APHIS Veterinary Services, National Center for Import and Export, Raleigh, North Carolina. Chapter 8, Terrestrial Vertebrate Species was prepared separately by the USDA-APHIS Wildlife Services, National Wildlife Research Center, Hilo, Hawai'i. The final document was edited by Kenneth Werner, USDA APHIS PPQ, Honolulu, Hawai'i.

The compilers of that original document would like to express their appreciation to the many federal, state and local officials in the Micronesia Region and the United States for their help and assistance throughout this project. The compilers wish to express their appreciation for the contributions to the Terrestrial Risk Assessment from the risk assessment teams from the USDA-APHIS Plant Protection and Quarantine, Center for Plant Health and Technology, Raleigh, North Carolina, the USDA-APHIS Wildlife Services, National Wildlife Research Center, Hilo, Hawai'i, the USDA-APHIS Wildlife Services, National Wildlife Research Center, Fort Collins, Colorado, the USDA-APHIS Veterinary Services Centers for Epidemiology and Animal Health, Fort Collins, Colorado, and the USDA-APHIS Veterinary Services, National Center for Import and Export, Raleigh, North Carolina.

EXECUTIVE SUMMARY

As a result of the Defense Policy Review Initiative conducted by the United States (U.S.) Secretary of State, the Secretary of Defense, the Japanese Minister of Foreign Affairs, and the Minister of Defense, the U.S. Department of Defense (DoD) has proposed relocation of U.S. military forces to the U.S. Territory of Guam and the island of Tinian within the U.S. Commonwealth of the Northern Mariana Islands (CNMI). The purpose of the relocation is to meet international agreement (Alliance Transformation and Realignment Agreement) and treaty (*U.S.-Japan Roadmap for Realignment Implementation*) requirements, and to fulfill U.S. national security policy requirements in the Western Pacific Region. Proposed actions include components of the U.S. Marine Corps, the U.S. Navy, and the U.S. Army.

To comply with the National Environmental Policy Act of 1969, 42 United States Code §§ 4321 et seq., as amended, DoD and other federal agencies must examine the environmental effects of the DoD's proposed actions for the relocation process. Council on Environmental Quality (CEQ) regulations (40 Code of Federal Regulations (CFR) §§ 1502.09 and 1502.20) govern supplemental and tiered environmental impact analyses. On behalf of DoD, the Department of the Navy prepared an Environmental Impact Statement (EIS) (Final EIS [FEIS] delivered July 2010) to inform decision makers of potential environmental consequences of the proposed Guam and CNMI military relocation actions so all parties can take measures to protect, restore, and enhance the environment.

According to the DoD FEIS, the military relocation beginning in 2011 and expected to peak by 2014¹ will have substantial impact on the population, economy, and environment on Guam. Other Micronesia Region islands and the state of Hawai'i will be impacted as well. DoD expects as many as 79,000 new residents on Guam by the peak year of the military relocation. Imports are expected to increase substantially with the increase in population during the military relocation and build-up, and may increase the risk of pests and diseases entering the Micronesia Region. Areas of U.S. jurisdiction under United States Department of Agriculture (USDA), Animal and Plant Health Inspection Service (APHIS) regulations 7 CFR § 318.13-1 and 9 CFR § 1-146 (under the Definitions subsection) include Guam, Hawai'i and CNMI (Saipan, Tinian, and Rota). These areas are defined the same as states (along with Puerto Rico, the U.S. Virgin Islands, and the District of Columbia) in regards to APHIS jurisdiction.

The primary objective of this terrestrial risk assessment is to propose detailed recommendations sufficient to prevent and mitigate risks to human health and safety, animal and plant health, the economy, and the ecology of the Micronesia Region from the intentional or unintentional introduction, spread, or establishment of terrestrial alien and potentially invasive animal, plants, and diseases. These recommendations are based on risk assessments by APHIS, APHIS regulations, and established policies

¹The National Defense Authorization Act (NDAA) for Fiscal Year 2012 (FY 2012), signed into U.S. law on December 31, 2011, by President Barack Obama, imposed restrictions on the Secretary of Defense's usage of funds to develop infrastructure associated with the USMC relocation to Guam. Additionally, Congress did not authorize or appropriate funding for the Guam realignment in FY 2012. As the pace of construction is subject to the availability of funds, it is anticipated that the realignment will proceed at a slower rate than originally anticipated (NDAA for FY2012).

to determine the risks of introduction of invasive species or pathogens from the transport of passengers, baggage, cargo, commodities, and construction materials to Guam.

The recommendations are based on the risk assessments of APHIS-Plant Protection and Quarantine (PPQ) personnel with extensive on-the-ground experience. These recommendations and suggested best management practices should help prevent invasive species damage to the region from the military relocation on Guam and the CNMI. While the recommendations vary in specificity, they do not provide a comprehensive blueprint for implementation. How these recommendations are implemented will determine their effectiveness.

In determining biosecurity recommendations, risk assessors identified pathways which could be carriers for the introduction of invasive species and pathogens. Risk assessors evaluated current literature, visited sites, and conferred with local subject matter experts to evaluate potential risks for the introduction of invasive species and studied these risks as predicted impacts from the military relocation and build-up on Guam.

Each group of APHIS risk assessors developed a specific methodology to determine risks and recommendations for biosecurity enhancements. For many pathways and species, information for making determinative rankings for risks was limited; therefore, risk rankings for most pathways and species in the APHIS risk assessments are qualitative.

Risks were determined for a wide range of animal and plant species and pathogens. Plant propagative material may present phytosanitary risks in the Micronesia Region as either a pathway for introduction of exotic plant pests or as propagated invasive species. The introduction of many livestock, poultry, and wildlife diseases could have severe consequences to animal and human health throughout the Micronesia Region and far-reaching impacts on trade for the rest of the United States. More smuggling could mean more health and ecological risks from exotic pets and recreational animals. The potential for importation of zoonoses that pose a major public health threat warrants increased surveillance for imported wildlife.

To determine biosecurity recommendations, the assessors reviewed U.S. and Guam statutes, regulations, and procedures for prevention and mitigation of biosecurity risks for general mitigation practices for all pathways (commercial, military, and private).

While federal, territorial, and military regulations may prevent and mitigate the introduction of invasive species and pathogens, the estimated increase in population and goods with the military relocation will strain current capacity for inspection and interdiction of illegal goods, and increase the likelihood of invasive species transported throughout the region. Already mitigation resources are stretched at air- and seaports in the Micronesia Region. Ports and diagnostic laboratories do not have sufficient detection and identification equipment. Surveillance for the detection of plant pests and the brown treesnake (*Boiga irregularis*) (BTS) is routine. Rapid response capabilities are limited to BTS and lacking for even BTS in many areas.

With its broad scope and complex risks, the challenge of protecting Hawai'i and the Micronesia Region from the multitude of threats requires an overarching framework for a successfully sustained biosecurity process. This Micronesian Biosecurity Plan includes components designed to reduce biosecurity risks through prevention with educational outreach programs and through risk mitigation measures including inspection, quarantine, monitoring, surveillance, rapid response, control, and eradication.

A comprehensive biosecurity plan requires an integrated process for regular reassessment and improvement as situations change and new risks become known. An improvement planning approach from the Department of Homeland Security (DHS), *Homeland Security Exercise Evaluation Plan*, will serve as an informative reference for continual improvement in biosecurity planning. Templates are available for scheduling and conducting improvement planning events and building successful prevention and mitigation programs and can be found at https://hseep.dhs.gov/pages/1002_Exerc0.aspx.

The challenges, risks, and costs of long-term control and eradication of an established invasive species are significant. The most cost-effective approach to protecting regional human health and agricultural resources is prevention and early detection. Success in preventing the transport, introduction, and establishment of invasive species in the region will require a coordinated and comprehensive approach based on information-sharing, funding of well-planned resources, and coordinated prevention and protection programs among all biosecurity partners and stakeholders. A regionally inclusive process will engage appropriate experts and decision makers fully, build consensus and commitments, and take advantage of expertise and resources within Micronesia.

1 INTRODUCTION

In compliance with EO 12114 and according to proposed events and anticipated impacts described in the FEIS, USDA-APHIS has developed this regional terrestrial risk assessment (RA) to assist in the protection of Guam, Hawai'i, CNMI, Federated States of Micronesia (FSM), Palau and the Republic of the Marshall Islands (RMI) as well as the broader Pacific from invasion by unwanted pests and disease agents during the increased U.S. military activity (EO 12114).

The terrestrial RA provides recommendations for protecting Hawai'i, Guam and other Micronesian Region locations based on USDA-APHIS Pest Risk Assessments (PRA), USDA-APHIS regulations, and established USDA mitigation procedures. Species life histories and current biosecurity practices have identified potential means of transport of invasive species into the Micronesia Region and Hawai'i. While the primary geographic focus is Guam, the terrestrial RA considered the CNMI, the Republic of Palau, FSM, RMI, and Hawai'i with particular focus on CNMI due to proposed military training activities with trans-shipment of relocation cargo through CNMI.

The APHIS assessment task was divided among four APHIS teams based on program expertise. The Plant Health Programs of APHIS-Plant Protection and Quarantine (PPQ) provided regulatory and risk mitigation guidance. APHIS-Veterinary Services (VS) analyzed risks to livestock from disease vectors. APHIS-Wildlife Services (WS) analyzed risks to wild terrestrial vertebrate animals from wildlife disease vectors and wildlife. The Center for Plant Health Science and Technology (CPHST) of APHIS-PPQ analyzed risks from invasive plants, plant pests, and plant diseases.

1.1 ASSESSMENT DESIGN

Chapter 1: Introduction, provides an overview of the objectives, scope, design, and caveats of the terrestrial RA.

Chapter 2: Military Relocation to the Mariana Islands.

Chapter 3: Existing Mitigations, describes current policies, requirements, and methods developed by Guam, APHIS, DoD, and other authorities for phytosanitary and general sanitary practices at all Guam ports. Ports for other jurisdictions were not detailed here and therefore will be covered in the implementation plan component of the Micronesia Biosecurity Plan.

Chapter 4: Recommendations, lists APHIS recommendations for enhancing biosecurity measures and programs during and after the military relocation.

Chapter 5: Outreach Plan, describes an approach to educate local populations and organizations about potential risks from invasive species and methods to prevent, report, and control their introduction.

Chapter 6: Monitoring and Surveillance, describes strategies and methods for a coordinated monitoring and surveillance process to detect and report high-risk species rapidly.

Chapter 7: Rapid Response, describes strategies, methods, and organizations involved with control and eradication of invasive species.

Chapter 8: Terrestrial Vertebrate Species, describes the unique biosecurity requirements for terrestrial vertebrate species.

The remaining chapters include compilations of APHIS risk assessments, pathway risk analyses, quality assurance measures, and references.

1.2 OBJECTIVES OF THE TERRESTRIAL RA

- Prevention of the introduction and spread of IAS to the jurisdictions of Micronesia and Hawai'i.
- Evaluation and integration of APHIS PRA information, risk ratings, and recommendations along with appropriate APHIS regulations and policies into a comprehensive strategy for biosecurity protection and response during and after the military relocation to Guam.
- Development of an outreach and education plan to increase awareness of risks from invasive species, encourage the adoption of practices to prevent the transport of invasive species, and describe mechanisms for reporting suspected introductions.
- Development of monitoring and surveillance risk-mitigation strategies for rapid detection of high-risk species and diseases.

1.3 CURRENT RISK ASSESSMENTS

This terrestrial RA integrates the APHIS risk assessments and recommendations developed by the CPHST, PPQ, VS, and WS risk assessment teams showing potential impacts to agriculture, ecosystems, and economies throughout the Micronesia Region from the introduction of invasive species during the planned military relocation on Guam and Tinian. For the purposes of this RA, references to “invasive species” include live animal and plant species, animal pests, vectors, and infectious agents. APHIS Terrestrial Risk Assessments are included in Appendix A.

1.4 SCOPE

This RA is framed by a closely defined scope on three levels: geographic, temporal, and operational. The geographic scope describes the locations of Micronesia Region islands and Hawai'i as well as foreign ports from which personnel and supplies originate. The temporal scope describes timing and duration of all plan requirements to be completed.

The basis for understanding risks of the military relocation phase is the evaluation of all military relocation activities as described in the FEIS issued in July 2010 (U.S. Navy 2010a); identification of all potential enhanced risk due to the unintentional introduction of invasive species associated with the relocation; and the integration of the risk profile and required protection enhancements into this RA. Any changes to the military relocation plan after delivery of the final draft of this RA may not be considered in the RA document.

The operational scope analyzes potential direct and indirect impacts from military relocation activities in movement of personnel and belongings, construction, commercial development, shipping and service industries, tourism, resource utilization, resource planning, etc. The operational scope also includes prevention and protection programs; education; awareness training on Guam and throughout Micronesia for military and civilian populations; and mitigation programs of inspections, monitoring, surveillance, and emergency response.

1.5 CAVEATS

The development of risk assessments and biosecurity planning recommendations for the military relocation to Guam and Tinian and potential impacts throughout the Micronesia Region depends on processes outside the control of RA developers, and therefore, certain caveats apply. The RA presents recommendations based on methodology for assessing mitigation capabilities and determining potential impacts. The caveats are addressed in Chapter 5: USDA-APHIS Risk Assessments.

2 MILITARY RELOCATION TO THE MARIANA ISLANDS

2.1 MEASURING IMPACTS FROM THE MILITARY RELOCATION

The proposed complex military relocation includes components of the Marine Corps, Navy, and Army as well as Air Force assets already on Guam. To accommodate the three major elements of the proposed actions, a substantial increase in construction and improvements (Marine and Army base residence, aviation maintenance facilities, etc.) as well as more frequent ship berthing would be necessary. According to the DoD FEIS (U.S. Navy 2010a), implementation of the proposed military actions would result in:

- Temporarily increased population related to the construction work force
- Permanently increased number of military and civilian personnel and dependents on Guam
- Increased transient presence on Guam and Tinian
- Increased numbers and types of major equipment assets to support military personnel and operations (e.g., aircraft, ships, amphibious watercraft)
- Increased numbers and types of training activities
- Construction of new facilities
- Improvements to existing facilities
- Improvements to infrastructure (including roads and utilities)
- Acquisition of additional land (required for three of the Marine Corps Relocation-Guam actions)

The risks from invasive species to Hawai'i, Guam and other Micronesia Region islands are linked most closely with the conveyance pathways that could transport the plant and animal species. Pathways are any means that allow the entry or spread of pests. A pathway risk assessment systematically evaluates the likely ways by which exotic pests or pathogens might enter an area and become established. A number of physical animal and plant pathways may move invasive species and diseases; however, most introductions to Hawai'i, Guam and other Micronesia Region locations are likely to be by commercial and military aircraft and maritime vessels.

Military relocation activities can impact multiple pathways in diverse ways. While data may be limited, interrelationships uncertain, and future events unpredictable, estimated numbers of personnel and contract workers are available and can be used to estimate potential impacts and necessary protections required to mitigate these impacts. Estimates are also available for the increase in construction materials needed to add or improve new military and residential housing, roads, and other infrastructure.

Planning and the allocation of funds will need to be part of any military relocation to the Mariana Islands. Even a scaled back version of the build up will be overwhelming in terms of the impacts it will have on the limited infrastructure, especially inspection capabilities for contraband and invasive species.

Military relocation will increase air transportation volume to and from Guam. Most military personnel and temporary workers will travel to Guam by commercial aircraft, increasing passenger volume on air transports substantially. Related pathways to this conveyance:

- Military and civilian passengers capable of transporting infectious diseases, disease vectors, and hitchhikers (species unintentionally transported in cargo, packing material, or containers)
- Baggage of passengers and all potential risk species that could be transported therein
- Commercial air cargo
- Garbage on board aircraft and from items confiscated at port
- Imported plants, plant products, animals, and animal products
- Smuggled biological items
- Unintentional transport of terrestrial vertebrates

New Guam residents and increased military activity on Guam and Tinian will require transport of equipment and materials and other cargo by maritime vessels for infrastructure and services.

- Construction equipment and materials shipped to Guam as containerized, break bulk, and bulk cargo
- Additional homes and buildings constructed to meet the demands of new residents and businesses
- Expansion of commercial and military port infrastructure
- Garbage generated on vessels
- Imported plants, plant products, animals, and animal products

New Guam and Tinian residents will conduct activities for business or pleasure, which could impact biosecurity.

- Mail and shipments to new residents on Guam and Tinian
- Landscaping
- Cultural activities (food preferences, religious ceremonies, aesthetic pursuits, hunting, fishing, boating, and other water water and terrestrial based activities)
- Scientific activities (zoological exhibitions and scientific research)

Leisure and business travel throughout the region and beyond by new residence and/or by visitors to residents

Military Impact Estimates

According to the DoD FEIS, Guam's current population of 177,718 (World Bank, World Development Indicators 2009) will increase by about 79,178 new residents, approximately 45%, at the peak of the military relocation. The post-relocation steady state will result in 33,608 new residents, an approximately 19% increase (U.S. Navy 2010a). DoD planning as of 2013 anticipates these numbers to be lower.

The DoD FEIS estimates shipments of containerized cargo to increase and then stabilize to a post-military relocation steady state (U.S. Navy 2010a).

It should be clear that these estimates are based on information which was current in 2010 but is no longer likely to occur. Changes will take place in regards to the buildup but exactly what these changes and associated impacts will be and at what levels was still undetermined as of August 2013.

2.2 PATHWAYS AND RISK SPECIES

Invasive species and disease agents threatening biosecurity on Hawai'i, Guam and other Micronesian Region islands are linked through their life cycles to specific pathways of transport. In most cases, these animals, plants, pests, and diseases move through more than one pathway. APHIS risk assessments have evaluated each of these relationships. Table 5-1 illustrates the range of mitigation measures employed at airport and maritime port facilities. Each of the following mitigations may be applied at both the air- and seaports: 1) inspection, 2) commodity identification, 3) control, 4) quarantine, 5) treatment or disinfection, 6) review of documents (permits, health or phytosanitary certificates, etc.), 7) training, and 8) approval to handle regulated garbage.

The pathway and risk profiles described in this section are designed as snapshots of the primary risk types, risk levels, mitigation measures, and recommended mitigation upgrades based upon APHIS risk assessments. Greater detail for biosecurity mitigation measures is in Chapter 6, *Existing Mitigation*. A more detailed, comprehensive description of the biosecurity recommendations for plants and plant products, livestock and poultry, and wildlife diseases is in Chapter 7, *Recommendations*. Specific recommendations for terrestrial vertebrates are in Chapter 11, *Terrestrial Vertebrates Biosecurity Plan*.

Table 5-1: Mitigation Measures for Risk Pathways

Pathway	Pre-test/certify	Permit or License	Monitor	Inspect	Identify	Quarantine	Treat-disinfect-decontaminate-dispose
Cargo	X	X		X	X	X	X
Wood Packing Material	X			X	X	X	X
Construction		X		X		X	X
Mail				X ^a			
Regulated garbage	X	X	X	X		X	X
Plant propagative materials	X	X		X		X	X ^b
Plant products	X	X ^c					X
Soil		X		X			X
Livestock	X	X		X	X	X ^d	X ^e
Poultry	X ^f	X		X		X	
Pet birds	X	X		X	X	X	
Dogs and cats	X ^g			X		X	X ^h
Other animals	X	X		X	X	X	
Animal products	X	X		X			X

^a Only international mail may be inspected without a warrant.

^b Plants from Hawai'i.

^c Fruits and vegetables.

^d All foreign livestock destined to Guam and associated territories would be quarantined on Hawai'i or in the continental United States.

^e Domesticated livestock imported to the United States is subject to inspection or treatment procedures; an inspector may require disinfection of livestock and equipment as a precaution against the introduction of animal diseases.

^f All imported hatching eggs from Exotic Newcastle's Disease-free regions must be accompanied by a veterinary health certificate as well as a USDA import permit.

^g Dogs imported to the United States, with limited exceptions, must be accompanied by a certificate for rabies vaccination; the entry of pets from areas affected by screwworms requires a health certificate; dogs must have a rabies vaccination certificate (Guam Administrative Rules and Regulations or GARR); cats must have a certificate of immunization (GARR).

^h Administration of two doses of rabies vaccine (GARR).

2.2.1 Aircraft

A.B. Won Pat International Airport manages hundreds of flights weekly of national and international cargo and passenger transport, with numerous flights originating or passing through major Asian and Pacific metropolitan areas. All flights are considered "foreign" for agricultural inspection purposes. During FY 2008-2009, flights into the international airport averaged 1,610/month (approximately 400/week) (Guam Airport 2009).

All aircraft pathways are considered high-risk due to their ability to transport Brown Treesnakes (BTS) and other IAS in stores, baggage, or cargo.

For military aircraft, risks were higher for conveyances departing on urgent missions, which are not delayed for BTS (or other terrestrial vertebrate) inspections.

Other factors mitigate the risk of introductions through the air transportation pathway. Most of the military personnel relocating to Guam probably will move from the United States including Hawai'i, origins with greater enforcement resources for intercepting potentially invasive species in transport. Much of Micronesia appears to be free from many high-consequence animal pathogens that affect other regions of the world (APHIS Terrestrial Risk Assessment, Appendix A), although it is difficult to substantiate this appearance without sufficient veterinary infrastructure and surveillance.

Risks from livestock are mitigated by a lack of exposure to suitable agricultural hosts. For example, mosquitoes carrying agricultural disease agents are commonly transported in conveyances, but inspection procedures and lack of susceptible hosts near ports make release of the vectors less likely. Air cargo inspection at the airline facility at the airport allows for better inspection conditions. Ticks often found in luggage or carried by humans are from countries of origin not of high risk for tick-borne exotic livestock disease to Guam.

2.2.1.1 ***Impact of the Military Relocation:*** it should be noted that the estimates expressed in this section are basic on 2010 planning projects which are no longer current.

The military relocation will cause a substantial increase in conveyance and passenger traffic to Hawai'i and the Micronesia Region. Passengers will be military personnel, temporary contract workers from foreign ports in the Philippines and China, and military and construction worker families. An estimated 9,000 permanent military personnel with 10,000 dependents will be transported to Guam by 2014 (U.S. Navy 2010a).² Approximately 20,000 construction workers will arrive in Guam, resulting in about 17,000 direct or induced jobs for needed services. Approximately 20,000 dependents will relocate to Guam, at least temporarily. Military families will transport baggage, household items, vehicles, and outdoor equipment. Each family is permitted up to 8,164 kg (18,000) pounds of household goods depending on rank (U.S. Navy 2010a).

The influx of the 59,000 workers and their families is likely to increase the demand for specialty ethnic items and impact the amount of plants and plant pests smuggled into the Micronesia Region.

Airport phytosanitary and general sanitary mitigation measures include inspection, permit review, control, quarantine, treatment, disinfection, and personnel training. According to military estimates, demand for airport services may increase as much as 51% during the peak of the military relocation (U.S. Navy 2010a). Therefore, these mitigation capacities may need to be evaluated to determine whether they can meet the increased demand or will require appropriate enhancements in resources and funding.

Current mitigation measures are not sufficient to protect Guam from invasive species introduction, and therefore also do not protect the rest of Micronesia nor the state of Hawai'i adequately. Recommendations that follow for improving mitigation practices should provide a suitable baseline of protection. The increased air traffic will stress the already strained inspection process on Guam. Additional resources and infrastructure improvements should be made to permit inspectors to protect

² Ibid, p. 2-1.

ports adequately from species introduction. Infrastructure and resources for inspection of arriving and departing aircraft should be increased to meet the expected increase in conveyance traffic to manage the influx.

2.2.2 Maritime Vessels

2.2.2.1 Pathways and Risk Species

Historically both commercial and military vessels have transported invasive species to new locations. Invasive species can be found in vessel passenger and crew cabins, food and garbage storage areas, and cargo holds. Cruise ships and smaller vessels like fishing and recreational craft are also potential pathways.

2.2.2.1.1 Hitchhikers

Maritime vessels often transport invasive species in ship interior cabins, food and garbage storage areas, and cargo holds. Passengers and crew can carry invasive species on their clothing and in baggage. High-risk species transported as hitchhikers include live plants and propagative materials, arthropods (ants, mosquitoes, ticks, bees, Khapra beetles), plant pests and diseases, small mammals (rodents and bats), reptiles (snakes), and amphibians. Historically rodents have presented substantial risks in their high populations in port cities, access to ships through mooring lines and cargo, and viability during long transports (WSTV PRA 2010).

2.2.2.2 Garbage

Disease-causing vectors for plants and animals could be transported in garbage stores aboard ships. Large stores of garbage also attract invasive wildlife and birds (MARPOL 2006). Vessels need to have SOPs for safe keeping of garbage and vessels when calling to port need to be inspected by biosecurity officers to make sure garbage is in an enclosed bin and secured. How garbage is handled when removed from vessels also needs to be described in SOPs to insure that disposal methods are adequate to prevent introductions.

2.2.2.3 Current Mitigation Measures

Ships entering Guam waters are inspected at Guam ports; GCQA, and the GDOA Biosecurity Division and Division of Aquatic and Wildlife Resources seize products, hold animals in quarantine, and prevent illegal imports.

Vessels may need decontamination if a source of contamination or infection is found or suspected on board. Vessels may require disinfection if restricted items were not transported in leak-proof containers. Decontamination of ships may also include de-ratting under Centers for Disease Control and Prevention (CDC) regulations.

The Defense Transportation Regulation 4500.9-R, Part V (DTR 5) establishes requirements for agricultural cleaning and inspection for the military.

Current mitigation measures are not sufficient to protect Guam from invasive species. Likewise, the planning for upgrading Guam capabilities has not been adequate.

2.2.2.4 Risk Rationale

Contraband items, drugs, and weapons may be much higher inspection priorities for GCQA. Limited time and insufficient staffing levels prevent GCQA from inspecting all ships adequately. Most maritime cargo is allowed to proceed for inspection from the seaport to the importer's premises. This practice increases the risk of pest dissemination.

Ship rodent protections may not prevent rodent infestation adequately, and therefore ships may depart from a port with rodents aboard. Inspection for rodents and other pest species needs to be conducted for all ship arrivals.

2.2.3 Cargo

2.2.3.1 Pathway and Risk Species

Invasive plant propagules, seeds, plant pests, insects, amphibians, reptiles, and small mammals may be spread in cargo through inadvertent transport of contaminated or infested household items, handicrafts, or agricultural products. Other invasive species incursions occur at shipping staging and loading areas (Frank and McCoy 1995; Hawley et al. 2006; Norman and Strandberg 1997; Smith and Moore 2008; USDA-APHIS-PPQ 2010a; Whinam et al. 2005).

Invasive species can be moved in shipping containers which may be infested prior to or during loading. Movement of pest species within containers is probably less common than with break bulk items which are open to the environment throughout the loading and transportation process..

Deliberate or accidental release of imported caged birds exposes livestock and poultry to disease agent hazards and disseminates vector hazards for establishment in suitable habitats.

2.2.3.2 Steady State Mitigation Measures

GDAWR and the GDOA PPQ Division identify confiscated products, hold animals in quarantine, and prevent illegal imports. Any importer or exporter of wildlife must obtain a permit from the USFWS and in some instances a permit from USDA-APHIS.

Chapter 511 of the DTR 5 requires GCQA inspection of all military cargo entering Guam, regardless of origin (DTR 4500.9-R, Part V, Chapter 511). The APHIS-PPQ Manual for Agricultural Clearance (USDA-APHIS-PPQ 2013) instructs inspectors to inspect cargo of agricultural interest. Cargo inspections are conducted at designated ports unless otherwise authorized by the Director of GCQA; however, inadequate maritime port inspection facilities often cause cargo to be moved off port for inspection at the importer's premises.

GCQA requires that all DoD cargo be available for inspection upon entry to prevent the introduction of plant and animal pests or diseases. DTR 5 establishes requirements for agricultural cleaning and inspection for all military cargoes. The U.S. military is responsible for meeting all regulations for foreign

host nations. Micronesian sovereign governments can insist on military compliance with appropriate regulations.

2.2.3.3 Risk Rationale

Because of the volume of traffic, not all containers are selected for inspection. The limited military training in invasive species can be particularly consequential for the cargo pathway. Smuggling may also become a bigger issue as the population of the region grows.

2.2.3.4 Impact of the Military Relocation

The risks from the re-deployment of military personnel are mitigated by the fact that most military personnel relocating to Guam probably will move from the United States, including Hawai'i. However, a large number of personal shipments of household goods would be transported.

2.2.4 Wood Packing Material

2.2.4.1 Pathway and Risk Species

Wood packing material (WPM) has been implicated in significant plant pest introductions worldwide. Historical interceptions include 80 families of insects from seven different orders, seven families of mollusks, and seeds of 27 plant families. Particular risks may be the introductions of ants, terrestrial mollusks, wood-boring beetles, nematodes, and fungi. Wood may contain plant propagules, seeds, soil, or a range of hitchhiking organisms (USDA-APHIS-PPQ 2010a).

2.2.4.2 Current Mitigation Measures

U.S. regulations and International Standard of Phytosanitary Measures (ISPM) No. 15 require either fumigation with methyl bromide or heat treatment according to specific schedules for all WPM entering the United States. Treated WPM must display a specified ISPM No. 15 stamp in a visible location to facilitate compliance checks at ports of entry. These regulations apply to WPM imported from foreign origins into Guam, Hawai'i, and the CNMI (ISPM). Movement of WPM between these U.S. jurisdictions is domestic and thus not subject to these regulations (ISPM No. 15 2009).

The USDA-APHIS MAC (USDA-APHIS-PPQ 2013) directs inspectors to check whether regulated WPM is compliant. The APHIS Miscellaneous and Processed Products Manual instructs inspectors to look specifically for timber pests, other insects, and unspecified hitchhikers (USDA-APHIS-PPQ 2012). This guidance is used by U.S. territories but may also serve as standards for other countries in the Micronesia Region.

DoD stipulates that all new WPM under DoD contracts or acquired by DoD must meet ISPM No.15 requirements for shipments both inside and outside of the United States (DSCC 2008).

2.2.4.3 Risk Rationale

Many species associated with WPM, if introduced, could cause severe damage to Micronesian native flora and agricultural production.

There are many challenges to measuring the risk from WPM. The diverse range of species limits the ability to predict the species that may be found on WPM.

Pests may be present in the WPM because the prescribed treatments are not completely effective against all pests, especially plant pathogens, and because WPM may be re-infested after treatment (Haack 2006; Biosecurity Australia 2006). Treatments may be applied incorrectly, and the ISPM No. 15 seal may be administered fraudulently.

Very little information is available to estimate the amount of WPM moved in trade. The quantity of WPM entering Guam and the Micronesia Region or what quantity will enter during the military relocation cannot be determined. Estimates range between 50 to 75% of maritime cargo and up to 33% of air cargo (NZ MAF 2003; Meissner et al. 2009). No data are available on the average amount of WPM present per shipment because not all containers are inspected.

Because WPM is a circulating product and routinely re-imported, its origin is not always the same as the origin of the commodity with which it is moved. Palau and the RMI are not signatories of ISPM No. 15. A percentage of military and commercial shipments containing WPM will always bypass existing regulations and guidelines (random USDA inspections revealed that about 1% of maritime shipment WPM and about 5% of the air shipment WPM arrive without the required stamp).

2.2.4.4 *Impact of the Military Relocation*

The lack of adequate inspection is expected to worsen during the military relocation. Unavailable data on the volume of WPM in cargo shipments make estimates of the increase due to the military relocation guided only by the increased volume of cargo shipments.

2.2.5 Construction Equipment and Materials

2.2.5.1 *Pathway and Risk Species*

Construction materials presenting a common pathway for the introduction of invasive species could consist of trucks, tractors, cranes, earthmovers, forklifts, and barriers, as well as packaged items and loose timber, gravel, sand, and soil. Many of the risks and recommendations for construction equipment are described in Section 5.2.3, *Cargo*. Imported construction materials are likely to be shipped in containerized, break bulk, or bulk cargo.

The source for the majority of construction materials will be the U.S. mainland, although significant portions will originate in China and Japan (Berthoud, personal communication). Some materials will be imported from the Philippines and Indonesia (Jimenez et al. 2009). Palau has been a source for wood imports (GovGuam 1995), and blocks of cement and concrete have originated in FSM (Berthoud, personal communication).

Significant introductions of invasive species may have occurred through the import of construction material. Construction projects in Micronesian island nations have been implicated as pathways of introduction for invasive snails, plants, coconut rhinoceros beetles, cogon grass seeds, and highly invasive giant African snails (Hawley et al. 2006; USDA-APHIS-PPQ 2010a).

More than 130 different species were found at U.S. ports in 394 total interceptions on quarry products and steel shipments from Asia between 2003 and 2009 (USDA-APHIS-PPQ 2010a). More than 271 interceptions occurred on general equipment, machinery, and vehicles arriving at U.S. ports of entry from 2003 through 2009 from Asia. Many of these interceptions were reportable pests, including insects, mollusks, beetles, weeds, and grasses (USDA-APHIS-PPQ 2010a).

Some invasive species may colonize environments more easily when altered by construction activities (e.g., invasive plants giant foxtail [*Setaria faberi*], redroot pigweed [*Amaranthus retroflexus*], and the highly invasive Argentine ant [*Linepithema humile*]) (Mulugeta and Stoltenberg 1997; Kennedy 1998).

2.2.5.2 Current Mitigation Measures

Following inspection by the GDOA PPQ Division, imports of construction equipment to Guam found to be contaminated with soil must be washed in designated areas. Those contaminated with pests must be treated or re-exported.

Saw logs with bark are prohibited from entering Guam, and debarked saw logs and lumber must be determined through inspection to be free of termites and wood-boring insects. Foreign timber must have an import permit detailing required treatment. Other Guam regulations apply to all commodities, allowing the GDOA to quarantine, inspect, fumigate, disinfect, destroy, or exclude any commodities infested with pests (GARR Title 8, Food and Agriculture).

All regulations and requirements listed for cargo apply to the import of construction material.

2.2.5.3 Risk Rationale

Similar to WPM, it is difficult to quantify the risk of hitchhiker pests by construction pathway. Precise information on the types and amounts of construction material and equipment entering or expected to enter Guam in the future is not available. Construction at Andersen Air Force Base (AFB) alone is estimated to require more than 1,361 metric tons (3 million pounds) of steel (PB International 2008). Overall, it is clear that imports of construction material and equipment will increase significantly as a result of the relocation and then level off after construction is complete. At this time, there is no information on whether materials will be imported from additional countries during the relocation.

On Guam, it remains unclear how consistently mitigation measures for timber, sand, and gravel are applied and how efficaciously they prevent pest entry. There are no entry requirements for other construction materials. In general, Guam inspections for construction material cargo may be inconsistent, ineffective, or non-existent. Timber may be particularly problematic for invasive species. Detection of hidden insects inside large volumes of timber is difficult, and prescribed quarantine treatments are not completely effective against all pests. These challenges and the diversity of pests with timber cause a significant risk of pest introduction to Guam through this pathway.

Because construction materials may be imported from other nations, biosecurity in those origins is important. No processes are in place for educating off-island workers about biosecurity and the potential impacts of introducing plant pests.

Construction activities disturb environments, making them more susceptible to establishment of exotic pests. Some pests preferentially invade disturbed sites (Mulugeta and Stoltenberg 1997; Kennedy 1998).

2.2.5.4 *Impact of the Military Relocation*

New housing, new utilities, municipal buildings, and roads will be constructed on Guam, and port infrastructure will be enhanced.

2.2.6 Mail

2.2.6.1 *Pathway and Risk Species*

Invasive species have been transported in domestic and international mail. Historical interceptions of mail packages sent from the Micronesia Region to Hawai'i demonstrate the possibility that pests introduced into the Micronesia Region could make their way to Hawai'i via the mail pathway (USDA-APHIS-PPQ 2010a). APHIS-PPQ has reported interceptions of various plants, high risk animal products and by-products, insects, and other invertebrate species from mail at U.S. ports, including seeds, fresh fruits and vegetables, propagative plant parts, nuts, live insects, and soil. Specific pests include a wasp parasite, bee and bumblebee colonies, nonnative nematodes, mites, disease agents, parasites, larvae of the Mediterranean fruit fly, the melon fly, the Oriental fruit fly, and the Malaysian fruit fly. Seeds are the most common type of intercepted material, demonstrating the potential for invasive plant species to be mailed into the Micronesia Region from anywhere in the world. Mailed propagative material carries the risk of introducing Huanglongbing, a serious citrus disease that has not yet reached the Micronesia Region (Gottwald et al. 2007). The impact on subsistence farmers may be significant if Huanglongbing is introduced. Betel nut pests may be of special concern, as betel nuts are frequently sent by mail.

Huanglongbing (CGD) is not currently present on Guam, Saipan, Tinian or Rota although its vector, the Asian citrus psyllid has recently been collected from Guam, Saipan and Tinian. Rota appears to be psyllid free at the moment. Most citrus in the Mariana islands is grown in residential areas, with relatively little grown by farmers. The impact of CGD would be the destruction of myriad backyard citrus trees, and the gradual decline of the few citrus orchards there are and of course the increased threat to the rest of the region. Betel nut in the Marianas is currently beset by pathogens that restrict its transport, hence the booming betel nut trade from disease free areas such as Yap to the Mariana islands.

All mail originating in the United States and most international packages destined for the Micronesia Region are processed in Honolulu, Hawai'i. Guam's Main Post Office in Barrigada processes domestic and international mail for the Micronesia Region (Murphy 1983; Jimenez et al. 2009). CNMI, RMI, Palau, and FSM receive mail processed on Guam.

2.2.6.2 *Current Mitigation Measures*

All mail originating in the United States and most international packages destined for the Micronesia Region are processed in Honolulu, Hawai'i. These parcels enter Guam as parts of the U.S. domestic first-class mail system. First-class mail in Guam and CNMI cannot be delayed or opened without either a search warrant or permission from the addressee.

While GCQA has a designated x-ray inspection area inside the post office, it is not fully functional, and the local postmaster does not always grant GCQA officers permission to access this area. Foreign origin mail cannot be opened and inspected by GCQA unless the addressee is present.

The Guam Post Office displays educational posters describing prohibited mail items, and post office clerks ask customers whether outgoing packages contain perishable items. Arriving packages stamped "perishable" are inspected by GCQA officers and sent to the Guam Plant Inspection Station when additional information or diagnostic assistance is necessary.

Military mail is handled by the Military Postal Service Agency (MPSA), the single DoD point of contact with the U.S. Postal Service (USPS), and is required to adhere to USPS rules, federal laws, and various international laws and agreements for movement of military mail. The MPSA also instructs military personnel about items prohibited in mailed packages.

2.2.6.3 *Risk Rationale*

Using interception data and mail approach rates, it is estimated that 300 plant quarantine materials along with an unknown number of animal products and byproducts arrive on Guam each week through public mail. However, specific information about the significance of the mail pathway in Guam and the Micronesia Region is scarce.

The lack of information may be due partially to the protection of mail by the U.S. Constitution (Fourth Amendment), which makes it illegal to delay mail or open it without either a search warrant or permission from the addressee (DoD 2002; USPS 2007). These protections apply in Guam and the CNMI. GCQA officers open and inspect the mail, but the addressee must be present in the facility for the parcel to be opened and inspected. The postal facility is not permitted to slow down the flow of domestic mail (USPS regulation). This restriction limits the number of packages that can be inspected with the available workforce.

Detector dogs have proved successful in establishing probable cause to obtain a search warrant for inspecting domestic mail. The USPS allows GCQA to use detector dogs in the facility after official permission has been granted to enter the facilities with canines. The permission to enter the premises for inspections is not based on processing schedules, but is granted only on a case-by-case basis. Requests from GCQA must be submitted every time canine officers want to enter the postal facilities. Many times the requests are denied. The lack of cooperation between agencies inhibits canine use in the postal facility and is recognized as a weakness in the safeguarding structure.

The increase in mail order purchases over the last several decades increases the risk of introduction by mail. Consumers are generally not aware of this risk.

All domestic mail for Micronesia is received and processed first in Hawai'i, then again in Guam, so biosecurity at Hawai'i mail processing centers is important for Guam and the entire Micronesia Region, and biosecurity at Guam's mail processing facility is important for the rest of Micronesia. It is unclear to what degree domestic mail entering Hawai'i is inspected in Honolulu because the Hawai'i Department of Agriculture recently experienced a drastic decrease in agricultural inspectors due to budget cuts.

2.2.6.4 *Impact of the Military Relocation*

The pathway traffic volume in mail cargo is expected to increase as a result of the military relocation due to demands for consumer goods by a larger population.

After the military relocation, an additional 207 plant quarantine materials are estimated to arrive in Guam through public mail each week. This is in addition to the estimated 300 plant quarantine materials arriving on Guam each week through public mail.

2.2.7 Regulated Garbage

2.2.7.1 *Pathway and Risk Species*

Garbage of agricultural concern is waste material derived in whole or in part from fruits, vegetables, meats, or other plant or animal material. Any other refuse associated with such materials is also garbage. Garbage is regulated if it has been aboard a conveyance that has been outside the United States and Canada within the previous 2-year period or if the means of conveyance has traveled within the previous 1 year between the continental United States and a U.S. territory, U.S. possession, or Hawai'i, or either directly or indirectly, to any U.S. territory or U.S. possession from any other U.S. territory or U.S. possession or from Hawai'i, or to Hawai'i from any U.S. territory or U.S. possession. Non-regulated garbage comingled with regulated garbage is also regulated. Regulated garbage must be either destroyed by incineration to ash, ground, and discharged into an approved sewage system or sterilized (heated to an internal temperature of 212 degrees Fahrenheit [°F] for 30 minutes) (7 CFR § 330.440-330.403; 9 CFR § 94.5).

Garbage as a pathway can carry diverse populations of plants, animals, and insects and other invertebrate species. Military, commercial, fishing vessels, and cruise ships generate refuse. Rejected cargo and prohibited items removed from passenger baggage at commercial and military airports and maritime ports of entry are treated as regulated garbage. Cargo shipments of garbage are common throughout Micronesia, although the importation of garbage into Guam and the CNMI is prohibited (9 CFR § 95 and 7 CFR § 330.400-403).

A wide range of potentially invasive insects, reptiles, amphibians, plant materials for plant propagation, and human and animal pathogens can be transported in garbage. Agricultural disease agents African swine fever (ASF), classical swine fever (CSF), foot and mouth disease (FMD), and swine vesicular disease

(SVD) viruses spread to swine readily through ingestion of contaminated meat, typically through garbage feeding (VS PRA 2010).

The food source and shelter of garbage attract a variety of invasive species, particularly rats and mice that could carry human and animal diseases throughout the Micronesia Region. How long disease agents remain infectious varies by agent and environmental conditions but many remain viable for weeks to months under the right conditions (e.g., *Brucella abortus*, avian influenza viruses, *Echinococcus* virus, and Exotic Newcastle's Disease [END]) (VS PRA 2010). Mice and rats are also prey items for predators such as Brown Treesnakes and the presence of such prey items in and around garbage likely increases the potential for accidentally transportation of these predators.

2.2.7.2 Current Mitigation Measures

APHIS-PPQ and its cooperators have responsibility for monitoring regulated garbage handling at airports, caterers, cleaners, cruise ships, fixed-base operators, hauling/cartage firms, marinas, military facilities, storage facilities, and transfer stations. There are insufficient governmental resources to monitor regulated garbage activities on Guam and CNMI. Adequate on-island disposal methods for garbage, either regulated and non-regulated, do not currently exist on Tinian, the proposed site for increased military training.

The APHIS-PPQ MAC (USDA-APHIS-PPQ 2013) guides monitoring of the handling of foreign regulated garbage within U.S. territory. Entities that handle regulated garbage must be approved by USDA-APHIS and either have a compliance agreement with or be supervised directly by APHIS or APHIS cooperators. Regulated garbage must be moved by entities approved by USDA-APHIS to handle regulated garbage under the direction of an inspector to an approved garbage-handling facility. There are nine companies on Guam and Saipan authorized to handle regulated garbage under compliance agreements with USDA-APHIS. Regulated garbage is monitored to prevent the movement and dissemination of pests and plant and animal diseases. Tightly covered, leak-proof containers must be used to store regulated garbage while inside U.S. territory, which includes Guam and other locations in Micronesia. This territory extends 12 nm off the coast. Regulated garbage must be stored in the proper container to move it from a conveyance for disposal.

Regulated garbage from commercial and military aircraft must be unloaded at an airport or military base approved to handle regulated garbage. On Guam, NAVFAC Marianas at the Apra Harbor Naval Station and Pacific Environmental Resources Incorporated at Andersen AFB are approved to handle garbage. Private companies handle the off-loading of regulated garbage at A.B. Won Pat International Airport including rejected cargo from maritime vessels.

2.2.7.3 Risk Rationale

Non-compliant (non-containerized) regulated garbage makes this pathway prone to incursion by numerous invasive species. There is a risk of regulated garbage entering at the airport or seaport without transport to an approved processor. Private aircraft arriving at A.B. Won Pat International

Airport, military aircraft entering at Andersen AFB, and private/commercial vessels arriving at commercial seaports represent the greatest risks because of the lack of oversight.

2.2.7.4 Impact of the Military Relocation

The relocation is expected to bring additional people, aircraft, cargo, and commercial and military ships from foreign countries (U.S. Navy 2010a). Therefore, the military relocation is expected to increase volume of all imports proportional to the population increase, including rejected cargo and prohibited items seized from passenger baggage.

2.2.7.5 Additional Mitigation Measures Recommended for the Military Relocation

To mitigate the risk presented by regulated garbage, it must undergo one of three processes: 1) incineration, defined as reducing garbage to ash by burning (with policy exemptions for glass and metal); 2) sterilization, cooking at an internal temperature of 212°F for 30 minutes; or 3) grinding and discharge into an EPA- and APHIS-approved sewage system.

To handle the immediate increase in garbage generated and regulated garbage off-loaded in Guam, building a waste-to-energy processing facility to reduce the amount of debris transported to a landfill and to increase the electrical capacity of the island should be considered. Tinian government and the U.S. military should collaborate to ensure adequate facilities and resources are available to properly dispose of regulated, as well as non-regulated, garbage on-island prior to the commencement of military training. Refer to Section 6.3.10, *Garbage*, for additional information.

2.2.8 Plant Propagative Material

2.2.8.1 Pathway and Risk Species

Whole plants, buds, bulbs, tubers, seeds and other propagative parts present phytosanitary risks in the Micronesia Region either as pathways for the introduction of exotic plant pests or as invaders.

The movement of plant propagative material is a primary means by which plant pests and small animals invade new areas. Plant propagative material can be transported in the baggage and cargo of planes and maritime vessels, in WPM and construction materials, in soil attached to military and construction equipment, and in garbage.

Plant material hitchhikers include insects, mollusks (snails, slugs), mites, and weeds; pathogens include viruses, fungi, bacteria, and nematodes. Potential hitchhikers include the Red palm mite, *Raoiella indica* (Acari: Tenuipalpidae). At U.S. ports of entry from March 2009 to March 2010, there were 5,600 interceptions of more than 16,000 pest specimens including insects (86 families), mollusks (16 families), mites (5 families), weeds (13 families) as well as viruses, fungi, bacteria, and nematodes (USDA-APHIS-PPQ 2010a). Potential plant pathogens include banana bunchy top virus, a disease of *Musa* (banana plants) for which there is no effective treatment (Thomas et al. 1994), and the bacterium *Candidatus Liberibacter*, which causes Huanglongbing in *Citrus* species (Wang 2009). It is worth noting that banana

bunchy top virus is already present in the region, specifically on Guam since at least the 1970s and was first detected in Hawai'i by University of Guam extension agent Frank Cruz.

The deliberate or accidental introduction of invasive plant propagative material may present phytosanitary risks in the Micronesia Region and Hawai'i. Examples are noxious weeds that pose ecological and economic threats, exhibit aggressive growth, and interfere with watershed functions. For example, *Miconia calvescens* (Melastomataceae), introduced to Hawai'i as an ornamental tree, is listed as a noxious weed (Loope 1997).

2.2.8.2 Current Mitigation Measures

For Guam the regulations for the import of foreign and domestic materials rest with APHIS and GDOA, respectively. All propagative plant materials imported into Guam, including trans-shipments to the CNMI, Palau, and FSM, are inspected at the GDOA Plant Inspection Station under agreement with USDA-APHIS-PPQ. Flowers and cut flowers are examined intensively for import violations. GDOA requires all plants entering Guam from Hawai'i to be treated with a hot water or citric acid solution drench prior to shipment and to be inspected for pests of concern to Guam.

Guam prohibits the entry of specific propagative plant materials from specified locations to prevent the introduction of pests of concern: citrus, coconut, banana, taro, and sweet potato planting materials are prohibited. Certain plants from areas infested with the European Corn Borer, *Ostrinia nubilalis* (Lepidoptera: Pyralidae) are restricted. However, the number of regulated pests is a small percentage of all pest organisms from propagative materials. Imports of plant material for landscaping on Guam are imported mainly from the United States, but other sources include Thailand, Taiwan, Philippines, Costa Rica, Ecuador, and Puerto Rico (McConnell 2010; Campbell personal communication).

2.2.8.3 Risk Rationale

Several factors influence risks from plant propagative materials as either hosts or carriers in Guam and the Micronesia Region. The DoD does not place restrictions on military personnel moving plants into Guam, increasing the risk of the unintentional introduction of invasive species. The current DoD landscape plan may facilitate the spread of potentially invasive plants; therefore, plants known to be invasive or to have a high invasive potential are common in Guam landscapes.

Some plant pests carried by plant propagative materials are unlikely to be detected by visual inspection because of their small size (e.g. mites). There is evidence that these pests often go undetected. Improper disposal of plants often increases the spread of plant pests from propagative materials.

There are no appropriate diagnostic tools for most plant disease pathogens feasible for plant quarantine purposes; thus, plant pathogens often are not detected unless the infected plant material expresses noticeable symptoms, often not the case. As an example, *Candidatus Liberibacter*, causative agent of Huanglongbing in *Citrus* species, can spread through infected propagative material without symptoms (Wang 2009).

No treatment requirements are in place for plants from the Caribbean and Florida, heightening the risk of introduction of plant pests from these locations.

The invasive potential of the propagative material itself is not considered in any regulation.

2.2.8.4 *Impact of the Military Relocation*

The military construction and the relocation of commerce will increase imports of plant propagative material, particularly landscape species, and may increase the risk of pests entering the Micronesia Region. These increases may well be in both volume and range of species imported.

Additionally, garden centers may increase their supply of ornamental plants to meet demands from a larger consumer base (homeowners, hotels, and commercial businesses). Garden centers may increase their supply of ornamentals, including plants that could become invasive.

Residents could demand imported home furnishings. Some plant propagative materials may also be intended as ethnic food products for foreign temporary workers on Guam.

2.2.9 Plant Products

2.2.9.1 *Pathway and Risk Species*

Plant products are commodities, foods, or other articles moved for trade or other purposes. Cut flowers and branches are fresh parts of plants intended for decorative use and not for planting. A variety of plant pests, plant disease vectors, and small exotic animals can be carried in plant products. Plant products can be transported by import in the baggage and cargo of planes and maritime vessels and through smuggling.

Christmas trees are of significant concern as potential vectors for non-native pests species. There are numerous records of non-native organisms hitchhiking to Guam and other ports as accidental passengers in Christmas tree shipments. Anticipated increases in U.S. mainland residence moving to the region will likely only increase the interest in shipping Christmas Trees and hence will also likely increase the potential for accident transport of pest species unless appropriate measures are installed throughout the region to address this pathway for invasive species.

Plant products can carry hitchhiking insects and mites and can be infected hosts for plant pathogens. Two potential plant pathogens include banana bunchy top virus, a nontreatable disease of *Musa*, and the bacterium *Candidatus Liberibacter*, which causes Huanglongbing in *Citrus* species (Thomas et al. 1994, Wang 2009).

2.2.9.2 *Current Mitigation Measures*

For Guam U.S. Federal regulations require an APHIS permit for the importation of fruits and vegetables. The APHIS-PPQ Fruits and Vegetables Import Manual guides PPQ and APHIS cooperators on fresh fruit and vegetable shipments (USDA-APHIS-PPQ 2010b). Chapter 5 of the APHIS-PPQ Treatment Manual

shows the treatment schedule for fruit, nuts, and vegetables (USDA-APHIS-PPQ Treatment Manual 2008).

Cargo manifests are reviewed to determine whether cargo contains fruits and vegetables of agricultural interest. Cargo of agricultural interest must be held until cleared by PPQ or its cooperators. Clearance of fruits and vegetables may be done by an inspection of the paperwork, an inspection of the commodities, or both. Inspections may be random, routine, or targeted. Guidance for inspections is from the APHIS–PPQ Fruits and Vegetables Import Manual (APHIS Manuals).

USDA-APHIS-PPQ regulations require phytosanitary certificates for the importation of plants and certain plant products from foreign sources. GDOA may require such certificates from other parts of the United States. Risk Rationale

Of particular concern are exotic plant products imported by temporary workers relocating from origins with plant pests and diseases not found on Guam. Often these products are marketed by roadside stands outside the realm of inspection and compliance.

2.2.9.3 *Impact of the Military Relocation*

The military construction and the relocation of commerce will increase imports for plant products.

2.2.10 Soil

Movement of soil, whether intentional or unintentional, is a well-known pathway for a wide variety of potentially dangerous organisms. Soil imported for landscaping and plant propagation can be moved unintentionally on construction equipment, military equipment, other construction materials, cargo, and shoe soles.

2.2.10.1 *Current Mitigation Measures*

For U.S. jurisdictions APHIS regulations (7 CFR § 318 State of Hawai'i and Territories, Quarantine Notice, Sub-Part-Sand, Soil, or Earth, with Plants from Territories and Districts; 7 CFR § 318.60 Notice of Quarantine) describe requirements for inspecting and, if necessary, treating imported soil (7 CFR § 318, 318.60).

Guam law prohibits importation of raw soil except in small quantities for research or testing at certified soil testing laboratories (Guam Administrative Rules and Regulations 1986, USDA-APHIS-PPQ Rules and Regulations). Guam's

hardware stores and plant nurseries import large quantities of packaged potting soil and soil amendments including compost, mulch, manure, peat, and sphagnum moss from the mainland U.S. These

imported packages are a potential pathway for invasive species entering Guam. Most imported potting soil and other processed soil amendments from the U.S. Mainland are currently not inspected on arrival in Guam.

2.2.10.2 Risk Rationale

Movement of soil (e.g. landscaping, plant propagation, construction, military equipment, construction materials, cargo, and shoe soles) is a common pathway for a wide variety of invasive organisms.

2.2.10.3 Impact of the Military Relocation

Military construction and increased commerce may increase the need for plant propagative materials, particularly of landscape species. Increased sales of commercial potting soil may introduce and facilitate the spread of pests on Guam (Berringer 2010). In general, each of these increases represents an increased risk from this pathway.

2.2.11 Livestock Imports

2.2.11.1 Pathway and Risk Species

The livestock pathway is determined by the risk assessment to be primarily legal import of domesticated equids (horses, mules, and asses). Domestic equids can be infected hosts, contaminated with disease agents, or serve as hosts to tick vectors of disease agents. Infected domesticated equids are primary sources for the etiologic agents of African horse sickness (AHS), contagious equine metritis (CEM), dourine, equine infectious anemia (EIA), equine piroplasmiasis (EP), and glanders. Through infection or as an infected host, fomite, or host to vectors, equids can transport nipah, rabies, VEE, Vesicular Stomatitis (VS) viruses, screwworms, *Echinococcus* spp., *Leishmania* spp. parasites, *M. bovis*, eastern equine encephalitis (EEE), Japanese encephalitis (JE), western equine encephalitis (WEE), West Nile viruses, ASF, CSF, and FMD viruses. Domesticated equids are hosts frequently for tick species as competent vectors for EP and less frequently for tick species as competent vectors for heartwater (VS PRA 2010; Estrada-Peña et al. 2004).

2.2.11.2 Current Mitigation Measures

Horses for import to Guam first must enter through ports in the continental United States for quarantine until negative results to specified tests, depending upon the country of origin, are obtained, and the horses are certified by the port veterinarian to be free from clinical evidence of disease.

Domesticated equids for import to the United States from regions affected by screwworm, CEM, and VEE are subject to inspection or treatment. Imported domesticated equids, with limited exceptions for those originating in certain countries, cannot enter the United States until they have been tested for EIA, EP, dourine, and glanders by an official test with negative results. Before a horse imported from any part of the world is released from the U.S. port of entry an inspector may require the horse and its equipment to be disinfected as a precautionary measure against the introduction of FMD or any other disease dangerous to livestock (9 CFR § 93.314).

According to GARR Title 9, Division 1, Chapter 1, no animals affected with or exposed to an infectious, contagious, or communicable disease or ectoparasite or originating in an area under state or federal

quarantine shall be introduced into Guam. Horses are subject to specific mitigations to prevent the entry of EIA, EEE, WEE, and VEE viruses.

2.2.11.3 *Risk Rationale*

Risk to livestock as a result of the introduction of invasive species to Guam and the Micronesia Region is limited for several reasons. Guam has a relatively small livestock population with minimal movement of livestock on the island. No livestock have been imported in the last 5 years. This fact reduces the likelihood that any disease agent has come into contact with Guam livestock. Ticks may be carried on invasive mammals, but pre-importation and inspection procedures reduce the probability of vector release and exposure to livestock.

Imports of domesticated equids to Guam might increase as a result of the military relocation, but the steady-state import of livestock is very small. Any domesticated equids imported probably will originate in the U.S. mainland due to federal regulations on importation of livestock. The United States is free of AHS, African animal trypanosomiasis, dourine, FMD, glanders, heartwater, JE, nipah virus encephalitis, screwworm, surra, and VEE (U.S. Animal Health Report 2008). The greatest risks might be from CEM, EP, and VS due to recent outbreaks in the United States.

There has been no evidence of smuggling of livestock to Guam. Illegal transport of large agricultural animals is not feasible, and this infeasibility is not expected to change during the military relocation.

2.2.11.4 *Impact of the Military Relocation*

Traffic volume in domesticated equids to Guam might increase slightly as an indirect result of the military relocation (increased demand for recreational activities). Federal regulations governing the importation of livestock make domesticated equids for importation to Guam highly likely to originate in the continental United States, which is free of most of the hazards for which domesticated equids are primary sources. The risk of importation or interstate movement of hazards for which domesticated equids might play significant roles in transporting them to Guam is mitigated by APHIS and Guam territorial regulations.

2.2.12 Poultry Imports

2.2.12.1 *Pathway and Risk Species*

Poultry are chickens, doves, ducks, geese, grouse, guinea fowl, partridges, peafowl, pheasants, pigeons, quail, swans, and turkeys, including eggs for hatching. Poultry can transport hazards in three roles: 1) they can be infected hosts, 2) they can be contaminated with disease agents and serve as fomites, or 3) they can serve as hosts to tick vectors of disease agents.

Infected or contaminated poultry can facilitate the transmission of many etiologic agents, including avian metapneumovirus, duck virus hepatitis, fowl typhoid, pullorum, EEE, END, highly pathogenic avian influenza (HPAI), WEE, VEE, West Nile viruses, screwworms, ASF, CSF, and FMD viruses (VS PRA 2010). Game fowl, pet, and exhibition poultry may have encounters with disease-carrying ticks.

Infected bird feces and secretions spread primarily through direct contact. People, other animals, vehicles, and equipment can become contaminated with poultry feces or secretions and can carry disease agents from one location to another; END, for example, is transmitted readily on fomites.

END and HPAI are some of the most severe poultry diseases throughout the world. Animal health consequences are significant. For both diseases, morbidity and mortality rates may approach 100%, 90% in susceptible chickens (VS PRA 2010). Introduction of END, HPAI, or other high -mortality avian diseases could have a catastrophic effect, perhaps local extinction, on the very small populations of the Micronesia Region's endangered bird species.

The World Health Organization (WHO) has reported rare cases of H5N1 HPAI in humans in Asia, Africa, the Pacific, Europe, and the Near East. Indonesia and Vietnam have reported the highest number of human H5N1 cases with mortalities of up to 60%, especially in cases hospitalized late in the course of the illness (WHO 2005).

2.2.12.2 *Current Mitigation Measures*

Importation of live poultry, poultry products, and hatching eggs is restricted from regions affected by END or HPAI; several of these regions are Asia-Pacific countries. Live poultry permitted to enter the United States (except those from Canada) must be inspected, quarantined for 30 days, and tested at a quarantine facility on the U.S. mainland (9 CFR §§ 93.201, 209, and 94.6).

Birds not of U.S. origin must be accompanied by an import permit issued by APHIS. All imported hatching eggs from END-free regions must be accompanied by a veterinary health certificate as well as a USDA import permit.

Interstate commerce of a bird for the purpose of participation in a fighting venture is illegal regardless of the law in the destination state, including Guam.

Guam territorial regulations require all imported birds and hatching eggs to be accompanied by an entry permit and a health certificate approved by the chief livestock sanitation officer or a state or federal veterinarian (9 GARR 1 §1110). The health certificate must be issued within 10 days prior to shipment attesting that the bird has been found free of ectoparasites and symptoms of transmissible disease. Any animal found to be clinically affected or recently exposed to any infectious, contagious, or communicable disease or infested with ectoparasites is returned to the point of origin or destroyed.

Guam import requirements for poultry include: 1) origin from flocks and hatcheries free from pullorum disease or with a pullorum-controlled status; in the latter case birds must test to be serologically negative for pullorum disease within 30 days of entry; 2) vaccination for Newcastle disease virus (NDV) between 30 to 60 days prior to shipment; 3) no symptoms of NDV or other communicable diseases at the time of shipment; and 4) a health certificate issued by an accredited veterinarian (9 GARR 1 §1110). Requirements 2, 3, and 4 do not apply to hatching eggs and day-old poultry with an affidavit from the shipper stating that the flock of origin has not been exposed to and has been free of NDV for 60 days

prior to shipment. All poultry and hatching eggs must be shipped in new (unused) containers and inspected by the territorial veterinarian or deputy prior to entry.

The USPS allows adult and hatchling poultry to be mailed with restrictions. Postal regulations prohibit mailing of hatchling (day-old) poultry vaccinated for NDV. Day-old chickens, ducks, emus, geese, guinea fowl, partridges, quail, and turkeys must be delivered to the addressee within 72 hours after hatching.

2.2.12.3 Risk Rationale

Illegal imports of poultry could increase temporarily as a result of the military relocation due to the popularity of cockfighting among foreign temporary workers from the Philippines. Historically, temporary construction immigration from the Philippines has increased fight attendance.

Similar to other islands in the Micronesia Region, a sizeable population of feral chickens roams freely on Guam. This feral population could facilitate the spread of poultry disease among domestic flocks.

Due to import regulations, most poultry breeding stock probably will continue to be imported from the continental United States and Hawai'i. The United States is free of ASF, CSF, END, FMD, HPAI, screwworms, and VEE; therefore, imported live poultry are unlikely to have contact with these agents and to serve as fomites for exposure of livestock to them (USDA-APHIS 2009a). Illegal traffic in live poultry, including hatching eggs, is known to occur.

The increased traffic volume that might be an indirect result of the military relocation cannot be quantified. Any significant influence on the number of imported poultry would be related most likely to the influx of foreign temporary workers.

2.2.12.4 Impact of the Military Relocation

The illegal import of poultry may increase temporarily from the influx of temporary workers from the Philippines. The number of live poultry legally imported to Guam or the rest of the Micronesia Region is unlikely to change as a result of the military relocation. The risk of hazard release through legal entry of live poultry to Guam is reduced by inspection and quarantine measures required by federal and territorial regulations.

2.2.13 Pet Bird Imports

2.2.13.1 Pathway and Risk Species

Import of pet birds for pets or for commercial trade is a common practice. Smuggling of pet birds is also common. Pet birds can be invasive species or transmit infectious diseases directly or through infected vectors. Infected bird feces or secretions spread primarily through direct contact. People, other animals, vehicles, and equipment can become contaminated with bird feces or secretions and can carry disease agents from one location to another (VS PRA 2010).

Like poultry, other birds can be infected by and serve as reservoirs for equine encephalomyelitis, END, HPAI, and West Nile viruses. Infected birds can be sources for etiologic agents of fowl typhoid and

pullorum. Reports of infestation of birds with screwworms are rare. Birds that have been in contact with affected premises can spread ASF, CSF, and FMD viruses mechanically (VS PRA 2010).

Psittacines (parrots, cockatiels, parakeets, budgerigars, and other parrot-like pet birds), the most popular pet birds in the United States, are uncommon hosts for vector hazards. A variety of buntings, sparrows, finches, and weavers (families Emberizidae, Passeridae, and Ploceidae), songbirds transported in the caged bird trade, are frequent hosts for European, Asian, or African ticks (VS PRA 2010).

2.2.13.2 Current Mitigation Measures

For Guam birds not of U.S. origin must be accompanied by an import permit and be received and inspected by USDA personnel at an approved port of entry with quarantine facilities. Approved bird quarantine facilities are located in New York, Miami, and Los Angeles. Birds are quarantined for 30 days, during which they are tested for certain communicable diseases. USDA maintains trade restrictions on the importation of live birds from certain countries in Africa, Europe, and Asia affected by HPAI (USDA-APHIS 2009a).

Importation of exotic birds into the United States must comply with APHIS and USFWS requirements. Certain exotic birds are protected by the Convention on International Trade in Endangered Species (CITES) (www.cites.org) and the WBCA (<http://www.fws.gov/international/laws-treaties-agreements/us-conservation-laws/wild-bird-conservation-act.html>). U.S. Customs and USFWS enforce the international trade regulations for exotic birds. USFWS requires an importation permit, and the WBCA has set a limit of two birds per year per person, who must have resided continuously outside the continental United States for at least 1 year.

All birds entering the territory of Guam must be accompanied by an import permit and an official health certificate approved by the chief livestock sanitation officer or a state or federal veterinarian issued within 10 days prior to shipment attesting that each bird has been found free of ectoparasites and symptoms of transmissible diseases. A leg band number should identify the scientific name of the animal. Any animal found clinically affected or recently exposed to any infectious, contagious, or communicable disease or infested with ectoparasites must be returned to the point of origin or destroyed (GARR Title 9, Division 1, Chapter 1).

Under 9 GARR §§ 2101-2102 pet shops and importers are required to keep a record of each sale for at least 90 days and to make the record available to the GDOA if a quarantine is placed on the premises by the territorial veterinarian (GARR Title 9, Division 1, Chapter 1).

Guam has introduced additional quarantine requirements for the importation of all birds (poultry and non-poultry) from the continental United States to prevent the introduction of West Nile Virus. All birds must be quarantined a minimum of 7 days in an approved quarantine facility or veterinary clinic followed by 30 days of isolation in a mosquito-proof cage (Poole 2009).

Under USPS regulations, non-poultry birds cannot be mailed (USPS 2009).

2.2.13.3 Risk Rationale

The small number of live non-poultry birds imported to Guam may increase as a result of the military relocation due to demand in the pet trade. At least 7% of military families reported keeping a pet bird (Anderson 1985). Residents of military base housing are not prohibited from keeping non-poultry pet birds.

Most live birds moved legally to Guam during the military relocation are likely to originate from the U.S. mainland due to federal regulations on importation of live birds addressed under mitigations. The United States is free of ASF, CSF, END, FMD, heartwater, HPAI, JE, screwworms, and VEE (U.S. Animal Health Report 2008).

The risk of hazardous release through legal entry of live non-poultry birds to Guam is reduced by inspection and quarantine measures required by federal and territorial regulations. Quarantine takes place off-island as there are no APHIS-certified quarantine facilities on Guam, and import regulations are strict.

Smuggling of pet birds may increase to meet a potentially higher demand from the increased population caused by the military relocation. An increase may also occur as a result of Guam becoming a more achievable pathway to other U.S. states and territories as a result of greater flight availability into Guam from Asia. The increase is not likely to be significant due to existing regulations, but enforcement can be difficult. Most smuggled live birds seized by U.S. officials between 2004 and 2008 originated from Mexico, Central America, and South America, but smuggled birds also come from Japan, Hong Kong, and Indonesia (USDA-APHIS 2006; USDA-APHIS-PPQ 2010a). The United States is one of the largest markets for the illicit global commerce in wildlife with wild birds as major commodities, mostly for exotic pets or tourist souvenirs.

2.2.13.4 Impact of the Military Relocation

The small number of live non-poultry birds imported to Guam may increase along with the anticipated human population increase on Guam as a result of the military relocation. The number of birds brought to Guam through legal means should remain relatively small compared to some U.S. mainland areas but increase more than proportionally if the 7% estimate is achieved (in recent years, fewer than 12 birds annually) (VS PRA 2010).

While no reliable estimates of illegal traffic volume of live birds for the pet trade are publicly available, the demand for illegal wildlife in the United States is likely to parallel U.S. demand for legal wildlife. Illegally imported live non-poultry birds bypass mitigations intended to reduce the likelihood of release of hazards.

2.2.14 Importation of Dogs and Cats

2.2.14.1 Pathway and Risk Species

Domesticated dogs and cats can be infected by and serve as reservoirs for rabies and can harbor screwworms, *Echinococcus* spp., and *Leishmania* spp., and *Trypanosoma* spp. parasites. Cats and dogs

are susceptible to HPAI virus and Salmonella pullorum infections. Dogs can be infected by AHS and VEE viruses, ASF, classical swine fever, or FMD. Viruses can spread mechanically by domestic dogs and cats in contact with affected premises (VS PRA 2010).

Dogs are common hosts for several tick species as competent vectors of EP and heartwater. In a few instances, hazardous ticks, specifically *Amblyomma* spp., have been found on dogs imported to the United States (VS PRA 2010).

2.2.14.2 Current Mitigation Measures

All pet dogs and cats arriving in Guam are subject to local quarantine requirements. The quarantine period is 120 days post-arrival for domestic dogs and cats (reduced to 30 days or less than 5 days for certain provisions made for dogs, cats, and other carnivores).

Cats and dogs imported to the United States are subject to inspection at ports of entry and may be denied entry for evidence of an infectious disease that can be transmitted to humans. Dogs imported to the United States, with limited exceptions, must be accompanied by a certificate for rabies vaccination; imported cats are not required to be vaccinated for rabies. The entry of pets from areas affected by screwworms is subject to APHIS regulations (9 CFR § 93), which require a health certificate stating that the pet was found to be free of screwworm infestation within 5 days of export (USDA 2000; USDA-APHIS 2009b).

Guam restrictions and prohibitions for the importation of cats and dogs are stricter than federal requirements, including quarantines. Cats and dogs must enter Guam through the A.B. Won Pat International Airport or the Apra Harbor maritime port. Every cat and dog must be accompanied by an entry permit, a health certificate signed by a veterinarian no more than 14 days prior to shipment, and a confirmed quarantine kennel reservation. Dogs must have a rabies vaccination certificate dated between 30 days and 1 year prior to shipment and a certificate of immunization against distemper, hepatitis, leptospirosis, parainfluenza, parvovirus, coronavirus, and bordetella. Cats must have a certificate of immunization for feline distemper, feline viral rhinotracheitis, calicivirus, panleukopenia and chlamydia (GARR Title 9, Division 1, Chapter 1). Regulations for the importation of cats and dogs into Guam require animal identification, quarantine procedures, and rabies vaccination and testing prior to arrival (GARR Title 9, Division 1, Chapter 1).

GDOA (5 GCA § 60108) regulates dog and cat imports. Title 10 Guam Code Annotated Chapter 34 Article 3 states that animals imported must complete a maximum 120 days of confinement in a commercial quarantine facility, 30 days of quarantine if they meet pre- and post-arrival requirements: administration of two doses of rabies vaccine, presence of adequate protective antibody titer, and a properly implanted identification microchip. A 5-day quarantine program is available for pets with a Fluorescent Antibody-Virus Neutralization test conducted by an eligible laboratory between 120 days and 12 months prior to entry (Guam Public 29-112). Some pets may qualify for the home quarantine option.

Animals originating from Japan, Hong Kong, Oceania, and the continental United States (except for counties on the Mexican border) can be quarantined on Guam. Animals originating from elsewhere must be quarantined in Hawai'i prior to entry. Cats and dogs originating from rabies-free areas, Hawai'i, New Zealand, Australia, and the United Kingdom, are exempted from quarantine if they comply with all other requirements.

All cats and dogs originating from Africa, Asia, or islands of the Pacific Ocean (except Australia, Hawai'i, and New Zealand) must have a certificate from the national chief livestock sanitation officer stating that the animals originated in a state, country, or political subdivision officially declared free of surra, animal African trypanosomiasis, and leishmaniasis.

Cats and dogs that do not comply with regulations may be declared ineligible to enter and remain in the custody of the carriers at a designated inspection area at the port of entry until sent back.

2.2.14.3 *Risk Rationale*

Most pet dogs and cats will be imported through legal channels. Total imports of dogs and cats may be limited due to import restrictions and costs. Most imported pets will come from the United States and Hawai'i with a few animals imported from Japan and the CNMI (VS PRA 2010). Temporary workers and tourists are unlikely to bring pets due to their nonpermanent status on Guam and the regulatory requirements of import.

Because Chagas disease is endemic in parts of the continental United States and the majority of pet dogs and cats will come from the United States, this disease agent must be considered a risk. Leishmania presents a similar concern.

2.2.14.4 *Impact of the Military Relocation*

Traffic volume (10 to 100 annually in domestic cats and dogs to Guam is likely to increase as result of the military relocation). Most domesticated cats and dogs intended for importation to Guam are likely to originate in the continental United States, which is free of most of the hazards for which domesticated cats and dogs are epidemiologically significant sources.

The risk of importation or interstate movement of hazards for which domesticated cats and dogs might play significant roles in transporting them to Guam is mitigated by U.S. military and Guam territorial regulations.

2.2.15 Importation of Exotic Animals

2.2.15.1 *Pathway and Risk Species*

Exotic species of animals are often imported for pets, cultural or scientific purposes, or zoological exhibition. These animals can be invasive species and can transport disease agents or vectors for native species. Worldwide, illegal trade in these animals is substantial and profitable, and the U.S. is the leading import market. There may be an increase in breeding of socially popular species which could have impact on Guam's environment.

Members of the genera *Amblyomma*, *Dermacentor*, *Haemaphysalis*, *Hyalomma*, and *Ornithodoros* frequently parasitize reptiles, particularly terrestrial chelonians, snakes, and lizards, in tropical regions (VS PRA 2010). Numerous ticks, primarily exotic species of *Amblyomma* and *Hyalomma*, have been found on reptiles imported to the United States. Exotic ticks introduced with imported reptiles could be infected with organisms pathogenic to domestic livestock populations; *E. ruminantium*, the causative agent of heartwater, was detected in *Amblyomma sparsum* ticks collected from imported tortoises (Burridge et al. 2002).

2.2.15.2 *Current Mitigation Measures*

Importation of zoo, fur-bearing, and other wild animals to Guam requires a permit in advance from the Director of Agriculture of Guam. USFWS designates Agana, Guam, as a special port for importing certain kinds of wildlife (including animal parts and products with a final destination of Guam). The GDAWR and the GDOA PPQ Division identify and hold animals in quarantine. Any importers or exporters of wildlife must obtain a license from USFWS.

2.2.15.3 *Risk Rationale*

The U.S. live animal trade in small mammals, reptiles, and amphibians has grown significantly since the 1990s, driven in part by the increasing popularity of exotic pets and demand for traditional foods and medicines. Worldwide, illegal trade in these animals is substantial and profitable, and the United States is the leading import market.

2.2.15.4 *Impact of the Military Relocation*

The larger human population resulting from the military relocation will increase demand for exotic pets and for traditional foods and medicines, and therefore, increase pathway traffic volume in small mammal, reptile, and amphibian species.

2.2.16 Animal Product Importation

2.2.16.1 *Pathway and Risk Species*

Animal products are defined as of animal origin, including meat, milk, blood and their products, skins, feathers, wool, hair, and animal feed containing products of animal origin.

Milk, eggs, meat, blood, and other tissues can serve as disease agent sources. While the probability of transmission through animal products is low, several high-risk disease agents may be transmitted, including FMD, bovine spongiform encephalopathy, END, classical swine fever, ASF, HPAI, and swine vesicular disease.

2.2.16.2 *Current Mitigation Measures*

GCQA is responsible for the inspection, of the import of animal products and by-products. GDOA monitors animal products found on wholesale and retail shelves.

2.2.16.3 Risk Rationale

Although many disease agents have demonstrated the capability to survive in animal products for months to years and under a variety of environmental conditions (e.g., ASF, CSF, FMD, SVD, and Bacillus anthracis spores) (WS Diseases PRA 2010), there is a low probability of transport of disease agents to the Micronesia Region through this pathway, i.e., the legal importation (many of the potential disease agents are spread primarily through routes other than direct exposure to contaminated animal products).

Most animal product imports originate in the continental United States (75 to 98%), a low-risk area for diseases of concern, and there are strict regulations for the importation of animal products and by-products (VS PRA 2010). Other foreign imports originate from New Zealand and Australia. Limited veterinary services and lack of slaughter facilities throughout Micronesia limit commercial trade in locally produced meat, eggs, and milk.

The increase in foreign temporary workers may result in smuggling of animal products from their home countries, or Guam retailers may carry products to meet the demand. Preventive regulations are in place, but enforcement can be difficult.

2.2.16.4 Impact of the Military Relocation

Pathway traffic volume in animal products will increase as a result of the military relocation due to demands for animal products by a larger population.

2.2.17 Other Activities on Guam

2.2.17.1 Pathway and Risk Species

Imported or smuggled materials for animal fighting, game hunting, religious ceremonies, research, or aesthetic pursuits may increase proportionally according to the population increase, especially for cultural preferences of temporary foreign workers.

Species can include the full range of biological commodities and exotic animals. High-probability items are poultry (animal fighting); amphibians, reptiles, birds and insects (pets, religious ceremonies); animal and plant products (foods, furnishings); and feral animals (game). Various animals could be for biocontrols and scientific research.

2.2.17.2 Current Mitigation Measures

Legal imports to Guam must follow all APHIS and Guam regulations for permits, inspections, quarantine, etc. for each plant and animal type (see above pathways or Chapter 6, *Existing Mitigations*).

2.2.17.3 Impact of the Military Relocation

Imports of plants and animals and their products are likely to increase proportionally to the increase of population, particularly that of foreign temporary workers and their families.

2.3 APHIS RISK RATINGS

Tables 5-2 to 5-4 list qualitative risk ratings for the various potential pathways for introduction of invasive species to Hawai'i, Guam and other Micronesian Islands. Each risk rating is specific to an APHIS risk assessment team, and each team developed a risk rating methodology suited to the types of risks evaluated. Additional information on the rating methodology and risk ratings justification is in each APHIS Terrestrial Risk Assessment report (Appendix A).

Table 5-2: APHIS-VS Risk Ratings

Pathway	APHIS Risk Ratings				
	Release Assessment Legal	Release Assessment Illegal	Exposure Assessment	Consequence Assessment	Overall Risk
Conveyance–Aircraft	Very low	N/A	Medium	Guam and Micronesia: Very low United States: Very low	Very low
Conveyance–Maritime vessels	Very low	N/A	Medium	Guam and Micronesia: Very low United States: Very low	Very low
People	Negligible	Negligible	N/A	N/A	Negligible
Livestock	Negligible	Negligible	N/A	Guam and Micronesia: N/A United States: N/A	Negligible
Poultry	Negligible	Very low	Medium	Guam and Micronesia: Low United States: Medium	Low
Non-poultry birds	Negligible	Very low	Medium	Guam and Micronesia: Very low United States: Very low	Very low
Cats and dogs	Negligible	Negligible	N/A	Guam and Micronesia: N/A United States N/A	Negligible
Animal products	Negligible	Low	Medium	Guam and Micronesia: Low United States: Medium	Low

Pathway	APHIS Risk Ratings				
	Release Assessment Legal	Release Assessment Illegal	Exposure Assessment	Consequence Assessment	Overall Risk
Garbage	Negligible	Very low	Medium	Guam and Micronesia: Low United States: Medium	Low
Other cargo	Very low	N/A	Medium	Guam and Micronesia: Very low United States: Very low	Very low

Table 5-3: USDA-APHIS-WS Terrestrial Vertebrates Risk Ratings

Pathway	APHIS Risk Ratings			
Conveyance–Aircraft	HIGH RISK			
Conveyance–Maritime vessels	HIGH RISK			
Cargo	HIGH RISK			
Construction	HIGH RISK			
Plant products	HIGH RISK			
WPM	HIGH RISK			
Garbage	HIGH RISK			
INTENTIONAL	Importation	Establishment	Hazard	Total Risk
Pet trade	3	3	3	9 HIGH
Aesthetic releases	3	2	3	8 HIGH
Food use	3	3	3	9 HIGH
Animals for entertainment	2	2	3	7 MODERATE
Game hunting	1	2	3	6 MODERATE
Biocontrol	1	3	2	6 MODERATE
Scientific research	1	3	3	7 MODERATE
Religious ceremonies	1	1	2	4 LOW
Bioterrorism	1	1	3	5 LOW

Pathway	APHIS Risk Ratings			
	Probability of Infection	Alternate Probability	Impact of Infection	Alternate Impact
Hantavirus	Moderate	-	Low	-
Rabies virus	Minimal	-	Low	-
West Nile Virus	Minimal	-	High	-
HPAI	High	-	Moderate	Moderate

Japanese Encephalitis Virus	High	-	Minimal	Low
Avian Malaria Parasites	High	Minimal	Moderate	Moderate
Henipaviruses	Minimal	High	Moderate	Moderate
NDV	Minimal	High	Moderate	Moderate
Yersinia pestis	Minimal	-	Low	-
Tick-Borne Encephalitis	High	-	Low	Moderate

2.4 HIGH-RISK SPECIES AND VULNERABLE MICRONESIAN LOCATIONS

Guam receives visitors and imports of commodities from multiple countries. Guam is also served by multiple shipping lanes; east/northeast waterways connect with Hawai'i, and the continental United States waterways running north and west connect to CNMI and Asian ports.

In 2002, Guam imported agricultural commodities primarily from Australia, Asia (China, Korea, Hong Kong, Japan, Malaysia, the Philippines, Singapore, Taiwan, and Thailand), the rest of Micronesia (Chuuk, CNMI, Palau, Pohnpei, and Yap), New Zealand, and the United States. Most visitors travel by air from Japan or Korea (WS Diseases PRA 2010). Most arrivals to CNMI in 2002 and Palau in 2007 demonstrated a similar trend. Most visitors to FSM arrived by air from the United States followed by Japan and Europe (WS Diseases PRA 2010). It should be noted that information from 2002 and perhaps from 2007 may well be outdated. More updated information should be considered.

Of particular concern is the introduction of invasive species from China, Korea, Hong Kong, Thailand, Malaysia, and the Philippines. The USDA-APHIS publication *Combined Animal and Plant Health Risk Ratings for Countries*, October 2010, lists each of these in the top 25 countries presenting the highest combined risk for animal and plant diseases and pests (USDA-APHIS-PPQ 2010c). China ranks as the highest risk country, and Thailand is third highest. Countries linked to Guam by trade include Japan (ranked 7th), Republic of South Korea (ranked 15th), and Indonesia (ranked 22nd). (See APHIS-Terrestrial Risk Assessments in Appendix A for more detail.)

International airports are located in the State of Hawai'i and the U.S. territory of Guam, the CNMI islands of Saipan (71% commuter, 18% commercial), Tinian (99% commuter, 1% commercial), and Rota (72% commuter, 27% commercial), the Republic of Palau, the FSM, and the RMI (CPA 2007a, b, c). Commercial air transportation traffic may increase among these islands, evidenced by the scope of improvements underway at airports on Saipan, Tinian, and Rota.

The complete list of invasive species presenting potential biosecurity threats to Hawai'i, Guam and other Micronesian Region islands is far too large for detailed descriptions in this plan. Greater detail on risk species is in the APHIS Terrestrial Risk Assessments (Appendix A). These species could produce significant impacts if introduced to Hawai'i, Guam and other Micronesian Region locations.

Chapter 7, *Recommendations*, recommends enhanced mitigations for Hawai'i, Guam and other Micronesian Region locations based upon risk assessments by PPQ-Center for Plant Health Science and Technology (plants, plant products, and plant pests), VS (livestock, poultry and pets), and WS (wildlife

diseases). Recommendations for Terrestrial Vertebrates are in Chapter 11, *Terrestrial Vertebrates Biosecurity Plan*.

3 EXISTING MITIGATION

3.1 INTRODUCTION TO MITIGATION AND PREVENTION STRATEGY

Biosecurity measures prevent and mitigate risks posed by invasive species and incorporate a wide range of preventive activities including public awareness, training, inspection, monitoring, detection, and eradication. Some of these measures may take place before conveyances arrive at the border. Determination of entry status, inspection, and treatment are usually conducted at the border. Post-border activities include control and eradication efforts for introduced species, public awareness programs, agreements with local businesses, and habitat improvement projects.

3.2 ORGANIZATIONS INVOLVED IN PHYTOSANITARY AND SANITARY PROTECTIONS FOR GUAM

Numerous organizations contribute to phytosanitary and general sanitary protections on Hawai'i, Guam and other Micronesia Region locations.

Each organization may have responsibility for a portion of the mitigation processes as described in Table 6-1. The following entities play significant roles in Guam mitigation activities:

Table 6-1: Biosecurity Organizations

Organization	Description
Aquatic Nuisance Species Task Force	The Aquatic Nuisance Species Task Force collaborates with the NISC Prevention Committee as the Pathways Work Team in support of the NISC Management Plan (NISC 2008).
CEQ	Coordinates federal environmental efforts with agencies and other White House offices in the development of environmental policies and initiatives (40 CFR §§ 1502.09 and 1502.20)
GCQA	GCQA clears aircraft, passengers, baggage, and cargo at airport and maritime ports, both civilian and military. Responsible for border inspections and monitoring regulated garbage handling at the ports of entry.
GDOA	<p>A Biosecurity Task Force has been approved legislatively to unify GCQA and GDOA activities conducted under the direction of USDA-APHIS-PPQ and GCQA. Members will be available to respond to of invasive species reports.</p> <p>Foreign agricultural import inspections are overseen by USDA-APHIS-PPQ and GDOA. GDOA also permits the importation of certain animal products and live animals including zoo, fur-bearing, and other wild animals. GDOA works with the University of Guam, USDA-APHIS-WS, and USFWS to manage invasive species. GDOA and PPQ identify confiscated agricultural products, hold animals in quarantine, and prevent illegal imports.</p> <p>A Biosecurity Task Force has been approved legislatively to help coordinate GCQA and GDOA activities conducted in cooperation with USDA-APHIS-PPQ. Members will be available to respond to invasive species reports and incursions.</p> <p>Foreign agricultural import inspections are overseen by USDA-APHIS-PPQ while domestic imports are under the jurisdiction of GDOA's Biosecurity Division. GDOA also permits the importation of</p>

Organization	Description
	certain animal products and live animals including zoo, fur-bearing, and other wild animals. GDOA works with the University of Guam, USDA-APHIS-WS, and USFWS to manage invasive species. GDOA and PPQ identify confiscated agricultural products, hold animals in quarantine, and prevent illegal imports.
GDAWR	A division of the GDOA, GDAWR identifies confiscated aquatic, marine, and wildlife products, holds animals in quarantine, and helps prevent illegal imports of such items.
Guam Invasive Species Council	Aligned with the Western Micronesia Regional Invasive Species Council, provides guidance when invasive species are detected, liaises to coordinate activities of Guam government agencies.
Guam Invasive Species Advisory Committee	Provides specialists to identify invasive species and determine distribution, identifies mitigation options, prepares cost/benefit analysis for mitigation options, and recommends emergency response actions to Guam Invasive Species Council.
JGPO	Serves as the NEPA proponent of proposed actions. The JGPO coordinates federal agencies having either jurisdiction over or technical expertise for certain components of proposed actions or a potentially affected resource.
NISC	The NISC Prevention Committee and Aquatic Nuisance Species Task Force collaborate as the Pathways Work Team in support of the NISC Management Plan (NISC 2008).
Quarantine Policy, Analysis and Support (QPAS)	An APHIS-PPQ program unit providing assistance on regulatory issues related to port inspection requirements and quarantine events. QPAS works closely with the PPQ Veterinary Regulatory Support (VRS) unit, which is dedicated to performing the same functions for animal products and by-products and regulated garbage.
University of Guam	The University of Guam conducts research and survey activities on invasive species, including plant disease and botanical identification in collaboration with GDOA and USDA-APHIS-PPQ.
USDA-APHIS-PPQ	PPQ oversees foreign agricultural import inspections as well as regulated garbage handling activities and handles invasive species events. PPQ Plant Inspection Station identifies plant products and plant pests seized in port inspections.
USDA-APHIS-WS	Conducts all BTS canine inspections, undertakes extensive BTS management efforts (trapping, fence line searches, and rapid response) and provides public outreach.
USFWS	Enforces international trade regulations on exotic birds and other wildlife. Any importers or exporters of wildlife must obtain a license from USFWS. USFWS designates the Agana, Guam port for importing certain kinds of wildlife (including animal parts and products with a Guam final destination).

Organization	Description
USGS BTS Rapid Response Team	USGS has a coordination office in the region which supports management agencies and NGOs involved in invasive species throughout all the jurisdictions covered by the MBP as well as the US Mainland. Support includes training courses for ED and RR, capacity building activities, community outreach, and coordinating ED and RR actions throughout the region. The RRT is manned by team members from all jurisdictions covered by the MBP as well as the US Mainland. Team members generally work for local, territorial, state, federal and private agencies and groups and in exchange for training are available to support field actions throughout Micronesia and Hawai'i as needed. The coordination office works with the governments throughout the region and supports their request for assistance. The USGS response coordination office also mans a 24/7 regional alien snake reporting hotline (671-777-HISS). The USGS response coordination office also supports other biosecurity and invasive species issues within the region when feasible, including servicing as a clearing house for information, facilitating linkages between locations, agencies, and experts and assist when possible with other taxa (other than snakes) response efforts.USGS has a BTS rapid response team capability on Guam. As of March 2013 the USGS coordination office has been vacant but capacity within the region for ED and RR still exists.
U.S. Marines	Relocation of force to Guam and training on Tinian.
U.S. Navy/NAVFAC PAC	Relocation of force to Guam.
U.S. Transportation Command	Oversees the movement of military personnel and equipment. The U.S. Air Force Air Mobility Command supports strategic and tactical military operations by airlifting personnel and cargo. Military cargo not consigned to commercial carriers would be transported by Air Mobility Command aircraft.
Veterinary Regulatory Support (VRS)	An APHIS-PPQ program unit providing assistance on regulatory issues related to port inspection requirements and quarantine events related to animal diseases. PPQ, Agricultural Quarantine Inspection (PPQ-VRS-AQI) provides regional support for animal product/by-product import inspections as well as regulated garbage handling activities
VS/National Center for Import and Export Technical Trade Services Staff	A program unit within APHIS-VS which is responsible for the import regulations and policy with respect to live animals and animal products. Provides import permits for imported and transiting commodities.

3.3 PROCEDURES

3.3.1 Safeguarding Standard Operating Procedures

Government agencies with safeguarding authority have developed SOPs for protecting pathways, ports, and mainland areas within the Micronesia Region and for mitigating the accidental or intentional introduction of infective or invasive species. SOPs for Guam and CMNI, developed in harmony with U.S. and international standards, are for monitoring, surveillance, and rapid response functions for plant pests. ERPs exist for all jurisdictions covered by the MBP (except Guam) for alien snake incursions.

These were created by each jurisdiction in coordination rapid response team coordination office (Stanford, personal communication). The FSM, RMI, and Palau all have ERPs for bird flu which SPC helped develop. Yap has an ERP for coconut rhinoceros beetles which was developed by RISC and their technical supporters. Other ERPs which generally include SOP language may also exist for other organisms and/or situations through the region and the state of Hawai'i. .

3.3.2 Port Infrastructure

Biosecurity planners evaluate the types of infrastructure required to monitor pathways so resources are available to detect and mitigate the introduction of plant and animal health risks on arrival. These facilities include having sufficient equipment and personnel at all ports and designated cargo handling stations during surge conditions as anticipated for the military relocation to Guam. While Guam has the best-equipped airport and maritime port locations in the Micronesia Region, certain deficiencies in the ports' infrastructure require the following improvements:

- Port staging areas
- X-ray equipment, detector dogs, and other inspection resources
- On-site decontamination/treatment areas
- On-site quarantine facilities
- Dedicated inspection facilities within the port environs
- Barriers to separate potentially invasive from native species
- Regulated garbage disposal equipment/facilities
- Information technology and necessary equipment

3.3.3 Port Operations (inspection, permit/certificate enforcement, and treatment)

Essential biosecurity components are capabilities for inspection, enforcement of regulatory requirements, and operable equipment and materials. In conjunction with their own policies and procedures, Guam and CNMI authorities utilize procedures from the APHIS MAC and individual animal product and plant port of entry manuals (USDA-APHIS-PPQ 2013). USDA-APHIS-WS is responsible for BTS inspections upon port departure (export) from Guam. It should be clearly understood that BTS inspections conducted by USDA on Guam for departing cargo and planes are not required by law but rather are conducted on a volunteer basis. Additionally, it should also be clear that these inspections are conducted only for BTS and are only conducted on Guam (no other jurisdiction has this type of program and the volunteer departure program on Guam is only for BTS detection, no other organisms are specifically searched for). Shipments from other areas of Micronesia are inspected upon arrival according to local regulations and policies. GDOA issues import permits for various commodities including eggs for consumption, live animals, and various plant materials.

3.3.4 Interdiction Procedures

3.3.4.1 *Guam*

GCQA clears aircraft, passengers, and cargo at the airport, seaport, and mail facility. There are approximately 120 GCQA inspectors stationed at these locations (based on 2009 figures). There are currently four trained agriculture detector dogs stationed on Guam primarily for air passenger clearance. The airport has three shifts for clearing international flights.

USDA-APHIS-PPQ and GDOA oversee propagative plant inspections at the Plant Inspection Station. The University of Guam (UOG), GDOA, USDA-APHIS-WS, and USFWS are tasked with handling invasive species issues.

A Biosecurity Task Force has been legislated, coordinating GCQA and GDOA activities in cooperation with USDA-APHIS-PPQ. Members would be available to respond to invasive species reports and incursions. Guam also has the Guam Invasive Species Council, which includes the Guam Invasive Species Advisory Committee to provide it with scientific recommendations. USDA-APHIS-WS has an active BTS trapping, hand capture, and dog detection program on Guam available at all times.

GDAWR and the GDOA Biosecurity Division identify confiscated products and pests, hold animals in quarantine, and prevent illegal imports. Any importer or exporter of wildlife must obtain a license from USFWS and in some instances a permit from USDA-APHIS.

All pet dogs and cats arriving at Guam are subject to local quarantine requirements. The quarantine period is 120 days post-arrival for domestic dogs and cats (reduced to 30 days or less than 5 days if certain provisions are made for dogs, cats, and other carnivores).

Importation of zoo, fur-bearing, and other wild animals requires a permit in advance from the Guam Director of Agriculture. USFWS has designated Agana, Guam, as a special port for importing certain wildlife (including animal parts and products with a Guam final destination).

BTS presents a unique biosecurity circumstance, especially to Guam and CNMI (Saipan, Tinian, Rota), due to the military impact on these islands. Accidental transport of BTS from Guam is also a significant concern to all of Guam's trade partners, which include the islands of the CNMI, the U.S. State of Hawai'i, the Republic of Palau, The Republic of the Marshall Islands, and the Federated States of Micronesia including the four states: Chuuk, Kosrae, Pohnpei, and Yap. Whereas most customs and quarantine inspections occur upon arrival and importation of goods, BTS inspections take place upon departure and export of goods, cargoes (e.g., vehicles, military field gear) and aircraft (i.e., military, commercial, private) as well as in staging areas. For most purposes, these pre-departure inspections are voluntary in nature.

3.3.4.2 *Commonwealth of the Northern Mariana Islands*

The CNMI is funded through the Office of Insular Affairs to conduct BTS interdiction work in Saipan, Rota, and Tinian. BTS interdiction efforts on Guam are conducted by USDA-WS. These inspections are a

critical step in preventing off-island dispersal of BTS. Work done at the receiving ports in the CNMI or elsewhere is typically a second-line of defense but is considered equally important and in fact at times primary inspections are only conducted at receiver ports for items which miss the voluntary inspections conducted on Guam by USDA-WS .

3.3.4.3 Saipan

Airport operations are 7 days a week and run from 0300 hours to 2200 hours. On October 1, 2011, austerity measures (32-hour work week) were implemented resulting in an inspection rate of 40%, which is well below the 90% measure of effectiveness. Also, overtime was not authorized. As of mid-April 2012, the BTS program has been given approval to work up to 40 hours and limited overtime on a weekly basis to provide the program with the flexibility to cover most arrivals (about 70%); however, most flights are done visually instead of with canines. A new canine handler is awaiting Airport Operations Area certification and can then start clearing arrivals at Saipan International Airport, which may further boost inspection percentages.

About 46 BTS traps are currently deployed at the airport with an additional 40 at the seaport. The CNMI has an on-going public relations campaign "28-SNAKE, Don't give snakes a break" to raise awareness of the BTS threat and includes a central reporting system for snake sightings. Saipan currently has five employees working on BTS intervention, including one canine trainer; three canine handlers (one undergoing training, with previous canine handling experience with USDA-WS in Guam); and one trapper with no canine experience. The intent is to have this person trained as a handler.

3.3.4.4 Rota

Inspections for BTS are currently conducted by a single individual who has been trained for visual inspections, trap lining, and early detection and rapid response capacities. This individual has a canine to assist with BTS inspection work. CNMI Quarantine officers also may assist at times with the clearance of arrivals from Guam for BTS, but it is not their priority.

3.3.4.5 Tinian

Inspections for BTS are currently conducted by a single individual who has been trained for visual inspections, trap lining, and early detection and rapid response capacities. This individual has a canine to assist with BTS inspection work. Tinian has a BTS quarantine area at the seaport where suspect cargo can be held until appropriately inspected. The BTS inspector is stationed at the seaport. Aircraft Inspection

GCQA officers collaborating with USDA-APHIS to enforce federal animal and plant health regulations have the authority to board all military aircraft and maritime vessels. USDA-APHIS provides guidance, information, and training to DoD for pre-clearance inspections. However, because GCQA has not authorized the DoD to conduct inspections on its behalf, pre-cleared DoD shipments are still subject to routine inspection upon arrival. The USDA-PPQ MAC contains information on the inspection of aircraft and maritime vessels for plant and animal health concerns by APHIS collaborators (USDA-APHIS-PPQ 2013). Military regulations (OPNAVINST 6210.2 06) designed to prevent the introduction and spread of

disease agents (human, animal, and plant), arthropod vectors, and pests of health or agricultural importance comply with regulations of the U.S. Departments of Health and Human Services, Agriculture, Treasury, DHS, Interior, and Commerce (OPNAVINST 6210.1; OPNAVINST 6210.2).

Current biosecurity inspections are the same for military and commercial aircraft upon arrival. Military aircraft are subject to agricultural quarantine inspections for animal and plant pests as well as invasive species, but are exempt from customs regulatory enforcement; however, passengers, cargo, and equipment are subject to both. Military aircraft departing Andersen AFB typically undergo canine inspection by APHIS-WS personnel for BTS to “the maximum extent possible,” with some exceptions for medical emergency missions (U.S. Navy 2005a; b). Since inspections of any aircraft departing Guam, commercial or military, are primarily to detect BTS (BTSCC 1996; U.S. Air Force 2007), other species not specifically targeted may be missed or overlooked. Arriving aircraft, military or commercial, are not usually inspected by APHIS-WS or GCQA for terrestrial vertebrates but are subject to inspections for other agricultural purposes.

APHIS-WS inspects the exteriors of planes that are not “quick turns” (on the ground for less than 3 hours) using both canine teams and visual inspections by personnel. Cargo contents are inspected generally within 2 hours of loading. Contents vary, and chartered planes not on regular commercial flight schedules require much more ongoing inspection coordination. APHIS-WS and GCQA very rarely inspects planes internally for BTS or for animal and plant health concerns. If a plane is down for extended service and its hatches, doors, or exterior compartments are open for extended periods, an internal inspection for BTS may be done. Military aircraft are exempt from inspection if the process could jeopardize national security.

3.3.5 Maritime Vessel Inspection

For maritime transportation, CFR Title 7 regulates articles from Hawai’i and the territories, Title 9 regulates movement of animals and animal parts, and Title 42 governs public health. Title 7 regulates plants and plant products (Subtitle B, Volume 5, Chapter 3, Parts 318.13-9 and 330.111) and requires notification to inspectors prior to ship departures or arrivals on Guam. Title 9 (Volume 1, Chapter 1, Subchapter D, Part 93) permits inspection of any ship from foreign locations without a warrant to determine whether it carries any animal or animal part subject to safeguard or disposal to prevent the spread of disease. Title 9 (Volume 1, Chapter 1, Subchapter D, Part 95) requires disinfection of ships transporting restricted items not in leak-proof containers.

Titles 7 and 9 permit the inspection of any ship for agricultural risk of animal diseases, plant pests or diseases, and animal or plant products, including ship infrastructure, stores, cabins, and equipment.

Information in the USDA-APHIS MAC on the inspection of ships details procedures for ship infrastructure, stores, and cargo (USDA-APHIS-PPQ 2013).

Agricultural clearance of commercial ships includes inspection of deck areas, ship stores, and crew quarters and may include cargo. Pets of crew members transported must be quarantined on board.

Hitchhiking pests or animals of agricultural risk must be removed or destroyed. If pests are found on fruits and vegetables in ship stores, the products are either sealed on board while in port or removed for destruction.

U.S. military ships are subject to inspection for agricultural concerns. In the United States, military personnel are trained to assist and expedite in completing ship inspection forms and spot-inspecting ship stores. GCQA and DoD are responsible for developing local policies to maintain these requirements for incoming vessels.

The Armed Forces Pest Management Board published Technical Guide Number 31 (AFPMB 2004) to describe cleaning and inspection procedures for retrograde washdowns.

NAVMED P-5010-8, *Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology*, covers the use of preventive measures and bait station anticoagulants for rodent control. NAVMED P-5052-26, *U.S. Navy Shipboard Pest Control Manual*, explains inspection and de-ratting procedures for ships. MIL-STD-904B guides detection and prevention of pest infestations (MIL-STD-904B).

3.3.6 Passengers and Baggage

Civilian and military passengers and their baggage arriving in Guam are subject to inspection by GCQA regardless of conveyance. Passengers are interviewed upon arrival to determine whether they have prohibited or restricted commodities. Limited time, inadequate inspection facilities, inoperable or absent x-ray equipment, and insufficient staffing levels prevent GCQA from inspecting all incoming passengers and their baggage. Four trained agriculture detector dogs are available, but current resources are far below what is needed to staff air arrivals fully. All arriving passengers are considered “foreign” and subject to the same agricultural restrictions regardless of their travel origins. For example, passengers arriving from Hawai’i undergo the same inspection procedures as those from Japan. Passengers transiting to other countries, including those in the Micronesia Region, are not inspected by GCQA.

3.3.7 Cargo

Container shippers are responsible for keeping containers and loading areas free of vectors, reservoirs of disease and contamination, and invasive pest species during the packing process. This type of shipping is a risk for the transport of insect pests and other wildlife as hitchhikers and in WPM for the cargo.

Air cargo shipments are of particular risk due to the speed of shipping. Fruits and vegetables for consumption, flowers and decorative plants, and propagative plants may present a greater risk in the introduction and establishment of plant pests and diseases.

While the movement of cargo from the United States to Guam is interstate, under CFR Title 7 (Subtitle B, Volume 5, Chapter 3, Parts 318.13-8 and 318.13-10) cargo moving between Guam, CNMI, Hawai’i, and

the continental United States is subject to agricultural inspection for plant pests and diseases. There are no such restrictions on cargo containing animal products moving between Guam, CNMI, Hawai'i, and the continental United States. All cargo originating in foreign countries is subject to inspection by GCQA. Cargo and passengers entering Hawai'i and the continental United States are inspected by DHS-CBP. The GOA authorizes GCQA to inspect cargo from the continental United States.

Parcels shipped through private mail (express courier operations) are regulated and inspected as cargo. GCQA has authority to inspect these packages without a search warrant. Privately shipped mail by commercial express courier operations (except diplomatic parcels) is inspected by GCQA through visual evaluation of the parcel and the declaration label. No x-ray equipment is available at the express courier operations and the inspection area is lacking equipment and lighting.

3.3.7.1 *Construction Equipment and Materials*

Following inspection, imports of construction equipment contaminated with pests or soil must undergo approved remedial treatment (if available) or re-export is required. The vast majority of problems with construction equipment are contamination with soil that can be washed away in areas designated for approved collection or drainage of the effluent, as into a system that treats sewage. There may be a plan for improvements, including additional inspection of imported construction materials and a military inspection site. On Guam, it is unclear how consistently mitigation measures for timber, sand, and gravel are applied and how well they prevent pest entry. There are no entry requirements for other construction materials.

Safeguarding measures prevent the spread of pests by timber. Saw logs with bark may not enter Guam, and de-barked saw logs and lumber must be inspected for termites and wood-boring insects. Foreign timber must have an import permit detailing required treatment. Other regulations authorizing the GDOA to quarantine, inspect, fumigate, disinfect, destroy, or exclude any commodities infested with pests are found in GARR Title 8-Food and Agriculture, Division 2-Plant Industry, Chapter 10, Importation of Plants and Plant Products.

3.3.7.2 *Propagative Material*

Guam inspectors employ extensive phytosanitary measures inspecting propagative plant shipments and cut flowers for plant pests and diseases and for import permit violations. Plants imported into CNMI arrive via Guam from California or Hawai'i for entry clearance by PPQ. Because of concerns about smuggling, every large bag or box brought into CNMI by foreign passengers is inspected visually.

Plant material for landscaping on Guam is imported primarily from the U.S., but Thailand, Taiwan, the Philippines, Costa Rica, Ecuador, and Puerto Rico are other sources. All imported propagative plant material, including transshipments to the CNMI, Palau, and FSM, is inspected at the GDOA/USDA Plant Inspection Facility.

GDOA requires treatment prior to shipment of all plants entering Guam from Hawai'i with a hot water or citric acid solution drench and inspection for pests of concern (by GCQA), primarily the coqui frog.

Guam prohibits entry of citrus, coconut, banana, and taro propagative plant materials from specified locations to prevent the introduction of specific pests of concern, and sweet potato planting materials are highly restricted. Importation of certain plants from areas infested with the European Corn Borer, *Ostrinia nubilalis* (Lepidoptera: Pyralidae) is also restricted (GDOA). Parts of this Guam regulation have been superseded by the Federal Plant Protection Act of 2000 (R. Campbell, Personal Communication).

3.3.8 Plant Products

GCQA conducts extensive inspections of incoming fruits and vegetables at several designated facilities on the island. Because these items are for consumption, they are of high priority for clearance. These very large shipments (consisting of many containers) necessary to supply the population of Guam occur very regularly via both air and maritime transport.

The APHIS-PPQ Fruits and Vegetables Import Manual guides PPQ inspectors and cooperators on shipments of fresh fruits and vegetables (USDA-APHIS-PPQ 2010b). Chapter 5 of the APHIS-PPQ Treatment Manual shows the treatment schedule for fruit, nuts, and vegetables (USDA-APHIS-PPQ 2008).

Clearance of fruits and vegetables may be by inspection of both the paperwork and the commodities if indicated. Inspections may be random, routine, or targeted.

Title 7 Part 319 of the CFR governs the importation of fruits and vegetables. All must have an APHIS import permit.

GARR Title 8, Division 2, Chapter 10 governs the importation of plants and plant products (GDOA 1997). Import permits and phytosanitary certificates are required to ship regulated articles into Guam.

3.3.9 Garbage

Garbage has been implicated in various animal disease outbreaks around the world (CRS Report 2001). Regulated garbage is monitored to prevent the movement and dissemination of pests and plant and livestock diseases. Sections in Titles 7 and 9 of the CFR state requirements for the handling and movement of regulated garbage (7 CFR, 9 CFR). Garbage is defined in 7 CFR § 330.400-330.403 and 9 CFR § 94.5 as waste material derived in whole or in part from fruits, vegetables, meats, or other plant or animal material. Any other refuse associated with such materials is also garbage. For purposes of this plan, trash is any waste material not in contact or associated with garbage and unregulated by APHIS for animal and plant disease concerns. Both trash and garbage are subject to EPA and local Micronesian regulations and restrictions (EPA 2013).

APHIS regulates garbage if the conveyance moving it has been outside the U.S. and Canada within the previous 2 years. Garbage on or removed from a means of conveyance is also regulated garbage, if at the time the garbage is on or removed from the means of conveyance, the means of conveyance has moved during the previous 1-year period, either directly or indirectly, to the continental United States from any territory or possession or from Hawai'i, to any territory or possession from any other territory

or possession or from Hawai'i, or to Hawai'i from any territory or possession. These regulations apply to Guam and CMNI. Regulated garbage may not be moved between the continental United States and U.S. territories, U.S. possessions or Hawai'i nor may regulated garbage be imported or discharged in any form into U.S. territorial waters (within 12 nm of the coastline).

Tightly covered, leak-proof containers must store regulated garbage within U.S. territorial waters. Garbage must be stored properly to move it from a conveyance for disposal. Regulated garbage can be moved under the direct supervision of a USDA-APHIS-designated inspector (e.g., GCQA or CMNI quarantine personnel) or by an entity operating under a compliance agreement with APHIS to an approved garbage handling facility. There are seven compliance agreements for regulated garbage handlers in Guam and five in Saipan. Approximately, 680,389 kg (1.5 million pounds) of regulated garbage was destroyed from 1 February 2009 to 1 February 2010 (Brown 2010). Ports without the capability to handle and process regulated garbage may not allow its removal from conveyances.

To mitigate the risk presented by regulated garbage, it must undergo one of three processes: 1) incineration, defined as reducing garbage to ash by burning (with policy exemptions for glass and metal); 2) sterilization, cooking at an internal temperature of 212°F for 30 minutes; or 3) grinding and discharge into an EPA- and APHIS-approved sewage system.

Garbage from commercial and military aircraft must be unloaded at an airport or military base approved to handle it. On Guam, NAVFAC marinas at the Apra Harbor Naval Station and Pacific Environmental Resources Incorporated at Andersen AFB are both approved to handle garbage. Regulated garbage from A.B. Won Pat International Airport is processed at the local aircraft catering company. Saipan International Airport has an incinerator owned and operated by the Commonwealth Ports Authority to handle regulated garbage. Site visits to Guam and Saipan noted multiple deficiencies on the premises of some compliance agreement holders (Jimenez et al. 2009).

Tinian has no functional equipment for the disposal of regulated garbage. The local landfill has been cited for multiple violations by the Saipan Division of Environmental Quality, and the EPA and the military's plan to move garbage generated on Tinian during training operations to Saipan or Guam for disposal until that time when and if a new landfill is complete violates APHIS regulations. Tinian has not repaired the equipment for processing regulated garbage and, according to the Saipan Tribune, the new Tinian landfill will be built within the area leased by the U.S. military (as of 2013 information on this remains vague), but will be closed during construction and training exercises. A transfer station will be built to store garbage generated by civilians during training exercises (Saipan Tribune 2010).

APHIS-PPQ has responsibility for monitoring garbage handling activities of airports, caterers, cleaners, cruise ships, fixed-base operators, hauling/cartage firms, marinas, military facilities, storage facilities, and transfer stations in U.S. locations; however, there are only two PPQ officers for Guam and CNMI. In Guam, GCQA assists with this effort.

The APHIS-PPQ MAC guides handling of regulated garbage. The APHIS-PPQ MAC also instructs inspectors to monitor regulated garbage handling on aircraft and ships in port as well as at land-based facilities

(USDA-APHIS-PPQ 2013). The Quarantine Regulations of the U.S. Navy require garbage handling in compliance with APHIS regulations (OPNAVINST 6210.2).

Other practices related to garbage present additional risks. Garbage not on a conveyance outside of U.S. locales and Canada may be regulated if fed to swine. Some local pigs are fed garbage collected in restaurants and perhaps from boats; however, pig owners are not licensed to feed this type of garbage (Poole 2009). CFR Title 9 § 166.1–166.2 states that only personal household garbage may be fed to pigs and that the farmers must be licensed to feed them other types of garbage.

3.3.10 Mail

Mail is a high-risk pathway for the movement of agricultural commodities and invasive species. GCQA monitors mail and seizes items of phytosanitary concern. Both GCQA and the local postmaster recognize domestic and foreign mail as a pathway for smuggling all types of commodities (Jimenez et al. 2009). Foreign mail may be inspected without a warrant only at the first port of arrival, after which it is considered domestic mail. Approximately 95% of the mail arriving on Guam comes directly from the U.S. or is international mail processed in Hawai'i. All (100%) of the international mail entering Honolulu destined for Guam is inspected by CBP.

The remaining 5% of mail arrives directly from foreign countries, primarily Japan and the Philippines. In 2008, 1.9 million parcels/pieces of mail came through the Guam Post office (Jimenez et al. 2009). Mail arriving in Guam destined to the CNMI is inspected in Guam.

First-class mail sent via the USPS is legally protected under the Fourth Amendment to the U.S. Constitution, making it illegal to delay or open such mail without either a search warrant or permission from the addressee. These protections apply also in Guam and the CNMI. GCQA officers open and inspect the mail, but the postal inspector and the consignee must be present. The postal facility legally may not slow down the flow of domestic mail, which limits the number of packages that can be inspected with the available workforce. The facilities are inadequate, and the x-ray machine is not fully functional (Jimenez et al. 2009). In addition, the present postmaster makes the use of detector dogs inside the postal facility very difficult. Using detector dogs inside the postal facility would facilitate the inspection process and reduce risks.

The USPS allows adult and hatchling (day-old) poultry to be mailed with restrictions. Postal regulations prohibit mailing of hatchlings vaccinated for NDV. Day-old chickens, ducks, emus, geese, guinea fowl, partridges, quail, and turkeys must be delivered to the addressee within 72 hours after hatching. Per USPS regulations, non-poultry birds may not be mailed (USPS 2009). Poultry from Hawai'i are transported on United Airlines as domestic mail (Jimenez et al. 2009).

The Guam Post Office displays educational posters describing prohibited mail items, and while currently not occurring as a common practice, post office clerks are encouraged to ask customers whether outgoing packages contain perishable items. When packages stamped "perishable" arrive on Guam,

GCQA officers inspect them and, when necessary, forward them to the Guam Plant Inspection Station for additional inspections or diagnostic assistance.

Military mail is handled by the MPSA, the single DoD point of contact with the USPS, which is required by military regulation to adhere to USPS rules, federal laws, and various international laws and agreements for movement of military mail. The MPSA also educates military personnel about items prohibited in mailed packages (Ericksen personal communication). Military mail may not be inspected by GCQA.

The USDA APHIS MAC provides direction for inspections at U.S. postal facilities receiving international mail (USDA-APHIS-PPQ 2013).

Information from GCQA and the USPS indicates that the mail flow will increase with the military relocation (Jimenez et al. 2009).

3.3.11 Wood Packing Materials

U.S. regulations and the ISPM No. 15 (ISPM No. 15 2009) require either fumigation with methyl bromide or heat treatment according to specific schedules for all WPM entering the country for use in commerce. Treated WPM must display a specified ISPM No. 15 stamp in a visible location for compliance checks at ports of entry.

These regulations apply to WPM imported from foreign origins into Hawai'i, Guam, and CNMI. Movement of WPM between these same locations is domestic and not subject to these regulations. Because the majority of cargo entering Guam is from domestic locations, this fact represents a potentially significant safeguard gap. FSM, Palau and RMI have no existing regulations to mitigate the pest risk from the importation of WPM. It is likely that a certain percentage of WPM always bypasses mitigation and sometimes live pests are found in properly marked WPM. In these cases for U.S. locations when an issue is detected, APHIS-PPQ determines either that the shipment was treated improperly or that ISPM No. 15 stamps were applied fraudulently, without treatment. Inspections of WPM with its cargo for pests and the required marking have detected wood pests in both stamped and unstamped WPM. There are obvious gaps in this process .

The USDA MAC directs inspectors to check whether regulated WPM is compliant or non-compliant (APHIS MAC). Guidance from the APHIS Miscellaneous and Processed Products Manual on this topic applies to Hawai'i, Guam and the CNMI (USDA-APHIS-PPQ 2012). Inspectors are instructed to look specifically for timber pests, other insects, and unspecified hitchhikers.

3.3.12 Livestock, Poultry, and Non-poultry Birds

For purposes of this terrestrial risk assessment, livestock and poultry are defined per APHIS regulations:

- **Livestock**—Domesticated ruminants (cattle, carabaos, sheep, and goats), domesticated swine (including feral swine), and domesticated equids (horses, mules, and asses).

- **Poultry**—Chickens, doves, ducks, geese, grouse, guinea fowl, partridges, peafowl, pheasants, pigeons, quail, swans, and turkeys, including eggs for hatching (9 CFR § 93.100).
- **Non-poultry birds**—Birds other than those listed above susceptible to communicable poultry diseases or capable of carrying those diseases or their arthropod vectors (9 CFR § 92.1). This definition includes wildlife species.

APHIS regulations (9 CFR § 92) refer to all species of the animal kingdom except humans, including: cattle, sheep, goats, other ruminants, swine, horses, asses, mules, zebras, dogs, poultry, and birds susceptible to communicable livestock and poultry diseases or capable of carrying those diseases or their arthropod vectors. APHIS regulations governing the importation of domesticated livestock, poultry, and non-poultry birds in 9 CFR § 93 pertain to movement of cattle, sheep, goats, pigs, horses, mules, asses, other livestock species, poultry, and other non-poultry birds from foreign countries into any of the 50 U.S. states, the Commonwealth of Puerto Rico, the CNMI, the District of Columbia, and any territories and possessions of the United States. Domesticated livestock for importation into the United States from any part of the world must be shipped directly to an approved port and be quarantined there until negative results to specified tests, depending upon the country of origin, are obtained and the animals are certified by the port veterinarian to be free from clinical evidence of disease. In special cases the APHIS Administrator may designate unapproved ports as quarantine stations. No ports on Guam are approved for importation of livestock, poultry, or non-poultry species; therefore, at this time these species for import to Guam first must enter through ports in the continental United States.

APHIS regulations on the interstate movement of domesticated livestock, poultry, and non-poultry birds in 9 CFR § 71-89 generally prohibit animals, including domesticated livestock, affected with any communicable disease from interstate movement.

In 2002, an amendment to the AWA made the import or interstate commerce of a bird or animal for the purpose of participation in a fighting venture illegal regardless of the law in the destination state, including Guam (APHIS-VS 2003). This amendment does not restrict the possession of poultry or dogs for breeding or as show animals.

GARR import requirements for live animals, organisms, and vectors require any animal found to be clinically affected or recently exposed to any infectious, contagious, and/or communicable disease or infested with ectoparasites to be returned to its point of origin or destroyed (9 GARR 1 § 1100-1113).

3.3.12.1 ***Livestock***

U.S. and Guam territorial regulations impose livestock requirements for horses and other livestock moving interstate or imported into Guam. Horses are subject to specific mitigations to prevent the entry of EIA, EEE, WEE, and VEE viruses (9 CFR § 75 and 9 GARR 1 § 1104).

3.3.12.2 ***Poultry***

Federal regulations restrict importation of live poultry, poultry products, and hatching eggs from regions affected by END or HPAI; several of these regions are Asia-Pacific countries (9 CFR § 93.201, 9 CFR §

94.6, and 9 § CFR 95.30). Live poultry permitted to enter the United States (except those from Canada) must be inspected, quarantined for 30 days, and tested at a quarantine facility on the U.S. mainland (9 CFR § 93.209). The importation of hatching eggs is restricted from countries affected by END and HPAI, including the Philippines and several other Asia-Pacific countries (9 CFR § 93.201 and 9 CFR § 93.209).

In addition to applicable APHIS regulations, Guam territorial regulations require an entry permit and a health certificate approved by the chief livestock sanitation officer or a state or federal veterinarian as well as serological testing and vaccination for poultry diseases of concern (9 GARR 1 § 1110). Poultry must be identified individually with a numbered leg band with the number indicated on the health certificate. (9 GARR 1 § 1110). Hatching eggs and day-old poultry require only an affidavit from the shipper stating that the flock of origin is free of NDV and has not been exposed to it within 60 days prior to shipment for import. All poultry and hatching eggs must be shipped in new (unused) containers and inspected by the territorial veterinarian or deputy prior to entry into Guam.

3.3.12.3 *Non-poultry Birds*

Federal regulations state birds not of U.S. origin must be accompanied by an import permit and inspected by USDA personnel at an approved port of entry with avian quarantine facilities. USDA imposes trade restrictions on the importation of live birds from countries affected by HPAI, including certain countries in Africa and Asia (USDA-APHIS 2009a).

Importation of wild or exotic birds into the United States must comply with APHIS and USFWS requirements. Certain exotic birds are protected by the CITES and the WBCA.

All birds entering Guam must be accompanied by an import permit and an official health certificate approved by the chief livestock sanitation officer or a state or federal veterinarian. Birds must be identified individually with a numbered leg band with the number indicated on the health certificate (9 GARR 1 § 1110).

Regulations for the importation of pet birds (all birds except poultry) under 9 GARR §§ 2101-2102 require pet shops and importers to keep a record of each sale made for at least 90 days and to make the record available to the GDOA if a quarantine is placed on the premises by the territorial veterinarian (9 GARR §§ 2101-2102).

Guam has introduced additional quarantine requirements for all birds (poultry and non-poultry) arriving from the continental United States to prevent the introduction of West Nile Virus requiring a 7-day quarantine in an approved facility or veterinary clinic followed by 30 days of isolation in a mosquito-proof cage.

3.3.12.4 *Dogs and Cats*

Under CDC regulations, 42 CFR § 71.51, dogs imported to the United States, with limited exceptions, must be accompanied by a certificate of rabies vaccination; imported cats are not required to be vaccinated for rabies (42 CFR § 71). The entry of pets from areas affected by screwworms is subject to

APHIS regulations (9 CFR § 93), which require a health certificate stating that the pet was examined and found to be free of screwworm infestation within 5 days of export (USDA 2000; USDA-APHIS 2009b).

The GDOA regulates importation of pets to Guam (5 GCA § 60108). Guam restrictions and prohibitions for the importation of cats and dogs are stricter than federal requirements. Cats and dogs must enter Guam through the A.B. Won Pat International Airport or the Apra Harbor maritime port. Every cat or dog must be accompanied by an entry permit, a health certificate signed by a veterinarian no more than 14 days prior to shipment, and a confirmed quarantine kennel reservation. Dogs must have a rabies vaccination certificate dated between at least 30 days and 1 year prior to shipment and a certificate of immunization against various canine diseases. Cats must have a certificate of immunization for multiple feline diseases. Regulations for the importation of cats and dogs into Guam require animal identification, quarantine procedures, and rabies vaccination and testing prior to arrival.

Title 10 GCA Chapter 34 Article 3 states that animals imported must complete a maximum of 120-day confinement in a commercial quarantine facility. Animals may undergo shorter quarantines under specific testing schemes for rabies and some pets may qualify for the home quarantine option.

Animals originating from Japan, Hong Kong, Oceania, and the continental United States (except for counties on the Mexican border) can be quarantined on Guam. Animals originating elsewhere must be quarantined in Hawai'i prior to entrance into Guam. Cats and dogs originating from rabies-free areas, Hawai'i, New Zealand, Australia, and the United Kingdom, may be exempted.

Import regulations for cats and dogs in 9 GARR 1 § 1109 include additional requirements for cats and dogs from other countries. Cats and dogs that do not comply with regulations may be declared ineligible to enter and remain in the custody of the carriers at a designated inspection area at the port of entry until sent back.

Military regulations for the import of dogs and cats published in the Quarantine Regulations of the Armed Forces (QRAF) comply with federal and state requirements. General requirements for the admission of cats and dogs include the following: 1) all animals arriving in the United States are subject to inspection by a public health or military quarantine officer; 2) animals will require testing and confinement when they appear to be not in good health or when they have been exposed during shipment to a sick or dead animal suspected to have a communicable disease; 3) unsanitary cat and dog containers arriving in the United States must be cleaned and disinfected before the animals can be admitted; and 4) a valid rabies certificate is required for dogs. The military requires dogs to be vaccinated for rabies and inspected at the port under quarantine regulations. All pets belonging to military personnel must meet the requirements for importation into Guam.

One of at least four private veterinary clinics on Guam maintains a quarantine facility for imported cats and dogs. The military has one veterinary clinic and a boarding and quarantine facility at Andersen AFB and another veterinary treatment facility at the Navy base. The Andersen facility maintains 14 canine kennels and six feline quarantine kennels. The Navy will construct a new facility with space for 10 military working dogs, a veterinary examination area, an outdoor dog wash, and four quarantine runs.

In recent years, effective mitigations have drastically reduced the risk of infectious disease in military dogs stationed overseas.

3.3.13 Wildlife

Importers or exporters of wildlife, wildlife parts, or products must obtain a license from USFWS and importers may be required to secure an import permit from APHIS or the CDC and subjected to additional APHIS and CDC regulations depending on the species (9 CFR § 93, 9 CFR § 95, 42 CFR § 71.52-71.56). Guam also requires permits for the import of zoological or menagerie animals, inspection by the territorial veterinarian, and any necessary quarantine conditions.

GCQA must notify the territorial veterinarian of the arrival of live wildlife. GDAWR assists GCQA in identifying confiscated animal products.

Routine activities to monitor the movement of vertebrate wildlife are limited to BTS. APHIS-WS is responsible for surveillance and monitoring.

3.3.14 Military Mitigation

DoD maintains customs and border clearance policies and procedures for wildlife, agricultural and animal products, pets, plants, and plant products. By mandate of the Military Customs Inspection (MCI), all passengers, crew members, accompanied baggage, and equipment boarding any DoD-sponsored ship or aircraft departing an overseas area for the Customs territory of the United States (CTUS) must meet all U.S. entry requirements. All personnel on military aircraft must complete a U.S. Customs Accompanied Baggage Declaration (DD Form 1854), and civilian crew members must complete Customs Form 5129. The MCI program does not extend to Guam because GCQA has not authorized inspections by DoD personnel on its behalf.

A DoD memorandum designates Navy personnel with authority to inspect and to issue ship sanitation certificates for Navy, Army, Military Sealift Command, Coast Guard, and National Oceanic and Atmospheric Administration vessels. This memo requires adherence to standard procedures and policy—IAW Article 39 of the International Health Regulations 2005—certificate (valid for 6 months) (WHO 2005).

AFJI 48-104, Quarantine Regulations of the Armed Forces, incorporates regulations to mitigate the risk of introduction and dissemination of arthropod vectors by movements of vessels, aircraft, and other Armed Forces transport arriving at or leaving U.S. and foreign ports, installations, or other facilities where arthropod vector-borne diseases exist. This requirement is included in the Military Entomology Operational Handbook.

3.3.14.1 *Military Aircraft*

Military aircraft departing Guam should be screened by USDA-APHIS-WS canine inspection teams prior to departure. Military aircraft that arrive at Guam from Asian ports in Japan, China, and Korea should be inspected for insects, mice, birds, and amphibian and reptile species trapped within cabin and cargo compartments or hitchhiking externally in wheel-well compartments.

3.3.14.2 *Vessels*

DoD rodent control on ships to guard or separate gangways from the shore extend to cargo nets and other devices in port and fit connecting lines with rat guards. Cargo found free or treated for rats must be loaded. Ships must be inspected for rats and fleas prior to departure.

3.3.14.3 *Military Personnel*

The DoD relies on individual military personnel to clean and inspect their clothing and personal property to prevent the introduction of plant pests. Military personnel undergo limited training in biosecurity for agriculture. They are not trained in pest detection and receive no comparable information about the risks of moving plant pests into Guam and around the Micronesia Region. Military personnel are informed about the risks of spreading BTS from Guam. No oversight, compliance checks, or quality control processes are in place to ensure that biosecurity procedures for personnel are effective.

3.3.14.4 *Cargo*

All DoD cargo must be available for inspection by CBP upon entry into the United States except for areas outside CTUS, such as the Micronesia region. GCQA and CMNI Quarantine are responsible for agricultural inspections on behalf of APHIS in their respective territories. DTR 4500.9, Part V includes agricultural cleaning and inspection requirements and indicates that DoD personnel will be assigned as agricultural and customs inspectors for pre-clearance programs (DTR 4500.9). USDA-APHIS provides DoD with guidance, information, and training for pre-clearance inspections. According to the agricultural cleaning and inspection requirements (Part 5, Chapter 505), no cargo may be loaded in a foreign country unless free from plant and animal contamination or pest infestations.

Chapter 511 of DTR 5 states that all cargo entering Guam, regardless of origin, is subject to inspection by GCQA. OPNAVINST 6210.2 authorizes USDA-APHIS-PPQ personnel to inspect cargo to prevent the introduction of plant and animal pests or diseases.

3.3.14.5 *WPM*

DoD stipulates that all new WPM under DoD contracts or acquired by the DoD must meet ISPM No. 15 requirements. Companies supplying WPM to DoD must comply with a quality control program administered by the American Lumber Standard Committee (ALSC) through an agreement with APHIS auditing for proper treatment and record-keeping practices. However, DoD may use old WPM not compliant with ISPM No. 15. Whether any of this noncompliant WPM is shipped to Guam is not known.

3.3.14.6 *Propagative Material*

The DoD Personal Property Consignment Instruction Guide Online system, which provides guidance to military and DoD civilian personnel assigned to foreign duty stations, states incorrectly that there are “No restrictions identified” for plant movement into Guam.

3.3.14.7 Mitigation Regulations and Requirements

Table 6-2 presents pertinent regulations for Guam inspections, quarantine, and treatment. Tables 6-3 and 6-4 detail other biosecurity guidance and the military regulations and requirements for biosecurity.

Table 6-2: Biosecurity Regulations and Requirements

Statute, Regulation or Requirement	Description
Animal Health Protection Act (AHPA)	The AHPA purpose is to prevent, detect, control, and eradicate diseases and pests of animals to protect animal health, the health and welfare of the people of the U.S., the economic interests of U.S. livestock and related industries, the U.S. environment, and U.S. interstate and foreign commerce in animals and other articles.
Animal Welfare Act (AWA)	A modification to the AWA, the Animal Fighting Enforcement Act of 2007, made interstate commerce of a bird for the purpose of participation in a fighting venture illegal regardless of the law in the destination state, including Guam.
National Defense Authorization Act, Public Law 110–181, Section 314	Requires prohibition on the transport and spread of BTS via aircraft.
National Environmental Policy Act (NEPA)	NEPA, 42 U.S. C. § 4321 as amended, of 1969.
Non-Indigenous Aquatic Nuisance Prevention and Control Act of 1990	Authorizes a cooperative program to control BTS outside its historic range.
Plant Protection Act (PPA)	The PPA consolidates all or parts of 10 USDA plant health laws into one comprehensive law, including the authority to regulate plants, plant products, certain biological control organisms, noxious weeds, and plant pests.
Title 8 Guam Administrative Rules and Regulations (GARR)	Division 2–Plant Industry, Chapter 10 regulates Food and Agriculture, Importation of Plants and Plant Products.
Title 9 GARR 1997	Division 1, Chapter 1 of the GARR regulates the importation of live animals.
	Section 2 of § 1103 (GARR) states that under no circumstances shall any animal be turned loose at the port and that hogs and sheep may be confined in temporary pens or crates, cattle and horses may be tied, and dogs and cats shall be confined in crates.
	Title 9 GARR, Division 1, Chapter 1, § 1109 requires that all cats and dogs originating from Africa, Asia, or islands of the Pacific Ocean (except Australia, Hawai'i, and New Zealand) have a certificate from the national chief livestock sanitation officer stating that the animals originated in a state, country, or other political subdivision officially declared free of surra, animal African trypanosomiasis, and leishmaniasis.
	Title 9 GARR 1 § 1110 requires all imported birds and hatching eggs to be accompanied by an entry permit and a health certificate approved by the chief livestock sanitation officer or a state or federal veterinarian.

Statute, Regulation or Requirement	Description
	Subchapters §§ 2101 and 2102 regulate the importation of pet birds (all birds except poultry).
Title 10 GDOA 5 GCA § 60108	The GDOA regulates the importation of pets to Guam. Title 10 Guam Code Annotated Chapter 34 Article 3 states that animals imported must complete a maximum of 120-day confinement in a commercial quarantine facility.
Wild Bird Conservation Act (WBCA)	Certain exotic birds are protected by the CITES and the WBCA. Importation of exotic birds into the U.S. must comply with APHIS and USFW requirements.

Table 6-3: Other Biosecurity Guidance

Other Guidance	Description
Animal Product Manual	Guidelines based upon the regulation governing the importation of specific animal products and by-products.
Combined Animal And Plant Health Risk Ratings for Countries	USDA-APHIS analysis of relative risks presented from other countries as a result of animal and plant diseases inside their borders (CPHST, VS Center for Epidemiology and Animal Health, October 2010).
Fruits and Vegetables Import Requirements (FAVIR) Online Reference	www.aphis.usda.gov/favir/
Manual of Agricultural Clearance	The APHIS MAC provides comprehensive guidance for practices required for safeguarding imported products and articles and handling regulated garbage. Safeguarding is a preventive action for handling, maintaining, or disposing of prohibited or restricted products and articles to maintain cargo control and eliminate the risk of plant and animal pest and disease dissemination. Nursery Stock Restrictions (M319.37–A & B)
USDA-APHIS-PPQ Manuals	Guidelines for regulating the importation and interstate movement of specific plants and plant products.

Table 6-4: Military Biosecurity Regulations and Requirements

Regulation or Requirement	Description
AFJI 48-104, Quarantine Regulations of the Armed Forces	Incorporates regulations to mitigate the risk of introduction and dissemination of arthropod vectors by movement of vessels, aircraft, and other Armed Forces transport arriving at or leaving U.S. and foreign ports, installations, or other facilities.
AFPMB Tech. No. 31 (2004).	Delineation of responsibilities for the military meeting USDA-APHIS requirements for internal and external inspections for terrestrial vertebrate species, insects, and plant species.
COMNAVMAR INST 5090.10a	Navy instruction for BTS training for military personnel.
DoD Memorandum	DoD Memorandum designates Navy personnel with authority to inspect and to issue ship sanitation certificates (ship sanitation control exemption certificate and ship sanitation control certificate) for Navy, Army, Military

Regulation or Requirement	Description
	Sealift Command, Coast Guard, and National Oceanic and Atmospheric Administration vessels to adhere to standard procedures and policy—IAW Article 39 of the International Health Regulations (WHO 2005)—certificate (good for 6 months) with section for observed rodent infestations.
DoD SDDC PPCIG 2010 Personal Property Consignment	The DoD Personal Property Consignment Instruction Guide Online system, which provides guidance to military and DoD civilian personnel being assigned to foreign duty stations, states that there are “No restrictions identified” for plant movement into Guam.
Guam and CNMI Military Relocation EIS/OEIS	The Guam and CNMI Military Relocation EIS/OEIS describes military relocation plans, schedules, impacts, and mitigations.
Naval Supplemental Publication Number 486, Volume 1	Naval policy contains information regarding APHIS requirements for foreign garbage.
NAVMED P-5010-8	Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology: Navy procedures for the eradication of animals.
OMNAVMARIANA SINST 5090.10A	Requirements for setting barriers for BTS.
OPNAVINST 6210.2	USDA-APHIS-PPQ personnel may inspect cargo to prevent the introduction of plant and animal pests or diseases.
Quarantine Regulations of the Armed Forces	The Quarantine Regulations of the Armed Forces state that cargo is subject to inspection by a USDA representative to prevent the introduction or spread of animal and plant diseases or pests (DoD 1992). For the purposes of these regulations, Guam is part of the U.S. DoD maintains customs and border clearance policies and procedures for wildlife, agricultural and animal products, pets, plants, plant products, and regulated garbage.
SECNAVINST 6210.2A AFR 161-4, DoD, 1992, Section 9	Outlines procedures for the use of rat guards at ports with known rodent infestations.
Subsistence Manual COMDTINST M4061.3C	Waste Disposal Requirements.

4 RECOMMENDATIONS

APHIS risk assessment teams from PPQ-CPHST, VS-Center for Epidemiology and Animal Health, and WS have developed phytosanitary and general sanitary recommendations for enhanced biosecurity necessary to protect Hawai'i and the Micronesia Region during and after the military relocation to Guam and Tinian. Recommendations are based on the specific pest risk assessments of each APHIS team and observed deficiencies in mitigation capabilities.

The primary focus of the MBP is to describe recommendations for additional biosecurity measures for Guam, Hawai'i, CNMI, FSM, RMI,, and Palau. Each of these jurisdictions has reason to be concerned about many of the same challenges related to the introduction of invasive species and the lack of resources for sanitary and phytosanitary protections. In general these islands have limited staffing, funding, infrastructure, and/or capabilities for airport and seaport border inspections; agricultural quarantine inspection programs; plant and animal pest and disease surveillance; control and eradication; and early detection and rapid response programs.

Several biosecurity infrastructure needs are common at each Micronesian location. Adequate x-ray capability for baggage screening and inspection must be improved at each commercial port, either by ensuring operability or adding additional equipment. The CNMI, FSM, RMI, Guam, Hawai'i, and Palau should expand their inspection capabilities for air and sea containers. Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be constructed and maintained, especially for construction vehicles arriving via water to Guam, Saipan, Tinian, and Rota.

In addition, a Micronesian Region monitoring and surveillance program for the occurrence of foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs. Special surveillance programs should be established for plant pests and diseases; exotic fruit flies, Khapra beetle, Rhinoceros beetle, and tropical wood pests should be trapped. All Micronesian Region islands and Hawai'i should improve early detection and rapid response capabilities.

Other biosecurity measures are recommended for specific Micronesian Region islands and Hawai'i, including additional inspectors, legislatively approved user fees, electronic systems for tracking manifests, container scanners, and a training and outreach program (see Appendix A for more detail).

4.1 GENERAL RECOMMENDATIONS: It is worthwhile to note that many of the recommendations within this risk assessment refer directly to Guam but that many of these same concepts can be applied to the other jurisdictions covered by the MBP. Additional recommendations and details will be provided in the SIP.

4.1.1 Infrastructure

4.1.1.1 *Funding*

Increase funding for regional biosecurity so necessary efforts to prevent, control, and eradicate animal and plant pests and diseases throughout the region are effective. A centralized regional group with

representatives from each country within the Micronesia Region should develop sustainable funding streams for efforts to manage interrelated risks that cross political boundaries. There should be sufficient funds to conduct routine surveillance, implement response plans, and provide outreach and education, in addition to port of entry exclusion activities and training for inspectors.

Ensure sufficient funding for agriculture and wildlife disease and pest exclusion activities by developing legislation to create a user fee structure similar to that employed by the DHS and USDA. Review penalty assessment structure for noncompliance with regulations covering animal and plant health as a source of additional funding. Military presence in the region calls for long-term allocation and ongoing management of biosecurity funds. Current funding for regional biosecurity is distinctly inadequate for the magnitude of the existing and emerging challenges posed by the military relocation to the current exclusion and control systems. In particular, a main challenge to an agency with the all-inclusive mission of GCQA is sustainable financial support and subsequent accountability. A reasonable solution would be user fees. User fees are assessed by the government to recover the costs of goods or services. USDA-APHIS levies user fees through statutory authority 7 CFR § 354.3 and 9 CFR § 130. In 2010, GCQA levied a \$6.36 per passenger combined Customs and Agriculture user fee to cover passenger and baggage inspections compared to \$10.50 per passenger fee for international arrivals to the rest of the U.S. (\$5.50 for Customs inspection collected by the CBP and \$5.00 for agricultural inspection services by CBP on behalf of USDA). There is an additional fee for immigration services. User fees are not charged for military passengers or conveyances. User fees cover inspection of commercial aircraft and maritime vessels as well as commercial maritime vessels or aircraft carrying military cargo. If passenger arrival totals remain at current levels, increasing the user fee to the same as that of USDA/CBP would represent an approximate 40% increase in revenues.

Ensure adequate long-term military funding is available for biosecurity efforts. The military must participate in regional biosecurity efforts.

Create community funding sources for local programs to promote environmental awareness and stewardship through local training, education, and eradication efforts

Ensure adequate long-term funding is available for equipment and infrastructure.

4.1.1.2 *Staffing and Resources*

Ensure sufficient staffing (inspectors, plant health safeguarding specialists, and surveyors) to accomplish all necessary inspection and quarantine activities in the Micronesia Region. Develop a staffing model that addresses all activities for inspection and quarantine. Already insufficient staffing levels will be strained further by the military relocation as the workload at airports, maritime ports, the mail facility, and the Plant Inspection Station increases. Quarantine officers with agriculture expertise should be on duty to clear cargo and conveyances whenever aircraft or maritime vessels arrive. Quarantine officers must be trained adequately in all aspects of their work and should receive periodic refresher training.

Activate the Guam Biosecurity Task Force. The Biosecurity Task Force has been approved by the Guam Legislature as a way to increase effective prevention of the importation of IAS. The source of funding is undetermined. This task force will have a total of 30 officers; 15 from GCQA and 15 from GDOA. The task force, a major step towards increased agriculture quarantine inspections and early detection efforts, should be funded fully for the success of the program.

Establish an MCI-excepted program on Guam. The program would include USDA-APHIS-trained military personnel to augment, conduct, and coordinate with GCQA agricultural inspections of foreign military arrivals. This program would augment and improve the import process to inspect all military maritime vessels in compliance with USDA and Guam statutory regulations and authorities. These MCI personnel could receive instruction from WS to recognize invasive species. The MCI program should be initiated on Saipan and Tinian as well.

Ensure availability of necessary equipment. Equipment necessary for effective safeguarding, hand lenses, microscopes, and computers, etc., must be available to quarantine officers. X-ray machines and other appropriate scanning technology and cleaning equipment must be provided where needed. A sufficient number of cranes must be available for sea cargo container inspections. All equipment must be maintained in working order over the long term. APHIS manuals provide detailed guidance for necessary equipment.

Ensure facilities for incoming passenger and cargo inspection are adequate for necessary inspections.

- Ensure that passengers arriving at A.B. Won Pat International Airport to transit Guam cannot move restricted or prohibited agricultural or wildlife products to other jurisdictions. GCQA personnel should be stationed with DHS, Transportation Security Administration (TSA) personnel for expertise in screening transiting passengers for restricted or prohibited materials or all transiting passengers should be routed through GCQA inspection before they move to the departure area.
- Build physically secure facilities at the Port of Guam with ample warehouse space and equipment and resources required to unload cargo and conduct agricultural inspections to centralize inspection of maritime cargo. Current import practices allow imported maritime shipments to proceed to destination for inspection. There are insufficient areas within the maritime Port of Guam to offload cargo and inspect contents of sea containers. These inspection facilities must have sufficient lighting, inspection tables, and dedicated areas as specified by APHIS–PPQ to detect and identify intercepted pests on foreign cargo, and confirm the integrity of animal product and byproduct shipments. Appropriate facilities will allow agriculture inspectors to increase their skills and abilities in pest detection.
- Maintain secure areas for storage of vehicles and cargo at the air and sea facilities to prevent the dissemination of plant pests and reduce risks of cross contamination of other cargo items. Sterile staging facilities for incoming and outgoing vehicles and other cargo must be maintained at military and commercial locations.

- Build out the foreign inspection area for passenger clearance in the main terminal at Andersen AFB to a sufficient size for physical inspections of passenger baggage. The facility lacks space, lighting, and equipment (e.g., x-ray equipment, tables, and materials for collecting samples) sufficient to enable GCQA to complete all aspects of inspection.
- Ensure there are sufficient inspection facilities for express courier operations at the airport.
- Replace the garbage grinder drainage pipes with pipes sufficient in diameter (minimum of 4 inches) for effective drainage and disposal of ground-regulated materials in the new GCQA cargo inspection facility at the A.B. Won Pat International Airport.

Develop/enhance the tracking system for all cargo with unique identifiers for cargo shipments.

Include an electronic system for tracking, identifying, and collecting data from manifests for containerized commercial cargo arrivals to Guam and Saipan to streamline the import process while maintaining biosecurity.

This recommendation is especially necessary for cargo that originates in areas affected with significant plant and animal pests and diseases. Implement a data collection system and incorporate it into a centralized, secure system that could be modeled on the one used by CBP. Though all arriving cargo is subject to inspection, selection of containerized cargo is based on the shipping company's paper manifest that itemizes container contents (Merfalen, personal communication). The paper-based system of recording, identifying, and tracking these manifests is vulnerable to missing or lost documentation, unregulated and recurring biosecurity breaches, and omission from integration with electronic tracking. Develop MOUs with other entities to share shipping information across the region.

Ensure an adequate number of canine inspection teams to detect animals, plant materials, plant pests, and animal products and by-products. Teams should be scheduled routinely at airports, maritime ports, and the USPS mail facility for screening baggage, express mail carrier packages, and other cargo or incoming mail.

Establish decontamination sites for cleaning military and civilian equipment. Such sites must be available at all locations where military training exercises will take place and at both military and commercial maritime ports and airports. The importer bears the costs of remedial cleaning. Procedures should meet USDA-APHIS standards for soil-contaminated vehicles and equipment. Wash racks planned for the naval facility are not available at the commercial port. They should have sufficient water supply with high-pressure cleaning capability and lifts or ramps for access to undercarriage areas. Remedial cleaning must include the interior and exterior, engine compartments, and trunk areas with special attention to undercarriage, wheel wells, etc., as sites for soil, plant materials, and invasive species. Decontamination sites should have a quarantine area for storing contaminated equipment prior to cleaning. Precautions must prevent contaminated water from running off into the soil. All wash sites and decontamination systems must be effective. At a minimum follow Technical Guide No. 31, *Armed Forces Pest Management Board, Retrograde Washdowns: Cleaning and Inspection Procedures (AFPMB)*.

4.1.2 Offshore Mitigations

Establish an agricultural pre-clearance program in Okinawa, Japan, for all military equipment and other assets transferred to Guam and throughout Micronesia. The Pacific Command does not participate in any voluntary military agriculture pre-clearance program for containers, retrograde cargo, vehicles, or other assets. USDA-APHIS trains military personnel to conduct pre-clearance inspections. Shipments then would be selected randomly for inspections to monitor program efficacy. Large amounts of military assets will be moved from the closed facilities in Okinawa. Military shipments noncompliant with agriculture regulations or in need of cleaning will be refused entry or required to undergo remedial cleaning for entry requirements, leading to massive bottlenecks at the seaport. The military should support and fund this regional program similar to other Commands.

Include requirements and provisions in military and civilian contracts for the relocation to reduce the risk of introduction of animal and plant pests and diseases. Along with increased containerized cargo and vehicles, there will be substantially increased bulk shipments entering through the Port of Guam for construction and infrastructure upgrades. In addition to U.S.-origin workers and materials, other sources will include China, Japan, Korea, the Philippines, Malaysia, and Indonesia (Guam Contractors Association, personal communication). Provisions should include: 1) contractor-provided education for employees on import requirements (educational materials should include penalties [firing, pay-docking, etc.] for workers violating import regulations and should be developed collaboratively by officials who will have the greatest direct impact from the relocation [DoD, USDA-APHIS, Guam, and CNMI]; 2) contractor compliance with all import requirements [import permits, procedures at port of entry and beyond, etc.]; and 3) company-driven pre-inspection of their own materials for plant pests.

Require weed risk assessment for the importation of exotic plant species. Prohibit the importation of all plant species exotic to and not yet naturalized on Guam unless deemed unlikely to become invasive by a weed risk assessment with exceptions for plants historically imported without becoming invasive.

Require treatment of all WPM according to ISPM No. 15. All domestic and foreign, military and non-military WPM entering the Micronesia Region should be required to comply with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help reduce the presence of wood-boring pests.

Require phytosanitary treatment of all imported timber, including timber from domestic locations to mitigate the risk of pest entry on this pathway. Required treatments should be effective in removing pests.

4.1.3 Point-of-entry Activities

Conduct agricultural inspection of arriving conveyances, military and non-military, for plant pests and animal contamination. Inspection must include a thorough search of the exterior and the interior of the conveyance for plant and animal pests and wildlife of concern. GCQA officers must be allowed to inspect military vessels as USDA-APHIS cooperators. Other jurisdictions must also have the ability to inspect U.S. DoD craft that enter their ports.

Minimize pest contamination of containers and WPM by:

- Minimizing outdoor storage
- Sealing storage site surfaces
- Keeping storage sites clean
- Controlling pests around storage sites
- Limiting use of nighttime lighting around storage sites

Treat storage areas with molluscicides or install barriers to prevent mollusks from infesting WPM and shipping containers. Remove weeds and other contaminants from container and WPM storage areas. Storage areas should be hard surface or gravel.

Conduct phytosanitary inspection of WPM. Thoroughly inspect an adequate percentage of all domestic and foreign, military and non-military WPM accompanying agricultural and nonagricultural cargo for pests. WPM must not harbor organisms. SOPs should require consistent inspection methods. All inspections and interceptions should be documented. Pest interceptions should be recorded in an appropriate database to be available for analysis that may contribute to safeguarding improvements and quality control.

Clean containers and conveyances that arrive in the Micronesia Region contaminated with soil or exotic plant pests. Follow all APHIS policies and guidelines as applicable. Evaluate the effectiveness of current cleaning methods, and improve as appropriate.

Conduct phytosanitary inspection for contaminating pests of all incoming construction materials including materials previously treated or cleaned (for recontamination after treatment) and construction material from the United States.

Properly clean all equipment (construction and military) according to APHIS guidelines prior to entry into any part of the Micronesia Region to remove hitchhiker pests and soil contaminations. Equipment must be cleaned before moving within the Micronesia Region (between countries or islands of the same country, and, where appropriate, between areas of the same island).

Adopt a local DoD-GCQA MOU to codify agreements, clarify collaborator roles, and establish protocols and procedures for military vessel and cargo inspections. GCQA must be allowed to monitor military ships to fulfill responsibilities under USDA regulations and authorities agreed upon with USDA-APHIS.

Improve detection methods for rodents and other wildlife on vessels and in cargo. Rodents and other wildlife have been implicated in the transmission of zoonotic diseases. Methods may include trapping, monitoring for signs, etc. Rodent detection methods are not well developed and other wildlife detection methods have not been well documented. NAVMED P-5010-8, the Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology (U.S. Navy BMS 2004) outlines preventive measures for rodent control on ships, including proper sanitation, pier side inspections, rat

guards, illumination and movement restrictions, glue boards, snap traps, and limitations on vessel access points.

Inspections are constrained by resources to only a portion of air freight conveyance crates and containers. Air cargo conveyance crates and containers tend to be inspected if shipments are labeled as containing agricultural products, have insufficient or improper documentation, or are from a country of concern. Standardized methods similar to the APHIS-PPQ Agriculture Quarantine Inspection Monitoring Program are needed for random container searches regardless of documentation, type of shipment, or country of origin. Allocate funding to increase the number of containerized and crated air cargo shipments to be inspected. Paperwork for air cargo shipments arriving in crates and containers should be automated for more rapid selection of containers to be screened and for new avenues for implementing pre-clearance procedures.

Mandate and enforce regulations for handling palletized cargo. Contamination can occur during the packing, handling, and staging processes prior to arrival as imported cargo or after arrival when staged for loading for inland transport. Optimally, packers should handle and pack cargo items individually, especially those of high risk. Mandate and enforce regulations for palletized cargo, including procedures for labeling, packing, and transport prior to arrival and for eventual staging and loading for inland transport after arrival. Personnel must be trained in identifying high-risk cargo and handling it to reduce contamination. The likelihood of visually detecting species in complexly combined cargo is lower than in cargo with few hiding places, especially for BTS detection by canine inspection teams.

Enhance collaboration between USFWS and GCQA. GCQA and other agencies with port-of-entry inspection responsibilities should work with USFWS to increase the effectiveness of interdiction capabilities and inspections for wildlife and their products at the ports of entry to prevent the introduction of animal and zoonotic diseases.

4.2 CARGO

Agencies responsible for enforcing USDA-APHIS regulations should have access to the APHIS ePermits system for assistance in clearance of restricted agricultural materials. APHIS import permits may be required, in conjunction with local import permits, for various agricultural commodities imported into Guam and CNMI. All officers acting under an MOU with APHIS inspecting for agricultural commodities need access to the ePermits system to validate APHIS import permits presented with incoming shipments.

Inspections are constrained by resources to only a portion of air freight conveyance crates and containers. Air cargo conveyance crates and containers tend to be inspected if shipments are labeled as containing agricultural products, have insufficient or improper documentation, or are from a country of concern. Standardized methods similar to those of the APHIS-PPQ Agriculture Quarantine Inspection Monitoring program are needed for random container searches regardless of documentation, type of shipment, or country of origin. Allocate funding to increase the number of containerized and crated air

cargo shipments to be inspected. Paperwork for air cargo shipments arriving in crates and containers should be automated for more rapid selection of containers to be screened.

Construction and other commercial equipment must be inspected, cleaned, and washed down at the port of entry, and military aircraft and other military vehicles arriving as maritime cargo must be inspected, cleaned, and washed down at a retrograde wash facility before entry. Washdown procedures for military vehicles should target soil, plants, insects, and other wildlife. Tracked vehicles can be cleaned on shore only if they can be reloaded without recontamination of the treads; otherwise they must be cleaned on the ship's well-deck. They should be cleaned to USDA-APHIS standards (USDA-APHIS-PPQ Treatment Manual 2008) prior to shipment from the port of departure. Vehicles may be cleaned at the port of entry provided wastewater soil is collected and drained fully into an approved collection system.

4.2.1 Live Animals

All health certificates and necessary permits should accompany imported livestock, poultry, and other animals. Make sure the animals are subject to health inspection by the territorial veterinarian and quarantined as required.

4.2.2 Animal Products and By-products

Require the use of USDA or GDOA VS import permits or for restricted animal products.

4.2.3 Plant Products

Standardize methods and implement the random inspection of air cargo containers regardless of documentation, type of shipment, and country of origin. Paperwork for air cargo shipments arriving in crates and containers should be automated for more rapid selection of containers to be screened, and for new avenues for implementing pre-clearance procedures.

4.2.4 Propagative Plants

There should be sufficient equipment and supplies at the Plant Inspection Station for the full range of necessary inspections. Processes and equipment should provide for intensive inspections for insect, plant pathogen, foreign weed seed, and invasive plant detection in propagative plant shipments.

4.2.5 Wood Packing Material

Re-export or treat infested or noncompliant WPM. Non-compliant and infested WPM should be treated as regulated garbage; if not re-exported it should be incinerated or sterilized. Chipped WPM may present a pest risk when the chips are re-used or improperly disposed.

4.3 MAIL

Follow a model similar to that established in Hawai'i by utilizing detector dogs for establishing probable cause for inspection of first-class (domestic) USPS packages.

Use appropriate x-ray technology for all foreign-origin mail. Ensure that all x-ray equipment is in working order and operable.

PPQ should work with CBP and the Hawai'i Department of Agriculture for an adequate level of inspection in Hawai'i.

Establish effective working relationships between customs officials, agricultural officials, and USPS personnel in Guam so safeguarding personnel can carry out their responsibilities. Guam safeguarding personnel must have sufficient access to the postal facility to conduct appropriate biosecurity screening at all times. This could be modeled after the USPS policies in Hawai'i. The USPS in Hawai'i granted U.S. Customs officers and canine full access to the facilities to perform all inspection activities while international mail is being processed or is in the facility. While domestic mail is being processed or is in the facility in Hawai'i, USDA PPQ officers and canine have full access to the mail to perform all inspection activities.

Develop secure procedures for opening international mail without customer witnesses.

Record and analyze data on pest interceptions in mail. Analysis should improve targeting of phytosanitary and general sanitary hazards.

4.4 REGULATED GARBAGE

Consider construction of a waste-to-energy facility on Guam. The current landfill is not EPA-compliant. The future landfill will have only an estimated 30-year capacity with the increased military presence (Cruz 2010). A waste-to-energy facility will incinerate garbage, reduce the need for landfills, reduce the exposure of the environment to agriculture diseases and pests, and provide electricity to a significant number of households. Such a facility would serve as back-up processor of regulated garbage if other equipment is inoperable.

Appropriate disposal mechanisms should be in place before training on Tinian and other locations begins. Each location should have mechanisms to dispose of garbage generated on-island as well as regulated garbage from other locations. The Tinian incinerator should be repaired ASAP since periodic DoD training has already started there. The incinerator owned by the Tinian government is currently inoperable, the overfilled local dump was ordered closed previously, and the military is not authorized to use facilities approved by EPA. Transporting garbage generated during DoD training events violate APHIS regulations over movement of regulated garbage between U.S. possessions (9 CFR § 94.5, 7 CFR § 330.400-403).

DoD should consult with PPQ or local governments so they institute appropriate mitigations for handling regulated garbage in compliance with APHIS and local regulations. Collaboration with appropriate officials of Tinian or of any U.S.-affiliated country should ensure that proper (land-filled, sterilized, or incinerated) on-island disposal can be achieved. Military activities are currently not compliant with appropriate measures for handling regulated garbage. Some of the known issues which need to be addressed include:

- The use of sterilizing equipment without automatic temperature/time recording devices.
- Failing to use appropriate containers to move regulated garbage.
- Authorizing dumping of pulped-food waste within 12 nm of the coast of Guam and other U.S. territories and affiliates.
- Planning to move garbage generated during training on Tinian to Guam or Saipan.

begins.

Unannounced monitoring of APHIS-regulated garbage compliance agreement holders should be conducted at least quarterly. Appropriate agency representatives must be trained to conduct enforcement visits to compliance agreement holders to monitor whether they follow required procedures.

Include specific information in the Port Authority of Guam Master Port Plan to address equipment and other resources needed to handle regulated international garbage properly. There is nothing in the Guam Master Port Plan addressing resources and equipment required to handle regulated international garbage.

Enforce current swine health protection regulations requiring cooking of certain types of food waste (heating to an internal temperature of 212°F for 30 minutes) before feeding to pigs. The proper cooking of food waste will prevent the dissemination of foreign animal diseases of concern (9 CFR § 166).

Consider all garbage within the passenger sterile area for incoming and transiting passengers at the A.B. Won Pat International Airport to be regulated garbage. Food, food materials, and other prohibited and restricted agricultural and wildlife materials discarded in sterile area receptacles and bathrooms are handled as routine trash. These materials go to the local dump without mitigation and can present a significant risk with increased numbers of temporary workers on Guam. This garbage should be removed and processed under USDA compliance agreements.

4.5 EXPORT

Preferentially load conveyances in a way that minimizes pest entry whenever possible. For example, avoid night-time loading because the lights attract insects. Workers should be trained in and cognizant of pest conditions at all times.

Provide a pre-clearance staging area for all military vessels requiring immediate departure from Guam.

Coordinate USDA-APHIS agreements with commercial air cargo shipping agencies to prevent invasive species transportation. Despite high levels of cooperation by most cargo export entities, APHIS-WS still makes regular discoveries of previously unknown cargo handling processes or companies, and there are several private companies on Guam that refuse to provide information on or access to outbound cargo for inspection purposes. Coordinate agreements and procedures with air cargo shipping agencies for

handling cargo, including packing, over-land transport, cargo-staging, palletizing, canine inspection, and final loading.

4.6 REGULATIONS, GUIDELINES, AND COMPLIANCE

Systematically review all guidelines and SOPs of agricultural relevance so they are clear, complete, detailed, and in compliance with appropriate laws and regulations. Develop guidelines or SOPs where lacking.

Put appropriate local and federal regulations in place to carry out biosecurity measures to prevent the introduction of plant and animal pests and diseases. Regulations should support the issuance of penalties and fines to enforce compliance.

Utilize the APHIS-PPQ port manuals as guidance in locations with APHIS cooperators as appropriate. The manuals contain information on port operations and commodity regulatory decision making designed to enhance biosecurity at the ports of entry.

Revise and update all military guidelines and SOPs for compliance with APHIS regulations where appropriate. In some cases, the military uses outdated guidance with inaccurate information. For example, the OPNAVINST 6210.2 lists only the States, District of Columbia, Guam, Puerto Rico, and the U.S. Virgin Islands as the U.S., notably excluding the CNMI and American Samoa (7 CFR § 330.400[a] and 9 CFR § 94.5[a]). The NAVFAC Guam Program Management Office/PSC 15 Jan 2010 *Summary of Navy Pollution Control Discharges Restrictions* authorizes the discharge of garbage containing pulped or comminuted food within 3 to 12 nm of the coasts of Guam and the CNMI. This instruction is accurate in only very specific situations; much of this garbage is regulated by USDA for agricultural issues.

The military should execute an MOU with all Micronesian countries and develop appropriate agricultural disease exclusion and invasive species SOPs for compliance when conducting activities in their respective countries. The U.S. Navy has a Seabee unit stationed in the Republic of Palau. How much this unit will participate, if at all, in the military relocation is unknown. Military officials do not inform Palau quarantine officials when aircraft arrive, leave trash for government officials to destroy, and drop cargo and supplies for Palau construction projects. Equipment is washed on the tarmac without proper drainage facilities.

Develop BMPs for contractors and construction sites. Work with industry to gain support preventing the introduction and spread of exotic plant pests. Implement “clean” practices at construction sites to minimize land disturbance that spreads plant pests.

Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other businesses as appropriate to promote the sale and use of native and noninvasive plants. This code of conduct should encourage businesses:

- To make their staff knowledgeable about invasive plants.
- To inform their customers about invasive plants.

- To report immediately any likely exotic pest organisms found on their premises.
- To use native or noninvasive plants locally sourced.

Revise the DoD landscape plan by removing plant species with the potential to be invasive in the Micronesia Region or Hawai'i. Request technical support from the University of Guam as appropriate.

4.7 TRAINING

Provide adequate information about the potential adverse consequences of the introduction and establishment of plant and animal pests and diseases and ways to prevent their spread. Provide a list of enterable and prohibited materials. Create awareness of the potential legal consequences of violations. Inform people how they can contribute to exotic species-prevention efforts. Alert the following groups: 1) military personnel and dependents; 2) nonmilitary workforces; 3) tourists; 4) the general public; and 5) private industry.

Provide training to increase inspection and identification expertise. Safeguarding inspectors (both civilian and military) should receive regular adequate training in proper techniques for detecting, collecting, recognizing, and identifying pests. A communication network for continuous sharing of new information is recommended.

Provide specific and detailed guidance to military personnel on how to inspect clothing and personal effects for plant pests.

Enhance training for military personnel and their dependents about phytosanitary and general sanitary regulations and the risks of sending or receiving agricultural and wildlife materials in the mail.

Train inspectors specifically on livestock, wildlife, and poultry diseases and pests.

Train appropriate agency representatives to conduct enforcement visits to APHIS Compliance Agreement holders handling regulated garbage. The number of personnel trained to monitor compliance agreement holders for functional equipment and appropriate procedures in handling regulated garbage is insufficient.

Develop a wildlife reference collection (i.e., taxidermy mounts or computer photo files with APHIS-WS) to aid identification of incoming species. Adequate resources (taxonomic keys, microscopes, etc.) should be available for assistance in taxonomic identifications.

4.8 EDUCATION AND OUTREACH

Develop education and outreach programs to inform the public and the military about the potential harmful effects of animal and plant pests and diseases with emphasis on consequences of smuggling animals and agricultural products. Provide adequate information on ways to prevent the spread of plant and animal pests and diseases. Provide reports and newsletters to educators, journalists, lawmakers, and business and community leaders; develop curricula for local schools; provide lists of

enterable and prohibited materials; place posters in private and public mail facilities; and conduct a pre-education survey of residents and other stakeholders to gauge their understanding of animal and plant pests/diseases introductions/invasions and subsequent impacts. Create awareness of the potential legal consequences of violations. The following groups should be included: 1) military personnel and dependents; 2) nonmilitary workforces; 3) tourists; 4) the general public; and 5) private industry.

Inform temporary workers about the consequences of carrying, mailing, or receiving restricted and prohibited agricultural and wildlife commodities or live organisms by working with contractors and other organizations hiring temporary foreign workers. Coordinate with contractors employing migrant workers and with overseas employment agencies for migrant workers. Communicate the reasons for prohibiting these materials in the Micronesia Region, including the potential loss of business if invasive species are introduced to Guam and other Micronesia Region locations.

Develop voluntary agreements between Guam government officials and pet stores and other businesses in the pet trade industry to curtail smuggling and create safe avenues for import (i.e. no imports or sales of prohibited animals or plant pests).

4.9 MONITORING, SURVEILLANCE, AND ADDITIONAL SAFEGUARDING PRACTICES

Conduct background surveys as soon as possible to establish baselines for plant pests and livestock and wildlife populations and diseases. Initial measures to prevent introduction of livestock, poultry, and wildlife diseases should be implemented with a surveillance and monitoring strategy to determine whether measures perform adequately. These measures then should adjust to improve biosecurity.

Develop a biosecurity surveillance system for improved data collecting, reporting, and information sharing. A paucity of information is available to fully assess risks from intentional and unintentional movements of animal and plant pests and diseases posing significant risks to biosecurity efforts in the Micronesia Region and Hawai'i. A biosecurity surveillance system could serve as an early detection program for plant, animal, and zoonotic pests and pathogens emerging in Pacific Rim countries. Sustained surveillance and record keeping of interceptions will facilitate tweeking biosecurity mechanisms to reduce future incursions ultimately decreasing risks from varying threats and changes in the ways cargo and people are moved in the future.

- A well-documented process of pest and disease prioritization, surveillance, data collection, and record keeping must be followed. The system should include routine surveillance for wildlife, livestock, and poultry diseases and vectors as well as plant pests.
- Specific surveillance methodology should be appropriate for target species, (i.e. modifying sampling programs to account for behavioral differences in diurnal and nocturnal lifestyles). Utilize systematic surveillance for plant pests following the model of the Cooperative Agriculture Pest Survey (CAPS), and include both military and civilian properties as appropriate.
- Such a system should improve communications of survey results among all island mitigation programs. The communications plan will allow GCQA and other responsible biosecurity

authorities to react to changing risks posed by travelers and cargo based on countries of embarkation or origin.

Encourage and participate in actions to preserve biodiversity.

Include actions taken by joint agency collaborations like the Micronesia Challenge and the Micronesia Regional Invasive Species Council.

Conduct periodic surveys of ethnic markets, pet stores, and grocery stores to identify and intercept prohibited animals and animal and plant products following the model of the USDA-APHIS-PPQ Smuggling, Interdiction and Trade Compliance program.

4.10 OVERSIGHT

Centralize biosecurity efforts for maximum effectiveness. A central group acting as a liaison can bridge gaps between formal and informal and military and civilian communications. A central group would outline the current network of biosecurity communications in the Micronesia Region; find communication gaps; publish information in appropriate formats for public, private, and military sectors; and issue media and news releases on biosecurity.

Establish a Pest Risk Committee with participants from various agencies and organizations responsible for managing exclusion and control efforts at the ports of entry. This group could function as the operational arm of the larger regional biosecurity group.

4.11 EMERGENCY RESPONSE

Develop a hazard response plan for animal and plant pests with all entities responsible for these activities. Include military and civilian public health authorities for diseases with serious animal health and zoonotic potential.

Improve rapid response capabilities at military and commercial airports on Guam and the CNMI Islands of Saipan, Tinian, and Rota. Rapid response measures prevent establishment of introduced pest species. Rapid response takes place at and within the border at levels ranging from federal to local community involvement. Review the current process for rapid response to border and post-border detections and unconfirmed reports or sightings.

Improve rapid response capabilities at military and commercial airports on Guam and the CNMI Islands of Saipan, Tinian, and Rota.

Conduct practice drills to hone response skills and test communications.

4.12 CONCLUSIONS

The scope of the MBP is to describe mitigation recommendations sufficient to prevent and mitigate risks posed to human health, animal and plant health, economies, and ecologies of the Micronesia Region from the intentional or accidental spread, introduction, or establishment of terrestrial animal and plant

invasive species and diseases as a result of proposed military activities. Guam must be emphasized because the proposed military activities are focused there. Prevention of both the introduction of invasive species to Guam and the transport and spread of BTS from that island are the broad objectives and priority concerns. Guam is a transportation gateway for the rest of the Micronesia Region, facilitating the wide-spread movement of species.

Risks of the introduction of invasive species and diseases to Guam and the Micronesia Region are diverse. Plant propagative material may present phytosanitary risks as either a pathway for introduction of exotic plant pests or as an invasive species. Increased importation of plant propagative material during the military relocation may increase the risk of pests entering the Micronesia Region. The current DoD landscape plan may facilitate the spread of potentially invasive plants. Increases in plant propagative imports as a result of the military relocation will place increased demands on customs staff and infrastructure resources and may allow more pests to enter the Micronesia Region.

The introduction of many of the livestock and poultry diseases considered in this risk assessment could have major consequences to animal and human health throughout the Micronesia Region and far-reaching impacts on trade in the rest of the U.S. With the arrival of increased numbers of pet dogs and cats, current resources for inspection and follow-up could be overwhelmed. There is no ongoing surveillance for livestock and poultry disease on Guam; therefore, it is difficult to know what disease agents are already in the region and to detect the introduction of an exotic disease agent. Lack of a diagnostic laboratory in the region also diminishes the ability to detect disease agents. Rapid detection is critical to timely responses to new disease introductions, especially with the highly transmissible exotic diseases considered in this assessment. The potential for importation of zoonoses that pose major public health threats warrants increased surveillance for imported wildlife in the United States and Micronesia.

Safeguarding Guam and the Micronesia Region during the military relocation is challenging with the number of pests continuously approaching their shores. While federal, territorial, and military regulations aim to mitigate effects of the introduction of hazards, the estimated increase in population and goods from the military relocation will strain current capacity for inspection and interdiction of illegal goods, and increase the likelihood of invasive species throughout the region. There is reason to believe that Guam's biosecurity protection systems and resources may be overburdened and underfunded and therefore not sufficient to inspect cargo, passenger baggage, and conveyances appropriately during the military relocation.

The challenges, risks, and costs of long-term control and eradication of an established invasive species could be significant. The most cost-effective approach to protecting natural and agricultural resources on Guam and throughout the Micronesia Region is prevention and early detection.

5 OUTREACH

To reduce the demand on protection program resources, an outreach program should increase awareness of risks from the introduction of invasive species, pests, and plant and animal diseases throughout the Micronesia Region. In support of outreach, a comprehensive training program should be developed to increase awareness of risks and consequences to agriculture, human health and safety, the environment, and the economy from the transport of potentially invasive plant and animal pests, diseases, and species to Guam and the other Micronesia Region islands.

5.1.1 General Outreach Program

The outreach program should include awareness and prevention training in sources, activities and conveyances (pathways). Knowledge of certain high-consequence or high-probability animal and plant types or species is essential to reduce the frequency of personnel, equipment, and cargo transport of infective or invasive species on conveyances within the Micronesia Region.

5.1.2 Strategic Plan

A strategic plan should be developed to set objectives, design components, assign roles, determine costs, and integrate outreach planning with the biosecurity plan leadership.

5.1.3 Target Groups

The outreach program should target the following audiences:

- Military personnel and dependents relocating to the Micronesia Region
- Local government entities
- NGOs
- Guam and other Micronesia Region residents
- Foreign contractors and temporary workers
- Agents of commercial airlines
- Owners of shipping, fishing, and recreational craft
- Local businesses (e.g. pet stores and purveyors of specialty foods)
- Community associations
- Schools and universities
- Visitors to the region

5.1.4 Program Components

All components of the outreach plan should be well-defined, including:

- Publishing a regular schedule of outreach events.
- Scheduling locations or venues for outreach events that are convenient for the target audiences.
- Formalizing a message development process for high-risk species and their pathways.
- Developing information delivery systems for print media (newspapers, periodicals, posters, handouts, etc.), television, radio, and the Internet.
- Developing a mechanism for outreach communications to military personnel.

5.1.5 Measures of Program Efficacy

A method of measurement should gauge the effectiveness of the outreach program. This metric could be determined in many ways specific to outreach program objectives. Each outreach event should keep a record, tracking participating organizations, venues, topics covered, and any lessons learned. This information should be analyzed to re-evaluate and re-target the outreach program content, format, venues, and audience as needed.

Suggestions for general metrics to measure program effectiveness:

- Number of outreach events
- Number of individuals or organizations reached
- Number of individuals or organizations participating in program events
- Number of reports from outreach targets of suspicious animals or plants
- Number of ancillary education or outreach programs developed by governments, businesses, schools, community organizations, and citizens

5.2 ORGANIZATIONS AND ROLES

A planning and coordinating body for each jurisdiction of Micronesia and Hawai'i should be designated to direct and manage outreach activities. Every organization with a stake in the biosecurity of the Micronesia Region and Hawai'i should engage in the outreach planning process. Existing programs should be leveraged wherever feasible. For example, the Office of Economic Adjustment and the Military Integration Management Committee conduct community outreach dialogue sessions on Guam, the CNMI, and other locations to hear citizen concerns. Such organizations could expand their charters to formal outreach and awareness programs using established educational materials. Another good example is that of the regional response team which has been conducting outreach on IAS in all jurisdictions (except Hawai'i) for 10 years. RISC as a regional IAS council for Micronesia should also be involved in this development process.

5.3 FUNDING RESOURCES

In accordance with planning, managing, and reporting outreach activities, a contracting officer and an oversight committee are necessary to develop a source of funding. The primary stakeholders, such as

the U.S. military, Guam, and other Micronesia Region islands, should determine appropriate funding sources for a comprehensive outreach program. Potential increases in current user fees or new fees could be imposed on permitted imports. Legislatively appropriated funds could be utilized for these activities. The justification for this legislation is that outreach efforts would be effective long-term prevention campaigns.

5.4 MICRONESIAN REGION AWARENESS TRAINING AND OUTREACH:

The outreach program should involve biosecurity partners throughout Micronesia. A representative body should coordinate outreach programs among sovereign nations for each of these programs.

A comprehensive and continued information program on identification and potential impacts of invasive plant and animal species in Guam should be developed. The information in this program should target: residents, visitors, military personnel, businesses, governments, and associations throughout the Micronesia Region.

The program should provide information through the distribution of printed materials that show examples of how various released species can become economic, ecologic, or human-health threats. Schools should be target audiences to educate children on the importance of preserving natural ecosystems.

A person or organization should be designated as responsible to the Government of Guam (GovGuam) for developing high-priority outreach messages about invasive species and their pathways. GCQA, GDOA, and the Guam Invasive Species Advisory Committee are candidate organizations.

Topics should be highest-rated risks as determined by probability of introduction and level of impact. Suggested biosecurity topics include:

- Import and export requirements
- Precautions in traveling to Guam and other Micronesia Region islands
- Recognition and reporting of BTS and other invasive species
- Risks from domestic and international mail
- Proper handling and disposal of regulated garbage
- Pre-inspection of cargo for shipment
- Procedures for reporting sudden deaths in wildlife
- Personal sanitary precautions—washing shoes, cleaning vehicle tires, and checking for invasive species and wildlife of concern
- Reports of illegal movement of restricted agricultural commodities or invasive species
- Reports of observed incidents of invasive species on Guam and other Micronesia Region islands

5.5 OUTREACH METHODS

5.5.1 Training

Official sponsors who assist with relocation of military personnel should be designated and trained per regulations on the movement of animal and plant products. Designated sponsors should work with contractors and temporary workers to identify potential introduction pathways and reduce risks of transporting invasive species wherever possible.

5.5.2 Educational Materials

Educational materials for the outreach program could include reports and newsletters to educators, journalists, lawmakers, and business and community leaders; curricula for schools; and a pre-campaign poll of island residents to gauge levels of awareness of species introductions/invasions and subsequent impacts. Educational materials should portray the hazards of the import of illegal animals and plants and their products and by-products. Information should be posted in public locations in USPS mail and express courier facilities to inform customers of the potential economic and environmental impacts of exotic plants and pests.

The education program should focus on the dangers of maintaining populations of invasive species for food or sport with examples of potentially invasive species (e.g., rabbits, banteng, water buffalo, Polynesian rat, spotted turtledove, water frogs, African snails).

5.5.3 Outlets and Media

The following outlets and media should disseminate essential outreach information and answer questions and concerns about the risks of invasive species:

- Meetings in local communities
- Radio and television public service announcements
- Newspaper articles
- Websites (e.g., military, local governments, and federal government) that address restrictions and regulations on movements of animals and plant materials

5.5.4 Monitoring

A response network should be developed for community members to report incidents of illegal sales (independent or retail), illegal releases of plants or animals, and invasive species sightings. Community monitoring efforts should be aligned with those of local governments in a formal monitoring and surveillance plan (see Chapter 9, *Monitoring and Surveillance Plan*) to enhance biosecurity efforts.

5.5.5 Incentives

Incentives to participate in an outreach program should be explored. For example, state or local governments could offer tax incentives or preference points for municipal projects, trade agreements,

or monetary awards. These measures would be codified in public proposals that solicit Micronesian projects, reducing the burden on other funding sources.

Nonprofit organizations and higher-learning institutions promoting outreach programs could receive direct grants. Private industries that initiate an awareness and education program could receive tax advantages or preferential consideration for government contracts. Outreach to trading countries could be on the terms of trading or shipping agreements. Local governments could receive direct grants or reductions in financial obligations to the state government.

6 MONITORING AND SURVEILLANCE

6.1 INTRODUCTION TO MONITORING AND SURVEILLANCE

A Micronesia Region monitoring and surveillance program is important to improve efficacy in detecting the occurrence of foreign animal and zoonotic disease and plant pest introduction on Guam and other Micronesia Region locations. The RA recommends establishment of specific baseline monitoring for each program.

The monitoring plan should select specific locations and conveyances of potential introduction of high-risk or high-probability invasive species. A surveillance plan should present methodologies to collect and analyze data leading to action taken to prevent and control the introduction and establishment of invasive species. The plan should describe the strategies, resources, and methodologies that should be developed and applied to manage a monitoring and surveillance program for high-consequence or high-probability risk pathways and species.

USDA-APHIS-PPQ promulgates standards for plant pest and disease monitoring. For current information on survey protocol for specific pests, please consult the USDA-APHIS-PPQ Domestic program manuals at: http://www.aphis.usda.gov/import_export/plants/manuals/domestic/index.shtml.

6.2 OBJECTIVES

Objectives for a Guam and Micronesia Region monitoring and surveillance program include the following:

- Develop a comprehensive biosecurity surveillance system for an improved data collection, reporting, and sharing network.
- Conduct periodical surveys of markets and pet shops to intercept prohibited animals and plants and their products.
- Implement pest survey programs for the early detection of pests from imported fruits and vegetables, WPM, garbage, and construction materials.
- Augment surveillance measures and equipment at military and commercial airport and harbor ports-of-entry.
- Inspect imports randomly (e.g., cargo containers) for plants, plant pests, insects, disease agents, and wildlife.
- Develop a system of routine systematic surveillance for livestock and bird and poultry diseases and vectors.
- Work with the military for access to military sites and activities to monitor for pest conditions.
- Establish standards for surveillance reports and systems to manage surveillance data.

6.3 COMMUNICATIONS SYSTEM

All organizations and offices associated with Guam and Micronesia Region monitoring and surveillance programs should establish a communication system for pest surveys, outreach programs, port inspections, and pest identifications. A SOP should be developed for communication with rapid response teams (Chapter 10, *Rapid Response Plan*). The communications plan should allow PPQ, GCQA, GDOA, and other authorities responsible for inspection and identification to react to changing risks based on countries of origin of arriving travelers.

6.4 MONITORING AND SURVEILLANCE PLAN

6.4.1 Regulations

APHIS and Guam regulations justifying a monitoring and surveillance program include:

- AHPA
- PPA
- NEPA, 42 U.S.C. § 4321 et seq.
- AWA
- WBCA
- GARR Titles 8, 9, and 10
- GDOA, 5 GCA § 60108
- APHIS plant health regulations (7 CFR)
- APHIS animal health regulations (9 CFR)

6.4.2 Scope

The plan objectives should determine the scope of monitoring and surveillance activities. Ideally, a regional monitoring and surveillance program should be integrated closely with each location's biosecurity program. The regional monitoring and surveillance organization should serve as a communication network, rapid response resource, and information source for identifying and reporting potential invasive species incidents.

6.4.3 Organization/Roles and Responsibilities

A coordinating body should be designated to plan and direct all monitoring and surveillance activities on Micronesia Region locations and this body should coordinate closely with similar authorities in Hawai'i (as well as other locations which are linked to Micronesia by trade and/or human transport). Roles and responsibilities for the Micronesia Region monitoring and surveillance program should be identified and described and responsible parties designated according to program expertise. Individuals from across the biosecurity spectrum should participate in the monitoring program. At a minimum, each organization should reach out to the public. RISC, jurisdictional ISC, and a regional ISC would be the

most likely components of this regional coordination body. Most jurisdictions already have IS councils which could feed information via their ISC to the RISC which in turn would support and guide the regional ISC who could then serve as the main point of contact with Hawai'i and other locations regarding IAS issues for Micronesia.

6.4.4 Identification of Target Species and Pathways

High-risk species and pathways should be priority targets for monitoring and surveillance. The APHIS Terrestrial Risk Assessments in Appendix A identify these pathways and targets.

6.4.5 Monitoring Methods

Local governments should determine monitoring methods including SOPs, according to the threat and in conjunction with each technical program area such as plant (APHIS-PPQ), agricultural animal (APHIS-VS), and wild animal (APHIS-WS). These methods should be integrated into a comprehensive monitoring program that leverages resources and aligns strategies across risk groups.

6.4.6 Locations/Schedules

Appropriate governmental entities should select high-priority surveillance locations. Monitoring activities should be based on current APHIS risk assessment data and recommendations associated with special-risk military operations and training events.

6.4.7 Resources

Sources for critical funding, personnel, equipment, and materials should be ascertained. Offices to determine resource needs, coordinate resource requests, and manage resource allocation should be established. A monitoring and surveillance coordinating body should take the lead in requesting needed resources.

6.4.8 Reporting

Reporting procedures for detections of invasive species through monitoring or surveillance programs are unique to each program area. See Chapter 10, *Rapid Response Plan*, for details.

6.5 CURRENT APHIS AND GUAM MONITORING AND SURVEILLANCE PROGRAMS

A monitoring and surveillance program should leverage existing programs of this type wherever possible. On Guam and in the CNMI, current ongoing monitoring activities are limited to BTS and plant pests. These programs can serve as foundations for a more extensive and far-reaching monitoring program for Guam and other Micronesian Region locations.

All current monitoring and surveillance programs should be enhanced. At this time, there is no ongoing systematic surveillance of livestock and poultry on Guam, an inadequacy that may hinder early detection of any introduced agricultural hazard.

APHIS-WS conducts the following disease monitoring programs in the United States:

Feral Swine Diseases. The National Wildlife Disease Program (NWDP) operates in management, research, surveillance, emergency response, education, and outreach for feral swine diseases. NWDP considers these animals, weighing up to 181 kg (400 pounds), non-native to the United States and invasive. They can be reservoirs of disease and can be hosts to a number of parasites threatening the U.S. domestic swine economy.

H5N1. Avian influenza is a Type A influenza virus found in some species of waterfowl and shorebirds. A particularly dangerous set of subtypes of this virus, called H5N1, is of particular concern for its potential impact on wild birds, domestic poultry, and human health if introduced into the United States.

Plague. Plague is a disease of concern to human, wildlife, and domestic animal populations within the United States.

Tularemia. Tularemia is a disease of concern to human, wildlife, and domestic animal populations within the United States.

6.6 NATIONAL MONITORING PROGRAMS

No national animal monitoring programs are current on Guam or other Micronesia Region islands. There are several programs that could serve as models for surveillance. The National Animal Health Monitoring System Program Unit conducts studies on health management of U.S. domestic livestock and poultry. Reports are available for aquaculture, beef cow-calf, beef feedlot, dairy, equine, food safety, goat, poultry, sheep, and swine. The National Animal Health Surveillance System is a program for animal health surveillance through ongoing systematic collection, collation, analysis, and interpretation of data and dissemination of information about animal health risks.

If opportunities such as on-island slaughterhouse operations arise, passive surveillance (e.g., sampling animals at slaughter for foreign and domestic animal diseases) should be conducted.

CAPS is a USDA-funded program that operates through cooperative agreements with state agriculture departments and universities. The CAPS program manages a plant pest list derived from a national survey committee through input from regional and state committees with support from leading scientific and regulatory specialists. CAPS uses a scientific system for prioritizing pests of significance to U.S. agriculture and the environment. The Global Pest and Disease Database system contains information for pest risk assessments. CAPS produces federally funded domestic surveys conducted by cooperators from National CAPS for plant pests, biological control agents, and weeds and provides a means of detection, documentation, and rapid dissemination of this information. Survey information is available from the National Agricultural Pest Information System database.

Domestic pest detection and survey activities traditionally have trapped exotic fruit flies and tracked occurrences of imported fire ants, gypsy moths, Japanese beetles, and witchweed. Other activities have been national surveys on various exotic plant pests, diseases, and weeds and some pest detection activities to help meet various export requirements of foreign countries.

The systems, methods, and resources of these programs could be applied to monitoring and surveillance on Micronesian Region islands. The monitoring and surveillance coordinating body should consult with APHIS experts to determine the feasibility and value of including Micronesian Region islands in these programs.

7 RAPID RESPONSE

A rapid response plan describes a formal process recommended for responses to reports of invasive species or animal disease outbreaks on Micronesian Region islands and the state of Hawai'i. This plan should identify authorities, policies, roles, resources, and procedures required for effective management of all plan components. A rapid response plan gives detailed guidance for awareness of potential invasive species and pathways; detection and identification of species or disease; deployment and management of resources; and reports to appropriate APHIS, Guam, and Micronesian Region authorities. The response plan should direct personnel in how to eradicate invasive populations when discovered through port inspection, reported through monitoring or surveillance programs, or established in a new Micronesian Region location.

Each plant or animal program should develop its own rapid response plan based on existing program policies, response structures, and procedures. Chapter 10, sections 10.9, 10.10, and 10.11, present information on emergency management and response processes developed for PPQ, VS, and WS, respectively. The plans, programs, systems, and resources described in these sections are included in this section as models and resources for invasive species emergencies on Micronesian Region islands and the state of Hawai'i.

APHIS has described emergency management structure and process in its Agricultural Health and Homeland Security Emergency Response Integration Plan (Volume 1, January 2007) developed by the APHIS Emergency Management Leadership Council, which provides guidance for rapid response plan development

(http://www.aphis.usda.gov/emergency_response/downloads/APHIS%20Emergency%20Integration%20plan%20final%202-1-07.pdf).

All Guam and Micronesian Region rapid response organizations and offices should establish a communication system and an SOP for incident reporting and rapid response.

7.1 RAPID RESPONSE OBJECTIVES

The primary objectives of the Micronesian Region Rapid Response Plan include the following.

- Community outreach and education is the most important part of any ED/RR effort. Without community engagement and education there will be nothing to respond to. The local communities are the eyes and need to be the reporters for potential invasive species incursions.
- Develop an emergency response plan or ERP in collaboration with appropriate stakeholders to mitigate, contain, and/or eradicate significant animal or plant pest and disease outbreaks with appropriate coordination. ERPs already exist in all jurisdictions for alien snakes and some jurisdiction have additional ERPs for other species, for example Yap has an ERP for Rhinoceros Beetles. These existing ERPs can be utilized to develop more generic ERPs for each jurisdiction.
- Support local rapid response teams for pest issues (most jurisdictions already have at least some staff which are trained and/or on standby for response actions).

- Improve rapid response capabilities at military and commercial ports on Guam, the CNMI, Hawai'i, Palau, Yap, Chuuk, Kosrae, Pohnpei, and the Marshall Islands.
- Expand the communication network system among responding agencies and groups for detection and reporting of suspected invasive plant, animal, and insect species and diseases of concern.
- Coordinate monitoring and surveillance programs with rapid response capability through community-watch groups and a pest species hotline to report sightings immediately. Most jurisdictions already have hotline such as the Pest hotlines for Guam and Hawai'i, and the BTS hotline for the CNMI. Jurisdictions which do not yet have dedicated hotlines often you a combination of key individual office and cell numbers and general emergency hotlines such as 911 for back-up. Ideally each jurisdiction will eventually have a dedicated pest hotline with trained staff answering, recording information from incoming calls and alerting proper authorities as needed.
- Leverage the BTS Rapid Response Team capability and utilize this existing framework as a partial model for development of truly regional early detection and rapid response capacities. The RRT team, although only a loose affiliation is in some respects regional and in the past has developed outreach programs across the MBP region, supported ERP development for each of the jurisdictions and has been involved in determining the credibility of potential IAS reports and response field actions for more than just BTS.

7.2 REGULATIONS

The development of a rapid response plan is justified in the following regulations:

- AHPA
- PPA
- Public Health Security and Bioterrorism Preparedness and Response Act
- DHS Presidential Directive 5

7.3 INCIDENT COMMAND

The National Incident Management System (NIMS)-Incident Command System (ICS) should be a framework to manage the response needs for single- or multiple-incident emergency situations. Upon evaluation of an incident, the lead program unit will determine if an Incident Commander (IC) is needed to manage it. If established, the IC or the unified command (for multiple-agency response) is responsible for all aspects of the response, including incident objectives and all incident response operations.

The IC includes the command staff and general staff. Command staff positions may include a public information officer, safety officer, and liaison officer as required and assigned by the IC. General staff includes operations, planning, logistics, and finance/administrative responsibility. If requirements for

these responsibilities warrant, they may be established as separate functions under the IC and managed by section chiefs. They may be supported by other functional units.

Personnel should be designated to fill key ICS roles in the rapid response plan:

- IC
- Planning Chief
- Operations Chief
- Logistics Chief
- Administrative/Finance Chief

Responsibilities of the incident command and its general staff:

- Providing response direction
- Coordinating effective communication
- Coordinating resources
- Establishing incident priorities
- Developing incident objectives and approving response strategies
- Assigning objectives to response managers
- Reviewing and approving incident action plans
- Integrating response organizations into the ICS
- Establishing protocols
- Safeguarding worker/public health and safety
- Informing the media

7.4 RESOURCES

Micronesian regional governments and the state of Hawai'i should find funding sources for rapid response. The APHIS Emergency Mobilization Guide, available at: www.aphis.usda.gov/emergency_response/downloads/APHIS%20Emergency%20Mobilization%20Guide.pdf, facilitates cost-effective, timely coordination of resources needed for successful responses to agricultural health and homeland security emergencies by standard procedures guiding operations.

7.5 EXISTING MICRONESIAN REGION RESPONSE PROGRAMS

Several rapid response programs are in operation on the Micronesian Islands. These programs can be foundations for a comprehensive regional emergency rapid response program network. Examples are listed below.

- A regional response team has been developed for alien snake incursions. This team has trained members in each jurisdiction covered by the MBP. Until recently this team was coordinated by a US federal office on Guam. Currently that office is vacant.
- USDA-APHIS-WS, USGS and DAWR on Guam, CNMI DFW on Saipan, Tinian and Rota, the Hawai'i DOA and DLNR (as well as the various ISCs), Palau Agriculture, FSM Quarantine, Yap Agriculture, Pohnpei Agriculture and EPA, Kosrae Agriculture, and the RMI R&D all have resources for alien snake detection work, albeit no agency nor group has extensive resources and most groups (other than WS and USGS) have general capacity for IAS response work instead of focusing specifically on snakes.

7.6 RAPID RESPONSE TEAM

Rapid response teams should respond to suspected or confirmed introductions of invasive species and to disease outbreaks. Rapid response team members and contact information for specific emergencies depend on whether the emergency is a threat to plant, agricultural, animal, or wild animal populations. Rapid response teams direct the overall response to the emergency.

7.7 DETECTION-ERADICATION TEAM

Detection-eradication teams respond to specific introductions of invasive species and to disease outbreaks. Detection-eradication team members are subject matter experts skilled in identification and eradication procedures for specific plant and animal risks.

7.8 LEAD APHIS PROGRAM UNIT

For each emergency, hypothetically an APHIS program unit could lead the response under established APHIS authorities where they apply. For incidents related to U.S. agriculture, PPQ serves as the lead program unit for plant health incidents (Section 10.9) and VS for animal health incidents (Section 10.10).

The introduction of invasive species and emergent agricultural incidents in U.S. territories and possessions should be reported to the APHIS Emergency Management Response System (EMRS) and APHIS program emergency response managers. Each program has specific reporting requirements in their individual emergency management guidelines (see Sections 10.9, 10.10, and 10.11 and the APHIS website).

In some instances, WS, Animal Care, or Biotechnical Regulatory Services may serve as the lead program unit for incidents in their mission areas (Section 10.11). For example, Biotechnical Regulatory Services responds to incidents involving genetically modified organisms.

For Micronesia which includes both US and non-US jurisdictions, a non-US Federal agency approach to regional response support may be the most appropriate approach.

Additionally agencies such as the USGS have supported development of regional response capacity to IAS and there are numerous groups and agencies already established within the region that have some

capacity in this regard. These varied efforts and groups should all be considered when ultimately determining how best to further regional capacity in regards to early detection and response to IAS.

7.9 PLANT EMERGENCY RESPONSE—PLANT, PROTECTION AND QUARANTINE

The APHIS-PPQ program safeguards U.S. agriculture and natural resources from the introduction, establishment, and spread of plant pests and noxious weeds. PPQ's Emergency and Domestic Programs unit provides national leadership and coordination in plant pest programs and emergency management. As the lead federal agency for plant health emergencies, PPQ cooperates with national and international plant protection organizations; federal, state, and local agencies; Native American tribes; universities; industries, and private entities in developing and implementing scientific frameworks for optimum protection against invasive pests and diseases.

APHIS uses offshore information and pre-clearance programs, port inspections, and extensive domestic surveillance to prevent, detect, and respond to plant health emergencies. The PPQ emergency management framework consists of four key elements: 1) prevention, 2) preparedness, 3) response, and 4) recovery.

Prevention. PPQ works with trading partners and international plant protection organizations to develop and implement offshore pre-clearance, inspection, early detection, and control strategies to prevent the entry of invasive pests and diseases into the United States. PPQ works with the U.S. DHS-CBP and other cooperators to continue the success of agricultural inspection operations at all U.S. ports of entry. PPQ regulates plant imports, effects international safeguards, and operates domestic pest detection programs.

The first line of defense against the entry of harmful plant pests and weeds into the United States and U.S. territories is through the inspection of commodities, conveyances, and passenger baggage by APHIS cooperators at seaports and airports outside of CTUS. PPQ trains these cooperators to detect and identify these pests.

Preparedness. PPQ works with federal, state, tribal, and local governments and with industries to prepare, build, and sustain operational capacity and capability for early detection, timely diagnostics, and effective control strategies against plant health threats.

Response. PPQ works with federal, state, tribal, and local governments and with industries to coordinate actions to contain, control, or eradicate plant pests and diseases. PPQ uses ICS, which helps agencies and entities with a unified strategy for working together in response to plant health emergencies.

Recovery. After an emergency response is complete, PPQ works with federal, state, tribal, and local governments and the private sector to develop and implement systems for long-term stability and protection from the pest or disease that caused the emergency. Recovery includes plant health regulations, eradication, BMPs, and restoration plans.

Table 10-1 identifies key PPQ Offices.

Table 10-1: Key PPQ Offices and U.S. Plant Health Non-Government Organizations

Office	Location
PPQ Emergency and Domestic Programs	Riverdale, Maryland
PPQ Western Region	Fort Collins, Colorado
PPQ Hawai'i State Plant Health Director	Honolulu, Hawai'i
PPQ Port Director	Guam

7.9.1 National Identification Services

APHIS' National Identification Services (NIS) coordinates the identification of plant pests to support USDA's regulatory programs and quarantine actions. NIS collaborates with scientists specializing in plant pest groups, weeds, insects, mites, snails, and plant diseases. These scientists are stationed around the country in federal research laboratories, plant inspection stations, land-grant universities, and natural history museums.

NIS supports the use of alternative diagnostic methods to enhance the speed and precision of the identification process. The Remote Pest Identification Program utilizes digital imaging of suspected pests and transmits them electronically to qualified specialists for identification. The Molecular Diagnostics Laboratory is responsible for biochemical testing services supporting the agency's pest monitoring programs.

7.9.2 National Plant Diagnostic Network

With support from USDA's National Institute of Food and Agriculture, from land-grant universities, federal agencies, state departments of agriculture, and other stakeholders, the National Plant Diagnostic Network (NPDN) is a consortium of plant diagnostic laboratories developing a nationwide network of public agricultural institutions with a cohesive distributive system that quickly detects high-consequence pests and pathogens introduced into agricultural ecosystems, identifies them, and immediately reports them to appropriate responders and decision makers. The NPDN has invested in plant diagnostic laboratory infrastructure and training, developed an extensive network of first detectors through education and outreach, and improved communication among agencies and stakeholders that respond to outbreaks and mitigate them.

Guam is served by the Western Plant Diagnostic Network, a regional member of the NPDN. The network is a consortium of land-grant institutions and state departments of agriculture throughout the western United States and Pacific U.S. territories with services for plant disease diagnosis, plant identification, and insect or pest identification. The Western Plant Diagnostic Network uses a common software interface to process diagnostic requests and to share information among diagnostic laboratories.

7.9.3 APHIS-PPQ Incident Command System

APHIS-PPQ emergency planners have developed the 2004 *USDA-APHIS-PPQ Incident Command System Guide* for development of an ICS during a plant health emergency. The guide offers the following information:

- Report requirements
- Notification procedures
- Exotic pest identification
- Pest status assessment
- Financial support
- Incident management teams
- Legislative and public affairs

7.9.4 Standards for Plant Health Emergency Management Systems

APHIS-PPQ emergency planners have developed *Standards for Plant Health Emergency Management Systems* to help state and federal plant health officials and state emergency managers determine their needs in mounting successful responses to plant health emergencies. Information includes:

- Emergency plans
- Written agreements
- Authorities and policies
- Plant pest survey, containment, control, and eradication
- Communications
- Training and education
- Funding and resources
- Standards for state plant health emergency management systems

7.9.5 Specific Plant Emergency Programs

APHIS-PPQ emergency planners have specific response programs for multiple plant disease and plant pest emergencies. APHIS-PPQ prepares new pest response guidelines for anticipated arrivals of new pests into the United States and for detected new pests already arrived. These guidelines are for many insect, mollusk, and virus pests that attack crops, wood, grain, nursery stock, and other resources.

Additional information is available at http://www.aphis.usda.gov/plant_health/index.shtml.

7.10 ANIMAL EMERGENCY RESPONSE—VETERINARY SERVICES

APHIS-VS safeguards U.S. poultry and livestock from the introduction, establishment, and spread of foreign animal diseases by regular surveillance of domestic animal herds and flocks and monitoring animal disease outbreaks around the world. APHIS-VS personnel also work with other federal agencies at airports and maritime ports to inspect and approve incoming shipments of animals and animal products.

APHIS-VS is responsible for detecting and responding to animal disease incidents that occur within the United States. The APHIS-VS National Center for Animal Health Emergency Management (NCAHEM) manages the agency's animal health emergency activities. The center develops strategies and policies for effective incident management and helps coordinate incident responses. As liaison to outside emergency management groups, NCAHEM keeps the agency's animal health emergency management policies, strategies, and responses current with national and international standards.

NCAHEM and VS programs are valuable resources in animal disease emergencies from invasive species on Micronesian Region islands.

7.10.1 National Veterinary Stockpile

The National Veterinary Stockpile (NVS) provides the veterinary countermeasures—supplies, equipment, field tests, vaccines, response support services—that states need to respond to large-scale, catastrophic animal disease outbreaks that terrorists or nature may create.

NVS provides USDA-APHIS expertise for responding to animal diseases by:

- Deploying countermeasures against the worst animal diseases: HPAI, FMD, Rift Valley Fever, END, and CSF.
- Helping states plan for, train, and exercise the rapid acquisition, receipt, processing, and distribution of countermeasures during an event.
- Focusing exclusively on NVS and state logistics of disease response.
- Coordinating logistics planning especially for large-scale, catastrophic outbreaks.
- Preparing states to acquire, receive, process, and deliver NVS countermeasures as well as those from other sources rapidly.
- Managing delivery time of countermeasures.

Countermeasures and response capabilities:

- Vaccines as alternatives to destroying animals
- High-speed vaccination equipment
- Personal protective equipment

- Animal handling and depopulation equipment
- Field diagnostic tests for rapid, presumptive identification of disease
- Decontamination supplies to eliminate disease agents
- Emergency transport of supplies, equipment, vaccines, reagents, samples, and trained personnel equipped to support state response

NVS outreach and exercise programs help states, tribes, and territories plan, train, and respond logistically to large-scale disease outbreaks. NVS personnel assist states in developing test exercises conforming to DHS Exercise Evaluation Program guidelines.

Additional Information about the NVS program and resources is available at:

http://www.aphis.usda.gov/animal_health/emergency_management/nvs.shtml

Emergency Management Response System

EMRS supports management of animal disease outbreak data with state and tribal partners with a secure, accessible nationwide system for data collection, management, and analysis in a web-based, comprehensive investigation, task, and resource management suite on a universal information platform. Primary EMRS users are federal, state, and tribal veterinary medical officers, animal health officials and technicians, animal disease specialists, and epidemiologists. EMRS provides APHIS-VS and cooperators with a management system for:

- Responses to animal disease outbreaks
- Routine surveillance of foreign animal disease
- Emerging disease incidents
- All hazard animal incidents

Access to EMRS requires registration at EMRS_Registration_Approvers@aphis.usda.gov. EMRS technical assistance is available from the APHIS Technical Assistance Center via phone (877) 944-8457, or E-mail, atac@aphis.usda.gov.

Additional assistance is available from EMRSupport@aphis.usda.gov.

7.11 ANIMAL EMERGENCY RESPONSE—WS

NWDP does wildlife disease monitoring and surveillance in all regions of the United States. NWDP wildlife disease biologists act as first responders through NWDP's Surveillance and Emergency Response System (SERS). NWDP collaborates with NGOs and officials from other countries to promote development of wildlife disease monitoring programs worldwide.

7.11.1 Surveillance and Emergency Response System

SERS, an essential NWDP component, is the primary emergency response contact point within APHIS-WS. SERS has a cadre of wildlife disease biologists ready to mobilize within 24 to 48 hours of a request. NWDP-SERS biologists have extensive ICS training, medical clearances for personal protective equipment, and experience in emergency response scenario drills. Selections for requested incident response teams depend on the specifics of the request (e.g., immobilization and euthanasia-certified, shooter) and the number of people needed.

SERS will respond to requests for assistance from the following agencies and organizations:

- APHIS-VS
- APHIS Animal Care
- APHIS-PPQ
- Non-APHIS Emergency Support Function (all-hazards event)
- Federal Emergency Management Agency (all-hazards event)

Whether the request for emergency resources comes from within APHIS or from emergency support functions of the national response framework, the SERS national coordinator immediately develops an incident response team of SERS biologists whose skills and training meet the needs of the request. Once the team is formed and dispatched, SERS tracks it for the duration of the emergency response.

8 TERRESTRIAL VERTEBRATE SPECIES³

8.1 EXECUTIVE SUMMARY

This RA is based on the USDA-APHIS-WS Micronesia Region Risk Assessment, provides recommendations for preventing and mitigating regional threats to human health and safety, the economy, and ecology of the Micronesia Region posed by intentional and accidental transport of terrestrial vertebrate invasive species resulting from three actions proposed by the DoD, namely the relocation of Marines from Okinawa, providing visiting aircraft carrier berthing, and establishing an Army AMDTF for Guam and the CNMI. The scope of this plan also covers the Republic of Palau, FSM, and the RMI, including Hawai'i and the continental United States, but focuses on Guam because a majority of proposed actions will occur there, it serves as a regional transportation hub thereby facilitating wide-spread species movement, and because preventing off-island transport of the BTS is a high priority.

Proposed military actions are expected to significantly increase the flow of transportation throughout the region, thereby increasing the likelihood of introducing species intentionally, both legally and illegally, and unintentionally as hitchhikers, in air and water conveyances, cargo and cargo conveyances, and on people and in their baggage. Biosecurity strategy emphasizes a holistic approach of sterilizing pathways by implementing measures pre-border, at-the-border, and post-border. Prevention is more effective and cheaper than eradication or long-term control of established species, and eradication is more effective and cheaper over time than permanent population control.

Five key issues pertain to all recommendations: funding, coordination and communication, education and training, control methods development, and enforcement (of regulatory drivers). General recommendations serve as a starting point for more formalized, pathway-specific recommendations. Several recommendations focus on preventing the BTS from leaving Guam because resulting impacts extend well beyond Guam's jurisdictional and physical boundaries. Funding issues are weak links for regional biosecurity, crippling law enforcement and inspection processes, decreasing the efficacy of control measures, and preventing new methods from being developed. Education, training, and awareness are key preventative measures in unintentional and intentional pathways. Biosecurity is compromised in military sectors because exemptions are often granted to personnel; deployment can be immediate at any time to any place; military transportation traffic in the region will increase over time; there is overlap between military and civilian/commercial pathways; and the multipurpose and technologically advanced aircraft, vessels, and equipment used by the military pose unique risks. Current agricultural inspections need to target terrestrial vertebrate species, and inspectors require added knowledge, equipment, and facilities for proper screening and reporting; improved detection; and safe handling of such species. Cargo pathways warrant particular attention, as they are most vulnerable to transporting species because of the diversity of goods moved, the wide array of exposure to various handling and packing procedures, and the multiple modes of transport used.

³ This chapter was prepared by USDA-APHIS-WS, compiled by: W.C. Pitt, C.V. Deringer, and J.M. Gaudioso. 6 November 2010.

The number of stowaways detected per inspection, in combination with the huge volume of transported products and expected increases in regional transportation traffic, implies a substantial number of species will go undetected. Regulations and enforcement need to be enacted and implemented to address illegal transport of species, which occurs insidiously, even via legal routes like the pet trade and food imports. Effective regional biosecurity requires a long-term commitment, adequate and sustainable funding, cooperation, and enforcement of regulatory drivers. This plan can be used in its entirety, or as individual pathway- or taxa-based sections for specific action plans.

8.2 INTRODUCTION

The Micronesia Region Biosecurity Plan for terrestrial vertebrate species focuses on threats posed by the intentional and unintentional transport and introduction of terrestrial vertebrate invasive pest species as a result of increased military activities in the region. The scope of this plan covers Guam, the CNMI, the Republic of Palau, the FSM, and the RMI, including Hawai'i and the continental United States.

Military relocation refers to three actions proposed by the DoD, 1) the relocation of Marines from Okinawa, 2) providing visiting aircraft carrier berthing, and 3) establishing an Army AMDTF for Guam and CNMI. The military relocation and post-relocation training and operations are expected to significantly increase the flow of cargo, people, and transportation conveyances into and out of Guam and the CNMI (Helber et al. 2006). The estimated increase of goods and people during and following military relocation increases the likelihood of transporting terrestrial vertebrate invasive pest species throughout the region.

This action plan provides background on biosecurity efforts in the Micronesia Region, reviews potential risks identified in a pathway-based risk assessment, and provides recommendations for developing a comprehensive operational biosecurity strategy to prevent or mitigate risks posed by terrestrial vertebrate invasive pest species. Risk assessment covers unintentional and intentional pathways, with unintentional pathways identified by mechanism of transport and intentional pathways identified by motive for transport. Risks and mitigating recommendations are general and specific, with general information being applicable to all pathways, both military and civilian sectors, and regardless of pest species and transport mode or motive.

We also incorporate applicable information from successful biosecurity strategies currently implemented by governments to safeguard their people, commerce, and environments against marine and terrestrial pest species and diseases. These jurisdictions include New Zealand (NZ MAF 2003), Australia (Australian Government 2009), Galapagos Islands (CDF and WWF 2002), Europe (EEA 2010), the Caribbean (Meissner et al. 2009), British Virgin Islands (Perry et al. 2006), the Pacific (Sherley and Lowe 2000; SPREP 2000), Hawai'i (Kraus and Duffy 2009), Fiji (FQD 2010), and Guam (BTSCC 1996). We also use information from reviews on policy and management at a global scale (SCBD 2001, Meyerson and Reaser 2002; Grotto and Tucker 2006; Reaser et al. 2007; Reaser and Waugh 2007; Hulme et al. 2008, Sheppard 2010) and at local/regional scales for Japan (Takahashi 2009), New Zealand (Pearson 2004; Takahashi 2005; 2006, NZ MAF 2008, 2009), Australia (VPC 2004, 2007a, b), Hawai'i (Beard and Pitt 2005; Kraus and Duffy 2009), and Europe (Pyšek et al. 2010).

8.3 BIOSECURITY STRATEGY FOR THE MICRONESIA REGION

8.3.1 Purpose

The goal is to provide a biosecurity action plan with a strategic approach to minimizing negative impacts to the region's human health and safety, economy, and ecology due to risks associated with the transport and introduction of terrestrial vertebrate species. Objectives are to summarize information on pathway transport and introduction of terrestrial vertebrate species based on the USDA-APHIS-WS Micronesia Region Risk Assessment of proposed DoD activities in the region, and recommend prevention and mitigation measures that safeguard against biosecurity threats.

8.3.2 Scope

The scope of this plan covers the relocation and post-relocation operational phases of military activity in the defined Micronesia Region. Biosecurity measures on Guam are unique in that efforts include screening and inspection of both arriving and departing people, cargo, and conveyances to prevent the transport and spread of the BTS from Guam to other locations. This plan summarizes pathways capable of transporting and introducing terrestrial vertebrate species, with an emphasis on BTS.

Issues and concerns regarding BTS extend well beyond Guam's jurisdictional and physical boundaries. Encounters with BTS outside of Guam (extralimital encounters) have occurred in a variety of place around the globe (Stanford and Rodda 2007). As a hub for commercial and military shipments in the Micronesia Region, transportation activity from Guam greatly increases the probability of BTS transport to new locations such as Saipan, Tinian, and Rota in the CNMI, and Oahu, Hawai'i.

Ecosystems on oceanic islands are particularly vulnerable to pest invasions (Loope et al. 1988), as evidenced by the history of BTS on Guam (Fritts and Leasman-Tanner 2001b). Numerous snake encounters have been reported for the island of Saipan with most of these encounters (but not all) being suggestive of BTS (Stanford, personal communication). The exact number of these encounters that is considered credible varies depending on the criterial one uses to define the term credible but what can be stated is that there have been numerous confirmed BTS captures on Saipan and that the number of credible encounters for Saipan is much higher than for any other island outside of the BTS's native range (other than Guam) (Stanford, personal communication). A variety of search efforts conducted on Saipan during the past 10 years has not confirmed the presence of an incipient BTS population there (Stanford, manuscript in preparation). Further, given that Saipan receives much of its cargo from Guam, and the other Mariana Islands receive most of their cargo from Saipan, BTS infestation of Saipan is possible and would be problematic if it did occur (Stanford and Rodda 2007). Similarly, a BTS infestation on Oahu increases the risk of introduction and spread throughout the main Hawai'ian Islands because of the amount of inter-island cargo traffic that occurs from Oahu (Stanford and Rodda 2007).

This plan allows for some flexibility in accommodating changes to the proposed military relocation, trainings, and operations, depending upon the types of changes proposed, the magnitude of change, and the timeframe for the change to be implemented.

8.3.3 Proposed Military Activity

This section provides a general description of the military relocation and post-relocation activities proposed in the Final EIS (FEIS), July 2010 (U.S. Navy 2010a). Military relocation includes three actions proposed by the DoD, 1) the relocation of Marines from Okinawa, 2) providing visiting aircraft carrier berthing, and 3) establishing an Army AMDTF for Guam and the CNMI.

The proposed relocation of Marines to Guam also includes development and construction of facilities for training and operations that would occur on Tinian. The MIRC FEIS includes training area/facilities on Guam, Rota, Tinian, Saipan, and Farrallon de Medinilla (FDM), and covers training on existing DoD land and on training areas in and around Guam and the CNMI; therefore, overlap exists between the two FEISs in the area of usage of existing DoD by Marine Corps units. The proposed Army AMDTF would be placed on Guam to defend U.S. interests on Guam; its defensive umbrella would ensure that local military assets are protected and remain available to meet their military missions.

All descriptions are based upon the “preferred alternatives” listed in the following documents, and are subject to change pending upon the final ROD:

- FEIS = FEIS/OEIS; Guam and CNMI military relocation; relocating Marines from Okinawa, visiting aircraft carrier berthing, and Army air and missile defense task force, July 2010 (U.S. Navy 2010a)
- IMP = Integrated Military Plan, July 2006 (Helber et al. 2006)
- MIRC = MIRC FEIS/OEIS, July 2010 (U.S. Navy 2010b)
- ROD = August 2010

8.4 MILITARY OPERATIONS, TRAININGS, MISSIONS

8.4.1 Military Relocation

As noted above, the three proposed actions of Guam military relocation include 1) the relocation of Marines from Okinawa, 2) providing visiting aircraft carrier berthing, and 3) establishing an Army AMDTF for Guam and CNMI. Proposed relocation of Marines includes the development, construction, and use of facilities for training and operations on Tinian because not all training can be accommodated on Guam. The concept for Tinian is to provide the next stage in the training progression, which includes development of ranges for tactical use of the basic weapons skills developed on Guam, skills that complement the elements of ground training (U.S. Navy 2010a, Vol. 3, pg. 2-1).

The Guam relocation of Marines includes four military elements:

1. Command Element, III (3rd) Marine Expeditionary Force (MEF). III MEF is the Marine Corps’ forward-deployed Marine Air-Ground Task Force (MAGTF); it has the ability to deploy rapidly and conduct operations ranging from humanitarian assistance and disaster relief to amphibious assault and high intensity combat. The MAGTF command element consists

primarily of headquarters (HQ) and supporting organizations. Collocation and communications connectivity is a primary facility citing requirement. Estimated personnel: 3,046.

2. Ground Combat Element (GCE), 3rd Marine Division Units. The GCE has the mission of locating, closing with, and destroying the enemy with fire, maneuver, and close combat. It supports MAGTF expeditionary operations with infantry, armor, artillery, reconnaissance, anti-tank, and other combat arms. It consists of Division HQ and subordinate organizations. Ground combat and combat support organizations require proximity to ranges and training areas as well as traditional base support facilities. Estimated personnel: 1,100.
3. Air Combat Element (ACE), 1st Aircraft Wing and subsidiary units. The ACE operates from a variety of sea- and shore-based facilities to support MAGTF expeditionary operations. The focus is to support the MAGTF during assault landings and subsequent operations ashore. The ACE includes the Marine Aircraft Wing HQ, expeditionary, and garrison supporting organizations. Unlike aircraft squadrons, aviation command and general supporting elements can be located close to the airfield and higher commands, and do not necessarily need to be located at the airfield. Estimated personnel: 1,856.
4. Logistics Combat Element (LCE), 3rd Marine Logistics Group (MLG). The LCE provides all support functions beyond the capabilities of the GCE and ACE units. Functions include: communications, engineering support, motor transport, medical, supply, maintenance, air delivery, and landing support. The LCE consists of MLG HQ and supporting organizations that provide a variety of direct logistics support to the rest of the MEF. The MLG HQ element would be sited in proximity to Command HQ and other HQs. Indirect and industrial support facilities of the LCE would be located in proximity to support activities and maximize efficiency, with efficient access to roads, ports and airfields. Estimated personnel: 2,550.

With the Marine relocation, training activities would be increased on Guam and in the CNMI to include training in major exercises that involve multiple strike groups and task forces. Major exercises provide multi-service and joint participation in realistic maritime and expeditionary training that replicates the types of events and challenges potentially faced during real-world contingency operations. Major exercises also include providing training to submarine, ship, aircraft, and special warfare forces in mission tactics, techniques, and procedures (U.S. Navy 2010b, Vol. 1, pg. ES-11).

Existing training capabilities on Tinian would be expanded to support company and battalion level live fire ranges; a battalion is a group of 5 companies, approximately 960 individuals. The main components of the proposed action are: 1) development and construction of live-fire training ranges: a platoon (42 Marines) battle course, 2) automated combat pistol range, 3) rifle known distance range, and 4) field firing range. These proposed training components complement the existing ground training practices undertaken at Tinian and in the CNMI as described in the MIRC (U.S. Navy 2010a, Vol. 3, pg. 2-1).

Operational training on Rota includes hostage crisis rescue operations, undercover operations or surveillance, fighting in urban areas, evacuating civilians during a war or natural disaster, preventing terrorist activities, and protecting troops while they are in combat situation. The training on Rota will be held at least twice a month, but frequency may increase depending on the kind of training that may be urgently needed (Todeno 2009).

Relocation activities would include aviation units and aviation support units that require runway and hangar space and maintenance, and supply and administrative facilities. There is also a need for air embarkation operations that are comparable to, compatible with, and co-located with, existing Andersen AFB operations on Guam. Air embarkation operations refer to loading and unloading cargo and passengers to and from aircraft, comparable to a civilian airport terminal (U.S. Navy 2010a, Vol. 2, Ch. 2).

Firing ranges are required for live and inert munitions practice by the Marine Corps, which generates the need for safety buffers called Surface Danger Zones, and special use airspace (SUA) on Guam for certain weapons [note: SUA not applicable to Tinian] (U.S. Navy 2010a, Vol. 3; U.S. Navy 2010a, Vol. 2, Ch. 2). Range Alternative A (preferred FEIS Alternative) would require the realignment of approximately 2.8 km (1.7 miles) of Route 15 to the interior of the existing Andersen South parcel. The total land area, not including submerged lands, is estimated at 441 hectares (1,090 acres) (ROD 2010).

Military Operations in Urban Terrain trains Marine Corps, Army, Air Force, Special Warfare, and Navy Expeditionary Combat Command personnel combat tactics appropriate for a small city environment inhabited by noncombatants but occupied by a hostile force to search out and capture or destroy the hostile force. Primary training area (PRI) is Guam: Andersen AFB South, Finegayan Communication Annex, Barrigada Housing, and Northwest Field. Secondary training area (SEC) is Tinian, Rota, Saipan (U.S. Navy 2010b, Vol. 1, Table 2-8, pg. 2-53). Non-fire maneuver ranges are required for vehicle and foot maneuver training by Marine Corps, including urban warfare training. Urban warfare training is conducted in buildings that simulate a city or town. These buildings would be arranged close together so that Marines can practice entering and maneuvering in tight spaces (U.S. Navy 2010a, Vol. 2, Ch. 2).

Maneuver training areas are used for training Marines in the variety of skills specified in the Infantry Training and Requirements Manual (NAVMC DIR 3500.87), as defined in the Required Capabilities Document. Generally, for company-level (200 Marines) training, a 3,108 hectare (12 square mile) maneuver space is optimal, but this amount of space is not available on Guam. Maneuver training can be conducted in smaller areas depending upon the size of the Marine units and the size and complexity of a training event. Proximity is an important characteristic for efficient-to-use training areas, as cost and difficulty of transportation directly diminish the amount of training that can be accomplished within a given budget (U.S. Navy 2010a, Vol. 9, Appendix M).

Proposed activities call for creating a U.S.-based forward operating port for modern littoral warfare ships, combat logistics force ships, submarines, surface combatants, and high-speed transport vessels by improving U.S. Navy's Naval Base Guam to serve as a forward operational and logistic support hub for a mix of platforms and joint operations (Helber et al. 2006). The development of a Navy Transient Aircraft

Capability on Guam: Polaris Point Preferred Alternative—this alternative would construct a new deep-draft wharf at Polaris Point with shore side infrastructure improvements:

- The existing Outer Apra Harbor Channel would be widened to 183 meters (600 feet) with minor adjustments to channel centerline and navigational aids. There is a sharp southward bend in the existing channel toward Inner Apra Harbor that would require widening to 183 meters (600 feet) and dredging to meet aircraft carrier requirements.
- A new ship turning basin would be established that would require dredging to -15.1 meters (-49.5 feet) Mean Lower Low Water plus 0.6 meters (2 feet) overdraft. The turning basin would be located near the wharf and north of the Inner Apra Harbor entrance channel. The eastern edge of the new wharf would not have the required full 183 meters (600 feet) of distance from the wharf face and care would be necessary to nudge the carrier into position. However, Commander, U.S. Pacific Fleet requirements show that ships can safely navigate the reduced clearance at this site. The aircraft carrier would be assisted by tug boats, pivoted within the minimum radius turning basin to be aligned starboard (i.e., right side when facing the front or “bow” of the ship) to the wharf and the bow would be facing east. On departure, the aircraft carrier would follow the same route.
- It is anticipated that a transient aircraft carrier and its escort ships would rely on shore side utility infrastructure for water, wastewater, and solid waste after 2015. Electric power would be provided in accordance with customer service agreements (CSA) between Guam Power Authority and the U.S. Navy. Any Guam Power Authority commitments for additional power to support the aircraft carrier and its escort ships will be determined by future CSA modifications. Any required changes in the shore side power infrastructure or their operations to meet the requirements for the aircraft carrier and its escort ships may require additional NEPA review.
- Pertaining to aircraft carriers arriving to Guam, a new Port Operations support building and various utility buildings would be constructed on a terrestrial vertebrate-proof staging area at the wharf. There would be an area established for morale, welfare, and recreation activities and vehicle parking (ROD 2010).

The Army AMDTF is a ground force and would not be accompanied by aircraft or ships. Components would include command and control, missile field teams, maintenance, and logistics/supplies support. Establishing an AMDTF includes developing facilities and infrastructure on Guam to support relocating approximately 600 military personnel and their dependents (U.S. Navy 2010a, Vol. 1, Ch. 2). The proposed Army AMDTF on Guam contains the following three missile components:

5. The Terminal High-Altitude Area Defense (THAAD) system is a long-range, land-based theater defense weapon that acts as the upper tier of defense against ballistic missiles. This system is designed to intercept missiles during late mid-course or final stage flight. The THAAD flies at high altitudes and provides broad area coverage against threats to critical assets such as population centers, industrial resources, and military forces.

6. Patriot Missiles target short-range ballistic missiles that threaten the THAAD or other civilian or military assets on Guam. This weapon system is a point defense option with limited range designed to strike ballistic missiles, aircraft, unmanned aerial vehicles, and cruise missiles just before impact. This system utilizes hit-to-kill technology.
7. A Surface-Launched Advanced Medium-Range Air-to-Air Missile (SLAMRAAM) engages targets to beyond line-of-sight and defends against the air threat from unmanned aerial vehicles and cruise missiles.

Two major categories of training would be required: individual/crew and collective. Individual/crew training would include basic rifle marksmanship and crew-served weapons training. Training ranges on Guam and in the CNMI are considered joint use (i.e., available to all U.S. forces). Consequently, the Army would utilize ranges within the MIRC for this type of training. Collective training would be required for the AMDTF. Regular crew training on all aspects leading up to and through a launch would be required for THADD, Patriot, and SLAMRAAM weapons systems. These training exercises would be conducted at the Army facilities and no training-specific facilities would be required. No live-fire missile launch training exercises would occur on Guam or in the CNMI (U.S. Navy 2010a, Vol. 5, Ch. 2).

Continue efforts to develop U.S. Air Force Global Intelligence, Surveillance, and Reconnaissance (ISR) and Strike hub. Aviation training areas used are either improved (paved runway) or unimproved (unpaved landing sites) used to practice landing/takeoff and air field support (including loading/unloading of fuel, munitions, cargo, and personnel). Aviation training includes use of both international airspace and U.S. controlled airspace within the MIRC area (U.S. Navy 2010a, Vol. 2, Ch. 2).

Waterfront functions serve transient (visiting) ships and assault crafts associated with the proposed Marine Corps relocation. The transient vessels support Marine Corps operations and transient forces that presently train on Guam and in the CNMI. These ships would continue to support Marine Corps requirements in the western Pacific after the proposed relocation, and would continue to require transient vessel support facilities on Guam. The planning criteria for harbors, regardless of usage, differ from those for land-based facilities (U.S. Navy 2010a, Vol. 2, Ch. 2).

Associated infrastructure, housing, quality of life improvements (IMP) (Preferred Alternative): This alternative would co-locate AMDTF support facilities with the proposed Marine Corps units at Finegayan. The Administration/HQ and Maintenance operations would be co-located in the eastern portion of NCTS Finegayan and would be compatible with adjacent proposed Marine Corps land uses. Housing facilities for unaccompanied personnel would be located within NCTS Finegayan. Accompanied personnel housing facilities would be co-located with the Main Cantonment housing areas in South Finegayan, while recreational and QOL facilities would be co-located within and adjacent to the housing areas (ROD 2010).

Munitions Storage Alternative 1 (Preferred Alternative): Munitions storage would be in three non-contiguous areas near the Habitat Management Unit (HMU) of the Andersen AFB Munitions Storage Area, the latter being Alternative 1 of candidate sites for ammunition storage. The proposed magazines

would be constructed at these two sites (requiring demolition) and at a third site located east of the HMU across an unnamed roadway. The area of ground disturbance including a buffer is estimated 2.5 hectares (6.2 acres). The existing Explosive Safety Quantity-Distance arc(s) at the Munitions Storage Area 1 would be expanded approximately 122 meters (400 feet) to the north to provide the required safety distances for the new munitions storage facilities (ROD 2010).

Combat Search and Rescue (CSAR) operations include fixed-winged aircraft, helicopters and submarines, and use tactical procedures to rescue military personnel within a hostile area of operation. The PRI is both Tinian (North Field), and Guam (Northwest Field), SEC is Orote Point Airfield, and Rota Airport (U.S. Navy 2010b, Vol. 1, Table 2-8).

ISR is conducted to evaluate the battlefield and enemy forces, and gather intelligence. For training of assault forces, "red cell" or "OPFOR" units may be positioned ahead of the assault force and permitted a period of time to conduct ISR and prepare defenses to the assaulting force. ISR training has occurred at urban training facilities at Finegayan and Barrigada on Guam, and both the EMUA and the LBA on Tinian. The PRI is Guam: Northwest Field, Barrigada Housing, Finegayan Comm. Annex, and Orote Pt. Airfield. The SEC is Tinian, Rota, and Saipan (U.S. Navy 2010b, Vol. 1, Table 2-8, pg. 2-56).

8.4.2 Post Relocation

8.4.2.1 *Speculative*

Speculative (notional) base loading (U.S. Navy 2010a, Vol. 7) includes:

- A brigade-sized portion of a MEF
- An Army Brigade Headquarters and Army Battalion (to be determined), and various U.S. Air Force mission support initiatives
- New forward support Littoral Combat Ships, High-Speed Vessels/Theater Support Vessels (HSV/TSV)
- Auxiliary Dry Cargo/Ammunition Ships (T-AKE) that will replace aging Auxiliary Ammunition Ships (T-AE) and Auxiliary Combat Stores Ships (T-AFS), in addition to existing homeport Nuclear Attack Submarines
- Berthing accommodations for a transient nuclear powered aircraft carrier (aircraft carrier, fixed wing, nuclear powered [CVN]) and support for the carrier air wing (CVW), infrastructure for transient ships that support Marine Corps embarkation activities, and various training and support elements
- Facilitate use of transient U.S. Navy Nuclear Aircraft Carrier CVN at Naval Base Guam
- Infrastructure improvements to fuel pumps and pipelines that extend from the Sasa Valley Fuel Farm to Andersen AFB. Project includes a new 25.3-km (15.7-mile) pipeline that is parallel and adjacent to existing pipeline and located within an existing 3.05-meter (10-foot) wide easement (PACAF A7P, Air Force and U.S. Navy). This action is scheduled for 2013 in Central Guam

- Amphibious assault vehicle training by the Marine Corps. Beach improvements: one concrete revetment at each beach, remove non-native vegetation, no inland water improvements. This action is scheduled for 2014 and beyond⁴
- One concrete boat ramp in southern end of Inner Apra Harbor, for one amphibious assault vehicle at a time, overland paved route to Tipalao includes steep descent to Tipalao Beach. Site improvements associated with amphibious training include a new ramp at the southernmost point of Inner Apra Harbor. Overland route would be along the wetland area between the inner harbor and Dadi Beach. This action, by the Marine Corps is scheduled for 2014 and beyond⁵
- Redevelopment of munition igloos at Andersen AFB

8.4.2.2 *Pertaining Specifically to Tinian*

All scheduled for 2014 and beyond⁶ for Marine Corps (FEIS Vol. 7 Ch. 4 Table 4.3-2):

- Additional construction to accommodate up to 3,000 personnel (housing, recreation, medical, etc.)
- Ammunition storage facility. Includes six igloo magazines, a segregation facility, operations building, security systems, and a road network
- Automated multipurpose range. Includes range support building, ammunitions storage, range observations tower, general instruction building, covered mess, covered bleachers, field range latrines, and 788 target emplacements
- 1.5 x 3 mile area for live-fire and maneuver training, including stationary and automated targets. Supports up to .50 caliber ammunition
- 2,000 x 4,000-foot area for live-fire and movement training. Supports up to 7.62-millimeter infantry weapons
- Areas for mortar and artillery firing points
- Paved area at North Field for helicopter landings, weekly aviation training. Includes fire protection and bermed area for fuel bladder
- Six pistol and rifle firing ranges, including stationary/automated targets, standard set of range support facilities
- 100 x 300-foot area for tank/fighting vehicle training. one firing point, central dubbed impact area
- Breakwater repair, pier face structures repair, loading ramp, holding yard for customs, storage/transfer area, harbor dredging. Includes demolishing the finger pier

⁴ Ibid, p. 2-1.

⁵ Ibid.

⁶ Ibid.

- Roadway improvements, electrical distribution changes, fire protection facilities, and access to Unai Dankulo on Tinian

8.5 PATHWAYS

8.5.1 Description

Overall biosecurity strategy emphasizes a holistic approach that focuses on sterilizing pathways capable of transporting terrestrial vertebrate pest species. Species are transported intentionally, both legally and illegally, and unintentionally as hitchhikers, moving to a different location in cargo, packing material, a shipping container used for transport, or on/in the conveyance of transport (Meissner et al. 2009).

Redundancy occurs among pathway recommendations where risks are similar and the same regulatory drivers apply. For implementation purposes recommendations are organized per pathway into stand-alone sections. For example, the Port of Guam would use those recommendations pertaining to water conveyances and vessel cargo pathways, as opposed to those in air transportation.

In general, terrestrial vertebrate species transport is via air transportation conveyances (hereafter aircraft) (e.g., airplanes, helicopters), water transportation conveyances (hereafter vessels) (e.g., ships, barges, fishing boats, amphibious landing crafts), cargo (i.e., types and associated packing materials) including cargo conveyances (e.g., containers, crates), and people and baggage.

8.5.2 Air Transportation

Recommendations in the air transportation pathways focus on the aircraft itself as the mode of species transport. The term ‘aircraft’ includes both fixed and rotary-wing aircraft in military, commercial, and private sectors. Different types of military, commercial, and private-owned aircraft currently visit, are home-based, or routinely operate on Guam, with air transportation traffic in all three sectors expected to increase from military activities during and after relocation. Plans for the relocation include training and field exercises conducted on the islands of Tinian, Rota, and Saipan, which involve aircraft operations from Guam and from aircraft carriers.

Aircraft pose several risks in transporting terrestrial vertebrate species. Aircraft are capable of rapid transit, equating to higher species survival during the short travel time. Global air transportation facilitates the widespread movement and dispersal of species. Aircraft are capable of harboring a variety of species, including birds such as Java finch (*Padda oryzivora*) and the Red-vented Bulbul (*Pycnonotus cafer*), snakes like BTS and rodents such as mice (*Mus musculus*). Aircraft are also capable of repeated introductions of species because of routine routes travelled and regularity of flight schedules. Further, aircraft cabins and cargo holds that are maintained at mild temperatures during transit, such as on passenger planes, offer hitchhikers in those craft recesses a thermal environment that is conducive to species survival during transport. All of these aspects increase the probability of successful species transport, including their myriad possible combinations.

Inspections of aircraft are mainly to detect agricultural pests such as insects, plants, and plant pathogens, and only target one terrestrial vertebrate species, BTS, when aircraft are departing Guam. Inspections do not occur for BTS on aircraft that have been grounded less than 3 hours, operate during

daylight hours, or require immediate departure, such as for military aircraft that depart Guam on urgent missions; however, aircraft leaving repair facilities for operational use are not usually inspected (Vice 2010a). Military aircraft are not exempt from agricultural inspections due to a MOU between GCQA and PPQ, where PPQ has granted GCQA the acting authority to inspect aircraft. However, military aircraft have the option of operating out of commercial and military airports, and military airfields, complicating inspection procedures. Also, military aircraft may be granted exemption in the following three cases: the aircraft is engaged in warfare, the cargo of the aircraft is classified, or pre-clearance procedures have been granted to the aircraft. Aircraft come into direct contact with the ground, giving terrestrial vertebrate species direct access to the craft. Aircraft can be difficult to inspect externally, depending upon the type of aircraft and its undercarriage configuration, but also internally, because of the numerous recesses, compartments, and storage holds aboard a craft, and the physical size of the craft. Chartered, personal, and airfreight aircraft are difficult to inspect because flight activities are hard to monitor, hence transportation of species can occur any time, to numerous places without detection. Despite the difficulties, inspection procedures and control efforts are efficient for aircraft. For example, USDA-APHIS-WS use visual and canine team detection methods to prevent BTS from departing Guam aboard an aircraft, and flight crews should adhere to sanitation regulations and be observant to signs of rodents. Aircraft are usually kept clean, reducing the attraction by species seeking a food source. External hitchhikers, such as those in wheel wells, may not survive the cold temperatures at high altitudes flown by some aircraft (Perry and Vice 2009).

8.5.3 Water Transportation

Recommendations in the water transportation pathways focus on the vessel itself as the mode of species transport, and include military, commercial, and private sector vessels. Types of vessels are numerous, including but not limited to, rigid inflatable boats, long-line fishing boats, sailboats, amphibious landing crafts, high-speed catamarans, container ships, cargo ships (bulk, break-bulk, roll-on/roll-off), aircraft carriers, landing craft utility vessels, barges, inter-island ferries, cruise ships and shuttles, platforms, and hovercrafts. Different types of military, commercial, and private-owned vessels currently visit, are home-based, or routinely operate on Guam with water transportation traffic in all three sectors expected to increase from military activities during and after relocation. Plans for the relocation include the construction and use of training ranges for field exercises and activities on the islands of Tinian, Rota, and Saipan, which involves water transport of materials, equipment, and vehicles for range construction, operation, and field exercises.

Typically, vessel access is limited; terrestrial vertebrate species either board themselves, or are intentionally and unintentionally brought on by persons or loaded as cargo. Species can board via fenders, mooring lines, and gangways that come into contact with land when vessels are at port, a pier, or a wharf, thus providing species with direct access to the hull. Departure from craft may be by the same routes plus directly through the water. Military vessels are not exempted from agricultural inspections due to a MOU between GCQA and PPQ, where PPQ has granted GCQA the acting authority to inspect craft. However, the arrangement that grants the authority for GCQA to conduct these inspections has been questioned. Military vessels such as Landing Craft Utility Vessels with direct access to the hull from beachheads via a ramp, and Amphibious Landing Crafts that can transport and spread

terrestrial vertebrate hitchhikers over water and land complicate inspection procedures. Also, military vessels may be granted exemption in the following three cases: the vessel is engaged in warfare, the cargo of the vessel is classified, or pre-clearance procedures have been granted to the vessel. However, these inspections are mainly to detect agricultural pests such as insects, plants, and plant pathogens, and do not target terrestrial vertebrate species specifically. Like military aircraft, vessels that depart Guam for urgent missions without inspection can harbor and transport terrestrial vertebrate species without notice. Vessel inspections can be difficult or easy to conduct, depending upon the type of vessel, its physical size, and the vessel configuration, both above and below deck (e.g., are there cabin areas, storage holds, bunk rooms, etc.). Chartered and privately-owned vessels and private, chartered, and commercial fishing vessels are difficult to inspect because boating activities are hard to monitor, hence transportation of species can occur any time, to numerous places without detection. Control efforts exist for safeguarding vessels from harboring unwanted species. Cargo exported from Guam via water transport is typically inspected by USDA-APHIS-WS canine teams prior to loading to detect BTS presence. Vessel captains have the option of using rodent guards on mooring lines to block mice and rats, the WHO's sanitation regulations for cleaning galleys and waste disposal reduce the probability of attracting and sustaining rodents and crews should be observant to signs of rodents.

8.5.4 Cargo

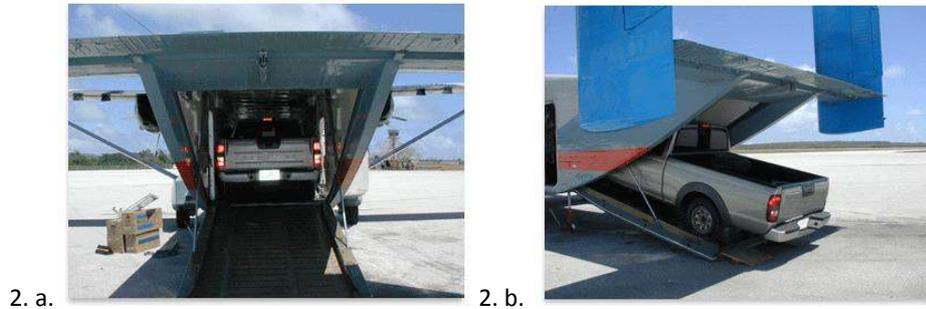

Recommendations in the cargo pathways focus on the cargo itself as a mode of species transport, including how cargo is packed and handled (e.g., crate, container, pallet, box, individual items); associated packing material; mode of transport (aircraft or vessel); shipping process, such as whether transport is via commercial or military-contracted commercial companies (e.g., Matson and Horizon vessels, passenger planes); military-owned transport systems (e.g., USTRANSCOM); or privately chartered shipping companies (Freedom Air 2010; Stratos 2010). Cargo is broadly defined as goods carried on a vessel or aircraft, or in a motorized vehicle. Cargo can be military, private, or commercial goods. Types of cargo vary and include both food and non-food goods. Types of cargo include, but are not limited to, personal checked airplane luggage; imported aquaculture (e.g., live fish or fish parts) and plants and plant parts (cut flowers, leis, nursery industry plants); animals imported legally and illegally (pet trade, personal pets, smuggling); vehicles such as cars, trucks, armored tanks, bulldozers, military vessels and aircraft (i.e., shipped aboard aircraft carriers, Landing Craft Utility vessels, Landing Craft Air Cushion vessels, hovercrafts); household goods; and empty shipping containers (for lease by shipping companies). Cargo can be handled and packed in a variety of ways. For example, household goods can be handled by private homeowners, commercial packers, or military personnel, with goods boxed and palletized for airfreight shipping, or further containerized for vessel transport, hence termed containerized cargo as opposed to palletized. Cargo like fuels, grains, and coal are termed bulk because the goods are transported unpackaged in large quantities and typically dropped or poured with a spout or shovel bucket as a liquid or as a mass of relatively small solids into a bulk carrier ship's hold. Break-bulk or general cargo must be loaded individually, as opposed to within intermodal containers or in bulk, and transport is via a cargo ship, whereas roll-on/roll-off cargo, such as vehicles, tanks, semi-trailers, and trailers which are driven on and off the vessels or aircraft on their own wheels. Different types and amounts of military, commercial, and private cargo is currently moved to, from, or through Guam and

the Micronesia Region, with cargo transports aboard aircraft and vessels in all three sectors expected to increase from military activities during and after relocation. Cargo pathways pose many risks in transporting terrestrial vertebrate species. Cargo originates from many sources, both within and outside the Micronesia Region, and species access can occur during the packing and handling process, or during transport, if contaminated from another source while en route, such as rodents moving from the vessel to the cargo shipment. Cargo is also transported to numerous destinations, making it difficult to track and monitor shipments while facilitating the widespread movement and dispersal of terrestrial vertebrate species. Cargo arriving to the region may be targeted for agricultural inspection of insects, plants, and plant pathogens if manifests declare it as coming from a country of concern, having agricultural goods, and using proper certification for packing materials, but such inspections do not target terrestrial vertebrate pests. Cargo departing Guam may receive USDA-APHIS-WS canine inspection for BTS, especially if deemed high-risk cargo or if originating from a location of high snake density; however, the probability of detecting snakes or any type of species is drastically reduced when cargo is sealed inside containers, or packed and staged in complex configurations that offer numerous hiding places and challenges for inspectors and canine teams. The type of cargo can influence the type of species being transported. Cargo such as nursery plants and associated growing mediums offer environments conducive for transporting amphibians; food shipments can attract and harbor rodents; equipment cargo can offer intricate hiding places for reptiles like snakes, anoles, and geckos; and outdoor household items, such as tubing from swing sets and barbecue grills, can transport BTS. Animals shipped live, including those for research, personal pets, the pet trade, work, or food, are a risk because escapees can contaminate other types of cargo, an aircraft, or a vessel. Illegal movement of species can occur through legal routes, such as frog eggs and tadpoles entering through the plant nursery trade and aquaculture industries, respectively. Further, transport durations and packing and shipping methods vary, thereby influencing species' survival probability differently.

Cargo inspections can occur on goods imported to and exported from the region. Arrival inspections are mainly to detect agricultural pests such as insects, plants, and plant pathogens, and do not target terrestrial vertebrate species. Departure inspections are also agricultural in nature, and on Guam and Saipan, all departing cargo should be inspected for BTS. The volume of cargo being moved in the region is difficult to inspect thoroughly because of a lack of resources to meet current and military relocation demands, the myriad shipping companies that process and move cargo, and the need to avoid delays in loading and unloading cargo at air- and seaport facilities. Chartered and private airfreight cargo is difficult to inspect because unlike typical commercial airfreight services, flight activities can be unscheduled, hence transportation of species can occur any time, to numerous places without detection. For example, the private company Freedom Air carries various types of cargo, including personal vehicles, which can be transported from Guam without inspection for BTS (Freedom Air 2010) (Figures 11-2a-2b.). Cargo moved through private routes present a risk; visiting sailboats, private aviators, and long-line fishing boats can transport and disperse species. Military cargo presents additional risks, including classification and therefore exemption from inspections, and immediate shipping without advanced notice for medical emergencies. Military cargo such as personnel field gear and training equipment can be transported directly from the field via amphibious landing craft,

helicopters, or personnel, as well as via commercial and military airports, and military airfields, complicating inspection procedures.

Figures 11-2a and 11-2b: Vehicle Transported as Airfreight Cargo Through Chartered Service Company

Source: Freedom Air

8.5.5 People and Baggage

Recommendations concerning people and baggage pertain to the travelers and their carry-on items (hereafter referred to as baggage). People tend to opt for the quickest mode of travel, making travel duration short and species survival high in this pathway. Risks associated with the recommendations for this pathway are due to intentional and unintentional transport of vertebrates. Transport of people and their baggage can occur either by air or water, and can be private, commercially or military-operated, with each mode differing in the inspection process at the border. Commercial air transport of people and baggage includes commercial airlines or private charters, while commercial water transport consists of cruise ships or private charter boat passengers. On the other hand, military air transport of personnel may be involved in purely transportation from airfield to airfield, routine aviation training, or immediate departures of urgency (warfare, medical). Similarly, military water transport of personnel includes transport from one base to another, training missions, and immediate departures or urgency (warfare, rescue).

While inspection agencies are in place at commercial ports, the inspections do not target for detection of vertebrate species, but rather target for direct human health and safety threats and agricultural pests. Also, the equipment available for the inspection procedures (x-ray machines) of passengers may be inadequate both in number and sensitivity for the detection of vertebrate species. For example, while GCQA has two x-ray machines at the airport, they were inoperable at the time this was documented and are awaiting replacement RapidScan machines (Berringer, personal communication). Furthermore, while paper-based agricultural forms are used for arriving passengers, the forms may not be reviewed quickly enough by inspection agents in order to address breaches in regulations, or passengers may be dishonest with their entries or have difficulty completing the form due to a language barrier.

Military personnel that travel on a military-operated passenger aircraft (<http://www.baseops.net/spaceatravel/>) must describe their travel by category (i.e., emergency leave, ordinary leave, retiree or dependents leave). Like commercial air travel, personnel and passengers departing Andersen AFB are subject to security screenings and carry-on baggage clearance operated and regulated by the TSA. However, exceptions to the regular passenger screening process apply to personnel whether they are departing from a civilian or military airport. For example, personnel do not have to remove their boots during the screening process unless the walk-through alarm sounds. While these exemptions expedite the travel process for personnel that must travel quickly due to the nature of their service, the exemptions leave gaps in the inspection process for vertebrate species. Personnel transported by water will utilize military-operated vessels such as high-speed catamarans, amphibious vehicles, or hovercraft departing out of Navy Base Guam, Apra Harbor.

Under the authority of the MCI, passengers, crewmembers, accompanied baggage, and equipment boarding any DoD-sponsored ship or aircraft departing an overseas area for the CTUS must be inspected or examined prior to departure. All travelling personnel must complete U.S. Customs Accompanied Baggage Declaration, DD Form 1854 while civilian crewmembers must complete Customs Form 5129. The MCI should accomplish this inspection or examination immediately before departure of the ship or aircraft. Urgent departures such as medical emergencies are still subject to MCI inspection. The mandatory inspection includes opening and examining baggage carried on by personnel and a physical search of personnel for prohibited items (as outlined in DD Form 1854), and breaches are addressed by military enforcement officials. Unfortunately, MCI does not yet operate in Guam, although its role is currently being supported by PPQ. The Navy is advocating instituting MCI on Guam.

8.6 SPECIES OF CONCERN

The level of risk to biosecurity is heavily influenced by the type of species and pathway of potential transport (USDA-APHIS-WS 2010). Species of concern are those that exemplify serious biosecurity risks pre-border, at the border, and post-border due to distinct biological and behavioral attributes documented for each species.

Species-specific characteristics that pose risks to biosecurity include the conduciveness of the species to enter a pathway (e.g., physical size and conspicuousness, number of individuals), and survival probability (individual fitness and thermoregulatory abilities). In addition, shipping logistics introduce risk depending upon the duration and type of transport, food availability during transport, air temperature and ventilation during transport, type of cargo, cargo packing and shipping method used, type of commodity, and origin of the shipment (e.g., history of incidence, large pet trade industry).

At the border, the stringency (see Chapter 3, *Regulatory Drivers*) and technology available regarding the inspection process of vessels and cargo influences the potential for introduction at the destination. If introduction does occur, the establishment of a population is again subject to support of the species' distinct biological and behavioral attributes (invasiveness, habitat matching, diet type, release from predators, increase in natural resource availability, circadian rhythm type). Also, establishment can be facilitated by interactions with other species, both native (e.g., prey shift) and non-native (invasional

meltdown) (Simberloff and Von Holle 1999), and humans (human-facilitated dispersion). Emerging issues of modernity include climate change and genetic introgression (genetically engineered captive-only species), which introduce further uncertainty and complexity.

In application, the following section may be used for taxa-specific action plan purposes. Species of concern are organized by taxa, and the recommendations that apply to each group are found within each section. More attention was given to taxa of highest risk, such as BTS and species involved in the pet trade.

8.6.1 Reptiles

8.6.1.1 *Brown Treesnake*

BTS is venomous, posing a risk to human health and safety. Approximately one in every thousand hospital visits on Guam is due to a BTS biting incident, with victims including infants, agricultural workers, and BTS field staff (Fritts et al. 1990; Fritts and Leasman-Tanner 2001a). Accidentally introduced to Guam via imported military cargo presumably at Apra Harbor in the 1950s (USGS 2005), BTS has been a nuisance species that continues to pose risks to Guam's ecology, economy, and human health interests. The snake's native range includes portions of Indonesia, New Guinea, the Solomon Islands, and Australia (Colvin et al. 2005), but extralimital populations currently thrive on Guam where the species occurs in very high densities of up to 40 individuals per acre (Colvin et al. 2005) due to optimal environmental conditions like abundant prey, absence of predators, decreased competition for food, and favorable breeding habitat and climate, as well as life history characteristics like high reproductive rates. On Guam, BTS has extirpated 10 of the 12 native forest bird species and 2 of the 11 native lizard species. It is associated with frequent power outages, with economic impacts including the loss of power generation, damaged equipment, and time needed to conduct emergency repairs to restore electrical services. Loss of power equates to human health and safety concerns when facilities such as hospitals and airport control towers are involved. Further economic impact is caused to the tourism industry on Guam when power outages notably disrupt vacationers' activities (Fritts and Leasman-Tanner 2001a). BTS appears to have a trophic cascade effect that indirectly affects insect populations; some bird species extirpated by BTS were primarily insectivores. With avian predators extirpated, insect populations typically increase in abundance, with negative economic consequences to the agricultural industry on Guam (Kraus 2009a, Chapter 3).

Extralimital occurrences of BTS have been documented for Pacific Regions and in air and sea transportation pathways, for both commercial and military sectors. Incidences with military crafts include BTS found in the landing gear of military cargo planes (Kwajalein), in an Air Force B-52 bomber (Darwin, Australia, n=1, 1984) (USGS 2005), and possibly but not confirmed, disembarking and disappearing from a cargo plane (Hickam AFB, Honolulu, Hawai'i, n=1, 1997) (Claiborne 1997; USGS 2005). The snakes enter residential and commercial structures in search of food and cover, and they have been detected in household items such as appliances, vehicles, lawnmowers, swing-set tubing, barbecue grills, and outdoor recreational equipment, making this species of extreme concern for military relocating from Guam. there are also numerous BTS encounter and capture reports for a variety

of locations that are not specifically tied to military activities. More specific information on locations and number of encounters can be found in Stanford and Rodda (2007).

The abundance of snakes on Guam, coupled with the tendency of BTS to hide in cargo and aircraft, creates a significant threat to the biodiversity and economic security of the tropical Pacific, as well as military operations on Guam. BTS is the single greatest threat to terrestrial ecosystems in the CNMI and the rest of Micronesia and is one of the greatest ecological threats to Hawai'i, making it a prime species of concern.

While it is unlikely that established populations of BTS will be completely eliminated with current technology where high densities exist (e.g., Guam), it is possible to control this species on a smaller scale (Rodda et al. 1999). An effective program for BTS interdiction must involve wide-area population suppression, snake-proof barriers, visual searches, and canine detection and interdiction, but also requires effective ED and RR capabilities for all areas at risk such as the jurisdictions covered by the MBP.

8.6.1.2 *The Asian Beauty*

The Asian Beauty snake (*Elaphe taeniura*) is native to Southeast Asia and Taiwan, but has been found on Okinawa since 1985, including gravid females. Although non-poisonous, this species poses an ecological threat as a potential predator of native mammals and birds (Ota 1999c; Ota 1999a) via intentional and unintentional transport. Due to its presence in the Ryuku archipelago, there is a high risk for its introduction to Guam via air or water transport related to military relocation efforts from Okinawa to Guam. In fact, one of these snakes was discovered in a shipping container holding munitions on Guam that had been shipped from Okinawa and held in storage for approximately 2 months in 2004 (Vice et al. In preparation). There is little information on effective control methods specific to *E. taeniura*.

8.6.1.3 *Habu*

The habu (*Trimeresurus flavoviridis*), a venomous viper, is native to the high islands of Amami and Okinawa. In these islands, the habu is a common human health threat, with high incidence of extremely painful bites. The venom can cause hemorrhaging and necrosis, and may progress to unconsciousness and death (Mishima et al. 1999). The incidence of habu bites varies with region; about 80% occurs in agricultural and residential areas, and up to 5.8 bites per 1,000 people can occur (Ota 1999b). The habu is also an ecological threat because it preys upon native birds, especially on islands with little or no rodent populations (e.g., Minnajima). The presence of an additional venomous snake on Guam could alter the effectiveness of current BTS interdiction measures. Unlike BTS, the habu is relatively sedentary and an affective attractant for habu traps has not been found (Hattori 1999), but trapping and barrier fences are the best methods available for control of the habu in residential areas. Due to its presence in the Ryuku archipelago, there is a high risk for its introduction to Guam via air or water transport related to military relocation efforts from Okinawa to Guam.

Only three snake species are mentioned here but it is worth noting that there are numerous species which could become established either through accidental transport or via pet trade. Various species

other than those mentioned in this section have already been recorded for various island in Micronesia and for the state of Hawai'i, the number of species and encounter incidents is much higher. Snakes in general are highly efficient predators which if allowed to establish will cause tremendous negative impacts to any of the islands within the region.

8.6.1.4 *Geckos and Lizards*

The mutilating gecko (*Gehyra mutilata*), and green anole (*Anolis carolinensis*) are introduced species found within the region that have the potential to be spread (Kraus 2009a, Chapter 3), and pose ecological threats to native ecosystems. Although a single individual generally will not lead to an incipient population, many lizard species are capable of parthenogenesis, a form of asexual reproduction found in females, where growth and development of embryos occurs without fertilization by a male. The lizard species of most concern for the region is *Carlia ailanpalai*, a lizard species already established in parts of the FSM (Buden 2009), and a known aggressive predator of the Pacific Blue-tailed skink (*Emoia caeruleocauda*) on Guam (Wiles et al. 1989). It is therefore considered a possible causal factor in the decline in native scincid lizards in the Marianas (Case and Bolger 1991; Rodda et al. 1991; Rodda and Fritts 1992). Furthermore, this scincid lizard is a main diet item for BTS, helping support the large population of BTS on Guam (Rodda and Fritts 1992). *Anolis* species can be transported via cargo containers, and the swimming ability of some enables them to jump ship in favorable scenarios, such as when the vessels are close to shore (Perry et al. 2006). *Anolis carolinensis* are known habitat generalists and the feeding behavior of these animals caused insect populations to collapse on the Ogasawara Islands of Japan, resulting in this species being listed as an Invasive Alien Species in Japan since June 2005. Although the green anole population on Guam has not recently undergone rapid growth, its density could nevertheless approach hundreds to thousands of individuals per hectare (Toda et al. 2010) in the absence of predators like BTS. Green anole populations on some of the islands of the CNMI are found at high density levels. Preventing invasions of small reptilian species such as geckos is often difficult to manage, and once established there are no known methods of eradication (Cole et al. 2005). Even the mangrove monitor (*Varanus indicus*) is not ubiquitous within Micronesia and it is known as a predator of sea turtles, crabs and birds. It is hoped that island which do not currently have populations of mangrove monitors can in fact be kept free of this predatory species.

Green iguana (*Iguana iguana*) are also a concern. They are known as IAS in other areas, are common in the pet trade and individuals have been recovered previously in both Guam and Hawai'i. Green iguana are known to be established in Florida, Puerto Rica, and on at least several islands in the Fiji island group (Pers Comm. J. Stanford).

Additionally it might be worth mentioning that Brown Anoles, Day Geckos and a few other lizards not yet known to be established in Micronesia are established in Hawai'i. Again, there is also likely potential invasive lizard candidates in places like the Philippines which might make it to Guam give the anticipated increases in the flow of people and goods from southeast Asia to Guam. Another lizard which we should be concerned about is *Calotes versicolor*. One individual has been found on Saipan and this species is a known invasive in some areas of Asia and also on Diego Garcia (Pers. Comm. J. Stanford).

Most lizards which become established not only will likely compete for resources with native biota as well as consume native species but they are also a great food source for predators which might establish like snakes and feral cats.

8.6.2 Amphibians

Guam has no native anurans, yet 13 anuran species have been discovered in Guam since 1937 of which at least 6 have established populations (Christy et al. 2007a). The modes most involved in alien anuran introduction are biocontrol, cargo, on/in shipping containers, food imports, plant trade, pet trade, and aesthetic release (Perry et al. 2006; Kraus 2009a). Due to their physical size and broad physiological tolerance, anurans can hide and survive various transport conditions, resulting in unintentional introduction on arrival if they remain undetected. Furthermore, anurans are most successful in transport survival when they are stowaways associated with living industry (e.g., plant propagation materials, live plants, and aquaculture) cargo, as the environmental conditions during transport are more likely to be optimal for anuran survival.

8.6.2.1 Cane Toad

The cane toad (*Bufo marinus*), native to Latin America, has been intentionally introduced in the tropics for the purpose of biocontrol, and unintentionally through air- and water-transported cargo, especially cargo associated with the plant trade (Kraus 2009a). As a generalist, the cane toad has proven to be an extremely successful invader throughout the Caribbean and Pacific (Lever 2001). It is a human health threat because it secretes bufotenine toxin that can potentially lead to serious illness or even human fatalities, particularly in children (Lever 2001). In addition, cane toads carry extremely high levels of pathogenic *salmonella*, specifically *S. waycross*, a species that contributes to high human salmonellosis rates on Guam (Haddock et al. 1990). Cane toads also pose ecological threats to native species through depredation; they are known to destroy nest burrows and prey on eggs and young nestlings of rainbow bee-eaters (*Merops ornatus*) (Boland 2004) in Australia. Further, the expected influences of global climate change on the worldwide problem of species invasions (Zhang et al. 2006; Ward and Masters 2007; Sommer et al. 2010) is evident in cane toads introduced into Australia; the species is rapidly expanding its range in part because of changing environmental and habitat conditions (Urban et al. 2007; Kearney et al. 2008).

8.6.2.2 Frogs

Introductions to Guam of the coqui frog (*Eleutherodactylus coqui*), Guenther's frog (*Rana guentheri*), spot-legged tree frog (*Polypedates megacephalus*), greenhouse frog (*Eleutherodactylus planirostris*), crab-eating frog (*Fejervarya cancrivora*), cricket frog (*Fejervarya limnocharis*), banded bullfrog (*Kaloula pulchra*), Northern Pacific tree frog (*Pseudacris regillii*), and the Mantella (*Mantella pulchra*) have occurred either through aquaculture or plant trade imports (Christy et al. 2007b), all of which have become established with the exception of the coqui frog and banded bullfrog (Vice 2009). Guenther's frog (widely known locally as the barking frog) was introduced to Guam in 2001 from an aquaculture shipment most likely originating in China or Taiwan, and has since flourished throughout Guam. A more recently introduced species is the spot-legged tree frog (in 2004), which was introduced via an

aquaculture shipment originating in China. The greenhouse frog arrived in Guam in 2003 through horticultural shipments originating in Hawai'i. An active horticultural trade exists between Hawai'i and Guam, and the species was found on Guam either at or in the vicinity of active plant nurseries or recent plantings (Christy et al. 2007a). All three established frog species pose ecological threats on Guam because they potentially may provide an additional source of food for non-indigenous invasive populations of rats, mongooses, and BTS. In fact, the barking frog and the green house frog are now found throughout Guam and in some areas can be found in remarkably high densities. Gut content of BTS from areas with high green house frog densities over the past several years have suggested that as the frog populations increase, so does predation on the frogs by BTS (Per Comm. J. Stanford).

The coqui frog and banded bullfrog were detected on incoming cargo to Guam (Christy et al. 2007a), the former found on horticultural material, while the latter in military cargo on a U.S. Air Force cargo plane. The coqui frog was also detected on Guam near a plant nursery (Christy et al. 2007b) but is not believed to have successfully established on the island. It has also been detected and intercepted on bulk palletized cargo shipped from Hawai'i (Vice et al. In preparation). The coqui frog is a significant economic threat in Hawai'i where it has negatively impacted the real estate market, nursery trade, and tourism industry, primarily due to the frogs loud and incessant calling behavior (Beard and Pitt 2005; Kaiser and Burnett 2006). The coqui frog also poses an ecological threat; in Hawai'i it has the potential to reduce endemic invertebrates and increase nutrient cycling rates, which may confer a competitive advantage to invasive plants in an ecosystem where native species have evolved in nutrient-poor conditions (Sin et al. 2008). The Northern Pacific tree frog is annually detected in imported Christmas trees shipments (Vice, personal communication); repeated introductions are likely to lead to the establishment of this species.

Prevention of the introduction and spread of anurans are the most efficient type of biosecurity measures for the taxa as attempts to rapidly eradicate invasive anurans in general have been unsuccessful, but some exceptions do exist. For example, if eradication is undertaken at an early stage of development (tadpole stage), success increases dramatically, as seen in the case of *Limnodynastes dumerilii* in New Zealand where all egg masses and individuals detected were destroyed quickly (Kraus 2009a). On the contrary, removal of adults may actually increase survivorship of metamorphs due to the release from cannibalism inherent in some species such as *R. catesbeiana* (Govindarajulu et al. 2005). However, most cases of anuran invasion pose more complex challenges to eradication efforts. In Hawai'i, *E. coqui* requires long-term management, and eradication is unlikely due to high incidence of repeated introductions and invasions. Still, *E. coqui* management options include intensive surveys and monitoring of populations, clearing of optimal habitat, and spraying (ground and aerial) of citric acid and hydrated lime to kill individuals. Management efforts of cane toads in Australia include the forming of the Cane Toad Task Force and implementing various short- and long-term control measures such as large-area barriers and fencing to prevent further dispersal of cane toads (Taylor and Edwards 2005; Sawyer 2006).

8.6.3 Mammals

8.6.3.1 Rodents

Introduced rodents have historically posed significant economic, ecological, and human health threats worldwide. Rodent species of concern to Guam include house mice and black rats (*Rattus rattus*). Both are transported as hitchhikers by air and water transportation pathways. Larger rodent species, such as nutria (*Myocastor coypus*) imported for fur ranching, also pose a threat.

House mice can economically threaten the food industry, and are known to be associated with salmonella, rickettsial pox, and choriomeningitis (Long 2003b). Also, the gnawing behavior common to rodents may cause damage to electrical wiring within the aircraft electrical equipment or infrastructure, threatening human safety and causing economic impacts. They also prey and therefore are attractive to other invasive species like BTS. The potential ecological destruction of established rodents may be exemplified by the infestation of more than 700,000 house mice on Gough Island off South America; since their establishment, these mice have physically tripled in size because they prey on albatross chicks in lieu of their typical insect and seed diet (Vidal 2008). House mice have been found hitchhiking aboard commercial airplanes, both within the cabin (Bodry 2008) and in wheel well compartments (Vice 2010b).

Black rats have reached about 80% of the world's islands, and are among the most successful invasive mammals (Caut et al. 2008). Rat infestations can occur in port facilities due to improper garbage disposal and handling, in addition to inadequate eradication measures (USDA-APHIS-WS 2010). These rodents can cause economic threats to livestock and poultry operations, crops such as rice, sugarcane, coconut, and macadamia, and damage to buildings and electrical materials. Rats can be reservoirs of zoonotic diseases, including *leptospirosis*, *typhus*, and *trichinosis*; rat fleas are vectors for *pasteurella* and *murine typhus* and plague; these all pose threats to human health through bites, contamination of food and water, and air-borne transmission. Lastly, ecological threats include predation on and extinction of native mammals, reptiles, and birds (Stenseth et al. 2003), either directly or by sustaining higher risk predators (e.g., BTS) as prey themselves (Fritts and Rodda 1998).

Furthermore, rodents may be transported along with a food source, thereby increasing their chance of survival during transport, such as a shipment of rodent-infested grain (Baker 1994a). Hitchhikers aboard civilian pathways include rodent pups discovered in the rear wheel well of an aircraft that had landed on Guam in March 2010 (Vice 2010b). Management of invasive rodents most often utilizes rodenticide methods, primarily anticoagulants. These methods are implemented in and around buildings, together with practices of exclusion, sanitation, and habitat modification (Timm 1994a, b). Day and night shooting is used with some larger species (e.g., nutria) (LeBlanc 1994). Most island eradications of rodents have utilized anticoagulant rodenticides, hand broadcast, in bait stations, or aerially broadcast (Howald et al. 2007). Military implementation of rodent control can be found in NAVMED P-5010-8, the Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology (U.S. Navy BMS 2004).

Established rodent and other small mammal populations provide excellent food sources which can support other non-native species, especially predators such as the BTS. There are a variety of rodent species already established in the region with some species overlapping and others not. More details on specific species can be found at the issg.org website.

8.6.3.2 Indian Mongoose

The Indian mongoose (*Herpestes javanicus*) is an example of an early attempt at biological control of an invasive pest species. It was introduced to the Hawai'ian Islands in an effort to control damage in the sugar cane industry caused by invasive rat populations that invaded the islands (Matthews and Turner 2009). The mongoose is established on some islands in Hawai'i but likely not all of them. A mongoose capture occurred recently on Kauai which prompted officials to set up a response system including interview formats based on those used by the alien snake team through the region (Pers. Comm. J. Stanford). Mongooses have also been introduced to control rats in Fiji, Mauritius, and to Amami-Oshima Island in Japan (Watari et al. 2008). Since their establishment, mongooses have contributed to the decline of populations of many native and endemic species of ground-nesting birds and reptiles, posing a serious ecological threat to Pacific islands. In addition, mongooses can also threaten mammalian health by their transmission of diseases such as *leptospirosis*, canine distemper, canine hepatitis, *toxoplasma*, *salmonella*, feline panleukopenia, *streptococcus*, and pulmonary virus.

Trapping and toxic baits placed in bait stations are the main methods used for control and eradication of mongoose, although success has usually been marginal (Roy et al. 2002; Quinn and Whisson 2004). Currently, National Wildlife Research Center scientists are working to identify attractants to better monitor and capture mongoose on Hawai'i. Additional methods development will further investigate effective, durable toxic baits and multiple-capture traps for mongoose. Where rabies exists, the development of an oral rabies vaccine for mongoose is also considered an important research goal due to the role of the mongoose as a vector for this virus (Quinn and Whisson 2004).

8.6.3.3 House Shrew

In high densities, the Asian house shrew (*Suncus murinus*), also known as the Musk shrew, poses ecological threats and impact on a wide range of other species, including plants, invertebrates, and vertebrates, either through predation or competition (ISSG 2005). This species can also act as a reservoir for the plague (Duplantiera et al. 2005), posing a serious human health threat. The house shrew is currently established on Guam, and due to their commensal nature, they are believed to be transported accidentally in cargo and personal effects (e.g., vehicles, cargo containers) (USDA-APHIS-WS 2010). The house shrew is thought to be anti-coagulant bait resistant and control measures rely on using baited snap traps (ISSG 2005). These shrews are also established on several other islands within Micronesia, including Saipan where they are found at much higher densities than on Guam (the reduced population on Guam is likely due to heavy predation by BTS).

6.3.4 Crab eating Macaque

Crab eating Macaques (*Macaca fascicularis*) are established on one island of Palau where they are produced tremendous negative impacts including reducing numbers of native bird species and impacting the human inhabitants by direct competition for food and destroying crops. While it is unlikely that macaques could “accidentally” stowaway and hitchhike to other islands, the fact that some humans consider the young to be valuable pets does make this a species of concern for the islands of Palau as well as the remainder of the region.

8.6.4 Birds

8.6.4.1 Wild Passerines

While there are several passerine species that have the potential to be introduced to Guam by air and water transportation pathways, wild passerine species of concern are those that are known agricultural pests of crops grown on Guam, possess highly invasive biological and behavioral characteristics, and exist along routes of frequent transport to and from Guam (Pacific Rim). The red-vented bulbul (*Pycnonotus cafer*) has been introduced to Australia, Fiji, French Polynesia, RMI, New Caledonia, New Zealand, Samoa, Tonga, and the United States via sea freight and more recently, Majuro (RMI) likely via the commercial air transport pathway. It is an agricultural pest (economic threat), an aggressive competitor of endangered native birds such as the Tahiti Flycatcher, a disperser of invasive plants like Lantana, and a prey source for BTS (ecological threat) (ISSG 2005). The black drongo (*Dicrurus macrocercus*), already introduced to Rota and Guam, continues to be an extremely aggressive species that harasses and displaces native bird species, a predator of bees, disperser of invasive plants, and prey source for BTS (ecological threat). The drongo also tends to nest on utility structures, in avoidance of BTS, meanwhile causing electrical damage (economic threat) (Fritts and Rodda 1998). Java sparrows (*Padda oryzivora*) are small passerine birds that are popular in the pet trade and have been introduced to many countries worldwide, including China, Myanmar, Thailand, Sri Lanka, Borneo, Sumatra, Ambon and Lesser Sundas, Fiji, Philippines, Taiwan, Japan, South Vietnam, Christmas Island, and Hawai’i. They feed on a variety of seeds in grasslands and are considered an agricultural pest of grain crops, especially rice (economic threat) (Koopman and Pitt 2007), and have a high reproductive rate with a modal clutch size of eight eggs (Islam 1997). While USDA Code of Federal Regulations prohibits the importation of this species into the United States and its territories, many states allow the possession and interstate traffic of captive-bred birds. Eurasian sparrows (*Passer montanus*) are well established on Guam and several other islands within Micronesia. These sparrows on Guam (as well as other bird species) are an additional food source for non-native predators such as the BTS. There also also a variety of other species including doves and pigeons spread throughout the region. Hawai’i has by far more non-native feral bird species established than any of the islands within Micronesia. Some of these feral population are from original pet stock.

8.6.4.2 Exotic Pet Birds

The pet industry is a well-organized and profitable industry in the United States (Ginsburg 2004). At least 94 species of introduced and invasive birds have become established in the United States, and most introductions originated from pets. Most of these are passerines (39 species), but many are psitticines (22 species), popular animals in the pet industry (Kraus 2003). The pet industry is a major pathway for

the introduction of vertebrates into the United States (Kraus 2003) because very few are prohibited from entry and can be imported legally with the proper permitting. Requirements of importation of exotic birds to the United States include a USDA import permit, 30-day quarantine at a USDA Quarantine Port Center, and veterinary certification of health from the country of origin (http://www.aphis.usda.gov/import_export/animals/nonus_pet_bird.shtml, accessed 9/14/10).

Once imported, release of caged birds may result in feral populations that can pose economic, ecological, and health threats, respectively to local industry (agriculture, electrical damage), native ecosystems (natural resource competition), and native bird species (host shift of ectoparasites). For example, the monk parakeet (*Myiopsitta monachus*), now established in the Midwest and Eastern United States, is a significant agricultural pest destroying up to 45% of some crops. In some regions, the monk parakeet utilizes native bird species' nest sites (introduced competition), or can cause electrical damage by nesting on utility structures. Currently, there are feral populations of pet bird species in Hawai'i and also likely within Micronesia. The continued importation of bird species for the pet trade sustains the potential risk of release of additional species and in new locations. Pet retailers on Guam are known to import exotic species such as Meyer's parrot, red-bellied parrot, green-cheeked conure, society finches, red-factor canaries, lovebirds, cockatiels, budgerigars, and ringneck doves (Guam pet retailer, personal communication). The non-native Java Sparrow (*Padda oryzivora*) has established at least one (if not more) small populations on Guam (Pers. Comm. J. Stanford).

Control methods for invasive bird species may include disrupting or destroying nests, targeted poisoning, trapping, and hunting. Farmers in Australia have shot more than 27 species of pest birds, but active control of invasive birds remains rather uncommon (Usher 1989). Characteristics inherent to birds such as ability to fly large-distances and high fitness, a commonality of invasive birds species, makes re-colonization a continuous issue, such that pest birds are very difficult to control.

8.7 BIOSECURITY RECOMMENDATIONS

8.7.1 Three-tiered Perspective

Biosecurity measures implemented to mitigate risks posed by terrestrial vertebrate species are necessary at three levels: pre-border, at-the-border, and post-border. Recommendations may be associated with one or more level and may overlap across levels, depending upon the mitigation measures. There are five key issues pertaining to all recommendations: funding, coordination and communication, education and training, early detection, rapid response, and enforcement (of regulatory drivers). For example, cooperative trade agreements, which would fall under coordination and communication, affect pre-border activities, while rapid response programs include at-the-border and post-border activities, and enforcement issues generally range across all levels. Prevention is more effective and cheaper than eradication or long-term control of established terrestrial vertebrate species, so exclusion of these species pre- and at-the-border should be the first line of defense. Eradication is more effective and cheaper in the long run than permanent control of a pest population, so eradication should be considered where feasible.

8.7.2 Key Issues Regarding General Recommendations

This section will discuss some overall, general recommendations for mitigating the risk of transporting vertebrate invasive species unintentionally. More specific recommendations are covered in other sections. These general recommendations should not be considered as the only, or the most important, recommendations. Rather, they should be viewed as a starting point for more formalized recommendations. Five key issues are central to successful implementation of the recommendations given here. These key issues are: funding, coordination and communication, education and training, control methods development, and regulatory drivers and enforcement.

8.7.2.1 Funding

Regardless of the biosecurity strategy developed, lack of sufficient and properly managed funds will be the weak link in any effort implemented. Military presence in the region calls for long-term allocation and ongoing management of biosecurity funds. Current funding for regional biosecurity is distinctly inadequate relative to the magnitude of the existing problems posed by invasive species, the emerging problems and associated risks to other islands, and the scope and magnitude of military activity in the region.

Short-term funding cycles hamper necessary methods development and interdiction activities and restrict the forward momentum needed for effective control programs. For example, because BTS efforts are currently underfunded, much higher costs are expected in the future to resolve expanding threats not addressed now. Cost-sharing among agencies and the transportation industry has advanced greatly, with more room for improvement. Although DoD supplies funding for interdiction on military facilities, the DOI Office of Insular Affairs (OIA) is carrying much of the funding responsibility at present for BTS. The Office of Insular Affairs is the primary entity supporting BTS rapid response. Both Interior and DoD support BTS research efforts. Greater and sustainable investment by DoD and other federal agencies is warranted as part of their efforts to reduce the comprehensive impact of military activities and their overall stewardship of natural resources on their lands.

8.7.2.2 Coordination and Communication

The multiple economic, ecological, and human health impacts of invasive species create complex challenges in policy formation and governmental coordination (Williams 2007). NISC was established by EO 13112 to provide coordination and planning, and to facilitate cooperation among the diverse federal agencies and to take a more comprehensive approach to invasive species. NISC is co-chaired by the Secretaries of Agriculture, Commerce, and the Interior; and includes a total of 13 federal agencies and departments that have a role in invasive species (Williams 2007).

Federal agencies that must work in coordination to maintain a biosecurity plan include USDA-APHIS, USFWS, CBP, Interior, DoD, Department of Commerce, Department of Energy, DHS, and the Department of Transportation, among others. Interagency coordination is pertinent, as is frequent and comprehensive communications. The communication network that occurs between government agencies results in information that can be compiled, consolidated, and reproduced in a manner suitable

and clear to the general public and private industry (e.g., transportation, construction). Local capacity-building is needed to support research, operations, and program management, and to improve local recruitment pools. Efforts could include cooperative university and government programs, so that funding is utilized in a most resourceful manner (Colvin et al. 2005). For example, the public outreach program on Saipan is a model, particularly the partnership with private industry. This public outreach effort, fielded by the Office of Economic Adjustment and the Military Integration Management Committee, conducts community outreach dialogue sessions on Saipan to hear concerns of citizens. This and other demonstration projects illustrate attempts at achieving biological, social, and economic objectives through managing invasive species on islands (Saunders et al. 2007).

In addition there are various local and regional entities which can and should be involved in biosecurity and IAS work. An important or potential important regional body which already is involved with IAS for Micronesia is RISC. This group, if better supported could become a key mechanism for regional communication and coordination activities and in some regards it already is. Many of the jurisdictions also already have established invasive species tasks forces or councils/committees. Groups such as the Pacific Island Learning Network (PILN), the Pacific Invasives Partnership (PIP), and Pacific Invasives Initiative (PII) are also already involved in supporting regional IAS efforts. A few of the jurisdictions also have invasive species coordinators and it is hoped that in the near future each of the jurisdictions could have such a position to support communication and coordination throughout the region on IAS issues. SPC and SPREP, 2 Pacific region groups, are also already very involved in IAS issues within Micronesia and it is hoped that the roles of both of these groups can be expanded to further the support they can provide in this regard.

8.7.2.3 *Education and Training*

Gaps in invasive species management can be bridged by increased education and training, with an emphasis placed on public outreach. Public perception and lack of support have affected efforts to manage or eradicate vertebrate species in the United States, as elsewhere in the world (NISC 2001). Knowledge levels regarding invasive species and the harm they can cause are relatively low among the general public (NISC 2001, Conover 2002). For example, reports on invasive species management in Hawai'i (TNC and NRDC 1992) concluded an overall gap in public awareness of invasive species. This resulted in the formation of the Coordinating Group on Alien Pest Species (CGAPS), a voluntary government/non-government partnership, formed in 1995 to increase public awareness of invasive species. Following the formation of the partnership, CGAPS launched a campaign in 2006, with television and print media and a new toll-free hotline number regarding the dangers of BTS. Encouragingly, follow-up surveys confirmed a rising awareness about BTS (Martin 2007). Educating the public on preventative measures must be continual, especially given that, over time, the longer an invasive species is not discovered, the further it tends to slide from public concern.

Furthermore, staff involved in the enforcement aspect of invasive species (e.g., inspection agents) need to be educated on biological risks on which they act daily. Knowledge of the impacts of introduction is bound to increase staff motivation and efficiency in the workplace. Training should include the taxonomic identification of species, continued education on species status updates, changes to

regulations, and new pest species listings (e.g., White List). In conjunction, multimedia educational material will further facilitate proper identification of species, with written descriptions, physical attributes, and animal behavior, as well as immediate human health and safety concerns (see Distance Diagnostic and Identification System, [University of Florida 2010]).

Rapid response programs are designed to implement immediate action on the detection of invasive species. They are comprehensive programs that require the melding of coordination, communication, education, and training. Rapid response actions and sightings are documented in incident reports, and response times are substantially reduced by emphasizing training and public awareness, as shown in the CNMI in 2003 (Colvin et al. 2005). The BTS review by Colvin et al. (2005) found rapid response to be most successful when the following aspects are incorporated into the program: extensive training, public awareness and outreach, use of technological advances, centralized documentation (e.g., SOPs), and networking that allows the program to operate on a regional level. These aspects are central to the recommendations for rapid response programs outlined in the review. Currently, the most developed rapid response programs exist in Guam, Saipan, and Hawai'i, but training and organizational efforts in other archipelagoes in the Pacific Basin are underway. For example, the USGS Rapid Response program has conducted BTS trainings for quarantine officers throughout Micronesia, including the CNMI, Palau, Chuuk, Pohnpei, Kosrae, Kwajalein, Ebeye, and Majuro (Stanford and Rodda 2007). It should be clear that while the BTS response team has existed for more than 10 years, it is not well funded in regards to being able to address issues such as regional outreach and staff turnover at participating agencies has been higher than expected. It has been moderately successful with regional networking, supporting response actions and working within the FSM, RMI, Palau and the CNMI on outreach initiatives due in large part to support from OIA and local authorities. Not all local agencies (none) are well funded and most are extremely understaffed and have little equipment and few training opportunities. Building a high capacity response team on a shoe string budget across multiple countries in an area bigger than the continental US is not an easy task. The fact that RRT has a regional team with trained responders on all of the major islands of the region and the Hawai'ian islands, is to be applauded. So while funds have been appropriated, but given the extent of the situation, those funds and the ability to use them to address ED and RR activities across the region are insufficient.

8.7.2.4 *Control Methods Development*

Methods development is also needed to facilitate prevention measures occurring at the pre-border stage, but its largest application is in mitigation at the post-border stage of introduction of an invasive species. Methods development is most productive when closely coordinated and integrated with SOPs to maximize efficient use of funds and execution in the field (Colvin et al. 2005).

While extensive progress has been made on many aspects of BTS biology and control measures, additional research is needed to facilitate control and interdiction, including topics such as bait and attractants, application of control agents, logistics of control measures (Colvin et al. 2005). Unlike BTS, there remains a lack of methods development for particular invasive species, such as the Asian beauty snake, garter snakes, gecko species, mongoose, and house shrews. Certain species require integrative solutions for effective control methods; characteristics inherent in their biology and behavior may make

some species more difficult to control. For example, effective baited trapping of BTS is feasible due to their large movements, while bait and attractants are not as effective on the more sedentary Habu snake (Hattori 1999). Successful methods development relies heavily on sufficient funding to fuel the education, training, human resources, and facilities required to pursue a comprehensive, integrative approach to control and management of invasive species.

8.7.3 General Recommendations

Address funding issues necessary for regional biosecurity. Regardless of the biosecurity strategy developed, lack of sufficient, consistent, and properly managed funds will be the weak link in any effort implemented, allowing for biological invasions of terrestrial vertebrates to occur in the region.

Military funding for biosecurity efforts in the region must be sufficient, consistent, and properly managed. Military presence in the region calls for long-term allocation and ongoing management of biosecurity funds, as many risks to biosecurity are associated not only with the relocation, but with continual and growing military regional activities resulting from the relocation. Management of funds outside the military sector is necessary to curtail gaps in the biosecurity system that hamper success. For example, although sustained military funding to implement biosecurity measures are in place for some species, like BTS, allocation of those funds can be drastically delayed when new transfers of military personnel solely in charge of those funds reassess the BTS threat, as well as the amount and timing of funds that are allocated. Military funding should address current needs, which are grossly inadequate for even basic biosecurity in the region. Military funding solely for the relocation is disproportionate to the need being created over the long term, and therefore funding should extend to cover ongoing and cumulative impacts of the relocation. For example, funding for BTS management should extend beyond the 1-year limit being imposed currently in the final ROD (pg. 104) following military construction and the permanent relocation of non-transient Marine Corps military units to Guam.

Re-authorize the BTS Control and Eradication Act (2004-2009). The 5-year BTS Control and Eradication Act expired in 2009 and needs to be reauthorized. This is an important regulatory driver pertaining to prevention, mitigation, and management of BTS and pertinent for protecting areas exposed to BTS from trade, travel, and tourism. Once reauthorized, USDA and Interior should engage in rulemaking to develop regulations that further protect Micronesia from the spread of BTS.

A centralized group should be responsible for creating avenues for funding within the Micronesia Region. Regional funding is necessary because many of the risks are interrelated and require efforts that cross political boundaries, and sustained efforts are required to effectively minimize risks. Representatives from all pertinent parties could act as a panel to organize priorities, ensure timely and adequate allocation of funds, and implement adaptive management practices of consistently reviewing and refining the funding processes to adapt to changes needed to maintain efficacy. In addition, a centralized group could apply checks and balances to quickly detect problems or shortcomings in the system.

Mandate and enforce regulations for handling cargo, including packing, transport, cargo-staging, palletizing, and loading. Because cargo originates and is destined for myriad locations increasing the potential for transporting unwanted terrestrial vertebrate species, the most cost-effective solution is to regulate the processes involved in cargo movement. Funding is required to adequately develop and enforce regulations for movement of cargo by military and civilian sources with an emphasis on terrestrial vertebrate species. Warehouse facilities that consent to and help facilitate inspections of cargo and cargo handling procedures, such as providing training to staff, and allowing inspections and control efforts to be implemented should be given incentives to maintain this proactive approach. Cargo staging area issues need to be addressed, for example, to reduce the cross-contamination between high- and low-risk cargo. Regulations need to be enforced to show that penalties not only apply, but are actively being implemented.

Centralize biosecurity efforts. The NISC was established by EO 13112 to provide coordination and planning, facilitate cooperation among the diverse federal agencies, and to take a more comprehensive approach to invasive species. However, the multiple economic, ecological, and human health impacts of invasive species create complex challenges in policy formation and governmental coordination (Williams 2007), so that efforts must be centralized in order to operate cohesively and effectively. A central group acting as a liaison can bridge gaps between formal and informal, and military and civilian communications. A central group would outline the current network of the biosecurity communications in the Micronesia Region; identify communication gaps; provide information in the appropriate format for public, private, and military sectors; and be a representative for media and news releases concerning biosecurity.

Develop a biosecurity surveillance system for improved data collection, reporting, and information sharing network. There is a paucity of available information from the military to fully assess risks associated with the unintentional and accidental movement of terrestrial vertebrate species, posing significant risks and undermining biosecurity efforts in the Micronesia Region (USDA-APHIS-WS 2010). Sustained surveillance of biosecurity risks to lead an adaptive response would decrease the risk due to changing threats and changes in the way cargo and people are moved in the future. Further, information sharing would allow programs to be fully integrated into new projects, new cargo routes, or new air and sea shipping companies.

Encourage and participate in action to preserve biodiversity. Include actions taken by joint agency collaborations, such as the Micronesia Challenge (Micronesia Challenge 2009).

Create community funding sources for local programs. Promote local programs, such as “Environmental citizenship” (Barry and Knab 2005), for local training, education, eradication efforts.

Expand and manage University programs. The universities of the region can serve as local facilities for education and training to enhance biosecurity measures.

Comprehensive and continued education is needed. Educate everyone who can help or positively influence the campaign against invasive species. Elements can include disseminating reports and

newsletters to educators, journalists, lawmakers, and business and community leaders; establishing local reporting systems for rapid response teams; developing curricula for the schools; and conducting a pre-campaign poll of island residents to gauge levels of awareness regarding species introductions/invasions and subsequent impacts (Holt 1997). Include military and military-civilian personnel.

Implement biosecurity measures for detecting myriad terrestrial vertebrate species. Biosecurity activities need to account for several species of terrestrial vertebrates in the Micronesia Region, but hazards and regulations currently driving biosecurity efforts on Guam are aimed primarily at preventing the transport and spread of BTS. Detection methods for various terrestrial vertebrate species would involve an increase in awareness, adequate training, and proper equipment for dealing with inceptions and the capabilities to report all incidences, including incidental sightings. Such an integrative approach also permits assessment of the cumulative effects of terrestrial vertebrate species movement in the region.

Ensure the number of USDA-APHIS-WS canine inspection teams at military ports. To adequately prevent the movement of BTS on military and commercial boats, the number and capacity of USDA-APHIS-WS Canine Teams should be increased in response, if necessary, to adequately cover boats departing Guam.

Enhance canine inspection teams in the CNMI. Enhance the capabilities of canine teams in the CNMI by increasing the number of personnel and canine teams available, training opportunities, the ability to conduct random inspections, and the number of inspections and amount of materials that can be inspected.

Create a centralized canine inspection station for USDA-APHIS-WS canine teams on Guam for the commercial airport, port facilities, and commercial warehouses. Make the existing canine housing facility on Guam a central inspection headquarters that houses the majority of canine teams. This centralized station may also serve as a community collection point for vertebrate terrestrial species information, and awareness/training programs, and also be a place where the public can report observations and bring specimens.

Develop a labeling and tracking system for all cargo. Implement a barcode-based data collection system, and incorporate it into a centralized biosecurity system. A barcode-based system will typically comprise any or all of the following components: barcode scanners, barcode-based mobile computers (including wireless scanners, pen/key-based terminals, and vehicle-mount computers), barcode printers, barcode labels and ribbons, and barcode data collection software. Provide funding to adequately manage and refine electronic tracking of cargo in the region. Implement adaptive management practices to continually refine the tracking abilities and the overall surveillance system.

Manage the grounds around ports to reduce populations of target invasive species. Unintentional transport of hitchhiking terrestrial vertebrate species may occur in a number of ways. Hitchhiking species may be initially attracted to certain physical or chemical conditions, such as rats nesting in

aircraft wheel wells (Vice 2010c), BTS sheltering inside shipping containers or packing material (Fritts et al. 1999), and mice feeding on grain and garbage shipments transported overseas (Baker 1994b). Use USDA-APHIS-WS-approved vertebrate-proof staging areas, spot-lighting checks at night, continual trapping, large area population suppression efforts, and sighting response capabilities.

Expand capacity and funding for control methods for BTS. While progress has been made on many aspects of BTS biology and control measures, additional or improvement of methods would facilitate control and interdiction procedures, including bait and attractants, repellents, large area suppression, additional interdiction techniques, and logistics of control measures (Colvin et al. 2005). Sustained funding to refine existing strategies and develop new methods would decrease the long-term costs of interdiction, improve efficacy, and reduce risk.

Expand capacity of barrier methods for BTS and other invasive species. Develop and use more cost-effective BTS barriers systems that may permanent or temporarily deployed. Develop cost-effective barrier technologies (both physical and chemical) that keep snakes from entering cargo and for use in large- and small-area control efforts.

Develop methods for reducing the risk of transporting amphibians and lizards. New technologies should be developed for detecting and preventing lizard and frog movement in cargo.

Improve detection methods for rodents on vessels and in cargo. Rodents are difficult to detect, whether aboard vessels, in aircraft, or within cargo. Preventing rodents from entering ports or cargo is the most cost-effective measure for reducing transport of rodent species. NAVMED P-5010-8 is the Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology (U.S. Navy BMS 2004) and outlines preventative measures for rodent control on ships. This includes proper sanitation, pier-side inspections, rat guards, increased illumination, craft/vessel movement restrictions, glue boards, snap traps, and efforts to limit access points to the vessel, aircraft, or cargo. The information available on rodent prevention measures is more extensive for vessels than that of aircraft or cargo. Current control methods for rodents in cargo consist of anti-coagulant bait, snap traps, and sticky traps. Most efforts regarding rodent presence on vessels and in cargo remain in the control realm, while methods on rodent detection are underdeveloped.

Assign trained, uniformed USFWS personnel to law enforcement at commercial and military ports. USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated animals, provide permits, provide education, provide assistance in handling and processing terrestrial vertebrates detected by USDA-APHIS-WS inspectors, enforce laws, and be part of rapid response plans at the border.

8.7.4 Unintentional Pathway Recommendations

8.7.4.1 *Air Transportation*

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to aircraft conveyances departing Guam in both military and civilian sectors. Comply with 100% BTS inspection of

military and commercial aircraft departing Guam as per the NDAA, Public Law 110-181, Section 314 that requires prohibiting the transport and spread of BTS via aircraft, and the Non-indigenous Aquatic Nuisance Prevention and Control Act of 1990 that authorizes a cooperative program to control BTS outside its historic range. Representatives of USDA, the Department Commerce, DoD, and Interior; the CNMI; the Territory of Guam; and the State of Hawai'i, who comprise the BTS Control Committee (formed in May 1993), all advocate for 100% BTS inspection of aircraft leaving Guam.

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to aircraft conveyances departing Saipan in both military and civilian sectors. For military and commercial aircraft, the BTS Technical Working Group Plan (2009) specifies 100% BTS outbound interdiction on Saipan and other areas where incipient populations may be evident in the future, such as Tinian and Rota where Guam-based military actions are proposed.

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to aircraft conveyances arriving to U.S. sites other than Guam, in both military and civilian sectors. For military and commercial aircraft, the BTS Technical Working Group Plan (2009) specifies 100% BTS inbound interdiction on U.S. sites other than Guam. This includes aircraft arrivals to the Hawai'ian Islands of Oahu, Maui, and Hawai'i from Guam and Saipan. Interdiction measures include inter-agency coordination, such as expanded communication networks to notify Hawai'ian airports and airfields of craft arrivals from Guam and Saipan that missed BTS inspection, and funding to increase inspection capacity for U.S.-bound aircraft departing from Saipan and Guam.

Expand the capacity of USDA-APHIS-WS canine teams for aircraft inspections on Guam. Current demand for canine inspections of aircraft arriving and departing Guam needs to be expanded to meet 100% BTS inspection policy for departing aircraft, as well as account for expected increase in air transportation activity due to the military relocation.

Enhance the capacity of canine teams in the CNMI for BTS inspections of aircraft on Saipan, Tinian, and Rota. Implementation of inspection capabilities for Saipan are necessary because Saipan receives much of its cargo from Guam and the other Mariana Islands receive most of their cargo from Saipan, and because of expected increased activity from military training and deployment missions and commercial travel. USDA-APHIS-WS canine inspections of aircraft departing Saipan need to be implemented to meet 100% BTS inspection policy for departing aircraft, and to meet expected increase in the island's air transportation activity due to the military relocation. USDA-APHIS-WS canine inspections for BTS on aircraft arriving on Tinian and Rota from Guam and Saipan are necessary to keep the islands BTS-free, protect the native ecology and the agricultural interests of each island, and to account for expected increased activity from military and commercial travel. Military training on Rota is expected to increase aircraft traffic, hence increasing the probability of species transport. Current canine inspections of aircraft operating on Tinian and Rota need to be created to meet 100% BTS inspection policy for departing aircraft, to inspect aircraft arriving from Guam or Saipan that missed BTS inspection at departure point, and to account for expected increase in the island's air transportation activity (arrivals/departures) due to the military relocation.

Increase aircraft inspections for BTS and other terrestrial vertebrate species during seasonal peaks in military and commercial air transportation to and from Guam. More commercial flights depart Guam during the summer months, which may reflect peak tourist season, school summer recess, and summer holiday travel (Vice and Pitzler 2008). During these seasonal peaks, aircraft departing Guam, when inspected for BTS, should also be screened to detect terrestrial vertebrate pests, such as amphibians and other reptile species.

Assign at least one USFWS personnel at military and commercial airports. USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated animals, assist in the handling and processing of terrestrial vertebrates detected by USDA-APHIS-WS inspectors, enforce laws, and be part of rapid response plans at the border should an aircraft-related incidence occur.

Conduct an internal and external inspection on military aircraft arriving to Guam. Military aircraft carrying classified cargo are exempt from inspection procedures by non-military entities and “enjoy sovereign immunity from interference by all other governmental authorities” including police, health, customs, and immigrations (U.S. Navy 2009b; Hart 2010), compromising biosecurity efforts undertaken to prevent further introductions of unwanted terrestrial vertebrate species to Guam. Certain military aircraft arrivals to Guam warrant internal and external inspections. Military aircraft arriving from locations with known IAS for which Guam is at high risk of receiving need to be inspected either before departing those locations (ideal situation) or immediately on arrive to Guam. Military aircraft that arrive to Guam from Asian ports such as those in Japan, China, and Korea should be inspected for species of mice, birds, and amphibian and reptile species trapped within cabin and cargo compartments or hitchhiking externally in wheel well compartments.

Improve rapid response capabilities at military and commercial airports on Guam, Hawai'i, Chuuk, Palau, Pohnpei, Yap, Kosrae, Marshall Islands and CNMI Islands of Saipan, Tinian, and Rota. Rapid response measures prevent the opportunity for introduced pest species to become established. Rapid response takes place at the border and post-border, at levels ranging from federal to local community involvement. Monies have already been appropriated for rapid response capabilities in the region, but the efforts implemented remain ineffective for dealing with terrestrial vertebrate species. Conduct a review of the current process for rapidly responding to border and post-border detections and casual sightings. Apply BMPs to refine and improve protocols and coordination of efforts. Conduct practice drills to hone response skills and test communications network. Expand the communication network system. Improve processes for notifying jurisdictions receiving high-risk aircraft from Guam (e.g., contains high risk cargo, missed BTS inspection before departure). Provide information on specific species like BTS to military and civilian residential communities adjacent to airports and military airfields, and allow the public to be part of rapid response programs, with involvement levels ranging from organized community watch-groups to individuals calling into a pest species hotline for immediate reporting of a sighting.

Perform internal inspections on all military aircraft during washdown procedures, both general and retrograde washdown, to detect and capture terrestrial vertebrate species located within the aircraft.

Military procedures for washing aircraft focus solely on external cleaning, with an emphasis on soils and agricultural pests like insects. Because internal cleaning and inspections are not performed, terrestrial vertebrates hitchhiking within an aircraft being washed go undetected. This includes aircraft involved in routine flight operations, aircraft transported as cargo items (via air or water transport), or those staged upon a departing aircraft carrier.

Minimize distance between washdown facilities (general and retrograde wash facilities) and airports of embarkation. Military aircraft departing from a washdown facility (general or retrograde) should cover a minimal distance to port of embarkation to prevent post-contamination prior to loading. For example, the final ROD (2010) states that after a training event on Guam is complete, “vehicles and equipment will return to the wharf or airfield” to be washed and inspected prior to being loaded on to the ships or flying off-island.” However, neither washdown facility locations, nor type (general or retrograde) at military airports and airfields like Andersen AFB, the NWF, and Orote Airfield are specified.

Implement measures to control terrestrial vertebrate species at and around washdown facilities. Terrestrial vertebrate species control efforts at washdown facilities are needed to prevent post-contamination of washed aircraft staged for loading, and to reduce populations of pest species in surrounding areas. Control efforts include constructing USDA-APHIS-WS-approved species-proof barriers around secured washing and staging areas, collection/screening of wastewater run-off, and implementation of trapping and perimeter searches for pest species like BTS and other terrestrial vertebrate species. Implementation of snake trapping and snake barriers will not assist in address issues with other vertebrate taxa such as flighted birds, amphibians, and some mammals and of course suggested measures to protect against vertebrates will also not reduce risk from other taxa groups such as invertebrates.

Military retrograde and general washdown procedures for aircraft departing Guam for the Hawai’ian Islands are not specifically for detecting hitchhiking terrestrial vertebrate pest species. Because BTS presence is likely missed by external washing and inspection procedures for aircraft departing Guam, transporting these aircraft does not comply with 100% BTS inspection of military and commercial aircraft departing Guam as per the NDAA, Public Law 110-181, Section 314 that requires prohibiting the transport and spread of BTS via aircraft to other U.S. locations. Further, other terrestrial vertebrate pest species are not targeted, and they are likely missed during inspections.

Conduct inspections on commercial/private aircraft arriving to Guam, and those departing Guam that do not meet the BTS criteria for screening exemption. Currently, aircraft departing Guam are typically inspected externally for BTS, using visual and/or USDA-APHIS-WS canine Inspection techniques. Internal aircraft inspections (both arrivals and departures) do not typically occur, even when departing aircraft fail to meet criteria for exemption, for example, if the aircraft has been on the ground more than 3 hours, was left on the tarmac overnight, or is dispatched immediately for emergency and medical needs. Further, there are currently no aircraft departure screenings to detect terrestrial vertebrate species other than BTS. Inbound commercial and private aircraft are rarely inspected, internally or externally.

Examples include planes pulled into service after being in storage or in a repair facility, privately owned or leased aircraft, charter planes, and airfreight aircraft.

Provide a pre-clearance staging area for all military aircraft requiring immediate departure from Guam. Urgent military missions such as search and rescue (CSAR) and medical evacuation (MEDEVAC), immediate humanitarian efforts, or special mission deployments by the military will not be delayed to accomplish a BTS (or other terrestrial vertebrate species) inspection. A USDA-APHIS-WS terrestrial vertebrate species-proof staging area can be built and staffed to accommodate aircraft solely for immediate departure at Andersen AFB and applicable airfields on Guam, including sustained funding and implementation of control measures in and around staging areas such as trapping, spotlight searches, bait stations, and USDA-APHIS-WS canine team inspections for BTS, trapping and baiting for rodent species, and toad-proof barriers for anurans.

Provide USDA-APHIS-WS-approved temporary barriers for military and commercial aircraft left on the tarmac overnight. The greatest concern regarding aircraft parked on the tarmac overnight is the potential for terrestrial vertebrate species to access wheel wells and baggage holds (Vice and Pitzler 2008). Temporary barriers minimize the probability of terrestrial vertebrate species access to stationary aircraft left unattended overnight. This recommendation would be fulfilled through the re-authorization of the BTS Control and Eradication Act of 2004 (H.R. 3479).

For military and commercial sectors, formalize a notification process for destinations receiving aircraft from Guam that missed BTS inspection, including creating increased capabilities for responding to notifications. The system that currently exists for notifying destinations that an aircraft departed from Guam without a BTS inspection is an informal process and is not necessarily followed. When notification is made, there is typically a limited response; locations do not have the ability to respond to those arriving aircraft. While the DoD has a more formal notification process, destination locations still lack response capabilities (Vice, personal communication).

Coordinate biosecurity among contractors (military and civilian) involved in regional military air transportation. Entities involved in air transportation activities need to be included in biosecurity measures to ensure regulatory compliance, close gaps in inspection processes, and improve effectiveness of inspection efforts. For example, the military recently solicited for Transient Alert Aircraft services on Andersen AFB, Guam (30 June 2010), to perform numerous and diverse services, including aircraft movement and operations, safety management, special events support, emergency and training support, requested vehicle escorts, and management of publications and forms (U.S. Air Force 2010). Mitigation includes establishing agreements to facilitate inspections, determining communication networks, and implementing efficient biosecurity measures.

Expand control efforts to reduce BTS populations around commercial and military airport and airfield facilities. Reducing pest populations at military and commercial aircraft arrival and departure points reduces the probability of contamination from surrounding sources, and limits the attraction by predatory species to sources of prey. Control efforts, which are already being performed for BTS,

warrant expansion of efforts, including ground searches, area-wide trapping and suppression efforts, upkeep of perimeter fencing, and fence line searches.

Expand control efforts to reduce rodent populations around commercial and military airport and airfield facilities. Control of rodents is usually done on a response-basis such that detected rodent evidence will typically illicit the response to trap. Response to rodents or rodent evidence detected (feces, evidence of gnawing) in airport buildings or the surrounding grounds should be immediate. Even a single mouse or rat species can endanger aircraft passengers and compromise aircraft operations by gnawing at cables and wiring (WHO/HQ 1995). The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes and standard operational control methods as practical ways of minimizing and eliminating pest species habitat and food sources at cargo warehouses, airports, ports, and storage areas; however, stable, long-term funding for enforcement would be necessary.

Address military-related aircraft training and operations. Aircraft training exercises that use either improved (paved runway) or unimproved (unpaved landing sites) to practice landing/takeoff and air field support (including loading/unloading of fuel, munitions, cargo, and personnel), need to implement and manage biosecurity measures, such as those used for BTS (e.g., USDA-APHIS-WS approved snake-barriers, spotlight/hand-capture, and trapping) and rodents (e.g., trapping), as well as for species not usually targeted, such as geckos and frogs.

Facilitate training/education programs regarding terrestrial vertebrate pest species for inspectors. Train personnel to detect myriad species and provide continued education on species updates, such as changes to regulations and new pest species listings. Hold regular meetings to discuss pertinent issues and needs pertaining to inspection/detection at pre-border and border screenings.

There are limited methods for dealing with terrestrial vertebrate pest species detected aboard aircraft. Biosecurity measures for responding to incidents of terrestrial vertebrate pest species aboard aircraft are limited; for rodents, snake species, and insects, aircraft fumigation is an option, but it does not guarantee finding or exterminating such species detected within the aircraft, and it does not specifically target amphibian species.

Expand capacity at Guam's airports and airfields (military and commercial) to conduct comprehensive terrestrial vertebrate pest species inspections of arriving and departing aircraft. Inspections at operational airports and airfields on Guam may not adequately detect a terrestrial vertebrate invasive species moving in aircraft for various reasons like outdated equipment, understaffing, or inadequate regulation and enforcement.

Agricultural inspections at operational airports and airfields on Guam may not adequately detect a terrestrial vertebrate invasive species moving in aircraft. Agricultural inspections focus on plant pests and diseases such as plant pathogens and insect species, hence they do not directly inspect for, or report on, terrestrial vertebrate pests.

Rapid response measures for aircraft detections need to address terrestrial vertebrate pest species in addition to BTS. Rapid response is necessary for preventing species spread at the border and post-border via responses to species sightings. Rapid response measures for BTS are insufficient for responding to and preventing introductions of other terrestrial vertebrate species like frogs and rodents. In a more ideal world there would be response teams for each taxa group, but its unlikely that this can be achieved. Micronesia and Hawai'i currently do have a regional response team of highly training IAS responders who's training has been based on one taxa group, alien snakes but it should be clear that that training while focused on alien snake ED and RR also took into consideration the reality of the situation and therefore was for many years provided in a broadened manner so that trained responders could in fact support response actions to various taxa. This was done in part since the reality is that for most of the islands of Micronesia, the same responders will be call on for most taxa so as much as possible the alien snake training was conducted with the understand of a board array of concepts and tools needs to be addressed as team members will likely participate in responses to multiple taxa groups. And this in fact has happened and will continue to happen. The regional response team has supported response and detection work on a variety of snake species as well as lizards. Ultimately much of the underlying components of a response situation will in fact be standardize (or should be) and with appropriate field leadership and some individuals to lead the specific field activities modified for the correct taxa group then successful responses can be mounted across taxa groups by the same core set of well trained responders. Incident command structure is what the alien snake team used in the past to set up and conduct its field work and all responses regardless of taxa group should be following the same or similar format adjusted as needed for the specifics of that group. This flexibility is in fact part of the core concept of ICS training. What the lacking is training for more individuals, especially for the non-U.S. jurisdictions and dedicated leadership or coordinators. The ability to training additional staff for ED and RR work is readily available if courses can be provided on site (within the various jurisdictions). Coordination and leadership for response activities could come from a variety of sources and it may be worthwhile to utilized the emergency response planning documents prepared by the RRT Coordination office in conjunction with each jurisdiction as these existing materials will provide a guideline for how best to develop a more generic response capacity for the region. Additionally, IS coordinators for each jurisdiction as well as a region IS position would greatly enhance the ability to respond effectively to expected incursions of IAS throughout the region.

Expand financial resources in the CNMI (Saipan, Tinian, Rota primarily) to maintain expensive control programs. Efficient detection and prevention of introductions of terrestrial vertebrate species depends on biosecurity measures implemented and the resources allocated to accomplish them, such as border inspections, control and eradication efforts, and rapid response programs. For example, lack of funds to purchase mice for BTS trapping efforts on Tinian create a risk in delaying or ceasing control/eradication efforts (T. Castro, K-9 Dog Handler, BTS Program, CNMI, USDA 2010).

Communication is inadequate between the military and BTS inspection officials on Tinian to allow for proper inspections of aircraft associated with military training to occur. Develop effective SOPs for communication between groups that promote formalized processes for inspecting all aircraft arriving on Tinian from Guam.

Change procedures for canine cargo inspections at indoor warehouse facilities. Canine inspections at indoor warehouse facilities are compromised when exhaust fumes from operating equipment such as trucks and forklifts cannot properly vent from the building, thereby influencing detection capabilities of dogs. Implement a hiatus of equipment activity and the running of ventilation fans half an hour prior to inspections, or move cargo to be inspected to outdoor USDA-APHIS-WS-approved staging areas.

8.7.4.2 Water Transportation

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to vessels departing Guam in both military and civilian sectors. Comply with 100% BTS outbound interdiction for vessels departing Guam as per the NDAA, Public Law 110-181, Section 314 that requires prohibiting the transport and spread of BTS from Guam, and the Non-indigenous Aquatic Nuisance Prevention and Control Act of 1990 that authorizes a cooperative program to control the BTS outside its historic range. Representatives of USDA, the Department of Commerce, DoD, and Interior; the CNMI; the Territory of Guam; and the State of Hawai'i, comprise the BTS Control Committee (formed in May 1993), advocate for 100% BTS inspection of vessels leaving Guam.

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to vessels departing Saipan in both military and civilian sectors. For military and commercial vessels, the BTS Technical Working Group Plan (2009) specifies 100% BTS outbound interdiction on Saipan and other areas where incipient populations may be evident in the future, such as Tinian and Rota, where Guam-based military actions are proposed.

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to vessels arriving to U.S. sites other than Guam, in both military and civilian sectors. For military and commercial vessels, the BTS Technical Working Group Plan (2009) specifies 100% BTS inbound interdiction on U.S. sites other than Guam. This includes vessels arriving to Hawai'ian Islands like Oahu, Maui, and Hawai'i from Guam and Saipan used as commercial, military, and military-contracted cargo and barge shipping vessels, and vessels used for military training and mission deployment. Interdiction measures include inter-agency coordination, such as expanded communication networks to notify Hawai'ian seaports of vessel arrivals from Guam and Saipan that missed BTS inspection; funding to increase inspection capacity for U.S.-bound vessels departing from Saipan and Guam; and pre-clearance arrangements with Hawai'ian port officials, both military and commercial.

Expand the capacity of USDA-APHIS-WS canine teams for vessel conveyance inspections on Guam. Current demand for canine inspections of ocean vessels arriving and departing Guam needs to be expanded to meet 100% BTS inspection policy for departing vessels, as well as account for expected increase in water transportation activity due to the military relocation.

Enhance canine teams in the CNMI for BTS inspections of vessels on Saipan, Tinian, and Rota. Implementation of inspection capabilities for Saipan are necessary because of BTS presence on the island, because Saipan receives much of its cargo from Guam and the other Mariana Islands receive most of their cargo from Saipan, and because of expected increased activity from military training and

deployment missions and commercial travel. USDA-APHIS-WS canine inspections of aircraft departing Saipan need to be implemented to meet 100% BTS inspection policy for departing aircraft, and to meet expected increase in the island's air transportation activity due to the military relocation. USDA-APHIS-WS canine inspections for BTS on vessels arriving Tinian and Rota from Guam and Saipan are necessary to keep the islands BTS-free, protect the native ecology and the agricultural interests of each island, and to account for expected increased activity from military and commercial travel. Military training on Rota is expected to increase aircraft traffic, hence increasing the probability of species transport. Current canine inspections of vessels operating on Tinian and Rota need to be created to meet 100% BTS inspection policy for departing vessels, to inspect vessels arriving from Guam or Saipan that missed BTS inspection at departure point, and to account for expected increase in the island's vessel transportation activity (arrivals/departures) due to the military relocation.

Assign at least one USFWS personnel at military and commercial seaports. USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated animals, assist in the handling and processing of terrestrial vertebrates detected by USDA-APHIS-WS inspectors, enforce laws, and be part of rapid response plans at the border should a vessel-related incidence occur.

Conduct an internal and external inspection on military vessels arriving to Guam. Military vessels "enjoy sovereign immunity from interference by all other governmental authorities" including police, health, customs, and immigrations (U.S. Navy 2009b; Hart 2010), compromising biosecurity efforts undertaken to prevent further introductions of unwanted terrestrial vertebrate species to Guam. Certain military vessel arrivals to Guam warrant internal and external inspections. Military vessels arriving from Saipan where an incipient BTS population exists need to be screened by USDA-APHIS-WS canine teams on Guam if the vessel was not inspected at its departure point, especially if the vessel is transient and departs Guam without a BTS inspection (i.e., for emergency/medical use). Military vessels that arrive to Guam from Asian ports such as those in Japan, China, and Korea should be inspected for species of mice, birds, and amphibian and reptile species hitchhiking within cabin and cargo compartments.

Continue to expand rapid response capabilities at military and commercial seaports on Guam, Pohnpei, Palau, Yap, Chuuk, Kosrae, Marshall Islands and the CNMI Islands of Saipan, Tinian, and Rota. Rapid response measures prevent the opportunity for introduced pest species to become established. Rapid response takes place at the border and post-border, at levels ranging from federal to community involvement. The expansion of capabilities of rapid response programs would result in an increase in training and rapid response skills, while expanding communication networks. In addition, these programs provide information on species of concern, like BTS, to civilian and military, including residential communities, adjacent to seaports, and allows the public to be part of rapid response programs, with involvement levels ranging from organized community watch-groups to individuals calling into a pest species hotline for immediate reporting of a sighting.

Perform internal inspections of vessels during washdown procedures, both general and retrograde washdown, to detect and capture terrestrial vertebrate hitchhiking species. Military procedures for

washing vessels focus solely on external cleaning, with an emphasis on soils and agricultural pests like insects. Because internal cleaning and inspections are not performed, terrestrial vertebrates hitchhiking within a vessel go undetected. This includes vessels involved in routine military training and operations, military deployment missions, and vessels staged as cargo for transport. Coordinate with the on-site commanders to supervise washdown facilities and inspection areas. For general washing, the 36th ABW may provide portable high-pressure washers and a cleaning area, and future plans include repair of a 36 Transportation Squadron vehicle washing area (U.S. Navy 2005b).

Minimize distance between washdown facilities (general and retrograde wash facilities) and seaports of embarkation. Military vessels departing from a washdown facility (general or retrograde) should cover a minimal distance to port of embarkation to prevent post-contamination prior to loading. For example, for military embarkation operations, "...a cargo staging and vehicle washdown area would be provided in proximity, but not adjacent to, the wharf" (U.S. Navy 2009a, Vol. 1, pg. 2-11, section 2.2.3.1), and the final ROD (2010) states that after a training event on Guam is complete, "vehicles and equipment will return to the wharf or airfield" to be washed and inspected prior to being loaded on to the ships or flying off-island." However, washdown facility locations, or type (general or retrograde), are not specified by the military.

Implement measures to control terrestrial vertebrate species at and around washdown facilities. Terrestrial vertebrate species control efforts at washdown facilities are needed to prevent post-contamination of washed vessels staged for loading, and to reduce populations of pest species in surrounding areas. Control efforts include constructing USDA-APHIS-WS-approved species-proof barriers around secured washing and staging areas, collection/screening of wastewater run-off, and implementation of trapping and perimeter searches for pest species like BTS and other terrestrial vertebrate species.

Conduct inspections on commercial and private vessels arriving to and departing Guam. Comply with 100% BTS outbound interdiction for vessels departing Guam as per the NDAA, Public Law 110-181, Section 314 that requires prohibiting the transport and spread of BTS, by conducting inspections on vessels departing Guam. Commercial and private vessels are rarely inspected, internally or externally. Such vessels include but are not limited to boats used for fishing, recreational sailing, and those in the charter industry. Expand the use of visual and USDA-APHIS-WS canine team inspections. Expand vessel inspections to include terrestrial vertebrate species other than BTS and rodents, and conduct internal vessel inspections for rodent, snake, and amphibian populations.

Provide a pre-clearance staging area for all military vessels requiring immediate departure from Guam. Compliance with 100% BTS inspection of vessels leaving Guam is not achieved if urgent military missions, immediate humanitarian efforts, or special mission deployments by the military depart without delay for a BTS (or other terrestrial vertebrate species) inspection. Such vessels include but are not limited to amphibious vessels like Landing Craft Air Cushions (LCAC), patrol boats such as PACV/ACV, PBL, PBR, and PCF, and rigid inflatable boats. A USDA-APHIS-WS terrestrial vertebrate species-proof staging area can be built and staffed to accommodate applicable vessels for immediate dispatch from

Guam at seaports and applicable beach launch sites (for amphibious craft), including sustained funding and implementation of control measures in and around staging areas such as trapping, spotlight searches, bait stations, and USDA-APHIS-WS canine team inspections for BTS, trapping and baiting for rodent species, and toad-proof barriers for anurans.

Provide USDA-APHIS-WS-approved temporary barriers for military and commercial vessels staged on land overnight. Vessels staged overnight on land for storage, cleaning, repair, or special deployment offer hitchhiking terrestrial vertebrate species access to external and internal compartments and storage holds. Temporary barriers minimize the probability of terrestrial vertebrate species access to vessels left unattended overnight.

Coordinate biosecurity among contractors (military and civilian) involved in regional military water transportation. Entities involved in water transportation activities need to be included in biosecurity measures to 1) ensure regulatory compliance, 2) close gaps in inspection processes, and 3) improve effectiveness of inspection efforts. Mitigation includes establishing agreements to facilitate inspections, determining communication networks, and implementing efficient biosecurity measures.

Expand control measures to reduce pest species populations around commercial and military seaport and beach access point facilities. Reducing pest populations at military and commercial seaports and beach access points where vessels arrive and depart reduces the probability of contamination from surrounding sources. Efforts include but are not limited to ground searches, upkeep of perimeter fencing, implementing USDA-APHIS-WS-approved terrestrial vertebrate species-proof barriers, and specific trapping for species of rodents and snakes. When rodents or rodent evidence (feces, evidence of gnawing) is found in buildings or the surrounding grounds, immediate control steps must be taken. Even a single mouse or rat species can endanger the health of ship passengers and compromise vessel operations by gnawing at cables and wiring. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating pest species habitat and food sources at cargo warehouses, airports, ports, and storage areas, and even establishing a regulatory basis for pre-clearance of cargo arrivals and departures; however, stable, long-term funding for enforcement would be necessary.

Address military-related vessel training and operations. Vessels used in training exercises at seaports or at beach access points require internal and external inspections for terrestrial vertebrate species, especially BTS. Further control measures should also be implemented at least for BTS (e.g., USDA-APHIS-WS-approved snake-barriers, spotlight/hand-capture, and trapping) and rodents (e.g., trapping, baiting), as well as for species not usually targeted, such as geckos and frogs.

Facilitate training/education programs regarding terrestrial vertebrate pest species for inspectors. Train personnel to detect myriad species and provide continued education on species updates, such as changes to regulations and new pest species listings. Hold regular meetings to discuss pertinent issues and needs pertaining to inspection/detection at pre-border and border screenings.

Increase vessel inspections for BTS and other terrestrial vertebrate species during seasonal peaks in military and commercial water transportation to and from Guam. This recommendation addresses seasonal increases in military vessel traffic, private vessel traffic, and commercial ship and barge traffic. During these seasonal peaks, when vessels departing Guam are inspected for BTS, they should also be screened to detect terrestrial vertebrate pests, such as amphibians and other reptile species.

Military retrograde and general washdown procedures for vessels departing Guam are not specifically for detecting hitchhiking terrestrial vertebrate pest species. Foremost, because BTS presence is likely missed by external washing and inspection procedures for departing vessels, movement of these vessels does not comply with 100% BTS inspection policy, as per the NDAA, Public Law 110-181, Section 314 that requires prohibiting the transport and spread of BTS via vessels.

Agricultural inspections at operational seaports on Guam may not adequately detect a terrestrial vertebrate invasive species moving in vessels. Agricultural inspections focus on plant pests and diseases such as plant pathogens and insect species, and do not directly inspect for or report on terrestrial vertebrate pests.

Expand capacity at Guam's seaports (military and commercial) to conduct comprehensive terrestrial vertebrate pest species inspections of arriving and departing vessels. Inspections at operational seaports on Guam may not adequately detect a terrestrial vertebrate invasive species moving in a vessel because of outdated equipment, understaffing, or inadequate regulation and enforcement.

Develop new methods and further develop current methods for detecting and controlling terrestrial vertebrate pest species aboard vessels. There are limited methods for dealing with terrestrial vertebrate pest species aboard vessels. Biosecurity measures aboard vessels include adhering to good sanitation practices (e.g., proper food storage and garbage disposal), routine checks by crewmembers (e.g., for rodent droppings, cast skin from ecdysis), screening all cargo coming aboard (e.g., on Guam and Saipan for BTS), and active trapping and baiting programs. Methods implemented must target multiple species. For example, methods that specifically target rodents do not guarantee effectiveness on other pest species such as amphibians.

Rapid response measures for vessel detections need to address terrestrial vertebrate pest species in addition to BTS. Rapid response is necessary for preventing species spread at the border and post-border via responses to species sightings. Rapid response measures for BTS are insufficient for responding to and preventing introductions of other terrestrial vertebrate species like frogs and rodents.

Expand financial resources in the CNMI (Saipan, Tinian, Rota primarily) to maintain expensive control programs. Efficient detection and prevention of introductions of terrestrial vertebrate species depends upon biosecurity measures implemented and the resources allocated to accomplish them, such as border inspections, control and eradication efforts, and rapid response programs.

Improve protocols for inspecting the holds of commercial and military ships. Transit times for ships sailing between Guam and Saipan are less than 1 day, increasing the probability of survival for species

stowed aboard. Ship inspections are inadequate and performed perfunctorily due to time and staffing constraints. Regulations only apply to cruise ship vessels but not routinely and not entirely.

Conduct USDA-APHIS-WS inspections on vessels staged at Guam Shipyard facilities. There is no mention of impact or mitigation measures for the increased activity at the Guam Shipyard as a result of military activity. The Guam Shipyard provides vital shore industrial support, repair, maintenance, overhaul, and dry-docking services to military vessels such as those of the Military Sealift Command, Coast Guard, and local federal agencies on island. They provide authorized repair to Jones Act commercial ships such as Matson Navigation and Sealand Services, and shore support services to GovGuam agencies. Guam Shipyard has facilities and capabilities not found elsewhere in the Western Pacific, including a foundry, the largest motor rewind facility in the Pacific, a special building for environmentally controlled sandblasting and painting, micro-miniature circuit board repair, corrosion control, and an industrial laboratory. It is the only facility in the Western Pacific certified by the U.S. Department of Transportation to perform re-certification requirements on breathing air and high pressure air cylinders. With these amenities and services, biosecurity measures must be implemented and maintained at Guam Shipyard. Such measures would include building and maintaining perimeter fencing and vertebrate-proof staging areas, using USDA-APHIS-WS canine team inspections (e.g., of facilities, stored vessels), adhering to proper sanitation and material storage procedures, enforcing noncompliance such as unpermitted actions like the loading of cargo (Aguon 2009), and continued trapping (e.g., rodents, snakes, geckos).

Increase inspection frequency and quality for commercial shipping vessels from the major shipping lines inbound to Guam. Commercial shipping vessels calling on the Port of Guam are typically cleared rapidly, within 30 minutes, by GCQA (Merefalen, personal communication), with emphasis on regulated waste inspections and reviewing cargo manifests. Both the number and thoroughness of inspections need to be increased, with expanding capacity to randomly inspect vessels without delaying shipping schedules. This requires increased staffing and training of inspection personnel and strong communication between port officials, inspection agents, and vessel owners/operators.

Require the use of rat guards on mooring lines. Military and commercial vessels at seaport facilities in the Micronesia Region should be required to use rat guards on mooring lines. Currently, rat guards are used at ports with known rodent infestations. Internal Health Regulations only require rat guards to be in place where plague is endemic to the port (Regulation 40-12 SECNAVINST 6210.2A AFR 161-4, DoD, 1992, Section 9, p 2). However, ships may harbor insidious rodent populations, or unknown rodent infestations may occur at seaports; therefore, rat guards should be made a standard requirement.

Rat guards on mooring lines may not prevent BTS from ship access. Use of rat guards by vessels in port may not prevent BTS or other arboreal species access to the ship via mooring lines. The maximum diameter of a rat guard is 122 centimeters (48 inches) or 96 centimeters (38 inches) (NAVMED P-5052-26 2008, BUMED Instruction 6250.14A Feb 16, 2001).

Amphibious craft laydown locations and facilities for storing, maintaining, and deploying amphibious vehicles (chapter 5, FEIS/FOEIS 2010) should incorporate control efforts to prevent transport and

spread of terrestrial vertebrate hitchhikers that could contaminate vessels. Amphibious vehicle laydown areas are required to store, wash down, maintain, and deploy amphibious vehicles, such as landing craft and amphibious assault vehicles. LCACs would also utilize this area. Specific components of the laydown area include two new concrete ramps, which are similar to recreational boat ramps seen at private marinas, paving for amphibious vehicle parking, personal vehicle parking, staging equipment, amphibious vehicle washing, four support buildings for administration, small boat storage, and maintenance

http://guambuildupeis.us/documents/final/volume_1/Vol_01_Ch02_Overview_of_Proposed_Actions.pdf.

There are proposed to be as many as 4 LCACs, 14 amphibious assault vehicles, and 8 small reconnaissance boats permanently based in such an area. Recommendations for amphibious craft laydown locations include constructing and maintaining USDA-APHIS-WS-approved terrestrial vertebrate species-proof barriers, implementing measures to control and reduce pest populations within buildings, in stored/staged vehicles, and the on surrounding grounds. The governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating pest species habitat and food sources; however, stable, long-term funding for enforcement would be necessary.

Implement protocol for preventing terrestrial vertebrate species transport via amphibious vehicle operation/use or transport. Amphibious military vehicles are both terrestrial and marine vessels, and as such, are capable of transporting and spreading terrestrial vertebrate hitchhikers over land and water (U.S. Navy 2005c). Amphibious vehicles include, but are not limited to, amphibious armored personnel carriers, amphibious assault vehicles, amphibious land rovers, amphibious bikes and ATVs, amphibious trucks and barges such as lighter, amphibious resupply, cargo vehicles, hovercrafts, and LCAC (Figures 11-3a to 3c). The amphibious task force would require an area to load and unload personnel, vehicles, and other cargo. Equipment cleaning and inspections associated with bio-hazard and customs requirements would also occur in this area. These operations are collectively referred to as waterfront embarkation. The amphibious ships would be berthed at Victor Wharf (the wharf traditionally assigned for amphibious shipping in Apra Harbor). A new port operations building would be constructed at the wharf, and a cargo staging and vehicle washdown area would be provided in proximity to but not adjacent to the wharf. Washdown facilities should follow biosecurity protocol (e.g., routine inspection of facilities and equipment staging areas, collection/screening of wastewater run-off, perimeter fencing, lighting for night activities, USDA-APHIS-WS-approved vertebrate-proof staging areas).

Implement terrestrial vertebrate species inspection procedures for vessels with ramp-loading capabilities. Vessels capable of loading at piers, wharves, or beaches via a ramp with direct access to the hull are used in support of military activity to transport equipment, troops, tracked or wheeled vehicles, and amphibious crafts to beachheads or piers via a ramp with direct access to the hull. These include Roll-on/Roll-off Ships, Landing Craft Utility vessels (Figures 11-4a to 4d), Joint High Speed Vessels (JHSV), and LCAC. Hitchhikers can gain access to these vessels when ramps are deployed, or from the cargo load.

Implement terrestrial vertebrate species inspection procedures for high-speed-military vessels operating in the Micronesia Region. HSV serve as Logistic Support Vessels, provide a technically advanced and highly capable platform for deployment of troops, equipment, and vehicles, and are advantageous because of their payload capacity, high-speed transport, and distance capabilities. Such vessels include the HSV Westpac Express catamaran (Marine Corps) operating in the area of Guam, Okinawa, and Japan (Tack 2010), HSV, JHSV, and LCAC (Figures 11-5a to 5d) The high speeds mean forces and cargo reach destinations in a shorter time with shorter intervals between trips. Shorter transit times equates to increased probability of species survival during transport, the long-distance

capabilities increase the range of potential spread of species, and increased payload capacities along with greater diversity in types of cargo transported equates to a higher probability of species presence.

Implement USDA-APHIS-WS inspections for aircraft carriers arriving and departing Guam. Given their ability to embark different combinations of aircraft, carriers are vessels that are highly flexible naval platforms. If the Port of Guam becomes a home port for an aircraft carrier fleet and/or is a port of call for visiting/transiting aircraft carrier activity in the Micronesia Region, USDA-APHIS-WS terrestrial vertebrate inspections on both arriving and departing carriers should be conducted, including staged equipment. Spell out criteria for inspection process; comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to ocean vessels departing Guam, and inspect arriving carriers when the last port of call was in a country of concern.

8.7.4.3 Air Cargo

8.7.4.3.1 Military Air Cargo

Recommendations in the military air cargo pathway focus on cargo itself as a mode of species transport, including how the cargo is packed and handled, the cargo conveyance (e.g., crate, container, pallet, box, individual items), and the associated packing material used. Overlap occurs between commercial and military sectors. Military air cargo includes cargo transported for the military via both commercial (military-civilian contracts) and military routes. For example, military-civilian contracted air shipments include cargo for military use that is ordered and received by commercial businesses for pickup by military personnel or military-civilian subcontractors. Military transport includes systems owned by, contracted for, or controlled by DoD; for example, U.S. Transportation Command (USTRANSCOM) (DoD 2003, 2004). Military air cargo poses a risk of terrestrial vertebrate species transport because transport typically involves short travel durations (increased species survival), species harborage is climate controlled (aircraft cabins), types of cargo are considered high-risk because of their use (e.g., personnel field gear and training equipment, vehicles), and varying inspection procedures (arrivals versus departures, immediate versus pre-scheduled flights).

Expand capacity of the USDA-APHIS-WS canine program on Guam to comply with 100% BTS inspection policy of outbound military air cargo. The canine detection programs are an efficient way to comply with 100% BTS inspection policy for military air cargo departing Guam, per the NDAA, Public Law 110-181, Section 314.

Establish capacity of the USDA-APHIS-WS canine program on Saipan to comply with 100% BTS inspection policy of outbound military air cargo. The canine detection programs are an efficient way to comply with 100% BTS inspection of military cargo departing Saipan, per the NDAA, Public Law 110-181, Section 314. The presence of BTS on Saipan warrants inspection of outbound cargo to prevent spread and transport of the species from the island.

Establish capacity of the USDA-APHIS-WS canine program on Tinian and Rota to comply with 100% BTS inspection policy of outbound military air cargo. The canine detection programs are an efficient way to comply with 100% BTS inspection policy for military air cargo departing Tinian and Rota, per the NDAA, Public Law 110-181, Section 314 requiring interdiction for areas where incipient populations may be evident in the future.

Implement rapid response procedures for terrestrial vertebrate pest species involving military air cargo shipments and transport, as for BTS. No response networks or capabilities exist for species other than BTS, either on Guam or the CNMI. Train personnel involved in the cargo transport and inspection processes about the importance of pest interdiction at the border. Include skills training for identifying, capturing, and containing detected species. Expand capacity for initiating rapid response efforts at the border, as well as post-border, and create the capacity to perform random inspections of cargo imports as a preventative measure. Develop clear response plans with specific goals and objectives, as well as roles and responsibilities.

Conduct USDA-APHIS-WS canine inspections for BTS on Tinian and Rota of inbound military air cargo from Guam and Saipan. Prevention is touted as the most cost-effective measure in biosecurity efforts against biological invasion. To prevent the insidious spread of BTS to Tinian and Rota via the transportation of military air cargo shipments during proposed relocation, adherence to the 100% BTS outbound inspections by USDA-APHIS-WS canine teams on Guam and Saipan should be coupled with inbound USDA-APHIS-WS canine inspections on Tinian and Rota for: 1) high-risk cargo items, 2) air cargo shipments that departed Guam and Saipan without a BTS inspection, 3) cargo conveyances that appear damaged, and 4) random checks for BTS and other terrestrial vertebrate pest species. Supporting military cargo that is air shipped to Tinian and Rota from Guam or Saipan in advance of the training exercise is subject to the routine cargo inspection processes conducted on Tinian and Rota for inbound cargo. Military air cargo shipment arrivals to Tinian and Rota need to be thoroughly checked by CNMI Quarantine Inspectors to ensure that a BTS inspection was conducted on Guam and/or Saipan, and shipments are not harboring other terrestrial vertebrate pest species such as mice or frogs (U.S. Navy 2005b). A USDA-APHIS-WS-approved terrestrial vertebrate species-proof barrier used at entry points on Tinian and Rota for staging inbound military air cargo for inspection would help prevent unwanted species introductions.

Military cargo for airdrop on Saipan, Tinian, and Rota warrant thorough USDA-APHIS-WS canine inspection before departing Guam. Air-dropped military cargo departing Guam must be thoroughly cleaned and packed to facilitate USDA-APHIS-WS inspections for BTS and other terrestrial vertebrate pest species immediately prior to cargo loading or for staging in a USDA-APHIS-WS-approved area until departure.

Military procedures for cleaning gear and equipment used after training and field operations do not target terrestrial vertebrate pest species. Tent cleaning and inspection processes emphasize agricultural pest risks and do not adequately address the risk of transporting an invasive terrestrial vertebrate species. The emphasis on preventing the movement of invasive species associated with tent cities is on departure from Guam and BTS. No emphasis is placed on the risk of bringing new invasive species to Guam.

Current agricultural inspections of military air cargo do not target terrestrial vertebrate species. Inbound military air cargo is subject to routine inspection processes conducted by respective jurisdictions, like Guam and CNMI Customs and Quarantine Inspectors; however, agricultural inspections of military air-shipped cargo at military and commercial airports on Guam, Saipan, Tinian, and Rota focus on detecting plant pests and pathogens, and do not target terrestrial vertebrate species like BTS, frogs, and mice.

All military air cargo departing Saipan is to be cleaned, inspected, and immediately loaded on the aircraft for transport. Some items included in military cargo are high-risk due to their exposure to the outdoors, such as camping gear. To prevent the spread of BTS from Saipan, military air cargo that has been thoroughly cleaned should receive USDA-APHIS-WS canine inspection for BTS, and be loaded quickly and efficiently. Immediate loading of cargo reduces the risk of contamination of staged cargo.

Facilitate inspection of military air cargo shipments to improve BTS detection by USDA-APHIS-WS canine teams. Detection of BTS via canine and/or visual inspection is less effective if cargo is: 1) sealed within a conveyance container or crate, 2) complex, meaning it is not symmetrically shaped and stacked, or 3) inspected indoors with fumes from operating equipment, such as forklifts and delivery trucks. Further, BTS are less likely to be detected if the air cargo shipment is delivered to the port area and loaded, with minimal disturbance, directly onto the aircraft; the nocturnal habits of the BTS make this assumption important during daylight hours (Vice and Pitzler 2008).

Develop a labeling and tracking system for high-risk military air cargo. The ability to label and track high-risk military cargo shipments and their inspection history can streamline the transportation process and open avenues for implementing pre-clearance procedures while still maintaining biosecurity from terrestrial vertebrate pest species. High-risk cargo includes cargo originating from high-BTS-density areas, break bulk items, and outdoor items. Examples of high-risk military air cargo include construction equipment/materials, military equipment returning from a near-jungle bivouac, and cargo used in military training and deployment missions. Because outbound air cargo items originate from numerous sources throughout Guam (Vice and Pitzler 2008), a labeling and tracking system can help to identify air shipments that: 1) have been exposed to high-risk areas, 2) contain high-risk cargo items, and 3) have received official inspections, with information including the date and location of inspection, and name of inspector. Implement a barcode-based data collection system, and incorporate it into a centralized biosecurity system. A barcode-based system will typically comprise any or all of the following components: barcode scanners, barcode-based mobile computers (including wireless scanners, pen/key-based terminals, and vehicle-mount computers), barcode printers, barcode labels and ribbons, and barcode data collection software.

Coordinate USDA-APHIS-WS agreements with military and non-military air cargo shipping agencies to prevent terrestrial vertebrate species transportation. Despite high levels of cooperation by most cargo export entities, USDA agents still make regular discoveries of previously unknown cargo handling processes or companies operating on or out of Guam, and there are several private companies on Guam that refuse to provide information on, and access to, outbound cargo for inspection purposes (Vice and Pitzler 2008). Expand capacity for inspections of cargo handling and packing facilities, with requirements for: 1) allowing frequent inspections (e.g., USDA-APHIS-WS canine, visual searches), 2) being subject to random inspections, 3) more stringent packing and handling procedures (e.g., inspections of complex-packed cargo prior to packing), 4) requiring use of vertebrate species-proof barriers, and 5) implementing long-term pest species control programs at facilities. Coordinate agreements and procedures with air cargo shipping agencies for handling cargo, including packing, over-land transport, cargo-staging, palletizing, USDA-APHIS-WS canine inspection, and final loading. Require packers to individually handle and pack cargo items, especially those labeled as high risk. Provide personnel training and equipment for dealing with detections. It is recommended that air cargo be packed and tightly contained rather than remain as bulk. The probability of visually detecting species like BTS in complex cargo is lower than in cargo with few potential hiding places; for example, cargo that is symmetrically shaped, stacked, palletized, and tightly wrapped will have fewer hiding places than loosely packed, unpalletized bulk materials (Vice and Pitzler 2008).

The military personnel (734th Air Mobility Squadron on Andersen AFB) responsible for the packing process must be trained in proper species' identification of White List and Black List species. When building up pallets, Air Mobility Squadron personnel will handle and stack each box individually; therefore, unless a hitchhiker is already inside the box or crate when it arrives at the warehouse, it is likely to be detected. Address the issue of hitchhikers already packed when arriving at military warehouses by expanding inspection capabilities and increasing stringency in packing/handling of cargo; without this, there is a gap in biosecurity for the military sector, and an increase in the potential for transporting BTS from Guam. Aircraft operate 24 hours a day, but with the exception of trans-shipments originating outside of Guam, any cargo that is loaded onto an aircraft needs to be inspected by the USDA-APHIS-WS canine team.

Reduce site-specific BTS populations at military airports and airfields on Guam and Saipan to support interdiction measures. Implement BTS control efforts at military airport and airfield facilities and their surrounding areas. Such measures include but are not limited to spotlight searches and perimeter trapping. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating BTS habitat and food sources at cargo warehouses, airports, and seaports, and even establishing a regulatory basis for pre-clearance of cargo arrivals and departures; however, stable, long-term funding for enforcement is necessary.

Reduce site-specific terrestrial vertebrate pest populations at military airports and airfields on Guam and Saipan. Similar to measures for BTS, specific control measures for terrestrial vertebrate pests like rodents, amphibians, and lizard species should be implemented around military air transportation activities to reduce local populations and decrease probability of species transport. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating pest species habitat and food sources at cargo warehouses, airports, seaports, and storage areas, and even establishing a regulatory basis for pre-clearance of cargo arrivals and departures; however, stable, long-term funding for enforcement would be necessary.

Expand capacity of USDA-APHIS-WS to implement BTS control measures at military airports and airfields on Guam during nighttime cargo loading and unloading. USDA-APHIS-WS should conduct BTS surveillance during nighttime military cargo loading, staging, and transferring activities. Further, USDA-APHIS-WS can coordinate BTS spotlight searches of staging areas, fence lines, and any tree lines/forest areas in proximity to runways/taxiways that are designated as drop zones. These areas should be targeted during inbound and exiting traffic times (U.S. Navy 2005a). According to Figure 2.1-1 of the FEIS, there are five aviation areas (three paved, two unpaved) where nighttime surveillance should be conducted.

All military air shipments inbound to the region containing agricultural items, both food and non-food, and construction equipment, should be inspected for terrestrial vertebrate pest species. Agricultural imports are known to transport terrestrial vertebrate pest species of amphibians and reptiles (Christy et al. 2007a; Christy et al. 2007b; Vice et al. In preparation), but inspections generally look for insects and plant pathogens, and do not target terrestrial vertebrate species. Shipments typically considered

elevated risk for accidental transport include ornamental plants, agricultural produce, aquaculture shipments (including eggs and fry), live Christmas trees, and construction materials and equipment (Vice et al. In preparation).

Air cargo, including military munitions, imported to islands in the Micronesia Region and departing from Guam and Saipan should receive USDA-APHIS-WS inspections for terrestrial vertebrate pest species. Pest species of snakes and frogs (Christy et al. 2007a; Christy et al. 2007b) have been found in military air cargo and munitions arriving from outside the Micronesia Region, indicating a need for inspections of such imports, given that agricultural inspections of imports do not target terrestrial vertebrate pest species. Departure of cargo and munitions from Guam and Saipan requires 100% BTS inspection by USDA-APHIS-WS canine teams. Inspections of imports should take place during daylight hours.

Expand control measures for amphibian and reptile species detected in military air cargo. There are limited control measures in use for amphibians such as frogs and toads, and reptiles like lizards and snakes that are transported in military air cargo. Expand the capacity for responding to, and controlling, detected amphibians and reptiles in air cargo shipments.

Facilitate military-civilian relations in the CNMI for inspecting military air cargo. Improve communication between the U.S. military and government officials on Saipan, Tinian, and Rota to allow for proper inspections of cargo associated with the military, especially cargo used in military training and field exercises. Expand capacity for inspecting military equipment and vehicles transported after field training. Develop and practice cleaning procedures for military cargo used in field training as a preventative measure. Implement and practice joint-agency rapid response capabilities.

All military personnel baggage transported as cargo to and from Guam and the CNMI on military planes and helicopters should be inspected for terrestrial vertebrate species. While regulations exist for the inspection of aircraft with a focus on BTS, checked military baggage inspection does not target terrestrial vertebrates. However, such inspection is needed because military personnel checked baggage transported via military air transportation may pose a high risk for smuggling species both in and out of the region.

Monitor if seasonal peaks occur for military air cargo transportation, and expand inspection capabilities during these peaks. Monitoring is needed if military air cargo increases in volume or frequency seasonally. If seasonal peaks do occur, inspection capabilities should be expanded during these peaks for the detection of BTS and other terrestrial vertebrates.

Monitor if seasonal peaks occur for military air passenger transportation, and expand inspection capabilities during seasonal peaks. Monitoring is needed if military air passenger transportation increases in volume or frequency seasonally. If seasonal peaks do occur, inspection capabilities should be expanded during these peaks for the detection of BTS and other terrestrial vertebrates.

Expand the inspection capabilities for military airfreight containers. Military containerized cargo is considered high risk because: 1) only a portion of containers are inspected; 2) some containers are permeable to snakes; 3) containers often sit open on the tarmac outside warehouses, providing opportunities to harbor hitchhikers; 4) climate-controlled containers may be of even higher risk because they may provide optimal environmental conditions to promote the survival of a hitchhiker; and 5) there are terrestrial vertebrate species such as snakes that can survive containerized air transport. Mitigation includes use of container scanners, which are currently not available on Guam, but are available on Saipan (currently in disuse because of insufficient funds).

Create and implement protocol to reduce contamination of low-risk cargo by high-risk cargo en route as well as on the ground. Low-risk cargo may become high-risk if handling processes expose it to potential species incursion (Vice and Pitzler 2008), particularly BTS. While air cargo such as mail is considered low-risk due to its contents and processing methods, the caveats of mail being less-containerized than freight and incurring a longer staging time while enough mail accumulates for a shipment, remain. Mail destined to other Micronesia Islands (Palau, Chuuk, Yap) is considerably higher risk for snake incursion. The potential for contamination of mail can be reduced by implementing a more-contained method of shipment for mail and continuing the same inspection process for the mail as freight, but not within the same warehouse nor within proximity to freight so that the potential for incursion is reduced.

Expand the capacity for pre-move inspections of military household goods at the residence. Andersen AFB's traffic management office has agreed that, as part of its pre-move inspections, it will identify any household shipments containing BTS high-risk materials. Arrangements are currently being made to train the inspectors to identify potentially high-risk items during these initial site visits. The proximity of each housing area to potential BTS habitat will be considered when determining risk factors. Specify the "pre-move" inspection plan components, such as training protocol, labeling procedures, how to estimate proximity to BTS habitat, and documentation of inspections.

Inspect military household goods before they are sealed in a conveyance. Detection probability decreases when household goods are packed, crated (in 4 x 8 x 8 foot wooden boxes), and sealed at the residence before being transported to the packing agent's facility (Vice and Pitzler 2008). Close/seal cargo containers staged overnight, or erect temporary barriers and employ control methods for terrestrial vertebrate species until containers are sealed for transport.

Change procedures for canine cargo inspections at indoor warehouse facilities. Canine inspections at indoor warehouse facilities are compromised when exhaust fumes from operating equipment such as trucks and forklifts cannot properly vent from the building, thereby influencing detection capabilities of dogs. Implement a hiatus of equipment activity and the running of ventilation fans half an hour prior to inspections, or move cargo to be inspected to outdoor staging areas.

Facilitate USDA-APHIS-WS inspections of military air embarkation procedures comparable to, compatible with, and co-located with, existing Andersen AFB operations for loading and unloading cargo to and from an aircraft. The Quarantine Regulations of the Armed Forces states that cargo is

subject to inspection by a representative of the USDA to prevent the introduction or spread of animal and plant diseases or pests (DoD 1992). For the purposes of these regulations, Guam is considered part of the United States.

Title 7 (Subtitle B, Volume 5, Chapter 3, Parts 318.13-8 and 318.13-10) of the Code of Federal Regulations states that cargo moving between Guam, CNMI, Hawai'i, and the continental United States is subject to agricultural inspection (7 CFR § 318). OPNAVINST 6210.2 states that USDA-APHIS-PPQ personnel may inspect cargo to prevent the introduction of plant and animal pests or diseases ; however, terrestrial vertebrate species are not targeted, hence incidents may go unreported, and particular species may go undetected.

8.7.4.3.2 Commercial Air Cargo

Recommendations for commercial air cargo focus on the cargo itself as a mode of transport, with packing and handling influencing the risk level. Overlap occurs between military and commercial air cargo sectors. One example is that checked baggage of military personnel traveling as passengers on commercial flights is considered commercial air cargo. Commercial air cargo poses a risk of terrestrial vertebrate species transport because transport typically involves short travel durations (increased species survival), species harborage is climate controlled (aircraft cabins), inconsistencies exist in inspection equipment availability (e.g., lack of x-ray machines for agricultural inspections), there are insufficient numbers of inspectors, and the volume of airfreight material being moved is substantial.

Expand capacity of the USDA-APHIS-WS canine program on Guam to comply with 100% BTS inspection policy of outbound air cargo. The canine inspection programs are an efficient way to comply with 100% BTS inspection of air cargo departing Guam, per the NDAA, Public Law 110-181, Section 314.

Establish capacity of the USDA-APHIS-WS canine program on Saipan to comply with 100% BTS inspection policy of outbound air cargo. The canine inspection programs are an efficient way to comply with 100% BTS inspection policy for air cargo departing Saipan. Comply with 100% BTS inspection of cargo departing Saipan, per the NDAA, Public Law 110-181, Section 314. The presence of BTS on Saipan warrants inspection of outbound cargo to prevent spread and transport of the species from the island.

Establish capacity of the USDA-APHIS-WS canine program on Tinian and Rota to comply with 100% BTS inspection policy of outbound air cargo. The canine inspection programs are an efficient way to comply with 100% BTS inspection policy for air cargo departing Tinian and Rota. Comply with 100% BTS inspection of cargo departing Tinian and Rota, per the NDAA, Public Law 110-181, Section 314 requiring interdiction for areas where incipient populations may be evident in the future.

Implement rapid response procedures for terrestrial vertebrate pest species involving air cargo shipments and transport, similar to those in place for BTS. No contact networks exist for species other than BTS either on Guam or the CNMI, and this is an area of much needed expansion for efficient and comprehensive response to species introduction.

Conduct USDA-APHIS-WS canine inspections for BTS on Tinian and Rota of inbound air cargo from Guam and Saipan. Because prevention is the most cost-effective measure in biosecurity efforts against biological invasion, preventing the insidious spread of BTS to Tinian and Rota via air cargo shipments requires strict adherence to the 100% BTS outbound inspections by USDA-APHIS-WS canine teams on Guam and Saipan; couple this with inbound USDA-APHIS-WS canine inspections on Tinian and Rota for: 1) high-risk cargo items, 2) air cargo shipments that departed Guam and Saipan without a BTS inspection, 3) cargo conveyances that appear damaged, and 4) random checks for BTS and other terrestrial vertebrate pest species. Air cargo arriving to Tinian and Rota from Guam or Saipan is subject to routine cargo inspection processes conducted by CNMI Quarantine Inspectors to ensure that a BTS inspection was conducted on Guam and/or Saipan, and shipments are not harboring other terrestrial vertebrate pest species such as mice or frogs (U.S. Navy 2005a). A USDA-APHIS-WS-approved terrestrial vertebrate species-proof barrier used at entry points on Tinian and Rota for staging inbound air cargo for inspection would help prevent unwanted species introductions.

Current agricultural inspections of military air cargo do not target terrestrial vertebrate species. Agricultural inspections of military air cargo (inbound and outbound) at military and commercial airports on Guam, Saipan, Tinian, and Rota focus on detecting plant pests and pathogens, and do not target terrestrial vertebrate species like BTS, frogs, and mice.

Facilitate inspection of air cargo shipments to improve BTS detection by USDA-APHIS-WS canine teams. Detection of BTS via canine and/or visual inspection is less effective if cargo is: 1) sealed within a conveyance container or crate, 2) complex, meaning it is not symmetrically shaped and stacked, or 3) inspected indoors with fumes from operating equipment, such as forklifts and delivery trucks. Further, BTS are less likely to be detected if the air cargo shipment is delivered to the port area and loaded, with minimal disturbance, directly onto the aircraft; the nocturnal habits of BTS make this assumption important during daylight hours (Vice and Pitzler 2008).

Develop a labeling and tracking system for high-risk air cargo. The ability to label and track high-risk air cargo shipments and their inspection history can streamline the transportation process and open avenues for implementing pre-clearance procedures while still maintaining biosecurity from terrestrial vertebrate pest species. High-risk cargo includes cargo originating from high-BTS-density areas, break bulk items, and outdoor items. Examples of high-risk air cargo include outdoor household goods like children's toys, garden hoses, camping equipment, and air freight shipments of larger items like barbecue grills, swing set components, or appliances, and construction equipment/materials/supplies. Because outbound air cargo items originate from numerous sources throughout Guam (Vice and Pitzler 2008), a labeling and tracking system can help to identify air shipments that: 1) have been exposed to high-risk areas, 2) contain high-risk cargo items, and 3) have received official inspections, with information including the date and location of inspection, and name of inspector. Implement a barcode-based data collection system, and incorporate it into a centralized biosecurity system. A barcode-based system will typically comprise any or all of the following components: barcode scanners, barcode-based mobile computers (including wireless scanners, pen/key-based terminals, and vehicle-mount computers), barcode printers, barcode labels and ribbons, and barcode data collection software.

Coordinate USDA-APHIS-WS agreements with commercial air cargo shipping agencies to prevent terrestrial vertebrate species transportation. Despite high levels of cooperation by most cargo export entities, USDA agents still makes regular discoveries of previously unknown cargo handling processes or companies operating on or out of Guam, and there are several private companies on Guam that refuse to provide information on and/or access to outbound cargo for inspection purposes (Vice and Pitzler 2008). Expand capacity for inspections of cargo handling and packing facilities, with requirements for: 1) allowing frequent inspections (e.g., USDA-APHIS-WS canine, visual searches), 2) being subject to random inspections, 3) more stringent packing and handling procedures (e.g., inspections of complex-packed cargo prior to packing), 4) requiring use of vertebrate species-proof barriers, and 5) implementing long-term pest species control programs at facilities. Coordinate agreements and procedures with air cargo shipping agencies for handling cargo, including packing, over-land transport, cargo-staging, palletizing, USDA-APHIS-WS canine inspection, and final loading. Require packers to individually handle and pack cargo items, especially those labeled as high risk. Provide personnel training and equipment for dealing with detections. It is recommended that air cargo be packed and tightly contained rather than remain as bulk. The probability of visually detecting species like BTS in complex cargo is lower than in cargo with few potential hiding places; for example, cargo that is symmetrically shaped, stacked, palletized, and tightly wrapped will have fewer hiding places than loosely packed, unpalletized bulk materials (Vice and Pitzler 2008). Implement procedures to reduce site-specific populations of terrestrial vertebrate species at air cargo facilities and grounds to support interdiction measures USDA-APHIS-WS. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating pest species habitat and food sources at cargo warehouses, airports, and seaports.

Reduce site-specific BTS populations at airports and airfields on Guam and Saipan to support interdiction measures. Implement BTS control efforts at airports and airfield facilities and their surrounding areas. Such measures include but are not limited to spotlight searches and perimeter trapping. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating BTS habitat and food sources at cargo loading areas and warehouse facilities, airports, and seaports, and even establishing a regulatory basis for pre-clearance of cargo arrivals and departures; however, stable, long-term funding for enforcement is necessary.

Reduce site-specific terrestrial vertebrate pest populations at airports and airfields on Guam and Saipan. Similar to the measures in place for BTS, specific control measures for terrestrial vertebrate pests like rodents, amphibians, and lizard species should be implemented around air transportation activities to reduce local populations and decrease probability of species transport. The Governments of Guam and the CNMI might consider establishing and enforcing sanitation codes as a practical means of minimizing and eliminating pest species habitat and food sources at cargo warehouses, loading areas, airports, and seaports, and even establishing a regulatory basis for pre-clearance of cargo arrivals and departures; however, stable, long-term funding for enforcement is necessary.

Expand capacity of USDA-APHIS-WS to implement BTS control measures at airports and airfields on Guam during nighttime cargo loading and unloading. USDA-APHIS-WS should conduct BTS surveillance during nighttime military cargo loading, staging, and transferring activities. Further, USDA-APHIS-WS can coordinate BTS spotlight searches of staging areas, fence lines, and any tree lines/forest areas in proximity to runways/taxiways that are designated as drop zones. These areas should be targeted during inbound and exiting traffic times (U.S. Navy 2005a). According to Figure 2.1-1 of the FEIS, there are five aviation areas (three paved, two unpaved) where nighttime surveillance should be conducted.

All commercial air shipments inbound to the region containing agricultural items, both food and non-food, should be inspected for terrestrial vertebrate pest species. Agriculture imports are known to transport terrestrial vertebrate pest species of amphibians and reptiles (Christy et al. 2007a; Christy et al. 2007b; Vice et al. In preparation), but inspections generally look for insects and plant pathogens, and do not target terrestrial vertebrate species. Shipments typically considered elevated risk for accidental transport include ornamental plants, agricultural produce, aquaculture shipments (including eggs and fry), live Christmas trees, and construction materials and equipment (Vice et al. In preparation).

All military personnel checked baggage transported to and from Guam and the CNMI on commercial, private, and chartered planes and helicopters must be inspected in compliance with the TSA 9/11 Act. Military personnel checked baggage for commercial air transportation poses a high risk for smuggling species both into and out of the region. In the Pacific Islands, smuggling is generally very easy because of poor inspections for contraband animals conducted on arriving baggage (e.g., Kraus and Cravalho 2001). The 9/11 Act, Chapter 10, requires the TSA to establish a system for industry to conduct 100% BTS screening of cargo transported on passenger aircraft in the United States at the piece-level, commensurate with passenger baggage. By August 2010, cargo not screened in accordance TSA-approved processes and procedures cannot be uplifted by a passenger aircraft in the United States (www.TSA.gov). In compliance with the 9/11 Act, TSA is an important operating entity at A.B. Won Pat International Airport to detect smuggled contraband of terrestrial vertebrate species, and staffing should be expanded to account for increased military use of commercial air transportation pathways, and the increase in commercial air cargo associated with proposed military relocation and expected passenger plane travel.

Expand the inspection capabilities for commercial airfreight containers. Containerized cargo is the most common type of air cargo being flown in and out of Guam and the Micronesia Region. For example, United Airlines exports the bulk of commercial airfreight leaving Guam, and approximately 90% of these shipments comprised general freight (Vice and Pitzler 2008). Containerized cargo is considered high risk because: 1) Customs and Quarantine agents only inspect a portion of containers; 2) some containers are permeable to snakes; 3) containers often sit open on the tarmac outside warehouses, providing opportunities to harbor hitchhikers; 4) climate-controlled containers may be of even higher risk because they may provide optimal environmental conditions to promote the survival of a hitchhiker; and 5) there are terrestrial vertebrate species such as snakes that can survive containerized air transport. Mitigation includes use of container scanners, which are currently not available on Guam, but are available on Saipan (currently in disuse because of insufficient funds).

Monitor if seasonal peaks occur for commercial air transport, and increase inspection capabilities during these seasonal peaks. There is a need for monitoring the volume and frequency of commercial air cargo during relocation and post-relocation. If seasonal peaks are found to occur, inspections of air cargo departing Guam should be expanded, with screenings targeting BTS and other terrestrial vertebrates.

Expand inspection capabilities during seasonal peaks in commercial air passenger transportation. More commercial passenger flights depart Guam during the summer months, which may reflect peak tourist season, school summer recess, and summer holiday travel (Vice and Pitzler 2008). During these seasonal peaks, aircraft departing Guam, when inspected for BTS, should also be screened to detect terrestrial vertebrate pests, such as amphibians and other reptile species.

Create and implement protocols to reduce contamination of low-risk cargo by high-risk cargo en route as well as on the ground. Low-risk cargo may become high-risk if handling processes expose it to potential species incursion (Vice and Pitzler 2008), particularly BTS. The risk of contamination actually can stem from mail containers being handled, staged, and shipped in the same manner as general freight (Vice and Pitzler 2008), because mail is then in proximity to the high-risk cargo during the inspection process. While cargo such as air mail is considered low-risk due to its contents and processing methods, mail is less-containerized than freight and incurs a longer staging time while enough mail accumulates for a shipment. Mail destined to other Micronesian islands (Palau, Chuuk, Yap) is considerably higher risk for snake incursion; outbound mail is stored in open containers that are stored on the ramp side of the United cargo facility at A.B. Won Pat International Airport (Vice and Pitzler 2008). The potential for contamination of mail can be reduced by implementing a more-contained method of shipment and continuing the same inspection process for the mail as freight, but not within the same warehouse nor within proximity to freight so that the potential for incursion is reduced.

Inspections are constrained by resources to only inspect a portion of air freight conveyance crates and containers, therefore increase funding and feasibility of these inspections. Air cargo conveyance crates and containers tend to be inspected if shipments are labeled as containing agricultural products, have insufficient or improper documentation, or are from a country of concern. Standardized methods need to be devised and implemented to randomly search containers regardless of documentation, type of shipment, and country of origin. Allocate funding to increase the amount of containerized and crated air cargo shipments that can be inspected. Paperwork associated with arriving air cargo shipments in crates and containers needs to be automated to allow for more rapid selection of containers to be screened, and open avenues for implementing pre-clearance procedures.

Inspect cargo at both departure and arrival points if transported on open barges. Cargo is considered high risk if sent on open barges because this type of transport generally moves a high proportion of break-bulk items that originate near heavily vegetated locations such as new construction sites where heavy equipment is stored in proximity to jungle areas (Vice and Pitzler 2008). Break-bulk roughly includes those items too large to be containerized, like heavy construction equipment (e.g., cranes, bulldozers, dump trucks), building materials (e.g., rebar, lumber, pipe, scrap metal, concrete forms,

cinder blocks), fuel canisters (e.g., oxygen, acetylene, propane tanks), small boats, and in some instances, private vehicles. Many inter-island shipments are on open barges where the ambient air temperature and air turnover rates increase the likelihood of species survival during transport (Vice and Pitzler 2008).

Inspect household goods before they are sealed in a conveyance. Detection probability for BTS decreases when household goods are packed, crated (in 4 x 8 x 8 foot wooden boxes), and sealed at the residence before being transported to the packing agent's facility (Vice and Pitzler 2008). Close/seal cargo containers staged overnight, or erect temporary barriers and employ control methods for terrestrial vertebrate species such as temporary barriers until containers are sealed for transport.

Change procedures for canine cargo inspections at indoor warehouse facilities. Canine inspections at indoor warehouse facilities are compromised when exhaust fumes from operating equipment such as trucks and forklifts cannot properly vent from the building, thereby influencing detection capabilities of dogs. Implement a hiatus of equipment activity and the running of ventilation fans half an hour prior to inspections, or move cargo to be inspected to outdoor staging areas.

8.7.4.4 *Sea cargo*

8.7.4.4.1 *Sea cargo Arrivals*

An estimated 90% of all imports to Guam come through the Commercial Port at Apra Harbor. This includes the majority of food, commercial goods, and many of the supplies that support the U.S. Military on Guam. The relocation on Guam will have a significant impact on container volumes during the construction phase and afterward. According to The 2008 Port Authority of Guam's Master Plan, during the construction phase, the containerized cargo volume will increase 500% above 2007 import levels. After construction, the volume will be approximately 200% greater than 2007 levels.

Increase the capacity to perform random inspections for terrestrial vertebrate species in containerized commercial cargo arriving to Guam and Saipan. GCQA does not routinely open containerized commercial cargo shipments; containers are tagged for inspection only if they arrive from a country of concern, have improper or suspect labeling, or contain items that pose an agricultural risk by potentially harboring soils, insects, and plant pathogens (Merfalen, personal communication). Similar inspection procedures are in place on Saipan and Tinian (USDA-APHIS-WS 2010). Agricultural inspections, when conducted, do not target terrestrial vertebrate pest species and therefore may miss potential hitchhikers. Further, persons involved in the intentional transport of species, such as legal imports for the pet trade or in illegal acts, may strategically ship from an origin of least concern in order to remain undetected. Inspecting for terrestrial vertebrate species and performing random inspections in addition to SOPs for inspecting containerized commercial cargo is a preventative measure against illegal acts of species transport, and increases the probability of detecting hitchhikers.

Build a centralized USDA-APHIS-WS-approved staging area for containerized commercial cargo arriving to Guam at the Port of Guam. Containerized commercial cargo arriving at the Port of Guam identified as requiring an inspection is tagged by GCQA and moved from the port to one of Guam's 78

freight stations until it is inspected at the station by USDA-APHIS-WS. This method decentralizes the inspection process of containerized cargo, with most cargo inspected in numerous warehouses

throughout the island. This presents a high risk for multiple, simultaneous introductions of terrestrial vertebrate species to Guam (USDA-APHIS-WS 2010). A centralized inspection facility at the Port of Guam for arriving cargo would reduce cargo transport, and hence species transport, from the port-of-entry.

Implement an electronic system for recording, tracking, and identifying manifests associated with containerized commercial cargo arrivals to Guam and Saipan to streamline import process while maintaining biosecurity. Although all arriving cargo is subject to inspection, containerized cargo is selected for inspection based on the shipping company's manifest that itemizes the containers contents (Merfalen, personal communication). Larger, established shippers like Matson and CSX tend to be more reliable than smaller, less established operations. The system of recording, identifying, and tracking these manifests is paper-based; these systems are vulnerable to missing or lost documentation, unregulated and recurring breaches in biosecurity, and being omitted from integration with other agencies using electronic tracking capabilities. Over the past several years, CBP required a shift to electronic access for cargo manifests for arrivals from the continental United States. In addition, USDA-APHIS recently initiated an electronic system for permits called ePermits. GCQA does not have access to either system, and still relies on paper manifests; it is expected that GCQA will have access to ePermits as soon as Guam PPQ allows, but this has not yet been decided at the time this document was written. Hand-held computerized devices (e.g., SuperTracker[®]) can be used by GCQA to organize manifest information for the inspection process.

Develop a system for selecting containers to be inspected for terrestrial vertebrate species. PPQ-Agriculture Quarantine Activity System is a set of sophisticated tools for selecting and monitoring containers for agricultural pests. Similar tools need to be developed to identify, monitor, and track containers for terrestrial vertebrate species inspections. Criteria would include type of cargo, origin of cargo material, shipping company, structural damage to the container, and random pick.

Expand capacity for increased random inspections for terrestrial vertebrate species in containerized cargo arrivals. Presently, USDA-APHIS and jurisdictional Customs and Quarantine agencies are unable to meet current inspection demands of containerized cargo arrivals to Guam and the CNMI. Expected increases in container cargo arrivals to the Micronesia Region will render the already burdened inspection process ineffective. If there are fewer containers targeted for agricultural inspections because of insufficient resources, and given that agricultural inspections do not focus on terrestrial vertebrate species, an even higher probability exists for transporting such species in containerized cargo. Increase the number of USDA-APHIS-WS canine inspection teams at Apra Harbor, for both the commercial port and COMNAVMAR.

Military aircraft transported as cargo (aboard an aircraft carrier or other military vessel with aircraft transport capabilities) must be inspected, cleaned, and washed down at the port-of-entry. Aircraft are considered cargo if transported to locations aboard another aircraft or vessel, and hence should be subject to inspections when unloaded from the transport conveyance. This is especially important

because while some aircraft will remain unused during transport, planes and helicopters aboard an aircraft carrier can depart and arrive as their support vessel moves, increasing the probability of transporting species from different points of origin should these aircraft depart the transport conveyance and land before returning. Aircraft as cargo arriving to Saipan from Guam, or to Guam from Saipan, must be inspected for BTS if the inspection does not occur upon departure, and officials at arriving locations need to be notified with the appropriate information. Expand capability of jurisdictions to respond to notification of missed BTS inspections. In addition, military aircraft must undergo and adhere to regulations for cleaning and washdown procedures before entry to Guam (as per USDA and APHIS guidelines), and additionally inspect for terrestrial vertebrate species, which are not targeted and therefore likely missed. Perform internal inspections during general and retrograde washdowns to detect and capture terrestrial vertebrate species located within the aircraft cargo. Military procedures for washing aircraft focus solely on external cleaning, with an emphasis on soils and agricultural pests like insects. Because internal cleaning and inspections are not performed, terrestrial vertebrates hitchhiking within an aircraft being washed go undetected. This includes aircraft involved in routine flight operations, aircraft transported as cargo items (via air or water transport), or those staged upon a departing aircraft carrier.

Military amphibious vehicles arriving via water must be inspected, cleaned, and washed down at a retrograde wash facility before entry to Guam. Washdown procedures for military vehicles do not target terrestrial vertebrate species per se, and therefore cleaning of military amphibious vehicles will likely miss such hitchhikers, including amphibian and reptile species, like coqui frogs from Hawai'i. Further, cleaning is focused on external surfaces, so those species within vehicles will travel undetected. Tracked vehicles can only be cleaned on shore as long as they can be reloaded without recontamination of the treads, otherwise they must be cleaned on the ship's well deck (AFPMB 2008).

Privately owned vehicles (POVs) arriving via water through military and commercial routes must be washed down at a port facility before they are permitted entry to Guam. Personal vehicle cargo originates from numerous sources, increasing the locations from which a species may be moved, and the types of species moved. Procedures for washing vehicles imported to Guam focuses on agricultural inspections and primarily of external surfaces, thereby missing terrestrial vertebrates potentially present. Further, a small percentage of vehicles arrive contaminated with soil. Vehicles suspected of carrying species, for example if detected by visual or auditory means during transport, should be quarantined. They should be cleaned to USDA-APHIS standards (USDA-APHIS-PPQ Treatment Manual 2008) prior to being shipped from the port of departure. Vehicles may be cleaned at the port-of-entry provided wastewater soil is collected and fully drained into an approved collection system to mitigate the risk of introduction amphibian species. For certain anurans like coqui (*E. coqui*), an aural inspection during peak time of vocalizations can be conducted to detect such hitchhiking vertebrates.

Military assault vehicles arriving as cargo via water must be washed down at a retrograde wash facility before they are permitted entry to Guam. Assault vehicles have the ability to cover large and remote tracks of heavily vegetated fields, exposing them to contamination by terrestrial vertebrate species inhabiting such terrain. Vehicles small enough to drive through the ships' side ramps, such as

High Mobility Multipurpose Wheeled Vehicles, must be cleaned and washed down in designated areas in the port facility. Large trucks that are too large for the side ramps will be transported by Air Cushion or hovercraft (LCAC) to a coastal cleaning area. Vehicles must be internally inspected. The battery and battery box should be removed, cleaned, and reinstalled because the crevices of the battery box provide hiding places. Trucks that are equipped with collapsible sides should have the sides disengaged, and all recessed areas and ledges cleaned (AFPMB 2008). Common areas to be inspected include top and bottom access points, paying particular attention to crevices. Also, control efforts around the washdown facility should be in place. Construct USDA-APHIS-WS-approved species-proof barriers to secure washing and staging areas, implement trapping and perimeter searches for pest species like BTS and other terrestrial vertebrate species, and expand large-area trapping efforts to reduce local populations.

Implement inspection procedures for vehicle cargo aboard high speed-military vessels. High-speed military vessels are used for rapid delivery of cargo. Vessels like the LCAC are capable of a 60 ton payload (up to 75 tons in an overload condition) at speeds greater than 40 knots. Such rapid transit increases species survival during transport, hence these vessels and their cargo pose a risk. Cargo can include vehicles and equipment that may harbor terrestrial vertebrate species.

Construction vehicles arriving via water must be washed down and inspected before being permitted entry to Guam, Saipan, Tinian, and Rota. No specifications were provided in the FEIS/OEIS regarding the types and amounts of construction vehicles to be used in the relocation on Guam or for construction of training ranges on Saipan, Tinian, and Rota, making this a high risk for importing unwanted species. Construction vehicles include machinery like bulldozers, excavators, and bobcats, as well as forklifts, concrete mixers and their pumps, dump trucks, and ATVs (Vice and Pitzler 2008). Construction vehicles can carry species from one work site to the next. Although construction is for military purposes, equipment transport will likely be by subcontracted construction company employees. Detailed cleaning and inspection of vehicles and equipment used in construction must be conducted at the port of entry. USDA-APHIS requirements must be met and should be augmented with internal and external inspections for terrestrial vertebrate species. Delineation of responsibilities for the military meeting these requirements is presented in AFPMB Tech. No. 31 (2004).

The Importer Security Filing (CBP) system, akin to that required for imports to the United States, should be implemented and enforced for break bulk arriving in Guam. Under the Importer Security Filing and Additional Carrier Requirements (“10 +2” program), break bulk cargo imported to the United States by vessel must be electronically submitted to the CBP in the form of an Importer Security Filing. This requirement only applies to cargo arriving in the United States by ocean vessel; it does not apply to cargo arriving by other modes of transportation. Failure to do so could ultimately result in monetary penalties of \$5,000, and increased inspections and delay of cargo. If goods for which an Importer Security Filing has not been filed arrive in the United States, CBP may withhold the release or transfer of the cargo; CBP may refuse to grant a permit to unlade for the merchandise; and if such cargo is unloaded without permission, it may be subject to seizure. Importer Security Filing Importers, or their agent, must provide eight data elements, no later than 24 hours before the cargo is laden aboard a vessel destined to the United States. Those data elements include: seller, buyer, applicant identification

number, consignee number, manufacturer, ship of party, country of origin, and Commodity Harmonized Tariff Schedule of the United States number.

Provide written animal and plant health import and interstate movement requirements (USDA-APHIS regulations) for all break-bulk import contractors, and engage in formal, signed agreements with these bulk imports contractors, especially those operating from origins of concern. There will be substantial increases in break bulk cargo to be shipped through the Port of Guam for construction and infrastructure upgrades due to the relocation. It is vital that contractors be aware of the requirements for pre-departure inspection and pest mitigation prior to export of these countries. Enforcement is needed during relocation to ensure contractors adhere to requirements or face fines or other penalties.

Create and implement protocols to reduce contamination of low-risk cargo by high-risk cargo en route via water as well as on the ground. Low-risk cargo such as mail may become high-risk if handling processes expose it to potential species incursion (Vice and Pitzler 2008), particularly BTS. The risk of contamination actually can stem from mail containers being handled, staged, and shipped in the same manner as general freight after arrival (Vice and Pitzler 2008), because mail is then in proximity to the high-risk cargo during the transport and inspection process. Implement procedures to separate low- and high-risk cargo on arrival, for staging and inspection purposes, as well as for quarantine reasons.

WPM arriving as cargo must be accompanied by proper forms and labels. WPM can harbor myriad terrestrial vertebrate species, including amphibians, mammals, and reptiles. To prevent hitchhikers aboard such cargo, material is required to be treated and marked at the place of origin, and accompanied by authentic phytosanitary certificates on arrival in Apra Harbor. Examples of WPM include crates, pallets, dunnage, packing blocks, drums, cases, load boards, pallet collars, skids, veneer peeler cores, sawdust, wood wool, wood shavings, raw wood cut into thin pieces, and cable spools. The treatment of WPM is enforced under the ISPM (USDA-APHIS 2007; ALSC 2009). The treatment and inspection of WPM is governed under 7 CFR. The regulations allow manufacturers and shippers two options: heat treatment or treatment with methyl bromide. For materials to receive the ISPM No. 15 quality mark, materials must be inspected by an agency accredited by either the ALSC for heat treatment (ALSC 2009), or the National Wood Pallet and Container Association for methyl bromide fumigation (NWPCA 2009). Inspection procedures by both agencies must follow ISPM No. 15 regulations. Part 305 of Title 7 covers phytosanitary treatments and states that treatments are to occur at USDA-APHIS certified facilities and are to be monitored by APHIS officials (Title 7, Part 305). Part 381 of Title 7 defines regulated WPM as dunnage, crating, pallets, packing blocks, drums, cases, and skids (Title 7, Part 318). Currently all regulated WPM are required to have the International Plant Protection Convention (IPPC) quality mark, unless it is a DoD shipment (USDA-APHIS 2010). The exemption of regulations on WPM shipped by DoD leaves a risk of introduction of pests and vertebrates through untreated WPM. Fraudulent or suspected fraudulent certifications or cargo manifests should be investigated with penalties implemented. Random inspection of such cargo can prevent illegal transport of species through a legal route and incidents of smuggling.

Mandate and enforce regulations for handling palletized cargo. Contamination can occur during the packing, handling, and staging process prior to arrival as imported cargo, or after arrival when it is staged for loading for inland transport. It is optimal for packers to individually handle and pack cargo items, especially those considered high risk. Mandate and enforce regulations pertaining to palletized cargo, including procedures for labeling, packing, and transport prior to arrival, and eventual staging and loading for inland transport upon import. Personnel must be trained how to identify high-risk cargo and handle it in a manner to reduce possible contamination. Palletized cargo should be packed tightly and symmetrically, as well as wrapped with a protective covering. The probability of visually detecting species in complex cargo is lower than in cargo with few potential hiding places. This is especially true with BTS detection by canine teams (Vice and Pitzler 2008).

8.7.4.4.2 *Sea cargo Departures*

Most water-transported cargo departing Guam is shipped as surface freight out of Apra Harbor. The harbor has two sides; the Commercial Port (GovGuam) and the COMNAVMAR (military). All vessel traffic is managed by The Port Authority of Guam (GovGuam), which assigns vessels to commercial or military berthing areas.

Comply with 100% BTS inspection policy for military and civilian sea cargo departing Guam. Comply with 100% BTS inspection of military sea cargo departing Guam, per NDAA, Public Law 110-181, Section 314.

Comply with 100% BTS inspection policy for military and civilian sea cargo departing Saipan. Comply with 100% BTS inspection of military cargo departing Saipan, per NDAA, Public Law 110-181, Section 314. The presence of BTS on Saipan warrants inspection of outbound cargo to prevent spread and transport of the species from the island.

Comply with 100% BTS inspection policy for military and civilian sea cargo departing Tinian and Rota. Comply with 100% BTS inspection of military cargo departing Tinian and Rota, per NDAA, Public Law 110-181, Section 314 requiring interdiction for areas where incipient populations may be evident in the future.

Comply with 100% BTS inspection policy specified in the BTS Control Plan applicable to cargo arriving to U.S. sites other than Guam, in both military and civilian sectors. For military and commercial sectors, the BTS Technical Working Group Plan (2009) specifies 100% BTS inbound interdiction on U.S. sites other than Guam. This includes cargo arrivals from Guam and Saipan, where BTS exist, being shipped to the Hawai'ian Islands of Oahu, Maui, and Hawai'i. Interdiction measures should be expanded to include improved inter-agency coordination of communication networks to notify Hawai'ian seaports of cargo arrivals from Guam and Saipan that missed BTS inspection, and funding to increase inspection capacity for U.S.-bound cargo departing from Saipan and Guam.

Inspection of departing military containers must be focused on higher-risk container types such as open top containers. The military uses several types of containers for shipment of gear, ranging from a tricon (triple container that is a lockable, weatherproof, reusable, prefabricated container with a cargo

capacity of 5,579 kg [12,300 pounds]) to standard commercial containers to open top containers (container without a permanent metal top, instead tarpaulin is used, supported by roof bows to protect cargo from the elements) (Defense Transportation Regulation Part II: Cargo Movement April 2010). Open top containers are the highest risk container type for the transport of BTS. No information was found on the staging of the open top containers. Procedures should be implemented to separate out these containers of cargo to prevent cross-contamination from adjacent cargo sources. Stage these containers separately, and perform random inspections.

Expand capacity to inspect departing freight containers including funds allotted for container scanners. The movement of invasive vertebrate species in containerized cargo is a significant pathway, and a large number of species may be moved (ANSTF and NISC 2007; USDA-APHIS-WS 2010). In addition, some transit times for ships sailing between Guam and other islands are short (less than 1 day), increasing the probability of survival for species stowed in cargo aboard. Cargo container inspections are regulated in international law under the sponsorship of the WHO. Inspection access is granted through WHA58.3 Revision of the International Health Regulations (WHO 2005). Containers and their cargo departing Guam are subject to 100% BTS inspection, in compliance with NDAA, Public Law 110-181, Section 314. Yet container scanners are currently not available on Guam. They are available on Saipan, but not used due to funding limitations even though containers are considered high risk items used in the shipping process (ANSTF and NISC 2007).

Commercial sea cargo shipping companies must comply with the 100% inspection policy, and no direct route for shipments from Guam to Hawai'i should be maintained. Surface cargo leaving Guam for the U.S. mainland is primarily shipped by two companies, the CSX Corporation and Matson. Shipments from these two companies are first routed through ports in Asia before arriving in the U.S. mainland and comprise only containerized cargo. CSX ships approximately 65 to 70 outbound containers per week containing items that originate on Guam, 25 to 30 (roughly 40%) are filled with household goods, and 7 to 8 (11%) contain vehicles; both high risk item types due to their extended exposure to the outdoors (Vice and Pitzler 2008). Matson conducts service to Hawai'i from Guam, via Oakland, California. BTS have been repeatedly found in the Hawai'ian Islands. Since 1981, eight BTS are known to have arrived on the island of Oahu through commercial and military aircraft from Guam (BTS Technical Working Group 2009). The indirect route of surface cargo from Guam to Hawai'i should be maintained. Cargo bound for Hawai'i should be inspected again prior to departure from Oakland, California, to prevent the establishment of BTS in Hawai'i.

The staging time of smaller commercial containers departing Guam needs to be reduced. Often, smaller commercial containers sit at residential lots under "door to door" services (Matson) for long periods of time before being transported to the port and sealed. Customers that use the "door to door" service are given the option of either using Matson trucking for pickup of the container at their residence, or they may hire their own trucking service approved by the Uniform Intermodal Interchange and Facilities Access Agreement. However, the staging time of the container at the residence is not heavily regulated, and the container sits unsealed for at least 1 week.

Develop procedures to reduce risks of transporting terrestrial vertebrate species in household goods containerized at the residence for shipment. Standard procedures for packing household goods within containers for shipping are currently insufficient in preventing terrestrial vertebrate species transport. Movers drop off a standard 20- or 40-foot shipping container to the residence; if packing is not done in 1 day, they may leave the container overnight. If containers are brought to the shipping facilities not full, companies will leave them open, usually outside, at shipping facilities while filling. While staged in these instances, open containers offer entry opportunities to species. Further, when containers are sealed at the residence and staged at the facility for inspection, the possibility of detecting species is greatly diminished. For example, BTS canine inspections of cargo are less effective when performed on the sealed container only.

Reduce the outdoor staging time for transporting POVs either by military personnel or the public, and construct USDA-APHIS-approved perimeter fencing around staging areas. POVs being shipped by military personnel arrive at the lot daily and often sit outside for several weeks before being containerized on site. WS agents inspect any newly arriving vehicles (interior and exterior) daily and any vehicles that are scheduled to be containerized that day (Vice and Pitzler 2008). Reducing the staging time in combination with installation of USDA-APHIS approved fencing will help prevent species such as BTS from hitchhiking onto POVs. Also, with the increase in POVs due to force flow (increase in population due to military relocation) there is a greater potential for inspections to be delayed or missed unless there is an increase in the number of WS inspectors operating at the Fleet Industrial Service Center.

Departing military amphibious vehicles being transported as sea cargo must be inspected, cleaned, and washed at a laydown area prior to departure. Amphibious vehicles will need to be deployed from Guam to neighboring islands such as Tinian, Rota, and Saipan. These vehicles must be inspected, cleaned, and washed down prior to departure to prevent the spread of BTS that may hitchhike aboard these vehicles. The amphibious vehicle laydown area created at Apra Harbor will be required to store, wash down, maintain, and deploy amphibious vehicles, such as landing craft and amphibious assault vehicles. LCACs would also utilize this laydown area. Vehicles must be vacuumed to prevent the transport of plant propagation materials and pests. Once at the retrograde washdown area, vehicles are exposed to either high pressure (minimum 90 pounds per square inch) water or steam. After vehicles are washed, they will be inspected to ensure all soil has been removed and also should be inspected for vertebrate pests (AFPMB 2008). Common areas to be inspected include top and bottom access points, paying particular attention to crevices.

Departing WPM are subject to inspection and should not be stored outdoors. Certain WPM poses a high risk of transferring BTS and other species, such that all WPM must be inspected prior to departure from Guam. If WPM is stored outdoors, it should be stored in a cage covered with insect-proof netting, vegetation should be removed from the storage site, and the storage site should be sealed with concrete and thoroughly cleaned on a regular basis.

Palletized military munitions must be inspected and should be packed tightly and symmetrically.

Munitions are typically palletized and shipped as sea cargo on military vessels. The Asian Beauty snake (*Elaphe taeniura friesi*) was discovered in a shipping container holding munitions on Guam that had been shipped from Okinawa and held in storage for approximately 2 months in 2004 (Vice et al. In preparation). Munitions primarily depart Guam from Kilo Wharf in Apra Harbor. Pallets of munitions are containerized in the Munitions Storage Area on Andersen AFB or Naval Ordnance Annex and are loaded directly onboard military vessels at Kilo Wharf. In some circumstances, pallets of munitions are moved directly from either base to Kilo Wharf, for staging prior to direct loading onboard. Currently, canine inspections are conducted on all munitions as needed; however, both the pallets of munitions and the container that carries the palletized munitions should undergo canine inspections prior to departure. A caveat to this recommendation is that BTS detections by canine inspection are reduced if sealed wooden crates are used. Further, area-wide trapping and spotlight searches for BTS can reduce local populations, and routine inspections with USDA-APHIS-WS canine teams of munitions storage facilities can help prevent accidental transport.

Create and implement protocols to reduce contamination of low-risk cargo by high-risk cargo en route as well as on the ground.

Surface mail delivered parcel post is picked up and processed in the same manner as air mail, up to the point it is dispersed from the main post office in Barrigada. After the sorting process, surface mail is loaded directly into a 40-foot container staged at the post office and delivered weekly to the Apra Harbor Commercial Port for shipment. Most notably, mail containers may sit open until they are filled or scheduled for shipping, offering entry opportunities for terrestrial vertebrate species. Currently there is an intensive trapping program that limits the potential for snakes to immigrate into outbound surface mail or the containers in which it is stored, and this program must be maintained and expanded with an increase in departing mail. Low-risk cargo may become high-risk if handling processes expose it to potential species incursion (Vice and Pitzler 2008). The risk of contamination can stem from mail containers being handled, staged, and shipped in the same manner as general freight (Vice and Pitzler 2008), because mail is then in physical proximity to the high-risk cargo during the inspection process. Close containers if staged outside overnight. Provide USDA-APHIS-approved temporary barriers to prevent reptiles, amphibian, and rodents from entering.

Construction equipment, vehicles, and supplies departing from work sites need to be cleaned on-site to prevent movement of terrestrial vertebrate species.

Movement of construction equipment from work sites can transport species to new inter-island locations, and then off island if cleaning is not performed at port of embarkation. Proper facilities and procedures need to be in place for cleaning equipment on site for terrestrial vertebrate species in particular, prior to moving it for transport. For example, all contractors doing major construction, excavation, or earth moving are required to have a free inspection of their site and equipment by CNMI-DFW's BTS staff, with contractors also required to have their workers participate in a free, brief on-site snake prevention training workshop provided by CNMI-DFW. There is no fee to the contractor or workers for this service (<http://www.dfw.gov.mp/Wildlife/Brown%20Tree%20Snake.html>).

8.7.4.5 *People and Baggage*

Recommendations concerning people and baggage pertain to the travelers and their carry-on items (hereafter referred to as baggage). People tend to opt for the quickest mode of travel, making travel duration short and species survival high for this pathway. Risks associated with the recommendations for this pathway are due to intentional and unintentional transport of vertebrates, and the agencies in place for inspections do not target this pathway for the detection of vertebrates. Transport of people and their baggage can occur either by air or water, and is either commercially or military-operated, with each mode differing in the inspection process at the border. Commercial air transport of people and baggage includes commercial airlines or private charters, while commercial water transport consists of cruise ships or private charter boat passengers. On the other hand, military air transport of personnel may be involved in purely transportation from airfield to airfield, routine aviation training, or immediate departures of urgency (warfare, medical). Similarly, military water transport of personnel includes transport from one base to another, training missions, and immediate departures or urgency (warfare, rescue).

Provide a separate screening area for inspecting military personnel and their baggage at commercial airports. Due to the nature of military service travel, personnel must move quickly through ports without delay. Screening of uniformed military personnel is cumbersome; fatigues contain many pockets and folds, boots have intricate lacing, and travel bags may be difficult to unpack and inspect quickly. Similar to separate screening areas in commercial airports for inspecting persons with disabilities, a separate screening area for inspecting military personnel and their baggage should be implemented when travel is through a commercial airport. In addition, personnel are exempt from some of screening procedures imposed on the civilian passengers; personnel are not required to take off their boots unless the walk-through alarm sounds. These recommendations will facilitate compliance with 100% BTS inspection policy for military air cargo departing Guam, departing Saipan, and arriving to Tinian and Rota, and allow military to continue without delay to gate boarding.

Agricultural forms for arriving commercial passengers must be available in multiple languages, given the lingual diversity of Micronesia. Incomplete or inaccurate descriptions on agricultural forms can lead to the unknowing import of prohibited vertebrates. While some incompleteness and inaccuracies may be due to dishonesty of the traveler, it may also be due to illiteracy of the default language on the declaration form; a less complex problem that can be solved practically. In addition, multi-lingual agents will be needed to review the forms and assist passengers with filling out the forms. A communications study found when individuals are forced to use a non-native language to communicate, their overall orientation to communication may change, resulting in increased apprehension, decreased willingness to initiate communication, and decreased perceptions of communication competence (Burroughs and Marie 1995). The most commonly used languages in the region most affected by the relocation are English, Chamorro, and Chuukese. The incorporation of all of these languages into declaration forms is likely to reduce incompleteness and inaccuracies due to language. Additionally, these three languages should be spoken by the staffed agents (collectively) assisting passengers with form completion.

Penalties such as fines must be publicized, disseminated on forms, and enforced. It is difficult to enforce regulations without repercussions in place. Biological invasions are likely to increase in number and magnitude without negative reinforcement (penalties) pertaining to regulations. The agencies charged with the enforcement of inspection regulations (TSA, USDA-APHIS) and issuing of fines must use communication and coordination as well as education and training to disseminate the penalties associated with particular violations of travel. Therefore, paperwork of violations and the penalties incurred must be filed within a well-organized system, forms must prompt comprehensive information, and documentation must be easily accessible to the enforcement.

Increase surveillance measures in military and commercial airports and harbors at port entry points and screening check points. Use of surveillance equipment and procedures can help alert officials and inspection staff to transport of terrestrial vertebrate species, either smuggled or imported without knowing that the species is prohibited (Black Listed). Military uniforms have lots of pockets, folds, and baggy areas and maybe used for the concealment of transported species. Also, importing contraband items is an issue as well. Surveillance is a way of finding out if the inspection and enforcement process is working and of refining the entire biosecurity system. Implement video surveillance to monitor activity, and provide plain clothes enforcement officers for initiating rapid response measures during peak travel times.

An MCI program should be initiated on Guam. Immediate military personnel departures such as medical emergencies or rapid deployment missions may pose a higher risk of vertebrate movement because they may undergo less stringent or missed inspections. However, by mandate of the MCI, all passengers, crewmembers, accompanied baggage, and equipment boarding any DoD-sponsored ship or aircraft departing an overseas area for the CTUS must be inspected or examined prior to departure. All travelling personnel must complete U.S. Customs Accompanied Baggage Declaration, DD Form 1854 while civilian crewmember must complete Customs Form 5129. Urgent departures such as medical emergencies are still subject to MCI inspection, and expeditious inspection should not preclude taking the steps necessary to detect prohibited articles prior to departure, as stated by MCI (<http://www.tpub.com/maa/137.htm>). While MCI does not yet operate on Guam, the institution of this program is much needed and advocated for Guam by the U.S. Navy and PPQ.

Expand the number and sensitivity of detection equipment (x-ray) for departure checkpoints at airports in Guam and CNMI and implement x-ray machine use at Apra Harbor. It is important for inspection checkpoints to be properly equipped with an adequate number of machine vision technology devices because detection probability increases with machine sensitivity. While some inspection procedures are manual, inspection agents rely heavily on technological equipment to assist in the screening process. Currently, x-ray machines are in use for screening of departing passengers and baggage at Andersen AFB and Francisco Ada International Airport, among other airports in the region, but are not in use at harbors as of yet. The two x-ray machines for screening departing passengers and baggage at A.B. Won Pat International Airport were inoperable at the time this document was written, and awaiting replacement machines (Berringer, personal communication). While x-ray machines are in place at these locations, the models may be outdated and lacking in sensitivity, as well as in disrepair.

New advances in technology such as an image-feature based approach (Chen et al. 2002) may increase detections of vertebrate species.

8.7.5 Intentional Pathway Recommendations

Intentional transport of terrestrial vertebrate species occurs for a myriad of reasons. Intentional transport of species can pose serious risks because many animals are moved by private individuals, unregulated industry retailers, and smugglers that use both legal and illegal routes of import/export. For example, illegal species of amphibians and their eggs can be accidentally or intentionally brought in through the legal import of aquaculture products, and individuals boarding planes may smuggle species such as snakes, crocodiles, and lizards in their carry-on luggage (Bodry 2007; 2008). Overall, intentional transport of terrestrial vertebrates is difficult to monitor and track, as well as to regulate and enforce, especially through military sectors, which makes these pathways of particular concern. Of note, the only mode for intentionally transporting species not discussed is fur ranching, due to very low risk impact and lack of examples from the Micronesia Region.

8.7.5.1 Pet Trade

- Risk of importation 3
- Risk of establishment 3
- Hazard 3
- Total risk 9 **HIGH**

Pet trade recommendations focus on the transport of live terrestrial vertebrate species, adults and juveniles, including eggs of amphibian and bird species. Pet trade animals can be species of reptiles, amphibians, birds, and mammals, representing a diverse group of species potentially transported. Included are all acquisitions of pet animals, whether purchased from commercial pet stores, Internet dealers, or wild caught and imported by interested individuals, as well as the deliberate release of animals to establish populations that will then be harvested to sell as pets (USDA-APHIS-WS 2010). Also included are hybrid species bred specifically for the pet trade that do not normally exist in the wild.

Develop a Black List of terrestrial vertebrate species for each jurisdiction, the entire region, or both, to ban from importation and possession, and conversely develop a White List of species cleared for importation. Lists of species that are cleared or banned from importation will aid inspectors as to which species pose threats to human health and safety, the economy, and native ecology. Updating information on these lists, including regulations and policies, also helps in dealing with new and emerging pests. In the United States, species importations are viewed as “innocent until proven guilty” (Gray Listed). However this is against BMPs of implementing prevention measures. Development of a Black List is much more effective at prohibiting unwanted species (Witmer and Fantinato 2003; Pitt and Witmer 2007; Fowler et al. 2008). Lists can be updated by USDA-APHIS and utilized regularly by inspection agents.

Create training and education programs for inspectors in proper identification of species both White and Black Listed. Military personnel inspectors, and those with USFWS and USDA, act as border agents to prevent transport of terrestrial vertebrate species. Familiarity with White and Black Listed species can prevent misidentification and introduction of unwanted species. Training would include taxonomic identification of species, continued education regarding species' updates, changes to regulations, and new pest species listings. Hold regular meetings to discuss pertinent issues and needs pertaining to inspection/detection at pre-border, such as effectiveness of screening equipment to detect terrestrial vertebrate species. Develop multimedia educational material to further facilitate proper identification of species, with written descriptions, physical attributes, and animal behavior, as well as immediate human health and safety concerns (e.g., venomous snakes) and rapid response contact information (see Distance Diagnostic and Identification System [University of Florida 2010]).

Assign USFWS personnel at military and commercial air and seaports of entry. Even when import restrictions on some pets do apply, illegal importation of species occurs and poses a high risk primarily because resources are insufficient to address issues surrounding smuggling (USDA-APHIS-WS 2010). USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated animals, be a presence for law enforcement, and be part of a rapid response plan at the border should an aircraft or vessel-related incident occur. USFWS personnel will need to be familiar with species that are White-Listed and those banned from import, as well as trained in proper taxonomic identification of species.

Utilize current available technology to monitor pet trade Internet activity. The Internet is often an unregulated pathway, thereby creating an opportunity to import and introduce terrestrial vertebrates without detection at the border point of entry. Surveillance of Internet activity in regards to the sale or trade of animals, including monitoring the frequency and popularity of specific websites, can reduce the transport of potentially unwanted species, and serves to prevent introduction. The Invasive Species Internet Monitoring System automates the process of searching the Internet for suspect sites (e.g., Internet storefronts, chat rooms) involved in the sale or trade of targeted species (Suiter and Sferrazza 2007). This information can lead to data on the most common routes and modes of transportation, and breaches in current importation bans (e.g., importing snakes to Hawai'i).

Facilitate an expansion in pet trade monitoring through a sense of community ownership regarding the negative impacts of the illegal pet trade. Implement educational programs and materials that convey the hazards associated with the import of illegal pets. Create a response network by which community members may report incidences of illegal pet trafficking, propagation of breeding stocks, sales (independent or retail), unintentional and intentional releases into the wild, and rapid response to species sightings in the wild. Coordinate community efforts with local jurisdictional governments to enhance biosecurity efforts by residents. Provide meetings and newsletters to plan and develop procedures, and answer individual questions and concerns.

Place restrictions on the transportation of psittacines. Whether species of psittacines are captive bred or wild caught, rapid and successful establishment of non-indigenous psittacine species is common

worldwide, with resulting human health impacts (e.g., from bird droppings, transmitted diseases like the HPAI subtype H5N1), economic impacts (control costs), and ecological impacts (e.g., increased competition for food and nest sites, displacement of native species). Among birds, wild caught species pose a greater risk of establishment than do species that have been bred in captivity for many generations, because they retain the instinctual ability to survive after release (Carette and Tella 2008). Create agreements with pet shops and animal dealers to educate and regulate trade in psittacines; develop avenues to curtail smuggling due to restrictions and regulations that make transport of species more difficult; and create a system for tracking and monitoring species that are imported, if only via the honor system. Restrict the import by individuals in the private sector of certain psitticine species (Black List).

Follow similar procedures to those of Hawai'i Department of Agriculture for import restrictions by private sector: "Require a pre-arrival seven-day (168 hours) isolation from mosquitoes under the supervision of an accredited veterinarian and must enter the State within 36 hours of completing isolation. In addition, a Certificate of Veterinary Inspection must state that birds were not vaccinated for any disease with a vaccine containing a live agent within 60 days of shipment. The Certificate of Veterinary Inspection must also list individual bird identification numbers (leg band, wing band, or electronic microchip) and contain a statement that the birds are 'Free of external parasites.' All birds entering the State must be kept in isolation from other resident birds for a period of 30 days at the importer's premises. All shipments shall be in mosquito-proof containers that are either new or those thoroughly cleaned to the satisfaction of the accredited veterinarian issuing the Certificate of Veterinary Inspection. Importation of animals through the USPS is not allowed. All imported psittacines, whether from foreign or domestic origin, should first enter Guam via A.B. Won Pat International Airport, which should be the only entry port for imported birds, with all shipments subject to inspection and penalties for non-compliance. Inspections should be conducted at the newly constructed Airport Animal Quarantine Holding Facility prior to release. An agent of the airline will submit the birds for inspection. The hours of operations when inspections can be performed to accommodate shipment arrivals must be posted, and an 'after-hours' staff for unexpected or re-scheduled commercial shipments or chartered/private freight arrivals should be assembled. Birds not meeting entry requirements are to be returned to a port of entry in the continental United States or a foreign port in the case of international movement, with notification of contaminated cargo and proper authorization to do so.

It is imperative quarantine the birds upon entry to protect human health and safety. Construct a Quarantine Holding Facility at the A.B. Won Pat International Airport. Confounding factors include screening of cargo for species in military aircraft arriving Andersen AFB and military vessels through the COMNAVMAR, privately owned and chartered (private and commercial) aircraft imports, and unscheduled commercial airfreight imports.

Restrict imports of snakes to island nations. Native species on islands evolved without any terrestrial predators, and hence are vulnerable to terrestrial vertebrate species that prey upon them. Snakes are insidious predators that, unlike rodents or other small mammals, may be difficult to detect because of nocturnal and/or arboreal habits of some species, they don't leave obvious signs of presence or make

noise, and they are difficult to control once established. Similar to regulations enforced by Hawai'i State Department of Agriculture for animal import by individuals in the private sector, at least restricting the import (Black List) of snakes should be considered.

Enforce existing regulations and expand regulatory drivers in the Pet Trade industry. Successful importation of unwanted terrestrial vertebrate pest species increases the probability of introduction and establishment, and is partly due to moderate and high public interest for importing pet species, and a lack of government regulations on the pet trade industry. Enforcement of existing regulations should be upheld, such as APHIS regulations for importing animals from foreign origin, 42 CFR § 71.51 (for dogs), Guideline for Transport from the CITES, protocols of the CDC, and the WBCA. Expand regulations for the pet trade industry to curtail acts of illegal importation, and create avenues for safe imports. Examples include developing and implementing the use of White and Black Lists, assigning a USFWS officer at borders, and coordinating voluntary agreements with pet stores and businesses in the pet trade industry.

8.7.5.2 *Aesthetic Releases*

- Risk of importation 3
- Risk of establishment 2
- Hazard 3
- Total risk 8 **HIGH**

Recommendations to prevent the unintentional and intentional release of animals for aesthetic reasons shares similarities with the Pet Trade recommendations. Animals may be intentionally released into the wild because the species is considered in some way desirable (Kraus 2009a). Examples include freshwater turtles and frogs released into backyard ponds, songbirds and some parrots because they invoke nostalgia, and lizards because of species' characteristics (e.g., eats insects, are colorful) (e.g., Long 1981; Kraus and Campbell III 2002). Mitigation is post-border, as animals released will most likely be from local residents or newly relocated persons. However, education is needed for inspectors and individuals at the border ports of entry, as an intentional release may stem from the person self-justifying the release of a 'wild' animal back into the wild, or the unintentional release of them not knowing the potential impacts the species may cause. Animals introduced via aesthetic release may be obtained legally from imported commercial stock (i.e., pet stores), Internet purchases, or illegal trading. Recommendations therefore overlap with those concerning the pet trade, including those that restrict movement of certain taxa like birds and reptiles (snakes and lizards). The availability of animals in Micronesia varies on the supply of local commercial stock, Internet purchases, illegal activity, and the frequency with which citizens travel overseas and return with animals. Military personnel travel is rarely restricted by inspection procedures, thereby making that pathway a concern for illegal imports.

Assign USFWS personnel at military and commercial air and seaports of entry. Even when import restrictions on some animals do apply, illegal importation of species occurs and poses a high risk primarily because resources are insufficient to address issues surrounding smuggling (USDA-APHIS-WS

2010). USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated animals, be a presence for law enforcement, and be part of a rapid response plan at the border should an aircraft or vessel-related incident occur. USFWS personnel will need to be familiar with species that are White Listed and those banned from import, as well as trained in proper taxonomic identification of species.

Create cooperative agreements with pet retailers to detect bulk and repeated purchases of animals.

USDA-APHIS and USFWS agents should work to create agreements with pet retailers operating in the Micronesia Region. Under such agreements, the agents will maintain open communication about topics such as noticeably large increases in sales and demand, types of species listed in inventories, and the types of clientele. An effective method of attaining such information is a routine online survey to be completed by the retailer.

Implement educational programs and materials that convey the hazards associated with the release of unwanted terrestrial vertebrate pest species.

Animal releases are primarily performed by the public. Public education can help prevent intentional or accidental importation and release of pest species (USDA-APHIS-WS 2010). Provide education through the distribution of printed materials that include examples of how released animals can become human health and safety, economic, and ecological, threats once established. Target schools to educate children on the importance of preserving natural ecosystems. Adults should be targeted as they will be the group most likely to release, smuggle and inadvertently harbor pest species. The military sector and foreign contract workers should be focused upon with extra effort.

Begin to regulate against aesthetic releases of terrestrial vertebrates. While specific regulations exist regarding the importation of pets (see GARR Title 9, 1997), regulations regarding release of animals are less developed and detailed, such that release remains relatively unmonitored. The only mention of regulation to prevent release is at the pier or airport inspection areas; Section 2 of § 1103 (GARR) states that under no circumstances shall any animal be turned loose at the port, and that hogs and sheep may be confined in temporary pens or crates, cattle and horses may be tied, and dogs and cats shall be confined in crates. Require specific taxa such as birds and mammals (rodents) be quarantined immediately upon arrival in compliance with existing APHIS requirements. Therefore the regulation only restricts release at the port of entry with no regulations against releases post-border, which is when aesthetic releases are most likely to occur. Under a new regulation, if an intentional release is known to occur in the community and is reported, individuals involved should be subject to a penalty such as fines.

8.7.5.3 Food Use

- Risk of importation 3
- Risk of establishment 3
- Hazard 3
- Total risk 9 **HIGH**

The importation of domesticated animals as a food source is common worldwide. The continued importation of animals via this pathway makes this a high-risk pathway. As a consequence, transport and release of domesticated food species onto islands lacking them is typically viewed as simply exercising the right to feed oneself, and the practice continues around the globe (Kraus 2009b). However, some domesticated animals introduced as a farmed food source can successfully establish and some species can be highly invasive and ecologically destructive (sheep, pigs, frogs). Also, newly introduced food species often coincide with the immigration of new ethnic groups to a place making this motive both culturally and demographically linked.

Imported poultry and eggs must be quarantined, and inspected, and poultry must be vaccinated by a Territorial veterinarian for health condition prior to entry on Guam under Title 9 GARR 1997 and USDA-APHIS regulations and inspection. All poultry and hatching eggs must remain on board or be confined on the pier or airport inspection area until passed by the inspector under this regulation. With poultry being the natural host for pullorum disease, health inspections and quarantine quell human health threats, as pullorum disease can also affect humans. In addition, poultry can carry NDV, a virus that may be present in high concentrations in the bodily secretions of infected birds. The virus is spread by air, contact with body secretions, and by contaminated water and feed (UNH Extension Program, http://extension.unh.edu/resources/files/Resource000792_Rep815.pdf).

Prohibit the farming of frogs and freshwater turtles for food. Large frog species continue to be known as an easy way to raise protein in one's backyard either for direct consumption or, more often, for commercial sale (Kraus 2009b). However, frog farming remains a difficult industry with limited success and commonly leads to introductions of frogs when failed farms are abandoned (Kraus 2009b). Frog farming has not been attempted much in Micronesian countries, and therefore it remains a plausible commercial endeavor in the region. Freshwater turtles such as the Chinese soft-shelled turtles, (*Pelodiscus sinensis*) have been introduced and spread through the farming industry. The inexperience of farming of these taxa makes the risk of introduction high for the Micronesia Region and the importation of these species for farming purposes should be prohibited as a preventative measure.

Aquaculture shipments entering Guam must have an import permit, certificate of origin, and health certificate, and should undergo physical inspection for amphibians and their eggs. Aquaculture shipments are not always physically inspected, even though these shipments are a known pathway for the unintentional and intentional introduction of amphibians and their eggs (Christy et al. 2007b; Kraus 2009a). Illegal import of terrestrial vertebrate pest species can occur through legal means, such as with aquaculture imports. USFWS only has nine ports in the United States that are designated to approve shipments of live fish and fish parts for aquaculture, and these are in the Continental United States and Hawai'i. The Designated Port Exception Permit is required if Guam or CNMI is the first port of entry for a fish shipment. USFWS approval of fish shipments is intended to prevent harmful exotic species from establishing and approval is typically granted contingent on the permit being complete. Aquaculture shipments should be physically inspected upon arrival, especially those containing live freshwater species such as catfish and tilapia, which are more prone to containing tadpoles that are not clearly

evident amongst the imported fish fry being shipped in nontransparent containers, which further complicates inspections.

Use digital resources to track the trade and importation of animals for food use in the Micronesia Region. The illegal import of terrestrial vertebrate pest species can occur through legal means, such as with animals imported for food use. The Internet can be used to identify the sale of prohibited or non-compliant importation of animals for food use. The Invasive Species Internet Monitoring System automates the process of searching the Internet for suspect sites (e.g., Internet storefronts, chat rooms) involved in the sale or trade of targeted species (Suiter and Sferrazza 2007) for the pet trade, and this tool may be applied to detect breaches in legal importation of animals for food use.

Educate the community about the dangers of maintaining populations of potentially invasive species for food. This education should include ensuring that overseas workers who may come to the region for construction and other projects are aware of the risks associated with such practices. Create educational materials, broadcast public service announcements on the radio, and submit newspaper articles outlining the impacts of establishing populations of species for food. These materials should include examples of species known to be introduced for food use, and also known to be highly invasive in one or more countries (e.g., rabbits [*Oryctolagus cuniculus*], banteng [*Bos javanicus*], water buffalo [*Bubalus bubalis*], Polynesian rat [*Rattus exulans*], spotted turtledove [*Streptopelia chinensis*], water frogs [*Rana ridibunda*]) (Crook 1973; Atkinson 1978; Long 1981; Lever 1994; Arano et al. 1995; Pagano and Schmeller 1999; Athens et al. 2002; Courchamp et al. 2003; Long 2003a; Pagano et al. 2003; Vorburger and Reyer 2003; Towns et al. 2006; Hunt 2007).

8.7.5.4 *Animals for Entertainment*

- Risk of importation 2
- Risk of establishment 2
- Hazard 3
- Total risk 7 **MODERATE**

Some species are imported purely to entertain members of the community. Two major examples of this in Micronesia include importation for stocking zoological facilities, and poultry importations for the popular and legal pastime of cockfighting. While the containment and display of these species is inherent to both zoological facilities and fighting cock owners, accidental releases to the wild occasionally occurs as a result of these practices.

Laws and regulations regarding zoological facilities need to be established and/or improved for all jurisdictions with the possible except of Hawai'i. Regulations for Hawai'i may in fact be an appropriate starting place for the other jurisdictions. The situation which occurred on Guam when the zoological facility in southern Guam closed last decade highlight the fact that there are gaps in existing regulations and protocols for Guam and likely other jurisdictions in this regard. In the Guam

case, some of the animals from the zoological facility which closed were never accounted for suggesting that they may have ended up in the general community or even been released.

Zoological facilities should update and maintain secure caging, as well as improve security measures at the facilities. Most records of releases at zoos are accidental due to non-secure caging, but there have also been several instances of intentional releases of animals by personnel at larger, public zoos (Shaw 1946; Long 1981). Zoological facilities should conduct and document inspections routinely of their caging structures, and weak points must be addressed immediately. The facilities should also selectively hire security staff to prevent instances of criminal animal release. Currently, there is one zoo on Guam (previously with two), one on Rota, and one on Saipan (Stanford, personal communication). A relatively low amount of activity makes the risk of importation rather low, but the rather poor maintenance standards evinced by many private zoos make risk of release into the wild rather high (Kraus 2009b).

Species in zoological facilities should be kept only in small numbers, and breeding pairs are of higher priority for cage maintenance. If large colonies or cohorts of breeding adults of both sex classes of a species are kept within the same cage, there is a higher risk of establishment if a release does occur. Cages that contain breeding pairs should be of higher priority for the inspection and maintenance of cage security.

USDA-APHIS agents, in coordination with GCQA, must verify permits and health inspections for animals being imported for the purpose of stocking zoological facilities. Importation of zoological stock animals to Guam requires an import permit obtained from Guam's office of the Director of Agriculture and animals are subject to inspection by the territorial veterinarian prior to entry to Guam (9 GARR § 1111) as well as the AWA, which is implemented by APHIS through its Enhanced Animal Welfare Act Enforcement Plan.

USDA-APHIS agents at airports throughout Guam and the CNMI must report and confiscate fighting roosters arriving from the U.S. mainland. While cockfighting events remain legal in Guam and the CNMI, the export of fighting roosters and associated cockfighting weapons from the U.S. mainland is considered a felony under the Animal Fighting Prohibition Enforcement Act of 2007. Guam is a known hotspot for cockfighting, such that all imported roosters arriving in Guam should be considered imported for cockfighting purposes. Eggs have less of a chance of surviving transport because of the higher physiological demands of eggs as compared to adult chickens. Under this recent piece of legislation, pressure has been applied to stop commercial airlines from transporting fighting roosters. Airlines such as United, Philippine, and Korean Airlines refuse to transport fighting roosters as a precautionary upholding of the Animal Fighting Prohibition Enforcement Act. This act will stop the importation of adult fighting roosters, reducing the overall number of domesticated birds entering Guam and the CNMI. People who claim their imported roosters are pets should be subject to a monitoring program using periodic paperwork and inspections to track the actual use of the roosters imported.

8.7.5.5 *Game Hunting*

- Risk of importation 1
- Risk of establishment 2
- Hazard 3
- Total risk 6 **MODERATE**

Game hunting on Guam and throughout the CNMI is a cultural practice, and also functions in game population management because it is a low-cost management tool to reduce feral animal populations; thereby reducing habitat destruction on the island (Conry 1988b). Game introductions typically include only mammals and birds; reptiles and amphibians are not moved for this purpose (Kraus 2003; 2009a). The animals hunted on Guam are all introduced species such as the Philippine deer, wild pig, and black francolin. Similar to other Pacific Islands (Hawai'i), pigs have the most negative impact on forests and agriculture on Guam (Conry 1988a). Many of the ungulates introduced for game purposes have proven very destructive of native ecosystems on Pacific Islands and elsewhere (Stone 1985; Conry 1988b; Wardle et al. 2001; Wiles 2005; Hughey and Hickling 2006; GISD 2010). This is both because of direct herbivory on native vegetation as well as trampling of the substrate (e.g., Duncan and Holdaway 1989), both of which lead to plant death and increased erosion (Kraus 2009b). Due to their negative impact on the environment (erosion, trampling vegetation), Asiatic water buffalo (carabao) can no longer be hunted, and populations are being controlled by hormone injections to reduce reproductive rates. Once popular game, the fruit bat and Phillipine turtle dove are no longer allowed to be hunted due to declining populations (<http://www.guamdawr.org/wildlife/hunting/>).

Regulations preventing further importation of feral animals for recreational hunting must be upheld and expanded. USDA-APHIS oversees the importation of feral animals from foreign ports through the facilitation of international trade and monitoring of animal health at the border. Uphold APHIS regulations for certain species whether feral or not for foreign origin imports to Guam; APHIS regulations take precedence when they are more restrictive than the laws and regulations of the U.S. federal government. APHIS regulations would not apply to shipments coming to Guam from the United States (non-foreign origin), but imports to Guam from the United States are not considered foreign imports. As it stands, feral animals may be imported to Guam with proper permitting and approval by the Director of the Department of Agriculture (Title 9, GARR 1997). There should be no further importation of feral animals for the purpose of recreational hunting, because the game densities are more than sufficient on Guam (e.g., wild pigs; Conry 1988a), especially if more hunting areas were to be opened for access.

Additional hunting areas should be opened for public access, and hunting by military personnel on military lands is encouraged. Guam law requires hunters to obtain written permission to hunt on private property, and public lands for hunting are often surrounded by military and private parcels, making hunting access logistics difficult (Conry 1988b). In particular, the Air Force and Navy already control large parcels of land where game is found, and Andersen AFB, NCS, and the Naval Facility have hunting programs, but access is restricted to military personnel. If personnel are not frequently hunting

on these lands, herds of game will accumulate and habitat degradation becomes rampant. The military should work with GDAWR and USFWS to facilitate public hunting access on military lands of lower-level restriction during regimented times. Also, with the increase in military personnel on Guam as a result of the relocation, there lies an opportunity to increase hunting on military lands.

8.7.5.6 Biocontrol

- Risk of importation 1
- Risk of establishment 3
- Hazard 2
- Total risk 6 **MODERATE**

Biocontrol introductions are those made for the purpose of providing predatory control of another pest species, and typically itself is also of alien origin. Ironically, most of these releases have failed to control the pests they were intended to destroy but have become pests themselves (Kraus 2009b). Classic examples include the introduction of cats for controlling rodents that damage agriculture (Dickman et al. 2010), mongoose for controlling rats and snakes (Long 2003b, a; Watari et al. 2008), and cane toads released for controlling sugar cane pests (Lever 2001), all involving governmental support. While government-backed biocontrol has become less common due to the large amount of failed examples, biocontrol by private actions remains a risk. There is a general lack of public knowledge regarding the dangers of biocontrol and some recent introductions are initiated by private entities, under the belief that the pest can be controlled directly by the predator without any indirect, adverse effects. Attempts of biocontrol by private actions will be closely associated with the pet trade, as this is the most likely source for exotic animals for intentional release.

Place USFWS and USDA-APHIS inspectors on military bases in Guam and CNMI and initiate proper training of Military Customs personnel to recognize and prohibit importation of potential biocontrol-use species. The importation of species by military aircraft is worsened by the fact that USFWS does not have inspectors stationed at military bases in the region, so the probability of interception is unlikely. Depending upon the species, APHIS may also have import regulation requirements. The military route has led to numerous illegal importations of banned reptiles into Hawai'i (Hawai'i Department of Agriculture records), and some of these species include those released elsewhere for control of house pests. Similar activities likely occur on military bases in Micronesia and would likely increase with the relocation of military personnel on Guam and in CNMI, making this a likely source of importations for the purpose of private biocontrol initiated by individuals (Kraus 2009b).

Educate the public about regulated and scientifically proven effective control measures in place for BTS and other biting snakes. BTS and other snakes pose human health risks due to painful bites which can be life-threatening, depending on the species. Approximately one in every thousand hospital visits on Guam is due to a BTS biting incident, with victims including infants, agricultural workers, and BTS field staff (Rodda et al. 1999), leading to a large-scale economic impact as well. Many people have a deep-seated fear of snakes, and the vast majority of people resent snakes inside homes, stores, and other

human environments (BTSCC 1996). Due to the high incidence of bites, it is natural for members of the community to want to protect themselves and others from snake pests, and they may resort to biocontrol under private actions. However, these attempts would be ineffective; there are no effective natural predators of BTS on Guam. Feral cats, feral pigs, and monitor lizards prey on snakes, but their effect is minimal (BTSCC 1996).

Furthermore, the introduction of the mongoose to Guam has been proposed due to its reputation as a snake predator even though they are not adapted to do so. Mongooses are diurnal and cannot climb well, unlike BTS. Previous introductions of mongooses to control the habu in Pacific Islands have failed, and resulted in additional ecological problems, including the extirpation of some native herpetofauna (BTSCC 1996).

Proposed biocontrol measures must be approached with extreme vigilance, and those considered for action must undergo long-term scientific trials. Vertebrate biocontrol releases have tended to have high probabilities of successful establishment (Long 2003b; Kraus 2009a) due to high propagule pressure. For example, the introduction of the mongoose to Pacific Islands was an early attempt of biocontrol of an agricultural pest species, with the approach rooted in predator-prey dynamics. Yet, the mongoose has proven too general of predator, causing the decline of native bird and reptile species (Simberloff 1992). In Hawai'i, 22% of 243 biocontrol agents were documented to attack organisms other than their intended targets (Funasaki et al. 1988). In application, the biocontrol attempt may often lead to unforeseen ecosystem consequences that worsen the original problem (Matthews and Turner 2009) or create new management problems.

While countries such as Australia (McFadyen 1989) and New Zealand (Fowler et al. 2000), have established effective regulatory policies for biological control, the United States does not have an integrated policy on the implementation of biocontrol, and policies can differ vastly in stringency by state (Messing and Wright 2006). For these reasons, proposed biocontrol measures must be approached with vigilance; rigorous, long-term scientific trials must be required and fielding of professional and community opinions is integral.

8.7.5.7 *Scientific Research*

- Risk of importation 1
- Risk of establishment 3
- Hazard 3
- Total risk 7 **MODERATE**

Releases associated with scientific research can be attributed to two main types: 1) deliberate or accidental releases from medical research facilities, and 2) deliberate releases to study ecology or behavior of the released specimens (Kraus 2009b). Accidental release from inadequate caging or mishandling of species may also occur. Examples of problematic releases from research facilities include the escape of monkey species, which quickly establish in the wild given the proper environmental

conditions and food availability (Long 2003), or the establishment and rapid spread of escaped frog species (e.g., *Xenopus laevis*) (Lafferty and Page 1997). The importation for scientific research will not be a common occurrence in Micronesia, because the region has few medical or research facilities, with one medical school found in FSM and various biological research labs at the University of Guam (Western Pacific Tropical Research Center, Cancer Research Center and Guam Aquaculture Development and Training Center).

Scientific research in U.S. territories that involve terrestrial vertebrates must be approved by the Institutional Animal Care and Use Committee and undergo routine inspections in compliance with the AWA. All U.S. research facilities where vertebrates are used for research must have an active Institutional Animal Care and Use Committee permit for research prior the implementation of protocols. For example, at the University of Guam, the committee inspects animal facilities at least semi-annually and reviews any practices involving pain to animals and the condition of animals to ensure compliance with the AWA, 7 U.S.C. § 2143 et seq.; 9 CFR 1, §2.31 and the standards of the United States Public Health Service as set forth in the Guide for the Care and Use of Laboratory Animals (http://www.uogonline.com/gateway/forms/rules_regs_proc_man.pdf, accessed September 30, 2010). Facility inspections will help to ensure proper secure caging is maintained and proper quarantine protocols are in place.

Caging and containment of vertebrates used in research must be routinely inspected and maintained, and security personnel must be in place at the facility. Research facilities should conduct and document inspections routinely of their caging and containment structures, and weak points must be addressed immediately. Like zoological facilities, there is a risk of accidental or intentional release by staff of captive vertebrates. The facilities should also hire security personnel to prevent instances of intentional animal release by individuals.

The importation of monkeys and *Xenopus laevis* for research use should be banned from Guam and the CNMI. Currently, the regulations on importation of vertebrates to Guam do not mention the policy on importation of vertebrates for the use of research (Title 9 GARR). However, the regulations should be updated to specifically address this motive for importation and restrict problem species such as monkeys and *Xenopus laevis*.

8.7.5.8 Religious Ceremonies

- Risk of importation 1
- Risk of establishment 1
- Hazard 2
- Total risk 4 **LOW**

Intentional releases of terrestrial vertebrate species can occur during religious ceremonies or because of religious beliefs. Birds and turtles are the most common terrestrial vertebrates used for release (Severinghaus and Chi 1999, Kraus 2009a), but mammals, frogs, and snakes are targeted as well

(Agoramoorthy and Hsu 2005, 2007; Corlett 2010). Many of these released animals are purchased from pet stores, with one study finding one-quarter of all birds stocked in Taipei pet stores slated for this purpose (Severinghaus and Chi 1999), making this motive tied to the pet trade and its associated risks and recommendations. Therefore, the risk of religious ceremony release can be intercepted if the recommendations suggested for the pet trade are successfully implemented.

Create agreements with groups of concern that are known to participate in religious releases of vertebrates. There are two major sources of vertebrate releases for religious purposes, the Buddhist and Taoist practice of releasing captive animals as an expression of compassion to improve one's karma (Shiu and Stokes 2008) and Christian snake-handling cults in the southern United States who release venomous snakes (Wilson and Porras 1983). The risk of establishment is high for this motive because of the typically large volume of animals released and the high frequency of release, leading to high propagule pressure. The risk from this motive is low for Micronesia at present, although this could change if larger numbers of practicing members of groups of concern immigrated to the region. Attempts should be made to create agreements with groups of concern directly regarding the release of vertebrates. This motive is very difficult to regulate, as releases occur in large numbers and may be incidental or routine, depending on the sect of the religious group. Educational materials that outline the human health and safety, economic, and ecological threats of vertebrate release should be disseminated to practicing groups of concern in Micronesia.

8.7.5.9 *Bioterrorism*

- Risk of importation 1
- Risk of establishment 1
- Hazard 3
- Total risk 5 **LOW**

Optimal characteristics for bioterrorism agents include being very small in size (microscopic), hazardous to humans, easy and inexpensive to produce, and rapid spatial dissemination. Well-known examples include anthrax, bubonic plague, and smallpox. Vertebrates do not fit these desirable characteristics themselves due to their relatively large size. One possible exception would be that a large number of venomous snakes could be introduced for such a purpose, but the numbers required for importation for the task (hundreds to thousands) could likely not easily be overlooked by a border-security system (Kraus 2009b). Therefore, the risk of this motive for vertebrates as bioterrorism agents themselves is low, and any importation for this purpose will likely be detected by inspectors. However, it must not be overlooked that bioterrorism agents may be tactically introduced via a domesticated non-human vertebrate host. Epizootic outbreaks may first be noticed in vertebrate species such as livestock, where the agent was introduced along with a host that was cleared at the border. Due to prolonged and close exposure of livestock to people, the zoonotic agent then infiltrates the human health circuit. The potential for introduction of a bioterrorist agent will be of particular concern for Guam due to projected extensive military presence on the island. In general, the increases in human population, both military

and civilian, are expected to significantly increase the likelihood of wildlife pathogen introductions and spread via humans.

Health certificates (issued by the USDA Animal Health Division or by the state veterinarian for the state of origin), must accompany imported livestock, and such livestock is subject to health inspections by the territory veterinarian(s) and quarantined if needed. All animals that have been exposed to, are suffering from, or appear to have the symptoms of a contagious or infectious disease, shall in addition to the inspection be subject to quarantine under regulations of the government of Guam (2 GARR § 1110.5) and required USDA-APHIS Animal Health Permits. Depending on the species of livestock, inoculations or pathogen assay tests may be required prior to entry (e.g., horses, cattle). Bird species, especially those in the pet trade like psittacines, should be quarantined upon arrival.

Livestock operations on Guam shall undergo routine inspections by the Department of Agriculture (Guam) to determine the health condition of all animals boarded at each farm. This mandate is in compliance with § 62104.3. Standards of Care for Livestock (GCA Government Operations: <http://www.justice.gov.gu/compileroflaws/GCA/05gca/5gc062.pdf>).

A network must be established for the reporting of animals exhibiting symptoms of zoonotic agents. A cooperative network for communication must be made involving the CDC, USDA-APHIS, livestock owners, and local veterinarians, among others to exchange information regarding detections of symptoms caused by hazardous pathogens in livestock. The goal of such a network is to readily disseminate alerts within the region to prevent further spread of bioterrorist agents in the case they are introduced.

8.8 CONCLUSION

Biosecurity is a management process that requires a specific and appropriate framework in which to operate effectively. Additionally, a biosecurity strategy requires sustained and managed funds, the capabilities to address myriad security issues, and flexibility to undergo regular assessment and refinement as needs change and new risks are identified. This biosecurity plan accomplished the following goals: 1) identified pathways by which species may be transported, introduced, and established; 2) identified risks associated with pathways and the threats posed to human health and safety, the economy, and ecology; and 3) provided recommendations for the prevention and mitigation of the identified risks. Furthermore, a comprehensive pathway analysis was used, which accounts for the interrelatedness of pathway use and overlap of military and civilian sectors.

This plan provides guidance and instruction to prevent and mitigate risks associated with the military relocation in the Micronesia Region; comply with stringent environmental legislation; and coordinate with agencies at the federal, state, and local level.

9 PORT-PATHWAY MITIGATION ANALYSIS

9.1 GUAM MITIGATION CAPABILITIES AND INFRASTRUCTURE

Table 12-1: Mitigation Measures for Guam Airports and Maritime Ports

Mitigation Capabilities/Infrastructure	Airports	Maritime Ports Containerized (DoD)	Maritime Ports Containerized Cargo All Sources	Maritime Ports Break Bulk Cargo	Maritime Ports Bulk Cargo

Monitor/transfer garbage to approved disposal company	X	X	X	X	X

9.2 GUAM CRITICAL INFRASTRUCTURE PROFILES

9.2.1 A.B. Won Pat International Airport-Guam

Table 12-2: A.B. Won Pat International Airport-Guam

Description	Current Mitigations	Impact of Military Relocation
300 flights per week. Seven international airlines and six air freight couriers operate out of the A.B. Won Pat International Airport. The airport has 21 aircraft parking positions with 18 common use terminal gates (55% commercial, 24% air taxi; 21% local general aviation; <1% transient general aviation) (AirNav 2007).	<p>Inspection of aircraft, baggage, and cargo by GCQA—about 120 inspectors assigned to airport and seaport.</p> <p>Collaborate with APHIS to enforce regulations.</p> <p>Monitor garbage.</p> <p>Port control measures: Quarantine, Decontamination, Treatment/washing</p> <p>Arriving commercial aircraft are not usually inspected for terrestrial vertebrate species. All aircraft departing Guam, commercial or military, are inspected for BTS (EO 13112, Invasive Species).</p> <p>Inspections are constrained by resources to only a portion of air freight conveyance crates and containers. Container scanners are not available on Guam.</p>	The large additional number of people arriving on Guam during the buildup will strain the already limited resources of GCQA.

9.2.1.1 ***Prioritized Actions-A.B. Won Pat International Airport–Guam***

- The international airport foreign inspection area is large enough to accommodate the increased flights and to enhance inspectional needs.
- However, personnel specially trained for agricultural quarantine inspections and equipment (e.g., x-ray machines) for inspection of all baggage must be increased.
- GCQA should designate agricultural specialists on all shifts. There should be additional personnel for passenger baggage and aircraft inspection daily (assigned to all shifts).
- GCQA should have inspectors that specialize in agricultural inspections. Due to shift work and the large number of inspection sites, GCQA should plan to increase total staff with specialists dedicated to agricultural inspection. Inspectors should be available for agricultural products on all shifts at the international airport.
- X-ray machines are inoperable. Obtain adequate capacity for inspection of luggage and large boxes. Expand numbers of x-ray stations from two to four with new x-ray units that have conveyor belts at ground level on front and back.
- Detector dogs should be available at all international airport shifts. Increase staffing of agricultural detector dogs from four to eight. Agricultural detector dogs should be used in mail and cargo inspections.
- GCQA should have access to the USDA-APHIS ePermits system. Access can be provided by APHIS.
- Legislation should allow full access to GCQA to CBP targeting databases so inspectors in Guam routinely can examine manifests and hold and release cargo for 2 to 3 days prior to ship arrivals.

Funding Priorities

- GCQA must explore all opportunities to expand legislative authority to increase user fees to allow GCQA to fund the necessary increase in inspectors and equipment for more entry inspections and a reliable mitigation infrastructure.
- GCQA should consider raising these fees for biosecurity and agricultural inspections. The funding structure of USDA and CBP can be utilized as a guide.

9.2.1.2 ***General Recommendations-A.B. Won Pat International Airport-Guam***

Resources

- Staffing at A.B. Won Pat International Airport for agriculture inspections should be expanded to permit GCQA inspection of all incoming passenger baggage during the increased military use of commercial air transportation pathways, the increase in commercial air cargo with the proposed military relocation, and expected passenger plane travel. Ensure adequate numbers of inspectors, identifiers, pest survey specialists, etc. to carry out mitigation measures effectively.

GCQA should be funded and staffed at optimum levels for all necessary inspection and quarantine activities.

- X-ray machines should be available and work properly to maximize baggage screening. Increase the number of detection equipment (x-ray) at airports in Guam from two to four. The sensitivity of the machines should be increased.
- There should be sufficient equipment (computers, microscopes, dissecting scope, hand-lenses and other diagnostic equipment) and supplies (e.g., reference materials, identification keys) at ports and plant and animal inspection facilities.
- Install container scanners at the port facility. Allocate funding to increase the number of containerized and crated air cargo shipments to be inspected.
- Ensure garbage collected in sterile areas are handled and processed as regulated garbage.

Inspection

- Conduct inspections on commercial/private aircraft arriving to Guam and departing.
- Inspect all arriving conveyances for illegal animals or animal products.
- Increase inspection rates of commercial air freight.
- Inspect passengers transiting to other locations in the Micronesia Region for regulated agricultural commodities.
- Air cargo conveyance crates and containers tend to be inspected if shipments are labeled as containing agricultural products, have insufficient or improper documentation, or are from a country of concern. Standardized methods should search containers randomly regardless of documentation, type of shipment, or country of origin. Paperwork with arriving air cargo shipments in crates and containers should be automated for more rapid selection of containers to be screened and for new avenues for pre-clearance procedures.
- All military personnel checked baggage transported to and from Guam and the CNMI on commercial, private, and chartered planes and helicopters must be inspected for compliance with USDA-APHIS regulations. Expand the inspection capabilities for military airfreight containers.
- A communications network for continuously shared relevant new information among inspectors is recommended.

Control

- Implement measures to control invasive species at and around washdown facilities. Control measures include barriers, trapping, and insect population reduction.
- Construct barriers around aircraft staging areas to protect aircraft from hitchhikers.

Treatment

- All military air cargo departing Guam should be cleaned, inspected, and loaded on the aircraft for transport immediately.

Surveillance

- Increase airport surveillance measures.

Rapid Response

- Improve airport rapid response capabilities.

9.2.2 Andersen Air Force Base-Guam

Table 12-3: Andersen Air Force Base-Guam

Description	Current Mitigations	Impact of Military Relocation
<p>Air Mobility Command aircraft transports military cargo not consigned to commercial carriers. Military aircraft used in medical/emergency missions depart Guam with little or no notice for inspection. Military training operations are conducted by the Army, Marine Corps, Air Force, and Navy.</p>	<p>Inspection of aircraft Vector/arthropod controls Medical and agricultural quarantine Aerosol disinfection</p> <p>Aircraft moving between Hawai'i, Guam, Puerto Rico, Virgin Islands, and the continental U.S. must undergo USDA/GCQA inspection by inspectors with authority to board military aircraft (Section II, Subsection C of the Quarantine Regulations of the Armed Forces Section 10 of OPNAVINST 6210.2, USDA requirements for movement of animal and plant diseases and pests). With no internal inspection and cleaning, hitchhiking pests and animals go undetected. Arriving military aircraft usually are not inspected for terrestrial vertebrate species. All aircraft departing Guam, commercial or military, are inspected for BTS according to EO 13112, Invasive Species, by APHIS-WS.</p> <p>Planned Improvements: Additional aircraft will be housed on Andersen AFB by the Marine Corps.</p>	<p>Unknown schedule or frequency of military flights aside from those supporting periodic training missions on Tinian.</p> <p>Increase in military flights and passengers to and from Guam.</p>

9.2.2.1 Prioritized Recommendations-Andersen Air Force Base-Guam

- The present passenger facility at Andersen AFB is far too small for baggage inspection. The facility should be tripled in size and it should have an inspection table with sufficient lighting and a conveyor belt.
- GCQA coordination at flight arrivals with Andersen AFB personnel must be improved so that advance notice may be given for all flight arrivals into Guam.

9.2.2.2 General Recommendations-Andersen Air Force Base-Guam

Resources

- There should be an adequate number of inspectors, identifiers, surveyors, etc. to carry out mitigation measures effectively.
- Military funding for biosecurity efforts in the region should be proportionate to the increase in cargo volume expected by the military relocation.
- There should be sufficient equipment (computers, microscopes, dissecting scope, hand-lenses, and other diagnostic equipment) and supplies (e.g., reference materials, identification keys) at ports.
- Place GCQA inspectors on military bases in Guam and initiate proper training of military customs personnel to assist in smuggling prevention, animal confiscation, law enforcement and coordination with rapid response teams.

Infrastructure

- A pre-clearance staging area for all military aircraft requiring immediate departure from Guam is needed.

Inspection

- Facilitate USDA-APHIS-PPQ and WS inspections of military air embarkation procedures comparable to, compatible with, and co-located with Andersen AFB operations for loading and unloading aircraft cargo. The Quarantine Regulations of the Armed Forces state that cargo is subject to inspection by the USDA to prevent the introduction or spread of animal and plant diseases or pests. For the purposes of these regulations, Guam is part of the United States.
- Conduct internal and external inspections on military aircraft arriving at Guam.
- MCI programs should augment and improve inspectional capacity for all military arrivals and departures.
- Expand the inspection capabilities for military airfreight containers.
- A communications network for continuously sharing relevant new information among inspectors is recommended.

Control

- Implement measures to control invasive species at and around washdown facilities. Control efforts include barriers, trapping, and insect population reduction.
- Construct barriers around aircraft staging areas to protect aircraft from hitchhikers.

Treatment

- All military air cargo arriving and departing Guam should be cleaned, inspected, and loaded for immediate transport.

Surveillance

- Increase surveillance measures in military airports and screening checkpoints.

Rapid Response

- Improve airport rapid response capabilities.

9.2.3 Apra Harbor

9.2.3.1 Apra Harbor Military Seaport-Guam

Table 12-4: Apra Harbor-Military Seaport-Guam

Description	Current Mitigations	Impact of Military Relocation
Military Maritime Traffic MIRC is a major naval training area that includes Guam, the islands of Saipan, Tinian, Rota, and Farallon de Medinilla, and the training area W-517 (U.S. Navy 2009a). Exercises involve 3 to 30 ships and last 5 to 21 days. Training events may occur 1 to 5 times per year. The southern end of Apra Harbor on Guam has four major wharves available for docking ships: Victor Wharf, Sierra Wharf, Polaris Point, and Kilo Wharf. Navy waterfront facilities are located in both outer and inner harbors. Waterfront facilities for the U.S. Coast Guard are located in the inner harbor.	Inspection Decontamination Treatment Monitoring garbage Port control measures Quarantine Treatment / washing GCQA has authority to inspect military vessels per an MOU with USDA-APHIS-PPQ. Planned Improvements: New embarkation area for loading and unloading ships new amphibious vehicle lay-down area, four waterfront projects	Large increase in military vessel calls and cargo expected to enter through this facility.

9.2.3.2 Prioritized Recommendations-Apra Harbor-Military Seaport-Guam

- The military port of Guam should have centralized points of inspection of break bulk and containerized cargo.
- DoD and GCQA should cooperate in a local MOU to enhance collaboration and develop protocols for inspection of military vessels by GCQA personnel for agricultural compliance purposes.
- Institute a military customs inspector program with GCQA and DoD agreement to augment inspections of military vessels.

- Initiate military pre-clearance program for cargo and military assets moving from Okinawa to Guam. This program should be aligned with other APHIS-PPQ military training and pre-clearance initiatives.
- APHIS-PPQ should train GCQA for conducting inspections, treatments, data analysis, and safeguarding methods.
- Priority for surveillance of exotic and destructive insects should include trapping for: 1) exotic fruit flies, 2) Khapra beetle (in cargo and cargo warehouses); and 3) tropical forest pests.
- An inspection pest risk committee to analyze pest detection information should be formed with participation of GCQA, APHIS, and territorial officials.

9.2.3.3 *General Recommendations-Apra Harbor-Military Seaport-Guam*

Resources

- There should be sufficient numbers of inspectors, identifiers, surveyors, etc. to carry out mitigation measures effectively.
- Military funding for biosecurity efforts in the region should be proportionate to the increase in cargo volume expected by the military relocation.
- There should be sufficient equipment (computers, microscopes, dissecting scope, hand-lenses and other diagnostic equipment) and supplies (e.g., reference materials, identification keys) at ports and plant and animal inspection facilities.
- Station GCQA inspectors on military bases in Guam and initiate proper training of military customs personnel to assist in smuggling prevention, processing insect pests, plant and animal diseases, and confiscated animals, enforcing laws, and coordinating with rapid response teams.
- Increase the number of agriculture and WS canine inspection teams at the seaport.

Inspection

- Inspect all arriving conveyances for illegal animals or animal products.
- A communications network for continuously sharing relevant new information among inspectors is recommended.
- Visually inspect all incoming construction vehicles, equipment, and materials, including those previously treated or cleaned (due to high chance of recontamination with hitchhikers).
- Manage the grounds around military seaports and beach access point facilities to reduce populations of target invasive species, and stop existing wildlife populations from interacting with introduced wildlife at ports of entry.
- Inspect all military arriving vessels internally and externally.
- Improve protocol for inspecting the holds of military ships.

- Implement inspection procedures for vehicle cargo aboard high-speed military vessels.

Control

- Implement measures to control invasive species at and around washdown facilities. Control efforts include barriers, trapping, and insect population reduction.
- Construct barriers around cargoes and aircraft staged on land overnight to protect from hitchhikers.

Treatment

- Military aircraft transported as cargo (aboard an aircraft carrier or other military vessel with aircraft transport capabilities) must be inspected, cleaned, and washed down at the port of entry.
- Military amphibious vehicles arriving via water must be inspected, cleaned, and washed down at a retrograde wash facility before entry.
- POVs arriving via water through military routes must be washed down at a port facility before entry.
- Military assault vehicles arriving as cargo via maritime vessels must be washed down at a retrograde wash facility before entry.
- WPM should be compliant with ISPM No. 15.

Training

- Provide training to improve inspection and identification expertise for WPM pests WPM.

Surveillance

- Increase surveillance measures in military and commercial air- and seaport entry points and screening check points.

9.2.4 Apra Harbor Commercial Seaport-Guam

Table 12-5: Apra Harbor-Commercial Seaport-Guam

Description	Current Mitigations	Impact of Military Relocation
<p>Jose D. Leon Guerrero Commercial Port of Guam is located at the northern end of Apra Harbor with commercial and recreational facilities in the outer harbor. The Commercial Port has six berths with the main cargo terminal for port access for vessels with unusual draft and cargo container handling requirements.</p> <p>The majority of the large ships are operated by Matson Navigation Company and Horizon Lines. The Kyowa Shipping Company also operates in the area from the ports of Busan, South Korea and Yokohama, Japan into the port on Saipan. Regional shipping from the ports of Guam and Saipan throughout the region is by Kyowa, Seabridge Marine, and Micronesia Express Service. Islands serviced by these providers in the region: Guam; Saipan and Tinian (CNMI); Majuro (RMI); Pohnpei, Chuuk, Kosrae and Yap (FSM); and Palau.</p>	<p>Inspection Decontamination Monitoring Port control measures Quarantine Treatment/washing</p> <p>GCQA inspect only a portion of containers. GCQA and USDA/APHIS/WS inspect containerized freight at Port of Guam’s 78 freight stations across the island (de-centralized). Planned Improvements: The Port of Guam plans significant improvements to present facilities.</p>	<p>Large increase in vessel calls and maritime containers.</p> <p>Source: Master Plan 2008, Port Authority of Guam</p>

9.2.4.1 *Prioritized Recommendations-Apra Harbor-Commercial Seaport-Guam*

- Improve pest exclusion by increasing GCQA staffing of inspectors significantly at the commercial seaport to inspect incoming ships and cargo for pests and invasive species.
- A significantly larger workforce is necessary without a centralized inspection area.
- There is a major risk of dissemination of pests and diseases with the present cargo/container system on Guam.
 - Ensure that GCQA can staff significantly more inspectors at the commercial seaport to inspect incoming ships and cargo fully. A significantly larger inspectional workforce is necessary without centralized inspection areas in Guam.
 - Port of Guam must develop facilities for inspection of containers and devanning of cargo. These facilities should be incorporated into the Port of Guam Master Plan and must adhere to standards for sufficient lighting and inspection tables as specified by the APHIS-PPQ Manual for Agricultural Clearance.

- Safeguarded areas for storing and staging vehicles and cargo must be maintained. Vegetation-free areas of 1.8 meters (6 feet) or more must be maintained around the area as well as physical barriers.

9.2.4.2 *General Recommendations-Apra Harbor- Commercial Seaport-Guam*

Resources

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at both the commercial and military seaports.
- There should be sufficient numbers of inspectors, identifiers, surveyors, etc., to carry out mitigation measures effectively.
- GCQA should be funded and staffed at optimum levels for all necessary inspection and quarantine activities
- Develop a reference collection of plausible insect pests and wildlife (i.e., taxidermy mounts) to aid in the identification of incoming species.
- There should be sufficient equipment (computers, microscopes, dissecting scope, hand-lenses and other diagnostic equipment) and supplies (e.g., reference materials, identification keys) at port offices.
- Increase the number of canine inspection teams stationed at Apra Harbor Commercial Port

Infrastructure

- Build a centralized USDA-APHIS-approved staging area for containerized commercial cargo arriving at the Port of Guam.

Inspection

- Inspect all arriving conveyances for insect pests and illegal animals or animal products.
- Expand the inspection capabilities for commercial containers. Containerized cargo is the most frequent type sent in and out of Guam and the Micronesia Region.
- Randomly sample imports (e.g., cargo containers) for insects, animal products, and wildlife.
- Implement x-ray detection for baggage screening.
- Improve protocol for inspecting commercial ship holds.
- Designate entry inspection requirements and personnel for construction materials.
- Visually inspect all incoming construction vehicles, equipment, and materials, including those previously treated or cleaned (due to high chance of recontamination by hitchhikers).
- Develop improved methods for inspecting timber.

- Inspect cargo at both departure and arrival points if transported on open barges moving break-bulk items that originate near heavily vegetated locations and new construction sites where heavy equipment is in proximity to jungle areas.
- A communications network for continuously sharing relevant new information among inspectors is recommended.

Control

- Manage the grounds around commercial seaports and beach access point facilities to reduce populations of target invasive species, and stop existing wildlife populations from interacting with introduced wildlife at ports of entry. Implement measures to control invasive species at and around washdown facilities. Control efforts include barriers, trapping, and insect population reduction. Construct barriers around cargoes and aircraft staged on land overnight to protect from hitchhikers.

Treatment

- POVs arriving via ships through commercial routes must be washed down at a port facility before entry.

Training

- Train inspectors in proper techniques for detecting, extracting, and recognizing pests from WPM.
- Create additional training and education programs for inspectors in proper identification of quarantine species.
- Facilitate training/education programs for inspectors in changing livestock and poultry hazards.
- Conduct background surveys at ports-of-entry so customs and quarantine personnel are familiar with the local animals.

Surveillance

- Increase surveillance measures in military and commercial airports, seaport entry points, and screening checkpoints.

9.2.5 Guam Marinas

Table 12-6: Guam Marinas

Description	Current Mitigations	Impact of Military Relocation
Guam also has two marinas, Hagatna Marina (Gregorio D. Perez Marina) and Agat Marina, administered by the Port Authority of Guam (PB International 2008). There are at least three major recreational fishing events that utilize these marinas (Guam Marianas International Fishing Derby, the Fisherman’s Festival, and the Annual Marianas Underwater Fishing Federation Competition). The fishing derby averages around 70 boats and 300 fishermen. A total of 75 teams participated in the derby departing from both the Agat and Hagatna Marinas in 2009.	Both have chain link fences on their perimeters but are in generally poor condition.	Additional unscheduled maritime traffic and events.

9.2.5.1 *Prioritized Recommendations - Guam Marinas*

- Provide advance notifications of arrival to GCQA inspectors.

9.2.6 Guam Postal Station

Table 12-7: Guam Postal Station

Description	Current Mitigations	Impact of Military Relocation
Domestic mail cannot be inspected without a warrant and the presence of the postal inspector.	Guam postal authorities do not always authorize access to mail x-ray facility.	Mail volume is expected to increase with population.

9.2.6.1 *Prioritized Recommendations-Guam Postal Station*

- Install new x-ray machine for inspection of international mail.
- Canine inspection teams should have daily access to mail. Canines should be scheduled on a standard shift.
- GCQA and APHIS must collaborate with the USPS to develop more efficient mail inspection protocol.
- These entities must work closely with the U.S. Attorney’s Office and the Federal Magistrate to establish, implement, and maintain a domestic mail program to enable inspectors to work with USPS to execute federal warrants for opening and inspecting first class mail.

9.2.6.2 General Recommendations-Guam Postal Station

Authority

- Grant GCQA the authority to inspect domestic mail from the United States with coordination of APHIS-PPQ, U.S. Attorney, and a Federal Magistrate.

Resources

- GCQA should be staffed at levels sufficient to inspect the increased number of packages expected as a result of the military relocation.
- Deploy canine inspection teams to mail facilities for faster and more efficient screening of international and domestic mail.

Inspection

- X-ray all incoming international mail parcels. The existing x-ray machine is not operable.

Survey

- Record and analyze and share with appropriate authorities and stakeholders data on pest interceptions in mail.

Collaboration

- Encourage collaboration between customs officials, agricultural officials, and mail facility staff with the overall goal of decreasing the number of quarantine plant materials introduced to Guam through the mail pathway.

9.2.7 Guam Plant Inspection Station

Table 12-8: Guam Plant Inspection Station

Description	Current Mitigations	Impact of Military Relocation
Guam Plant Inspection Station	All plants and plant materials must be inspected at a Plant Inspection Facility on Guam.	Increased shipments of propagative plant material.

9.2.7.1 Prioritized Recommendations - Guam Plant Inspection Station

- With increases in population and traffic, the present staffing would be overwhelmed. Staffing must be augmented by following new positions: 1) botanist, 2) data entry personnel, and 3) agriculture commodity inspectors.

9.2.7.2 General Recommendations - Guam Plant Inspection Station

Resources

- There should be sufficient equipment (computers, microscopes, dissecting scope, hand-lenses, and other diagnostic equipment) and supplies (e.g. reference materials, identification keys) at plant and animal inspection facilities.

9.3 MICRONESIA LOCATION PROFILES

9.3.1 Commonwealth of the Northern Mariana Islands

9.3.1.1 Saipan-Francisco C. Ada Saipan International Airport

Table 12-9: Francisco C. Ada Saipan International Airport

Description	Current Mitigations	Impact of Military Relocation
<p>Several major airlines and a commuter terminal, mostly commuter flights. Direct flights from Guam, Japan, Korea, Hong Kong, Manila, and China. Tourism is an economic driver.</p>	<p>Cleared by Saipan Customs and Saipan Quarantine. 14 quarantine officers (24/7). Specifically trained BTS inspectors with the CNMI DFW and rapid responders including three BTS canine teams., visual inspectors, and trappers.</p> <p>Immigration and Customs officials are available during scheduled operations, or by prior arrangements with the chief of Immigration Saipan. Container scanners are not operable. No baggage x-ray machine available.</p> <p>Planned Improvements: Improvements underway at airport.</p>	<p>The major impact of military relocation will be increased tourism for Saipan.</p>

9.3.1.1.1 Prioritized Recommendations-Francisco C. Ada Saipan International Airport

- Increase the number of inspectors to meet anticipated demands with appropriate coverage.
- Explore legislative measures for user fees to expand staffing and to procure necessary vehicles and equipment.
- Acquire one new baggage x-ray machine for more efficient baggage and box screening.
- Establish a trapping and surveillance program for exotic and injurious plant pests and diseases. Trapping should include: 1) exotic fruit flies, 2) Khapra beetle, 3) tropical wood pests, and 4) Rhinoceros Beetle. Already have a BTS trapping program at both the air and sea ports in Saipan.

9.3.1.1.2 General Recommendations-Francisco C. Ada Saipan International Airport

Resources

- Expand the number and sensitivity of detection equipment (x-ray) at airports in CNMI.
- Expand financial resources in the CNMI to maintain and enhance border inspection, control and eradication, and rapid response programs. Consideration legislatively-approved user fees for arriving air passengers and cargoes.
- Implement an electronic system for recording, tracking, and identifying manifests for containerized commercial cargo arrivals to Guam and Saipan to streamline import process while maintaining biosecurity.
- Install container scanners or repair those in disuse because of insufficient funds.

Inspection

- Expand the inspection capabilities for air and sea containers and increase and strengthen performance accountability.

Treatment

- Maintain permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment at the seaport in Saipan.
- Wash down and inspect construction vehicles arriving via water before entry to Guam, Saipan, Tinian, or Rota.

Monitoring and Surveillance

- A Micronesia Region monitoring and surveillance program for foreign animal and plant introduction would improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others

9.3.1.2 Tinian-Tinian Air Transports

Table 12-10: Tinian Air Transports

Description	Current Mitigations	Impact of Military Relocation
Mostly commuter flights. Night flights from Saipan and Guam for the hotel and casino; 90% of tourists visiting the CNMI from East and Southeast Asia. Flights to Tinian are 0.33% of Guam’s flight volume.	Immigration and Customs officials are available during scheduled operations, or by prior arrangements. No baggage x-ray machine available.	Estimates will be considerably increased during military exercises in Tinian. The major impact of the military relocation for Tinian will be greatly increased use of the island for regular and frequent military exercises and other

	<p>One BTS canine team.. and trapping for BTS with CNMI DFW.</p> <p>Planned Improvements: Improvements underway at airport.</p>	<p>purposes.</p>
--	---	------------------

9.3.1.2.1 *Prioritized Recommendations-Tinian Air Transports*

All Micronesian island economies share similar challenges and issues (Guam less so than the other jurisdictions):

- Understaffed and underfunded agricultural quarantine/inspection programs.
- Lack of surveillance for plant and animal pests and disease.
- Lack of sufficient infrastructure for air and sea cargo inspections.
- Inadequate resources for regulated garbage.

Prioritized Actions

1. Construct and maintain a military-use washrack facility for cleaning soil-contaminated vehicles and equipment returning to Guam from regular military exercises.
2. Acquire new x-ray machine for examination of baggage and boxes.
3. Explore legislation for user fees for incoming passengers, cargo, and conveyances to fund biosecurity and agriculture quarantine/inspection.
4. Set up a trapping and surveillance program for exotic and injurious plant pests and disease. Trapping should include, but not limited to: 1) exotic fruit flies, 2) Khapra beetle, 3) tropical wood pests, and 4) Rhinoceros Beetle. Already have trapping program for BTS.
5. Ensure adequate resources for the disposal of domestic garbage (landfill) and regulated garbage (sterilizer or incinerator).

9.3.1.2.2 *General Recommendations -Tinian Air Transports*

Resource

- Expand financial resources in the CNMI to maintain border inspection, control and eradication, and rapid response programs.
- Expand the number and sensitivity of detection equipment (x-ray) at airports in the CNMI.
- Initiate proper training of military personnel to assist in smuggling prevention, animal confiscation, law enforcement, and coordination with rapid response teams.
- Establish appropriate operations for handling regulated garbage.

Inspection

- Ensure appropriate advance notice of arrival provided by military to CNMI agriculture officials.
- All military personnel baggage transported to and from Guam and the CNMI on commercial, private, and chartered planes and helicopters must be inspected in compliance with federal and territorial regulations.

Treatment

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at the commercial seaport in Tinian.
- Construction vehicles arriving via water must be washed down and inspected before entry to Guam, Saipan, Tinian, or Rota.

Monitoring and Surveillance

- A Micronesia Region monitoring and surveillance program for foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others.

9.3.1.3 Rota-Rota Air Transports

Table 12-11: Rota Air Transports

Description	Current Mitigations	Impact of Military Relocation
Rota has an emerging tourism industry targeting service members, increasing development, and has legalized gambling. Flights to Rota are 1.18% of Guam’s flight volume.	Immigration Customs and Quarantine are available during scheduled aircraft operations and upon prior arrangements with field supervisors. No baggage x-ray machine available. One BTS canine team and trapping for BTS with CNMI DFW. Planned Improvements: Improvements underway at airport.	The major impact of military relocation will be increased tourism due to the proximity to Guam.

9.3.1.3.1 Prioritized Recommendations-Rota Air Transports

All Micronesian island economies (except Guam) share similar challenges and issues:

- Understaffed and underfunded agricultural quarantine/inspection programs.
- Lack of surveillance for plant and animal pests and disease.
- Lack of sufficient infrastructure for air and sea cargo inspections

With Rota building a gambling casino, there will be more traffic from Guam and other locations. Therefore, due to the proximity to Guam:

1. Enact legislation for user fees to increase staffing and inspectional capacity for prevention of spread of invasive species.
2. Set up and establish a trapping and surveillance program for exotic and injurious plant pests and disease. Trapping should include: 1) exotic fruit flies, 2) Khapra beetle, 3) tropical wood pests, and 4) Rhinoceros Beetle. Already have a trapping program for BTS (but this could be improved).

9.3.1.3.2 General Recommendations-Rota Air Transports

Resources

- Expand financial resources in the CNMI to maintain border inspection, control and eradication effort, and rapid response programs

Treatment

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at the Commercial Port.
- Construction vehicles arriving via water must be washed down and inspected before entry to Guam, Saipan, Tinian, or Rota.

Monitoring and Surveillance

- A Micronesian Region monitoring and surveillance program for foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others.

9.3.2 Federated States of Micronesia

Table 12-12: Federated States of Micronesia

Description	Current Mitigations	Impact of Military Relocation
The four FSM states of Micronesia: Kosrae, Pohnpei, Chuuk, and Yap, form an independent nation that has signed a Compact of Free Association with the United States.	Any aircraft or vessel entering FSM are subject to inspections by customs, immigration, agriculture, and administrative personnel (LIS). All aircraft are inspected for stowaways, presumably human. The FSM developed a National Biosecurity Biodiversity Strategy and Action Plan (NBISAP) in 2002. Each of the four FSM states has a Biodiversity Strategy Action Plan Three trained ED/RR personnel in Pohnpei	The impact of the military relocation will include: 1) some increase in tourism, 2) increased employment in Guam for FSM population, and 3) increased air travel to and from Guam.

9.3.2.1 *Prioritized Recommendations -Federated States of Micronesia*

All Micronesian island economies share similar challenges and issues (Guam less so than the other jurisdictions):

- Understaffed and underfunded agricultural quarantine/inspection programs.
 - Lack of surveillance for plant and animal pests and diseases.
 - Lack of sufficient infrastructure for air and sea cargo inspection activities
1. Enact legislation for user fees to fund infrastructure improvements for entry inspection
 2. Establish public outreach program for workers and visitors to Guam on entry requirements to and from FSM.
 3. Set up and establish a trapping and surveillance program for exotic and injurious plant pests and disease. Trapping should include: 1) exotic fruit flies, 2) Khapra beetle, 3) tropical wood pests, and 4) Rhinoceros Beetle.

9.3.2.2 *General Recommendations - Federated States of Micronesia*

Resources

- Expand FSM financial resources to maintain border inspections at their air and sea ports and expand control and eradication and rapid response capabilities.
- Obtain and maintain operability of detection equipment (x-ray) at all FSM airports for baggage screening and inspection.

- Expand the inspection capabilities for air and sea containers and for the exportation of agricultural products.

Treatment

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at the Commercial Port.

Permanent operational heat and fumigation capacity.

Monitoring and Surveillance

- A Micronesia Region monitoring and surveillance program for foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, , including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others.

9.3.3 Republic of the Marshall Islands

Table 12-13: Republic of the Marshall Islands

Description	Current Mitigations	Impact of Military Relocation
<p>The RMI is an independent island group that has signed a Compact of Free Association with the United States.</p> <p>Main ports are Kwajalein and Majuro.</p>	<p>All aircraft and vessels entering or leaving RMI are subject to inspections by immigration, customs, agriculture, public health, or administrative personnel. Aircraft known or suspected to harbor insects or agricultural pests must be sprayed with an insecticide. Any employee of the RMI Ports Authority may enter an aircraft for the purpose of inspection.</p> <p>Three trained ED/RR staff in Majuro</p>	<p>The impact of the military relocation will be: 1) some increase in tourism, 2) increased air travel to and from Guam and Hawai'i.</p>

9.3.3.1 *Prioritized Recommendations-Republic of the Marshall Islands*

All Micronesian island economies share similar challenges and issues (Guam less so than the other jurisdictions):

- Understaffed and underfunded agricultural quarantine/inspection programs.
- Lack of surveillance for plant and animal pests and diseases.
- Lack of sufficient infrastructure for air and sea cargo inspections.

Prioritized Actions

1. Enact legislation to fund infrastructure improvements and increased inspections for agricultural and environmental pests and diseases.
2. Establish public outreach program for workers and visitors to Guam on entry requirements to and from RMI.
3. Set up a trapping and surveillance program for exotic and injurious plant pests and disease. Trapping should include: 1) exotic fruit flies, 2) Khapra beetle, and 3) tropical wood pests.

9.3.3.2 *General Recommendations-Republic of the Marshall Islands*

Resources

- Expand financial resources in the FSM to maintain border inspections at the airport and seaport, and control and eradication and rapid response capabilities.
- Obtain and maintain operability of detection equipment (x-ray) at all FSM airports for baggage screening and inspection.
- Expand the inspection capabilities for air and sea containers.

Treatment

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at the Commercial Port.
- Permanent operational heat and fumigation capacity.

Monitoring and Surveillance

- A Micronesia Region monitoring and surveillance program for foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others.

9.3.4 Palau

Table 12-14: Palau

Description	Current Mitigations	Impact of Military Relocation
Palau is an island nation that has signed a Compact of Free Association with the United States.	All aircraft and vessels entering or leaving Palau are subject to inspections by immigration, customs, agriculture, public health, or administrative personnel. Aircraft known or suspected to harbor insects or agricultural pests must be sprayed with an insecticide. Any employee of the Palau Ports Authority may enter an aircraft for the purpose of inspection. Two trained ED/RR staff	The impact of the military relocation will be: 1) increased tourism due to greater availability of recreational activities and interest in ecotourism activities on Palau, and 2) increased air travel to and from Guam.

9.3.4.1 Prioritized Recommendations –Palau

All Micronesia island economies share similar challenges and issues (Guam less so than the other jurisdictions):

- Understaffed and underfunded agricultural quarantine/inspection programs.
- Lack of surveillance for plant and animal pests and disease.
- Lack of sufficient infrastructure for air and sea cargo inspections.

Prioritized Actions

1. Enact legislation to fund infrastructure improvements and increased inspections for agricultural and environmental pests and diseases.

2. Ensure appropriate biosecurity within Palau in regards to the established Macaque Monkeys in Anguar to prevent spread to the rest of Palau as well as other locations within Micronesia.
3. Establish public outreach program for workers and visitors to Guam on entry requirements to and from Palau.
4. Set up a trapping and surveillance program for exotic and injurious plant pests and disease. Trapping should include: 1) exotic fruit flies, 2) Khapra beetle, and 3) tropical wood pests.

9.3.4.2 *General Recommendations-Palau*

Resources

- Expand Palau’s financial resources to maintain border inspections at the airport and seaport and control and eradication and rapid response capabilities.
- Maintain operability of detection equipment (x-ray) at Palau’s airport for baggage screening and inspection.
- Expand the inspection capabilities for air and sea containers.

Treatment

- Permanent operational wash racks for inspection and cleaning of soil-contaminated vehicles and equipment must be maintained at the Commercial Port.
- Permanent operational heat and fumigation capacity.

Monitoring and Surveillance

- A Micronesia Region monitoring and surveillance program for foreign animal and plant introduction should be established to improve communications of survey results among all island mitigation programs.

Rapid Response

- Improve airport and seaport rapid response capabilities, including training more local staff for ER/RR of potential IAS such as the BTS, Rhinoceros Beetle, and others.

9.4 AIRPORT OPERATIONAL STATISTICS FOR GUAM AND CNMI INTERNATIONAL AIRPORTS

Table 12-15: Aircraft Operational Statistics for Guam and CNMI International Airports

	Guam ^a	Tinian ^b	Saipan ^c	Rota ^d

9.8 PATHWAY IMPACTS AND MITIGATION PROCEDURES

Table 12-19: Pathway Impacts and Mitigation Procedures

Group	Pathway	Pathway Risks	Control Point	Military Impact on Pathway	Required mitigation
A	Military personnel/families transport from U.S. to Guam—commercial aircraft	Invasive hitchhikers/Exotic (import) plant or animal	Aircraft passenger-crew	Commercial passenger flight increases (not able to be determined due to unknown schedule/pace for relocation)	Inspection, hold of passengers, crew
			Aircraft cabin, hold		Inspection, hold of conveyance
			Aircraft exterior		Inspection, hold of conveyance
			Air baggage		Inspection, hold of baggage
			Air cargo		Inspection, hold of cargo
		Invasive plant/pest	Plant or plant product import		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal import		
		Animal pest or pathogen/vector	Animal or animal product import		
		Zoonotic infection	Aircraft-passenger-crew		Inspection
B	Off-island construction workers and dependents and off-island workers for Induced jobs/dependents Transport from Pacific rim to Guam—commercial aircraft	Invasive hitchhikers	Aircraft passenger-crew	Increased flights to Guam are expected to increase the transport of invasive pests and diseases.	Inspection
			Aircraft cabin		Inspection, control, treatment
			Aircraft exterior		Inspection, control, washing
			Air baggage		Inspection
			Air cargo		Inspection, control
		Invasive plant/pest	Plant or plant product (import or smuggled)		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal (import or smuggled)		
		Animal pest or pathogen/vector	Animal or animal product (import or smuggled)		
		Zoonotic infection	Aircraft passenger-crew		Inspection

Group	Pathway	Pathway Risks	Control Point	Military Impact on Pathway	Required mitigation
C	Military cargo transport from Okinawa to Guam—commercial or military vessel	Invasive hitchhikers	Vessel crew	Expected to increase during buildup due to relocation of military resources. (Source: Master Plan 2008, Port Authority of Guam)	Inspection
			Vessel cabin, hold		Inspection, control, treatment
			Vessel exterior		Inspection, control, washing
			Bulk cargo		Inspection, control
			Break bulk cargo		Inspection, control
			Packaged cargo		Inspection, control
			Containers		Inspection, control
			Garbage		Monitoring, disposal
		WPM	Inspection, control, treatment		
		Invasive plant/pest	Plant or plant product import		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
Invasive animal	Animal import	Permit review, inspection, identification, quarantine, treatment			
Animal pest or pathogen/vector	Animal or animal product import	Inspection			
Zoonotic infection	Vessel crew	Inspection			
D	Shipment construction equipment/materials from Pacific Rim or Micronesia to Guam—commercial vessel	Invasive hitchhikers	Vessel crew	Estimated cargo shipments to greatly increase during military buildup. Expected to remain well above 2011 levels after buildup for (Source: Master Plan 2008, Port Authority of Guam)	Inspection
			Vessel cabin, hold		Inspection, control, treatment
			Vessel baggage (crew)		Inspection
			Vessel exterior		Inspection, control, washing
			Stone, sand, etc.		Inspection, control, treatment
			Garbage		Monitoring, disposal
			Equipment/vehicle		Inspection, control, treatment, washing
			WPM		Inspection, control, treatment
		Invasive hitchhikers/wood boring insects/	Timber		Inspection, control, treatment
		WPM	Inspection, treatment		

Group	Pathway	Pathway Risks	Control Point	Military Impact on Pathway	Required mitigation
		Zoonotic infection	Vessel crew		Inspection
E	Domestic and international mail from Hawai'i to Guam	Invasive hitchhiker (seed, insect)	Package/Post office	Larger mail volume with increased population on Guam.	X-ray inspection
		Bioterror agent (zoonotic)			X-ray inspection
		Invasive plant/pest	Plant or plant product		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal		
		Animal pest or pathogen/vector	Animal or animal product		
F	Military exercises from Tinian to Guam—amphibious vessels, vehicles; 1 week 12 times per year	Invasive hitchhikers	Aircraft cabin, hold	Special events	Inspection, control, treatment
			Aircraft exterior		Inspection, control, washing
			Munitions		Inspection
			Personnel		Inspection
			Gear		Inspection
G	Military exercises from Tinian to Guam—aircraft; 1 week 12 times per year	Invasive hitchhikers	Vessel cabin, hold	Special event, unscheduled	Inspection, control, treatment
			Vessel exterior		Inspection, control, washing
			Munitions		Inspection
			Personnel		Inspection
			Gear		Inspection
		Invasive plant/pest	Plant or plant product import		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal import		Permit review, inspection, identification, quarantine, treatment
		Animal pest or pathogen/vector	Animal or animal product import		Permit review, inspection, identification, quarantine, treatment
		Zoonotic infection	Aircraft-passenger-crew		Inspection

Group	Pathway	Pathway Risks	Control Point	Military Impact on Pathway	Required mitigation
H	Transport from Guam to Hawai'i—commercial aircraft	Invasive hitchhikers	Aircraft cabin, hold	Commercial passenger flight increases are possible from Hawai'i.	Inspection, control, treatment
			Aircraft exterior		Inspection, control, washing
			Air baggage		Inspection
			Air cargo		Inspection, control
		Aircraft passenger-crew	Inspection		
		Invasive plant/pest	Plant or plant product (import or smuggled)		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal (import or smuggled)		Permit review, inspection, identification, quarantine, treatment
Animal pest or pathogen/vector	Animal or animal product (import or smuggled)	Inspection			
Zoonotic infection	Aircraft-passenger-crew				
I	Domestic and international mail from Guam to Micronesia	Invasive hitchhiker (seed, insect)	Package/Post office	Insignificant increase expected.	X-ray inspection
		Bioterror agent (zoonotic)			X-ray inspection
		Invasive plant/pest	Plant or plant product import		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal import		
		Animal pest or pathogen/vector	Animal or animal product		
J	Civilian air travel (personnel, contractor family, friends)—to/from Guam, other Micronesian Region islands	Invasive hitchhiker	Aircraft cabin, hold	Commercial passenger flight increases are expected.	Inspection, control, treatment
			Aircraft exterior		Inspection, control, washing
			Air baggage		Inspection
			Air cargo		Inspection, control
		Aircraft-passenger-crew	Inspection		
		Invasive plant/pest	Plant or plant product (import or smuggled)		Permit review, inspection, identification, quarantine, treatment
		Infectious plant pathogen/vector			Permit review, inspection, identification, quarantine, treatment
		Invasive animal	Animal (import or		Permit review, inspection,

Group	Pathway	Pathway Risks	Control Point	Military Impact on Pathway	Required mitigation
			smuggled)		identification, quarantine, treatment
		Animal pest or pathogen/vector	Animal or animal product (import or smuggled)		Inspection
		Zoonotic infection	Aircraft-passenger-crew		Inspection
K	Military exercises on Tinian—amphibious vessels, vehicles—from Guam to Tinian; 1 week 12 times per year	Invasive hitchhikers	Aircraft cabin, hold	Special event, unscheduled	Inspection, control, treatment
			Aircraft exterior		Inspection, control, washing
			Munitions		Inspection
			Personnel		Inspection
			Gear		Inspection, control,
L	Military exercises on Tinian—aircraft—from Guam to Tinian; 1 week 12 times per year	Invasive hitchhikers	Vessel cabin, hold		Inspection, control, treatment
			Vessel exterior		Inspection, control, washing
			Munitions		Inspection
			Personnel	Inspection	
			Gear	Inspection, control	

9.9 APHIS-VETERINARY SERVICES RISK RATINGS

Table 12-20: APHIS-VS Risk Ratings

Pathway	Release Assessment - Legal	Release Assessment - Illegal	Exposure Assessment	Consequence Assessment	Overall Risk	Likely Sources
Conveyance-Aircraft	Very low	N/A	Medium	Guam and Micronesia: Very Low U.S.: Very low	Very Low	
Conveyance-Maritime vessels	Very low	N/A	Medium	Guam and Micronesia: Very Low U.S.: Very low	Very Low	

Pathway	Release Assessment - Legal	Release Assessment - Illegal	Exposure Assessment	Consequence Assessment	Overall Risk	Likely Sources
People	Negligible	Negligible	N/A	N/A	Negligible	U.S. Mainland, Hawai'i, Philippines, China, Korea
Livestock	Negligible	Negligible	N/A	Guam and Micronesia: N/A U.S.: N/A	Negligible	
Poultry	Negligible	Very low	Medium	Guam and Micronesia: Low U.S.: Medium	Low	
Non-poultry birds	Negligible	Very low	Medium	Guam and Micronesia: Very low U.S.: Very low	Very Low	
Cats and dogs	Negligible	Negligible	N/A	Guam and Micronesia: N/A U.S. N/A	Negligible	
Animal products	Negligible	Low	Medium	Guam and Micronesia: Low U.S.: Medium	Low	
Garbage	Negligible	Very low	Medium	Guam and Micronesia: Low U.S.: Medium	Low	
Other cargo	Very low	N/A	Medium	Guam and Micronesia: Very low U.S.: Very low	Very Low	

9.10 APHIS-WS TERRESTRIAL VERTEBRATES RISK RATINGS

Table 12-21: APHIS-WS Terrestrial Vertebrates Risk Rating

Pathway	Total Risk	Likely Sources
Conveyance-Aircraft	HIGH	
Conveyance-Maritime vessels	HIGH	
Cargo	HIGH	
Construction	HIGH	
Plant products	HIGH	
WPM	HIGH	
Garbage	HIGH	

Table 12-22: APHIS-WS Terrestrial Vertebrates Risk Rating

INTENTIONAL	Importation	Establishment	Hazard	Total Risk	Likely Sources
Pet trade	3	3	3	9 HIGH	
Aesthetic releases	3	2	3	8 HIGH	
Food use	3	3	3	9 HIGH	
Animals for entertainment	2	2	3	7 MODERATE	
Game hunting	1	2	3	6 MODERATE	
Biocontrol	1	3	2	6 MODERATE	
Scientific research	1	3	3	7 MODERATE	
Religious ceremonies	1	1	2	4 LOW	
Bioterrorism	1	1	3	5 LOW	

9.11 APHIS-WS WILDLIFE DISEASES RISK RATINGS

Table 12-23: APHIS-WS Wildlife Diseases

Pathway	Probability of Infection	Alternate Probability	Impact of Infection	Alternate Impact	Likely Sources
Hantavirus	Moderate		Low		
Rabies virus	Minimal		Low		
West Nile Virus	Minimal		High		
HPAI	High		Moderate	Moderate	
Japanese Encephalitis Virus	High		Minimal	Low	
Avian Malaria Parasites	High	Minimal	Moderate	Moderate	
Henipaviruses	Minimal	High	Moderate	Moderate	
NDV	Minimal	High	Moderate	Moderate	
Yersinia pestis	Minimal		Low		
Tick-Borne Encephalitis	High		Low	Moderate	

10 QUALITY ASSURANCE AND IMPROVEMENT

Every security plan is measured by how it achieves its stated objectives. The MBP was developed to prevent the introduction of invasive species and pathogenic agents into Hawai'i, Guam and the Micronesia Region, a lofty goal with the broad range of potentially invasive species and frequency of conveyances that can transport plants, animals, pests, vectors, and pathogens to these locations. The MBP must assist biosecurity planners in doing their best to prevent unintentional introductions. The MBP must adequately describe in detail:

1. Risks for specific pathways and species
2. Compliance, inspection, treatment, and other mitigation procedures
3. Pre-clearance, monitoring, and outreach programs that can prevent introductions
4. Military relocation events that could affect the types and frequencies of releases
5. Rapid response teams, resources, and procedures for species eradication

Few security plans effectively cover all requirements, particularly early in the process. An improvement planning program is essential for continual MBP review for gaps, inconsistencies, and any other required improvement. Too often, organizations delay such review processes until a critical gap causes an unfortunate event. The MBP therefore builds in a process for continual improvement. Each of the five features listed should to be tested regularly, as should command and control, communications, funding, and resource allocation, all important support functions.

10.1 INTRODUCTION TO MBP IMPROVEMENT PLANNING PROGRAM

The MBP Improvement Planning Program is an overarching framework for planning and implementing MBP upgrades based on a concept of operations, federal authorities, best practices, and a system of capabilities-based training and tests within an overall objective of continual improvement in MBP effectiveness. The Improvement Planning Program is the foundation for all aspects and processes in MBP TT&E events and a mechanism for needed improvements.

10.2 CONCEPT OF OPERATIONS

The Concept of Operations is the foundation for TT&E Program framework. It includes major planning areas required to build the program:

- MBP scope, policies, and procedures
- Authorities and requirements
- Program objectives
- Roles and responsibilities
- Maintaining executive-level support

- Budgeting, funding allocation, and resource management
- MBP integration with partners and stakeholders
- Training on biosecurity policies, roles, and processes
- Development planning meetings and event coordination
- Multi-year TT&E schedule (calendar of events)
- Collaborative biosecurity agreements with external organizations
- TT&E program design and planning
- Corrective action plan
- Reports to headquarters, partners, and stakeholders

10.3 MBP IMPROVEMENT PLANNING DEVELOPMENT EVENTS

To develop an effective MBP improvement plan, various types of planning, training, and test events are recommended. A comprehensive improvement planning program includes:

- Training seminars
- Improvement planning conferences
- TT&E workshops
- TT&E events
- After-action conferences

10.3.1 Training Seminars

A training seminar should be scheduled annually to present current MBP policy, regulations, procedures, and responsibilities to key personnel, partners, and stakeholders. The event is an opportunity to make changes to the plan, especially in light of events in the field and observations from test exercises.

10.3.2 Improvement Planning Conferences

An improvement planning conference should be scheduled annually for an opportunity to communicate recovery objectives, identify resources, and track Improvement Plan (accomplishments and actions against current capabilities. The conference would be a forum for key personnel to review MBP actions recorded in previous year's after action reports and corrective action plans. The improvement planning conference will:

- Evaluate current MBP capabilities.
- Review progress toward achieving assigned corrective actions.
- Set new priorities for future TT&E events.

- Announce new policy, regulations, and procedures when appropriate.
- Establish biosecurity planning priorities for the current year.

The improvement planning conference would be held at least 60 days before the first TT&E event of the year. Improvement planning conference participants should be aware of their recovery planning responsibilities and be prepared to prioritize outstanding improvement planning corrective actions.

Participants should establish a multi-year training and exercise plan schedule during this conference. This living document schedules and tracks training and test exercises best planned according to a building-block process that designs test events according to current capabilities and realistic objectives.

10.3.3 TT&E Workshops

The TT&E event workshop should design a specific TT&E event in according to improvement planning conference objectives and priorities. Planning decisions for the type of exercise, event schedule, format, participants, emergency scenario, and actual content should all be influenced by improvement planning conference priorities and objectives as well as perceived capabilities. This performance and capabilities-based approach is consistent with the tiered, building-block plan for improving recoverability.

Table 13-1: Improvement Planning Events

Improvement Planning Events	
Seminar	Schedule an annual seminar to train key personnel on MBP authorities, strategies, plans, policies, procedures, protocols, response resources, and concepts for the biosecurity planning processes.
Planning Conference	Conduct regular planning conferences with the MBP Improvement Planning Committee or Working Group to determine training and testing budgets, resources, formats, objectives, and schedules and to manage the improvement plan and the Corrective Action Plan.
Workshop	<p>Conduct a workshop with the MBP Coordinator, Planning Committee, and participating representatives to plan TT&E event objectives, agenda, formats, participants, location, and logistics.</p> <p>TT&E Event Planning, Design, and Development</p> <p>The important considerations for design and development of the various TT&E events include:</p> <ul style="list-style-type: none"> -TT&E Format -Training and testing schedule -Test objectives -Logistics (event Information, equipment, and supplies) -Event roles and responsibilities -Emergency scenario design -Exercise documentation (guides, evaluation templates, etc.) -Review of actions for lessons learned -Metrics for assessment of biosecurity capabilities <p>TT&E Events</p>

	Test formats based upon objectives are chosen from decision- and operations-based test events.
Decision-Based Test Events	
 <p>Table Top Exercise</p>	In table top exercises, key personnel discuss hypothetical scenarios in an informal and relaxed setting. Table top exercises test knowledge and abilities to access plans, policies, and procedures; systems and operations needed to prevent, mitigate, and respond to incidents. This format depends on the engagement of participants, their assessment of current policies, procedures, and plans, and their recommendations for improvements.
Games	Games are simulations of operations involving two or more teams depicting an actual or assumed real-life situation. Games explore decision making processes and their consequences.
Operations-Based Test Events	
Drills	Drills are coordinated, supervised activities to validate a single, specific operation or function.
 <p>Functional Exercises</p>	Functional exercises evaluate individual capabilities, multiple functions, function activities, or interdependent functions through an exercise scenario with event updates that drive management activity. Functional exercises present complex problems that require rapid, effective responses by trained personnel in highly stressful, time-constrained environments. They utilize incident command systems, unified command, and multi-agency coordination centers (e.g. Emergency Operations Centers (EOCs)). Movement of personnel and equipment is simulated; adversarial groups can stress the incident.
 <p>Full-Scale Exercises</p>	Most full-scale exercises are complex, multi-agency, multi-jurisdictional, and multi-organizational exercises that validate many facets of preparedness. The focus is on implementing and analyzing plans, policies, procedures, and cooperative agreements developed in discussion-based exercises. Operational realities present complex and realistic problems that require critical thinking, rapid problem-solving, and effective responses by trained personnel. A scripted scenario has built-in flexibility for updates to drive activities. Full-scale exercises are conducted in real time, creating a stressful, time-constrained environment closely mirroring real events. They may include first responders under NIMS principles and may include functional play from multi-agency coordination centers, EOCs, or hospitals not at the exercise incident response site.

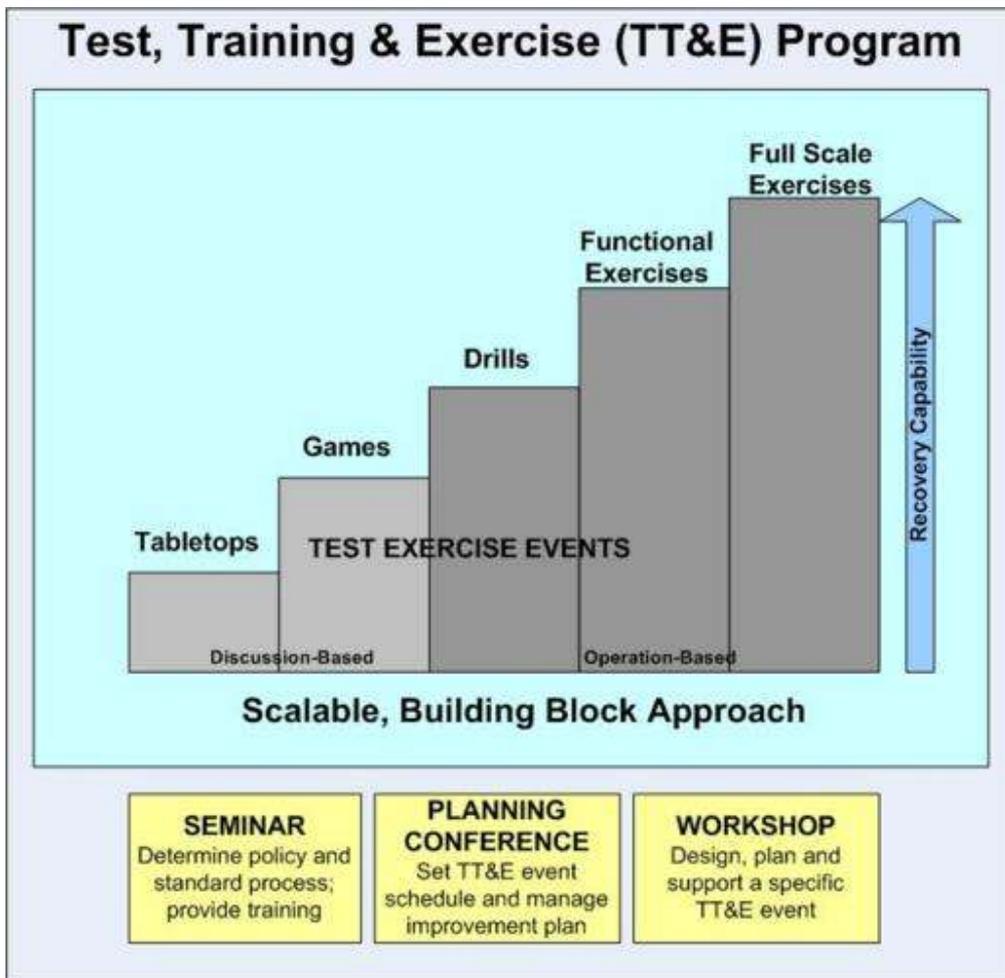

10.4 TT&E PROGRAM PLANNING PROCESS

Table 13-2 depicts the appropriate TT&E event for accomplishing each Improvement Planning Program component.

Table 13-2: Improvement Program Planning Events

TT&E Component	Seminar	Planning Conference	Planning Workshop	TE	Drill	Functional Exercise
Train in MBP policies, regulations, standards, and procedures	X					
Establish a planning and implementation framework for determining long-term objectives, policies, and processes		X				
Establish roles and responsibilities		X				
Design a multi-year MBP training and testing schedule		X				
Decide test event objectives, schedule, design, and format			X			
Discuss the effectiveness of MBP policies and procedures				X		
Test the performance of a specific function or operation					X	
Test the capability to perform comprehensive MBP operations in actual work situations and environments						X
Assign duties for plan remedies from after-action recommendations		X		X	X	X
Manage Improvement Plan		X				

Figure 13-1: Types of TT & TT&E Formats

10.5 ROLES AND RESPONSIBILITIES

Table 13-3 depicts typical roles in improvement planning events and common responsibilities for event design, production, facilitation, and reporting.

Table 13-3: Improvement Planning Roles and Responsibilities

Exercise Role	Responsibility
Improvement Planning Coordinator or Committee	This individual or committee manages all objectives, designs, plans, developments, and assessments. Sets MBP improvement planning program objectives. Develops TT&E Concept of Operations for improvement planning. Implements MBP policies and directives. Directs or oversees TT&E event planning. Approves TT&E event objectives. Manages MBP improvement planning resources and funding. Encourages participation and coordination of TT&E event activities.
Event Planner	Directs and budgets event resources. Implements event objectives received from the planning conference and event workshop. Develops a suitable test emergency scenario. Designs the TT&E format and agenda. Develops discussion topics to target test objectives. Designs and produces event documents (participant’s, facilitator’s, and observer’s guides). Designs and produces a participant assessment survey and Exercise Evaluation Guide.
Facilitator	Provides pre-event guidance, leads the test exercise events, leads discussions, and generally guides events toward stated objectives. Executes the event plan as determined by the workshop. Directs event staff and instructs observers. Keeps proceedings to planned agenda and objectives. Inserts emergency scenario information into the test event. Keeps proceedings on schedule and within scope. Offers questions and leads discussions. Encourages input and records responses from participants, leads review of “Lessons Learned.”
Controller	Directs all or a select area/component of on-site response events during functional or full-scale exercises.
Evaluator	Judges responses in real time during functional or full-scale exercises.
Observer	Observes actions and discussions during functional or full-scale exercises.
Players	Also referred to as participants, these individuals are the subjects of the training and testing; during the event, they are immersed into a fictitious emergency scenario and asked to respond appropriately according to their responsibilities.
Simulators (actors)	Actors with a script to “act out” during an functional or full-scale exercises (e.g. playing perpetrator or victim roles).

10.6 TT&E EVENT PLANNING

Improvement planning personnel adopt a “crawl-walk-run” or “building-block” approach in designing long-term objectives and event schedules. Early TT&E events focus on basic skills, knowledge, requirements, and capabilities, and successive events build in additional test demand as capabilities are proven. For all events, test design and emergency scenarios establish realistic and achievable goals for participants.

For each TT&E event, planners must ask:

- What objectives should be accomplished?
- How should these objectives be accomplished?
- Who should be responsible for the objectives?
- How effective are plans in obtaining required information and guiding planning and response actions?

The answers to these questions change as capabilities and test challenges increase.

Test event planning requires decisions on planning components:

- Event type and format
- Event date, timeframe, and location
- Person or persons designated as event planner(s)
- Personnel invited as participants
- Primary test objectives
- Personnel invited as observers
- Event documentation for reference and reporting
- Logistics (documents, refreshments, etc.)
- Evaluation of event activities and outcomes

10.7 TEST EXERCISE DOCUMENTATION

Develop effective exercise documentation for all facilitators, controllers, exercise players, and observers.

Table 13-4: Test Exercise Documentation

Document	Purpose
Situation Manual	Participant handbook for discussion-based exercises, particularly table top exercises. Includes background information on exercise scope, schedule, and objectives and presents the scenario narrative to drive participant discussion.
Exercise Plan	Used for operations-based exercises. As an exercise synopsis is distributed to players and observers in advance; addresses objectives and scope, assigns roles and responsibilities. Does NOT reveal detailed scenario information like the hazard.
Controller and Evaluator Handbook	Supplements the Exercise Plan with more detailed information about the exercise scenario and describes exercise controllers' and evaluators' roles and responsibilities. Distribution closely controlled.
Master Scenario Events List	Chronological timeline of expected actions and scripted events (i.e., injects).
Player Handout	A 1 to 2 page quick reference for exercise players (distributed before exercise) on safety procedures, logistical considerations, exercise schedule, and other essentials.
Exercise Evaluation Guides	Help evaluators collect and interpret relevant exercise observations. Briefs evaluators on tasks they should see completed or discussed during the exercise; includes space to record observations and questions to address after the exercise as a first step in the development of the After Action Report/Improvement Plan.

10.8 CORRECTIVE ACTION PLANS

The after action report documents TT&E event outcomes and incorporates observations into a formal set of recommendations for improvements. An after-action conference informs participants, planning committees, and stakeholders of after action report priority recommendations.

- Analyze strengths and areas for improvement in formally evaluating biosecurity; report in the after action report lessons learned from exercise data.
- Develop a corrective action plan to track needed improvements and related responsibilities.

39			

1 **A1 INTRODUCTION**

2 This risk analysis was developed by the U.S. Department of Agriculture (USDA) Animal and Plant Health
3 Inspection Service (APHIS) at the request of the U.S. Department of Defense (DoD). It is intended to
4 serve as a basis for the development of the biosecurity plan to mitigate plant and animal health risks
5 posed to the Micronesia Region by a planned U.S. military relocation in the Region as referred to in the
6 Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) prepared by the
7 Department of the Navy for the proposed military relocation (U.S. Navy 2010a). For the purposes of this
8 risk analysis, the Micronesia Region is defined as Guam, the Commonwealth of the Northern Mariana
9 Islands (CNMI), the Federated States of Micronesia (FSM), the Republic of the Marshall Islands (RMI),
10 and the Republic of Palau (Figure A1-1).

11 The objectives of this risk analysis are to

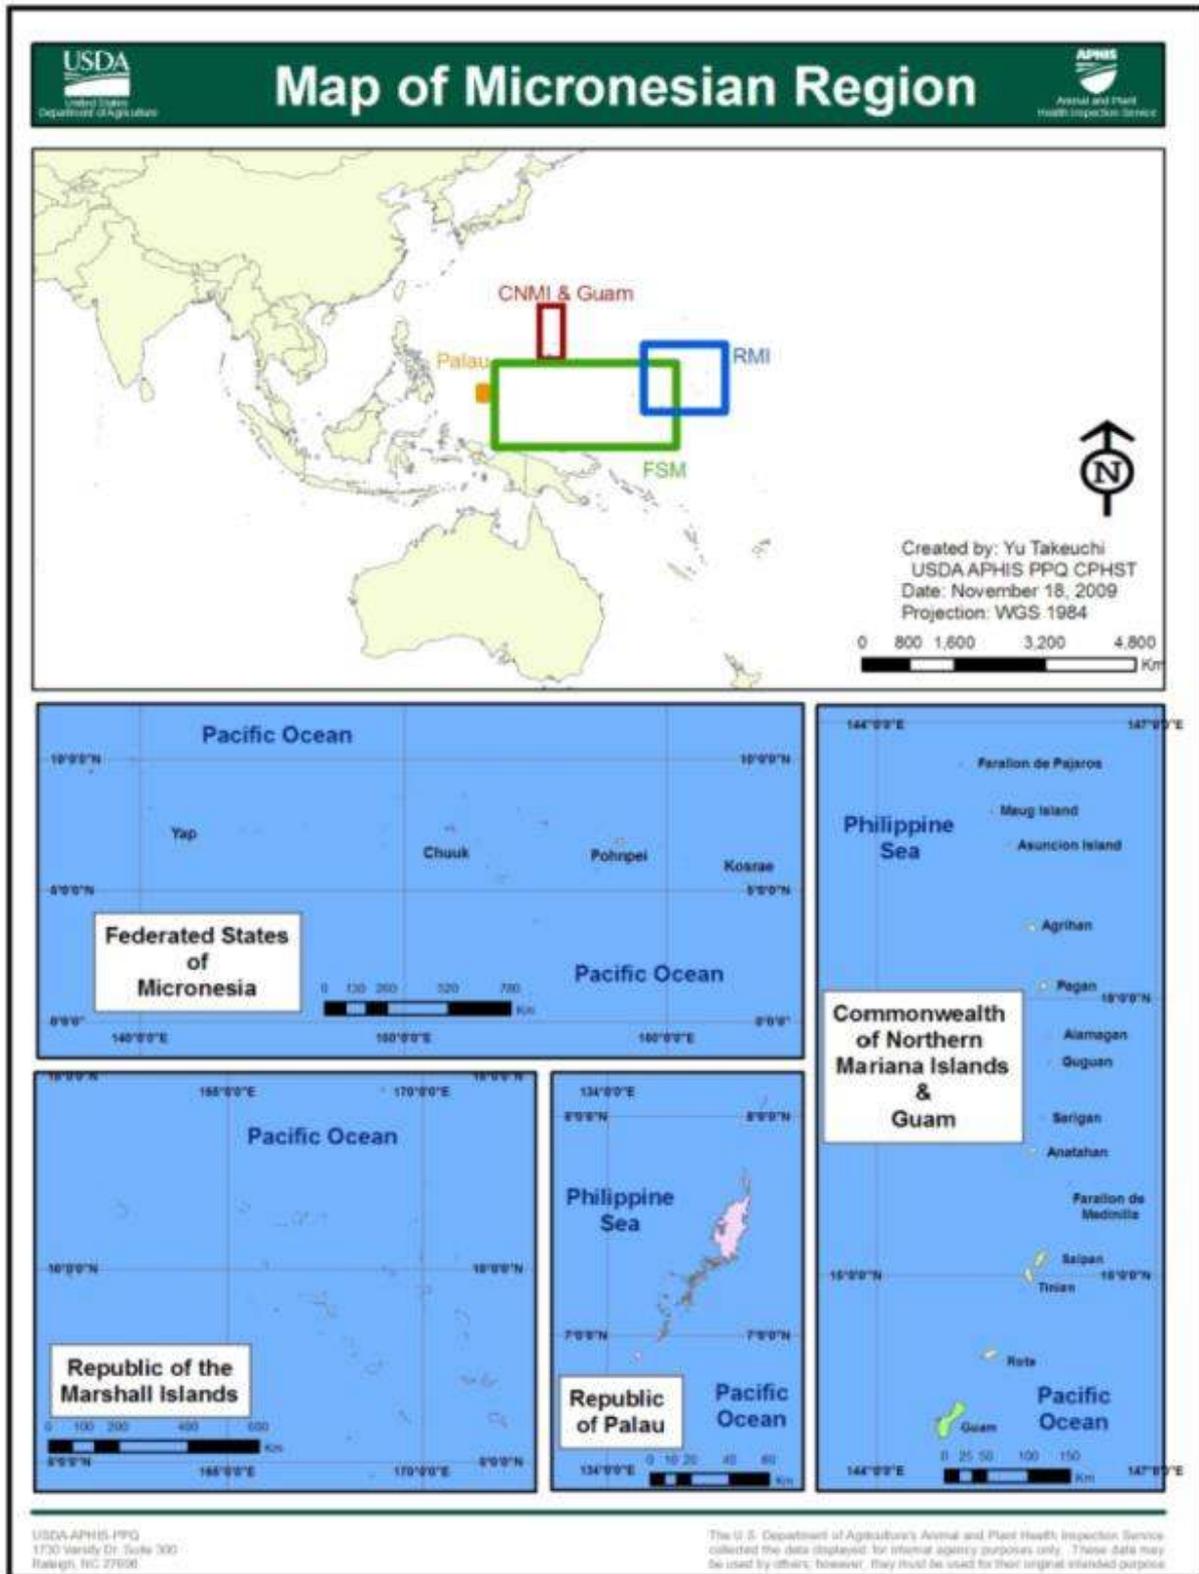

- 12 • Identify exotic terrestrial vertebrates, animal disease agents, and plant pests and diseases
13 that may pose a threat to terrestrial animal and plant health if introduced into the
14 Micronesia Region;
- 15 • Identify the pathways by which these organisms may be moved;
- 16 • Evaluate the relative importance of these pathways with regard to the likelihood that these
17 organisms will be moved; and
- 18 • Evaluate the expected impact of pest introductions on terrestrial animal and plant health in
19 the Micronesia Region.

20 This risk analysis was conducted collaboratively between APHIS-Plant Protection and Quarantine (PPQ),
21 APHIS-Wildlife Services (WS), and APHIS-Veterinary Services (VS). The document is organized into four
22 main sections: plant pests, terrestrial vertebrates, wildlife diseases, and livestock diseases. While a
23 general approach was coordinated among the collaborating groups, each group selected the specific
24 methodology most appropriate to their primary focus.

25 While the scope of this risk analysis includes the entire Micronesia Region, many of the perspectives
26 presented herein focus on Guam. The majority of DoD activities will occur directly on Guam, making this
27 the area for which the most specific information exists and where consequences will be felt most
28 immediately. Guam is the largest point of entry for the Micronesia Region, serving as both the gateway
29 and bellwether for the rest of the Region; one assumption of this analysis is that exotic species issues
30 significant in Guam are relevant throughout the Micronesia Region.

1

Figure A1-1: Map of the Micronesia Region

2

1 **A1.1 OVERVIEW OF THE PROPOSED MILITARY RELOCATION**

2 The three main components of the military relocation as proposed by the DoD are: 1) relocation of U.S.
3 Marine Corps forces to Guam; 2) construction of a nuclear-powered aircraft carrier transient berthing
4 facility in Apra Harbor, Guam; and 3) establishment of an Army Air and Missile Defense Task Force on
5 Guam (U.S. Navy 2010a). The expected consequence of these actions is an increase in the number of
6 people living on Guam and, consequently, increased traffic to and from Guam, increased construction
7 activities, and increased commodity imports.

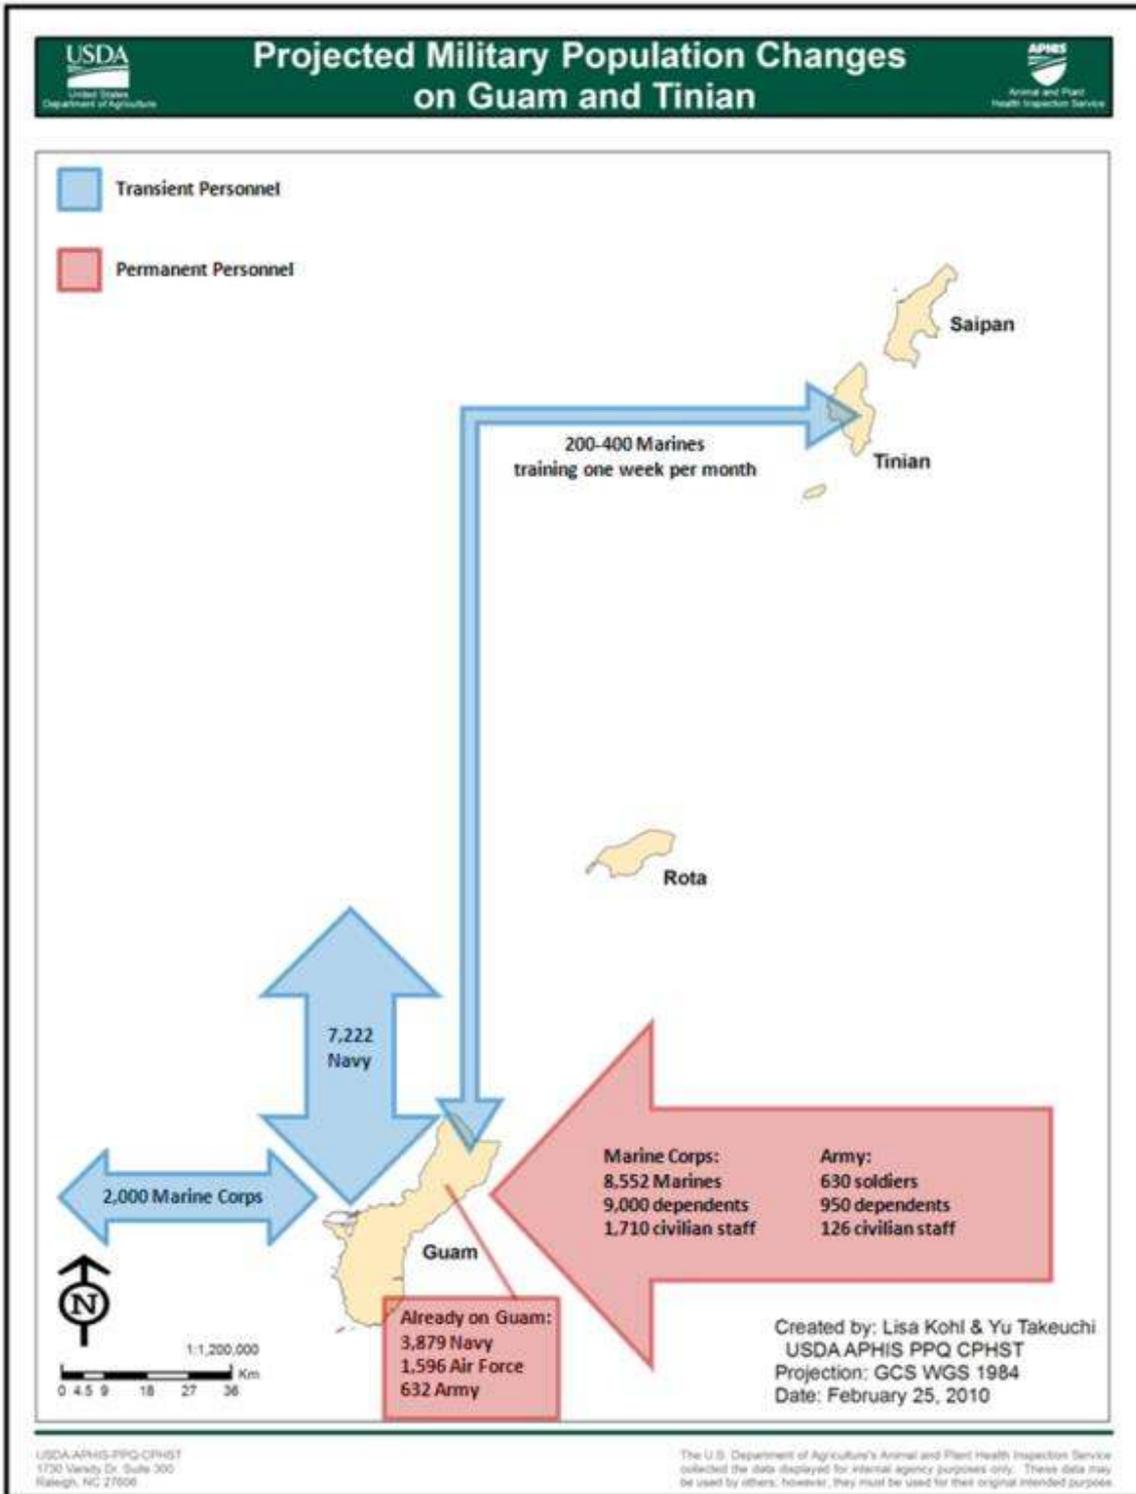

8 Approximately 8,600 Marines and 9,000 dependents will be relocated to Guam (Figure A1-2) (U.S. Navy
9 2009f). In addition, there will be a transient population of approximately 2,000 personnel (U.S. Navy
10 2009h). Port capacity will be expanded to accommodate transient berthing of a nuclear-powered
11 aircraft carrier in Apra Harbor (U.S. Navy 2009b). The aircraft carrier is part of a Carrier Strike Group,
12 which includes aircraft and escort ships. In total, a Carrier Strike Group includes more than 7,000
13 personnel. The Carrier Strike Group would be in port for a maximum of 63 days per year, for up to 21
14 days per visit (U.S. Navy 2009b). An Army Air and Missile Defense Task Force (U.S. Navy 2009e),
15 requiring movement of approximately 630 Army personnel, 126 civilians, and 950 dependents to Guam,
16 is also proposed. The U.S. Armed Forces personnel stationed in Guam will originate from a variety of
17 duty stations.

18 Infrastructure improvements on Guam will be needed to accommodate the relocation (U.S. Navy
19 2009h). Utility, roadway, housing, and port expansion construction projects related to the proposed
20 actions are expected to result in population increases due to an influx of workers. The size of the
21 population on Guam from off-island is forecast to peak at almost 40,000 in 2014, resulting in an increase
22 in movement of people and goods into and throughout the Micronesia Region.

23

1

Figure A1-2: Projected Military Population Changes on Guam and Tinian

2
3

Source: U.S. Navy 2009h

1 **A1.2 POLITICAL RELATIONS AND RELEVANT LEGISLATION**

2 Several U.S. federal laws are directly applicable to the proposed action, including the National
3 Environmental Policy Act (Title 42, United States Code [U.S.C.] section 4321) which requires federal
4 agencies to address the impact of invasive species on their actions; the Endangered Species Act (16
5 U.S.C. § 1531 et seq.) which requires federal agencies, in consultation with the U.S. Fish and Wildlife
6 Service (USFWS) and/or the National Oceanic and Atmospheric Administration, to ensure that actions
7 they authorize, fund, or carry out are not likely to jeopardize the continued existence of any listed
8 threatened or endangered species or result in the destruction or adverse modification of designated
9 critical habitat of such species; and the Federal Noxious Weed Act (7 U.S.C. § 2814), which requires
10 federal agencies to develop management programs for the control of weeds. The Federal Seed Act
11 authorizes USDA to regulate the trade of seeds, and the Plant Protection Act authorizes USDA to
12 regulate the trade of plant materials to control and minimize the economic, ecological, and human
13 health impacts that harmful plant pests can cause. The Animal Health Protection Act (8 U.S.C. § 8301 et
14 seq.) authorizes USDA to regulate the import, export, and interstate movement of animals and articles
15 to prevent the introduction or dissemination of livestock pests or diseases. APHIS uses these authorities
16 to protect U.S. agriculture, forests, and other natural resources from harmful pest species. USDA
17 implementing regulations include those listed in Titles 7 and 9 of the U.S. Code of Federal Regulations
18 (CFR): 7 CFR § 319.56 for regulation of agricultural commodities for consumption; 7 CFR 319.37 for
19 regulation of plants for propagation; 7 CFR § 319.69 for regulation of agricultural packing materials, and
20 9 CFR § 70-99 for regulation of import, export, and interstate movement of animals and animal
21 products.

22 **A1.2.1 Guam and the Commonwealth of the Northern Mariana Islands**

23 Guam is an unincorporated, organized territory of the United States, and its people are citizens of the
24 United States. The powers of the government of Guam are set forth in the Organic Act of Guam, and
25 part of the U.S. Constitution applies to its governance. The Act permits the Governor to establish
26 agencies and regulations as needed to protect public health and prevent the spread of disease (Guam
27 2004). The Guam Department of Agriculture (GDOA) carries out pest survey and control programs
28 (Berringer 2009). Guam law authorizes GDOA to quarantine, inspect, fumigate, disinfect, destroy, or
29 exclude commodities infested with pests or any article that is or may be injurious to the agricultural
30 industries and forest resources of the territory (Guam CQD 1997; 9 GARR, Division 1, Chapter1). GDOA is
31 further authorized to enforce applicable regulations governing the importation into Guam of any
32 agricultural commodities from anywhere outside of the territory, at any time or place within the
33 territory (Guam CQD 1997; 9 GARR, Division 1, Chapter 1).

34 The Director of GDOA issues permits required for importation of regulated plants and plant products
35 into Guam. Phytosanitary certificates are required for the importation of rooted plants and seedlings;
36 cuttings and grafts of woody plants; ornamental plants and other horticultural plants; cut flowers;
37 flower bulbs, corms, tubers, rhizomes, and other vegetative plant propagating materials; fresh fruits of
38 regulated plants; seeds meant for propagation purposes; and soil. These certificates must be issued by
39 the Plant Protection Service of the country of origin of the plants. If the country from which a

1 consignment is imported into the territory of Guam is not the country of origin, the consignment must
2 be accompanied by a phytosanitary certificate of the country of origin; in case of importation of fruits,
3 the certificate may also have been issued by the country from which the consignment was last
4 dispatched (9 GARR, Division 1, Chapter 1).

5 Each shipment of plants into the territory of Guam must be marked to show name and address of
6 shipper or owner, name of consignee, contents, and the state and country where the contents were
7 grown. Any person transporting, receiving, or importing plants, plant products, or soil must have an
8 import permit. All shipments of plants are examined at their port of entry and, if found infested with any
9 pest liable to be detrimental to agriculture, the shipments are destroyed, treated, or processed at the
10 owner's expense. All plants shipped into the territory of Guam must be free of soil, and all regulated
11 articles (9 GARR, Division 1, Chapter 1) are subject to inspection upon arrival in Guam. Shipment or
12 transport of live insects, plant pathogenic agents, and all other plant pests into the territory of Guam is
13 prohibited. Specific commodities from various countries are also regulated (9 GARR Division 1, Chapter
14 1).

15 All importations of domestic animals into the territory of Guam from foreign countries are subject to the
16 regulations of, and require permits from, USDA. In general, no permits are required for animals
17 imported from the United States. Feral animals, reptiles, insects, and birds may only be imported into
18 the territory with a permit issued by USDA (9 GARR, Division 1, Chapter 1). All animals are subject to
19 inspection upon their arrival in the territory; those animals that have been exposed to, are suffering
20 from, or appear to have the symptoms of a contagious or infectious disease are subject to quarantine.
21 Animals must enter the territory through commercial ports or the international airport. Specific animal
22 types are further regulated (9 GARR, Division 1, Chapter 1).

23 The CNMI is an unincorporated, organized commonwealth, and its people are citizens of the United
24 States. The constitution of the CNMI can be modified only with consent of both the U.S. Congress and
25 CNMI (DOI OIA 2007; 2009b). Citizens of the CNMI elect a non-voting member to the U.S. House of
26 Representatives, but they have no vote in the electoral college (110th Congress 2008).

27 Port operations in both Guam and the CNMI are guided by U.S. federal regulations. Agricultural
28 inspectors at Guam and CNMI ports of entry have access to USDA inspection manuals that specify the
29 percentage of cargo to be inspected and additional risk management principles. While these resources
30 are available, specific requirements are determined by locality, not the United States. The municipalities
31 comprising the CNMI create and enforce local laws, including laws that regulate agricultural materials;
32 local laws do not preempt those of the Commonwealth. The GDOA Biosecurity Division, Guam Customs
33 and Quarantine Agency (GCQA), and CNMI Department of Lands and Natural Resources Division of
34 Agriculture are charged with preventing the introduction and establishment of alien species in their
35 respective territories (Guam CQD 1997; GDOA 1997). GDOA, GCQA, and the CNMI Department of Lands
36 and Natural Resources collaborate with U.S. federal agencies to prevent the introduction of invasive
37 pests. USDA-APHIS-PPQ provides oversight and support for agricultural quarantine and inspection
38 activities for both Guam and the CNMI. However, the actual work associated with agricultural

1 quarantine and border inspection activities is carried out by GCQA and the CNMI Department of Lands
2 and Natural Resources, each providing officers that serve as APHIS cooperators.

3 **A1.2.2 The Freely Associated States: Federated States of Micronesia, Republic of the Marshall 4 Islands, and Palau**

5 FSM and RMI became independent nations in 1979, followed by Palau in 1994 (DOI OIA 2009c, d, a).
6 After gaining their independence, FSM, RMI, and Palau each entered into a Compact of Free Association
7 with the United States. As part of this agreement, the United States has unlimited access to the land and
8 waterways belonging to each of these nations. In return, the United States provides financial assistance
9 and defense (DOI OIA 2009c, d, a). Unlike territories or commonwealths, nations in free association are
10 not bound by the U.S. Constitution, but they have agreed to be bound by certain U.S. laws such as the
11 National Environmental Policy Act.

12 **A1.2.2.1 *Federated States of Micronesia***

13 FSM is composed of more than 600 islands which are organized into four states: Chuuk, Kosrae,
14 Pohnpei, and Yap (DOI OIA 2009d). The Code of the Federated States of Micronesia (FSMC) (updated
15 1997) describes authorities to regulate agriculture and livestock (FSMC Title 18, Chapter 2 § 206). Key
16 provisions include authorization of a coconut development authority to engage in manufacture,
17 processing, trading, marketing, and quality control of all products derived from the coconut tree,
18 reflecting the importance of coconut in the Micronesia Region.

19 Quarantines may be used to prevent the introduction and further dissemination of injurious insects,
20 pests, and diseases into and within FSM. The Secretary of Resources and Development issues plant and
21 animal quarantines and regulations relating to their administration and enforcement. Agricultural
22 quarantine inspectors appointed by the Secretary of Resources and Development enforce the provisions
23 of plant and animal quarantine controls, quarantines, and regulations. The Secretary of Resources and
24 Development possesses the power to deputize anyone to serve and enforce the FSM laws including
25 customs and immigration inspections (FSMC Title 18, Chapter 2 § 206).

26 All animals and plants or parts thereof, including seeds, fruits, vegetables, and cuttings entering or
27 transported within FSM are subject to inspection by agricultural quarantine inspectors and may be
28 treated, destroyed, or refused entry into or movement within FSM if they are known to be, or are
29 suspected of being, infected or infested with disease or pests (FSMC Title 18, Chapter 2 § 206). All
30 aircraft and vessels or their cargoes, including baggage, ship's stores, and ballast, entering or moving
31 within FSM are subject to inspection by agricultural quarantine inspectors; U.S. Armed Forces aircraft
32 and vessels are subject to existing military security regulations. Vessels and aircraft traveling into or
33 within FSM and known or suspected to be harboring plant pests are subject to spraying with insecticides
34 or other treatment. FSM inspectors also monitor the shipment of vehicles. It is possible that the
35 shipment of used vehicles may have assisted with the spread of Giant African Snails to Kosrae.

36 Any animals, plants, or other quarantine material in transit through FSM on aircraft or vessels must be
37 kept aboard while in port. If it is necessary to transfer quarantine material from one vessel or aircraft to

1 another, such transfer must be made under the direction of an agricultural quarantine inspector, and
2 with safeguards as deemed necessary.

3 **A1.2.2.2 Republic of the Marshall Islands**

4 RMI consists of more than 1,200 islands and atolls, most of which are uninhabited (RMI EPPSO 2005b).
5 The RMI Chief of Agriculture administers plant and animal quarantine controls and regulations (PacLII
6 2004a). Agricultural quarantine inspectors, under the direction of the Chief of Agriculture, enforce said
7 provisions. All animals and plants or parts thereof, including seeds, fruits, vegetables, cuttings, etc.,
8 entering or transported within RMI are subject to inspection and may be treated, destroyed, or refused
9 entry into or movement within RMI if they are known to be, or are suspected of being, infected or
10 infested with disease or pests. All aircraft and vessels or their cargoes, including baggage, ship's stores,
11 and ballast, entering or moving within the Republic are subject to inspection; U.S. Armed Forces aircraft
12 and vessels are subject to existing military security regulations (PacLII 2004a). Vessels and aircraft
13 traveling into or within RMI and known or suspected to be harboring insects or other agricultural pests
14 are subject to spraying with insecticides or other such treatment (PacLII 2004a).

15 Any animals, plants, or other quarantine material in transit through RMI on aircraft or vessels must be
16 kept aboard while in port, unless such material is otherwise enterable. If it is necessary to transfer such
17 quarantine material from one vessel or aircraft to another, such transfer must be made under the
18 direction of an agricultural quarantine inspector with safeguards as deemed necessary.

19 **A1.2.2.3 Palau**

20 Palau consists of more than 340 islands, nine of which are inhabited (Palau OPS 2008). Palau Animal and
21 Plant Quarantine Regulations (Palau BAMR 2006) stipulate that every conveyance and all of its cargo,
22 people, baggage, garbage, and provisions are subject to inspection and examination, treatment, or
23 quarantine. Garbage is prohibited entry to Palau without express permission and may require treatment
24 or destruction. Plants and plant material are prohibited from Palau without a permit, and plants and
25 plant material in transit through Palau are subject to quarantine or safeguarding measures; permission
26 to transit is required. Imported plants and plant parts must be free from soil; timber imports are subject
27 to inspection and treatment upon arrival and timber with bark attached is prohibited entry, unless
28 treated for pests. Grass, bamboo, and palm fronds are prohibited entry into Palau; soil, sand, and gravel
29 must have a permit in order to be allowed entry (Palau BAMR 2002; 2006).

30

1 **A2 TRAFFIC AND TRADE DATA**

2 **A2.1 PEOPLE**

3 Below, we summarize population sizes and movement patterns of people to and within the Micronesia
4 Region. We compiled these data from the November 2009 Guam and CNMI Military Relocation draft
5 EIS/OEIS and final EIS/OEIS (U.S. Navy 2009a; 2010a); government tourism and statistics office reports;
6 and other publicly available sources. Comparison of statistics among the island groups and among data
7 sources is complicated by differences in data availability, definition of terms such as visitor and tourist,
8 and data collection and analysis methods. However, the information that we present below should
9 provide insight into the current and forecast volumes and patterns of people movement to and within
10 the Micronesia Region.

11 **A2.1.1 Micronesia Region: Population and Visitors**

12 The total population of the Micronesia Region in 2009 was approximately 423,000 (Table A2-1) (USCB
13 2010). Most of the population lives in Guam or FSM (USCB 2010). The number of visitor arrivals in the
14 island groups in recent years has totaled more than 1.7 million annually, with most accounted for by
15 arrivals in Guam or the CNMI (RMI EPPSO 2008; SPC 2008).

16 **Table A2-1: Population Size and Number of Visitors to the Micronesia Region**

Region	Population ^a		Visitors ^b	
	Number	Percent	Number	Percent
Guam	178,430	42	1,225,323	71
FSM	107,434	25	20,150	1
RMI	64,522	15	6,959	<1
CNMI	51,484	12	389,261	22
Palau	20,796	5	93,031	5
Total	422,666	99 ^c	1,734,724	99 ^c

17 ^a Estimated midyear population, 2009 (USCB 2010).
18 ^b Visitor arrivals. Guam, CNMI, Palau, FSM: 2007 (SPC 2008). RMI: fiscal year (FY) 2007,
19 visitors to Majuro (RMI EPPSO 2008).
20 ^c Due to rounding, total does not equal 100.
21

22 **A2.1.2 Guam**

23 Most visitors to Guam arrive by air (BSP 2009a). Of those, most are from Japan or Korea (Table A2-2),
24 and most are traveling for pleasure (Table A2-3). Of the visitors who arrive on passenger vessels by sea,
25 most are from Japan or the U.S. mainland (PB International 2008). Approximately 20% of international
26 arrivals in Guam by sea are from cruise ship visits (Green 2004). In recent years, 4 to 10 cruise ships have
27 visited Guam per year, carrying an average annual total of approximately 2,900 passengers and crew,
28 and generally remaining in port for less than 24 hours (Table A2-4) (PAG 2010a). Most other
29 international arrivals by sea are from military and merchant ships, including traffic from U.S. Navy ships
30 and courtesy calls from the navies of Australia, New Zealand, and various Asian countries (Green 2004).

Total	14,337	32

10 Source: PAG 2010a.

11 ^a Passengers and crew.

1 **A2.1.3 Commonwealth of the Northern Mariana Islands**

2 Most (90%) of the population of the CNMI lives on Saipan, with 5% each on Tinian and Rota (U.S.
3 Department of Commerce 2001). Some areas within the CNMI are very sparsely populated, with a total
4 of six individuals counted in the 2000 Census on one such area, The Northern Islands municipality.

5 Most visitors to the CNMI arrive in Saipan, mainly as tourists from Japan or Korea (Table A2-5) (CNMI
6 Department of Commerce). Much of the economic activity on Tinian is associated with a casino, tourism
7 related to the island’s role in World War II, or marine activities (U.S. Navy 2010a). Most of the visitors to
8 the casino are from Asia, mainly from China, Japan, and Korea. The comparatively few visitors to Rota
9 are predominantly visitors from Guam or elsewhere in the United States, or from Japan.

10 **Table A2-5: Visitors to CNMI, by Region of Origin of Visitor**

Region of origin	Visitors (2002) ^a	
	Number	Percent
Japan	293,921	69

12 ^a Fiscal year.

13 ^b Due to rounding, total does not equal 100.

14

15 A large proportion of the movement of people within the CNMI occurs by sea (Green 2004). The ports of
16 Rota and Tinian each handle a large volume of passenger ferry traffic daily. Most of the international
17 arrivals by sea are from merchant vessels or cruise liners. In general, merchant vessels carry few people
18 on frequent port calls, whereas cruise liners carry more people on fewer port calls.

19 **A2.1.4 Federated States of Micronesia**

20 Most of the population of FSM lives in Chuuk (50%) or Pohnpei (32%) (FSM Division of Statistics 2013).
21 Most visitors to FSM are from the United States or Asia (Table A2-6), traveling as tourists or on business
22 (Table A2-7). It is worth noting that the information in these tables may very well only be from visitors
23 arriving via aircraft, although this has not been ascertained. Most movement of people and goods
24 among the islands of FSM occurs by ship (Green 2004) (This may be less true in 2013 than a decade ago
25 when this information was published). International arrivals by sea are mainly from fishing vessels and
26 merchant ships.

1

Table A2-6: Visitors to FSM, by Region of Residence of Visitor

9

A2.1.5 Palau

11 Most of the population of Palau lives in Koror (64%) or Airai (14%) (Palau OPS 2006). Approximately 80%
 12 of visitors to Palau are from Asia, mainly from Japan and Taiwan (Table A2-8) (Palau OPS 2009b). More
 13 than 90% of visitors to Palau are tourists Table A2-9 (Palau OPS 2009a). Similar to the case for CNMI and
 14 FSM, much of the movement of people and goods among the islands of Palau occurs by sea, mostly by
 15 inter-island trading vessels and ferries (Green 2004). Most international arrivals by sea are from fishing
 16 vessels and cruise ships. The cruise ships arrive primarily from Guam and Asia.

1

7

A2.1.6 Republic of the Marshall Islands

9 Most (68%) of the population of RMI lives in Majuro or Kwajalein (RMI EPPSO 2005a). Kwajalein is home
10 to the Ronald Reagan Ballistic Missile Defense Test Site, which is owned by the U.S. government and is
11 home to approximately 75 U.S. government personnel, 1,600 contractor staff, and 1,000 family
12 members (GAO 2002). Approximately half of the visitors to Majuro are from Asia, mainly Japan; almost
13 one-fourth are from the Americas (Table A2-10) (RMI EPPSO 2008). Most visits to Majuro are for
14 business or holiday (Table A2-11) (RMI EPPSO 2008). As is the case for other island groups in the
15 Micronesia Region, much of the domestic movement of people and goods in RMI occurs by sea (Green
16 2004). Most of the international arrivals by sea are from fishing vessels and merchant ships.

1

Table A2-10: Visitors to Majuro, RMI, by Region of Residence of Visitor

Region of residence	Visitors (2007)	
	Number	Percent
Americas	1,690	24
Japan	1,600	23

6

1 **A2.1.7 Population Impacts of Proposed Actions**

2 The estimated changes in Guam’s population size from 2010 to 2020 are shown in Figure A2-1.

3 **Figure A2-1: Estimated population on Guam from Off-Island, 2010-2020¹**

4

5 ^a Does not include transient population of up to 7,222 personnel associated with aircraft Carrier Strike

6 Group, and transient population of up to 6,213 personnel associated with Marine Corps vessels

7 berthed at Apra Harbor (U.S. Navy 2010a).

8 ^b Source: U.S. Navy 2010a

9

10 The population from off-island is forecast to grow through 2014,⁷ concurrent with the planned increase

11 in DoD project construction work and the planned arrival in 2014⁷ of most of the Marines that are to be

12 relocated to Guam (U.S. Navy 2010a). The total number of individuals from off-island is estimated to

13 peak in 2014⁷ at almost 80,000. From 2014² to 2017, the DoD and non-DoD populations from off-island

14 are forecast to decrease with the completion of construction projects. In 2017,⁷ the population from off-

15 island is estimated to decrease to approximately 33,400. The changes in estimated population size on

16 Guam from off-island from 2010 to 2020⁷ are shown by population category in Table A2-12 (U.S. Navy

17 2010a).

¹The National Defense Authorization Act (NDAA) for Fiscal Year 2012, signed into United States law on December 31, 2011, by President Barack Obama, imposed restrictions on the Secretary of Defense’s usage of funds to develop infrastructure associated with the U.S. Marine Corps relocation to Guam. Additionally, Congress did not authorize or appropriate funding for the Guam realignment in FY 12. As the pace of construction is subject to the availability of funds, it is anticipated that the realignment will proceed at a slower rate than originally anticipated.

1

2 Source: Modified from U.S. Navy 2010a

3 ^a Does not include transient population of up to 7,222 personnel associated with aircraft Carrier Strike Group, and transient population of up to 6,213 personnel associated
4 with Marine Corps vessels berthed at Apra Harbor (U.S. Navy 2010a).

5

1 From 2010 to 2014,² the largest proportions of the estimated total population from off-island are
 2 accounted for by non-DoD workers and their dependents for DoD construction projects, and workers
 3 and their dependents for indirect and induced jobs. Most of the estimated increases from 2015 to 2020
 4 are due to increases in the number of Marine Corps and Army personnel, DoD civilians and their
 5 dependents, and workers and their dependents for indirect and induced jobs. The non-DoD construction
 6 worker and indirect or induced populations are forecast to decrease sharply after peaking in 2014 with
 7 the peak in construction activity. These decreases might not be as sharp or as large as forecast,
 8 depending on the number of workers who remain on Guam (U.S. Navy 2010a).

9 The population estimates described above do not include an estimated maximum number of 7,222
 10 personnel in port at any given time associated with the aircraft Carrier Strike Group, and a transient
 11 population of up to 2,000 personnel associated with Marine Corps vessels berthed at Apra Harbor (U.S.
 12 Navy 2010a). These two groups are not expected to be in port concurrently.

13 The estimates also do not include training visits to the Micronesia Region by Japan Self Defense Forces
 14 personnel. The training is expected to include various types of ground, air, and maritime training in
 15 Guam, the CNMI, and surrounding sea and airspace. Each type of training exercise could involve
 16 approximately 500 to 3,000 personnel, training for 1 to 4 weeks, 1 to 6 times per year (Table A2-13).

17 **Table A2-13: Japan Self Defense Forces Training in the Micronesia Region**

Total number of personnel ^a	Duration (weeks per visit)	Frequency (times per year)	Training Location	Military Service
3,000	4	1	Guam, Tinian, Pagan, and surrounding sea and airspace	Japan Self Defense Forces, U.S. forces

19 ^a Maximum training requirements for the Japan Self Defense Forces in the Micronesia Region; rough estimates
 20 prepared for the Guam and CNMI Military Relocation EIS/OEIS.
 21

² Ibid. pA2-6.

1 **A2.2 MARITIME TRAFFIC AND CARGO**

2 The Micronesia Region is well connected through maritime shipping routes to Asia (China, Japan, and
3 Korea) and the United States (Figure A2-2). The majority of maritime traffic in the Region moves
4 between the U.S. west coast and Guam, between Asia and Guam, and within the Region (Figure A2-2)
5 (PB International 2008). On a less frequent basis, vessels operate between Australia, Papua New Guinea,
6 and Guam (PB International 2008). Container ships, larger vessels such as break-bulk cargo ships, and
7 smaller regional vessels usually operate on routine schedules in the Micronesia Region. Waterways to
8 the east/northeast connect with Hawai'i and the continental United States, while the waterways
9 running north and west connect to the CNMI and with ports in Asia. Horizon Lines and Matson
10 Navigation Company operate large container ships that navigate the route from China to California,
11 returning to China by way of Hawai'i and Guam, with potential stops at other Micronesian ports, such as
12 RMI and FSM.

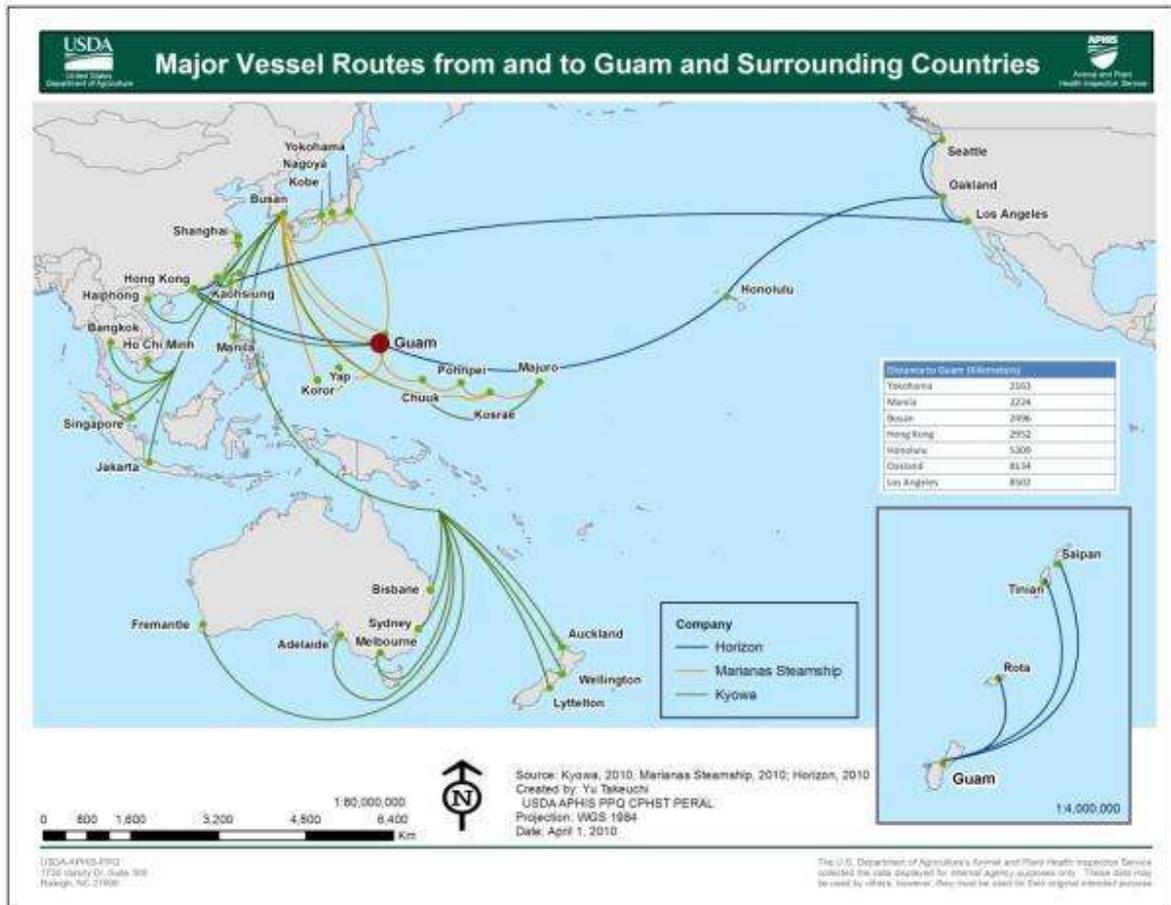

13 **A2.2.1 Civilian Ports**

14 The Jose D. Leon Guerrero Commercial (Maritime) Port of Guam is the main port in the Micronesia
15 Region, handling almost 90% of all imports to Guam (PB International 2008) and serving as the
16 transshipment hub for the Region; the port also receives cargo for the military bases on Guam (Table
17 A2-14). Data availability is very limited, especially regarding military vessels, and port statistics often do
18 not differentiate between vessel types (e.g., container vessels, break-bulk cargo vessels, and petroleum-
19 carrying vessels). Horizon Lines and Matson Navigation Company operate the majority of large ships in
20 the Region (Horizon Lines 2010b, c; Matson 2010a, b). The military relocation is expected to increase
21 maritime vessel traffic to Guam (PB International 2008) by an estimated 149 container vessels per year
22 (U.S. Navy 2009a), in addition to a substantial increase in the number of break-bulk vessels (PAG 2010b)
23 (Table A2-14). Container volumes will also increase (Tables A2-14 and A2-15).

24

Tourist charter boats	6,000	5,000	100	400	610
Fishing–local	-	1,000	500	200	4,000
Local work boats	600	600	-	250	230
Local craft	-	4,000	-	15,000	12,500

2 Source: Nawadra et al. 2002; Green 2004

3 ^a Estimates based on 2002 to 2004 data.

4 ^b Traffic numbers for FSM are totals for the ports of Pohnpei, Weno, Yap, and Okat. These figures may
5 include “double-counting” if vessels were included in more than one port’s total.

6 ^c Merchantmen vessels are those carrying commercial cargo and include container ships, bulk cargo,
7 and roll-on roll-off vessels. In Saipan, 330 container vessels arrive per year. In Palau, mostly
8 containerized cargo arrives from vessels originating in Guam.

9 ^d N/A: Data not available.

10
11 The Cargo Preference Act of 1904 (10 U.S.C. § 2631) requires that all supplies purchased for the U.S.
12 Armed Forces be transported on U.S. flag vessels when transported by vessels at sea (US DOT 2009).
13 Waivers for cargo moving between elsewhere in the United States and Guam can only be granted by the
14 Secretary of the U.S. Department of Homeland Security (US DOT 2009). Of interest, Matson Navigation
15 Company (a leading U.S. flag ship carrier operating in the Pacific) has purchased four new vessels for an
16 Asian service that conducts weekly service to Guam (PB International 2008). The types and volumes of
17 maritime vessel traffic at ports in the Micronesia Region are summarized in Table A2-15.

18 The Port of Saipan clears approximately six cargo vessels (250 cargo containers) per week; the Port of
19 Tinian clears up to two cargo vessels per week and two daily inter-island passenger vessels (Berringer
20 2009). Cargo vessels occasionally arrive at the Port of Rota. Most vessels arriving in Saipan and Tinian
21 carry transshipments from Guam. Vessels from Guam calling in Saipan often stop in Tinian first.

22 Palau is well connected to Asia and the mainland United States, as well as to other islands in the region.
23 Shipping lines service Malakal Commercial Dock, operating on a 30-day interval, bringing cargo from the
24 U.S. west coast, Japan, Australia, Taiwan, Hong Kong, the Philippines, Guam, and elsewhere. Another
25 shipping line operates mostly in Asia and brings cargo from Korea, Japan, the Philippines, Hong Kong,
26 Taiwan, Saipan, Guam, and Yap. Transshipments between Guam and Palau are routine (Berringer 2009).

27 Small vessels, including privately owned outboard motor boats, move freight between the islands of
28 Palau. These vessels are multipurpose, moving people and freight together. The exact number of small
29 vessels involved in transport is not known, but at least several hundred outboard motorboats operate in

1 the area (Jimenez et al. 2009). Freight often consists of firewood and perishable commodities including
 2 fruits and vegetables.

3 **A2.2.2 Cargo**

4 Break-bulk cargo volumes are expected to substantially increase due to the amount of construction
 5 materials that will arrive on Guam in response to the proposed military relocation (PB International
 6 2008). The Port of Guam processed 155,000 revenue tons of break-bulk cargo during 2007. It is
 7 anticipated that the volume of break-bulk cargo processed through the Port of Guam will increase from
 8 current levels to 270,000 to 320,000 revenue tons per year during 2010 through 2013 (PB International
 9 2008). However, these figures may change if construction plans change.

10 The maritime port in Guam processes more containers than any other port in the Region and serves as
 11 the main transshipment hub. Approximately 94,000 sea cargo containers arrived at the Port of Guam in
 12 2009. This number is expected to more than double by 2015 (approximately 95,900 more containers
 13 arriving), mostly due to the military relocation (Tables A2-14 and A2-16) (PAG 2010b). The number of
 14 containers associated with construction projects and military container shipments (e.g., household
 15 goods, private vehicles, and commissary products) is anticipated to increase and peak in 2015, after
 16 which the majority of the construction is expected to be finished and the relocation of military
 17 personnel to Guam completed (PB International 2008). DoD containers are expected to account for
 18 approximately one-fourth of total container volume processed through the Port of Guam (PB
 19 International 2008). The number of containers handled to support imports for the local/tourist market is
 20 projected to steadily increase. Little change is projected for the volume of transshipment containers
 21 coming into Guam (PB International 2008). Detailed data regarding container traffic at other maritime
 22 ports in the Micronesia Region were unavailable.

23 **Table A2-16: Forecast Number of Sea Cargo Containers Entering Guam**

Year	Number of containers			
	Total	Type		
		Transshipment	DoD	Local and tourism
2010	129,000	12,000	39,000	78,000
2011	149,000	11,000	58,000	80,000
2012	172,000	11,000	78,000	83,000
2013	178,000	11,000	81,000	86,000
2014	182,000	11,000	85,000	86,000
2015	190,000	11,000	89,000	90,000
2016	180,000	11,000	76,000	93,000
2017	152,000	11,000	46,000	95,000
2018	146,000	12,000	38,000	96,000
2019	148,000	12,000	38,000	98,000
2020	150,000	12,000	38,000	100,000
2021	151,000	12,000	38,000	101,000
2022	153,000	12,000	38,000	103,000
2023	155,000	12,000	38,000	105,000
2024	157,000	12,000	38,000	107,000
2025	158,000	12,000	38,000	108,000

24 Source: PAG 2010b

1 Transshipped containers enter a country through one port, are then loaded onto a different vessel, and
2 exit for their final destination in a different country (PB International 2008; PAG 2010b).

3 **A2.2.3 Military Seaport**

4 Approximately four contract cargo vessels per week arrive at Naval Base Guam, as well as naval ships
5 carrying personnel and cargo (Berringer 2009). Currently, the number of U.S. Navy ships operating in
6 and around Guam at any given time ranges from 0 to 10; ship lengths range from 110 meters (361 feet)
7 for a nuclear submarine (SSN) to 333 meters (1,093 feet) for a nuclear aircraft carrier (CVN). The number
8 of naval ships operating in and around Guam may increase with the military relocation; specific
9 estimates were not provided in the EIS/OEIS. Training activities involving vessel movements occur
10 intermittently and are short in duration, ranging from several hours to several weeks (U.S. Navy 2009b).

11 **A2.3 AIR TRAFFIC AND CARGO**

12 **A2.3.1 Civilian Air Traffic and Air Cargo**

13 From September 2008 to September 2009, there were 20,985 flight arrivals, about 20 daily flights, at
14 A.B. Won Pat International Airport, of which fewer than 2% were dedicated cargo flights (Table A2-17)
15 (GIAT Operations Division Records 2009). The amounts of air cargo processed through the airport in
16 2003 to 2008 are summarized in Table A2-18. Passenger arrivals and departures at A.B. Won Pat
17 International Airport are projected to increase 3% to 4% per year from 2008 to 2023 and air cargo (in
18 metric tons), which includes shipments of agricultural commodities, is projected to increase 7% per year
19 during the same time period (Tagawa and Torres 2007) which may increase the number of dedicated
20 cargo flights arriving at the airport. The airport hosts several flights to Japan, Korea, China, Taiwan, the
21 Philippines, Indonesia, Australia, and Hawai'i.

22 Within the Micronesia Region, A.B. Won Pat International Airport provides air service to the CNMI (Rota
23 and Saipan), FSM (Chuuk, Kosrae, Pohnpei, and Yap), Palau (Koror), and RMI (Kwajalein and Majuro).
24 Saipan International Airport services approximately 13 flights daily; Rota International Airport averages
25 2 to 3 inter-island flights per day, as well as one direct flight from Japan per month; and Tinian
26 International Airport services inter-island flights (Berringer 2009). The Palau airport provides 7 weekly
27 turn-around services between Guam and Palau, with stops on Yap and Saipan (Law-Byerly 2010b).

1 **Table A2-17: Number of Flight Arrivals at A.B. Won Pat International Airport, by Month,**
 2 **September 2008 to September 2009**

Month	Number of flight arrivals	
	All flights ^a	Dedicated cargo flights
2008		
September	1,541	29
October	1,509	34

9 ^a Commercial air cargo.

11 **A2.3.2 Military Air Traffic and Cargo**

12 Andersen Air Force Base (AFB) is located on the northern end of Guam and is home to the 734th Air
 13 Mobility Squadron, 36th Operations Group, and the Helicopter Sea Combat Squadron (HSC-25) (U.S.
 14 Navy 2009a). Aircraft arrivals at Andersen AFB include military flights, contract flights for military
 15 dependents, and approximately 10 cargo flights per week (Berringer 2009). Civilian and military air
 16 traffic will increase to accommodate the population increase associated with the military relocation. The
 17 percent increase in commercial flight traffic during the relocation is unknown. However, the number of
 18 flight operations of helicopters, jets, and propeller aircraft at Andersen AFB is projected to increase 45%

1 by 2014 (U.S. Navy 2009a). In addition to flight traffic, air cargo traffic will increase to accommodate the
2 increase in population and relocation activities.

3 Andersen AFB supports Air Mobility Command flights for military personnel and their dependents. In
4 2006, 29,524 flight operations were conducted at Andersen AFB (U.S. Navy 2009a). The Air Force plans
5 on increasing its use of the base, bringing the total number of annual airfield operations up to 68,139 by
6 2014. Of these airfield operations, 18,951 are expected to involve the HSC-25 Squadron's MH-60S
7 Knighthawk helicopters, and 732 are expected to be transient operations generated by the air wing
8 associated with the visiting aircraft carrier. The remainder will be local and transient operations.

9 Of the flight operations conducted in 2006, only 18,951 operations involved equipment based at
10 Andersen AFB (all helicopters) (U.S. Navy 2009a). In addition, 602 jet operations, 52 rotary wing
11 operations, and 78 helicopter operations were conducted with equipment associated with visiting
12 aircraft carrier wings. Finally, 9,841 local and transient operations were conducted. Under the proposed
13 actions, additional aircraft would be based at Andersen AFB by the Marine Corps. Equipment based at
14 Andersen AFB would be used in 23,416 operations in 2014³ (18,852 helicopter; 4,564 jet) (U.S. Navy
15 2009a). Under the proposed actions, 1,704 jet operations, 156 rotary wing operations, and 234
16 helicopter operations would be conducted in 2014⁴ using equipment associated with visiting aircraft
17 carrier wings. The addition of these aircraft would result in 25,510 sorties at Andersen AFB in 2014 .
18 Under the proposed actions, up to 59 aircraft would reside at Andersen AFB on a space-available basis
19 when a CVN is in port. A typical air wing might include 20 Hornet aircraft, 10 Super Hornet aircraft, five
20 EA-6B aircraft, four E-2C aircraft, and six SH-60 aircraft.

21 **A2.4 AGRICULTURAL COMMODITIES**

22 **A2.4.1 Plants and Plant Products: Imports**

23 Some of the main types of plant products imported to Guam include fruits and vegetables, cut flowers,
24 and wood. Because Guam is a domestic trading partner with the rest of the United States, neither the
25 federal government nor Guam now systematically collects data regarding the specific amounts of
26 commodity trade between the two locations. As opposed to current practices, in 2002 (and before)
27 GDOA personnel collected such data. Data collected during these activities illustrate both the diversity
28 of plants and plant products imported into Guam and the diversity of their origins. These data are
29 summarized in the list below; the values in parentheses are the weight of the imported commodity in kg
30 and pounds rounded to the nearest pound. The total weight imported in 2002 was 13,148 metric tons
31 (28,986,463 pounds). It should be noted that these data do not include imported furniture from
32 Indonesia. It is worth noting that while the information presented below is interesting, it is outdated,
33 some locations which do export plant products to Guam such as Kosrae and Yap are not included and
34 some of the information is simply incorrect, for example Pohnpei does not produce alfalfa sprouts.

29 (302,733/667,412); yam (9,091/20,043); yucca (472/1,041); zucchini (2,547/5,616)

30 **Yap**–betelnut (110,647/243,935); kava (266/587); piper leaf (3,323/7,327); taro (16/36)

31 An important caveat to the data presented above is the omission of many cereal crops. Data regarding
32 the volume and value of cereals imported from the United States to Guam are not available. However,
33 imports of cereals from non-U.S. origins to Guam totaled more than \$3 million in 2008, with the majority
34 of shipments originating from Thailand, Japan, and Taiwan (Table A2-19) (GTIS 2010).

35

Table A2-19: Cereal Imports to Guam, 2006-2008

Reporting country or region	U.S. dollars		
	2006	2007	2008
Thailand	871,307	2,067,395	3,198,206
Japan	3,341	2,045	14,918
Taiwan	62	182	2,874

India	5,533	0	0
Philippines	136,526	0	0
South Korea	0	42	0

Source: GTIS 2010

In 2002, the United States was the largest source of live plants for propagation imported into Guam, which totaled 76,907 kg (169,550 pounds) (see above). Hawai'i and Florida are significant sources of ornamental plants. Orchids are imported primarily from Thailand and Taiwan, while most bromeliads are imported from the Philippines. As shown in the list above, relatively small amounts of live plants are imported from the FSM, CNMI, and Palau (Campbell 2010d). Cut flowers imported into Guam likely originated from South America (Colombia and Ecuador) with some originating from Asia (USDA-APHIS-PPQ 2010a).

Wood imports to Guam from foreign trading partners totaled more than \$3 million in 2007 (GTIS 2010). The majority of these imports were finished products or building materials from neighboring Asian nations. In 2008, trading partners within the Micronesia Region exported fruit and vegetable commodities to Guam worth \$1.3 million (GTIS 2010).

FSM imported \$2 million to \$4 million in cereals each year from 2007 to 2009 from the United States (GTIS 2010). Data for other areas within the Micronesia Region were not available.

Another important caveat to the list above is the lack of information regarding informal imports such as the importation of taro from Palau and the FSM. These items are typically imported by family members for home consumption or by the small scale markets that cater to the various island and Asian groups now living on Guam. As an example, the Alii Fish Market in Dededo, Guam regularly imports Colocasia and Cyrtosperma taro and other Palauan food items for sale to its mainly Palauan clientele. The same generalizations regarding food imports to the informal sector also can be made for the other Micronesian island groups who reside on Guam. The import of taro plants and fresh taro products is prohibited to Guam, in order to prevent the dissemination of taro diseases. Per regulations, the Alii Fish Market imports taro (both Colocasia and Cyrtosperma) that has been cooked, frozen and wrapped in plastic.

A2.4.2 Plants and Plant Products: Domestic Production and Exports

Guam produces a variety of fruit, including coconuts, melons, papaya, guavas, mangoes, mangosteens, and nuts (FAO 2010a) (Tables A2-20 and A2-21).

Table A2-20: Non-Animal Agricultural Production on Guam, 1998-2008, by Hectare

Commodity	Number of hectares harvested, by year		
	1998	2003	2008
Bananas	10	15	15
Coconuts	9,300	9,300	9,600

3
 4 Of these commodities, some percentage is exported, although the majority of production is consumed
 5 by the domestic market. Historically, the primary recipients of exported fruit and vegetable commodities
 6 are Canada, the United Kingdom, and the Netherlands (GTIS 2010). The majority of exported vegetables
 7 are legumes; Canada, Iceland, and the Netherlands are primary recipients (GTIS 2010). Wood is also
 8 exported from Guam, and is sent to India and the Philippines (GTIS 2010). The primary destination for
 9 Guam plant product exports is FSM (Table A2-22).

10

1

Table A2-22: Plant Product Exports from Guam, June 2008 to March 2010

Number of shipments	Destination	Commodity	Total weight (pounds)
3	CNMI, Rota	Fruits and vegetables	445
10	CNMI, Rota	Live plants	142
56	CNMI, Saipan	Cut flowers	11,855
8	CNMI, Saipan	Live plants	452
1	CNMI, Saipan	Seeds	10

1	RMI, Majuro	Fruits and vegetables	960
1	Texas	Coconut	52

2

Source: Data provided by GCQA

3

4 Coconut is the largest crop, in number of metric tons harvested in RMI (GTIS 2010); production totaled
5 27,500 metric tons (60,627,122 pounds) in 2008 (FAO 2010a). Export data for FSM and RMI were not
6 available.

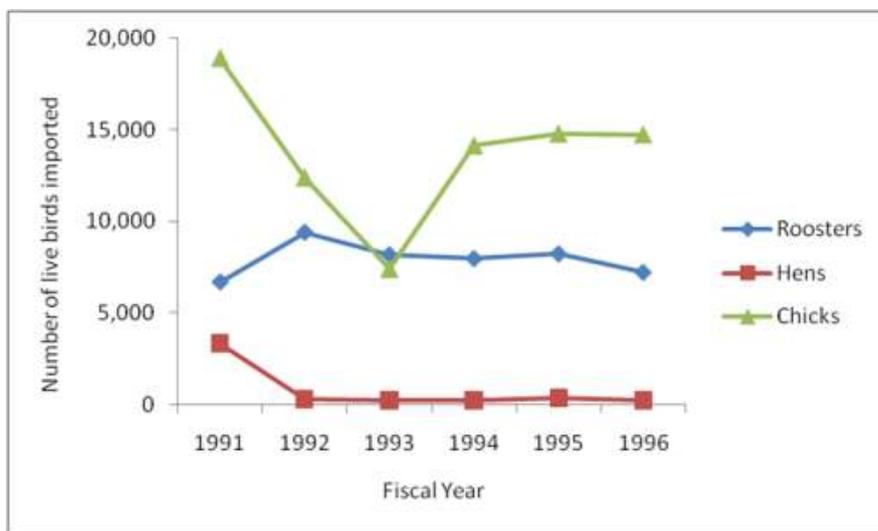

7 **A2.4.3 Animals and Animal Products: Imports**

8 Data on livestock imports were available from the Global Trade Atlas (GTIS 2010). Guam has
9 experienced a decline in annual live animal imports after a peak in 2003 and 2004 totaling more than
10 10,000 per year. The number of animals imported dramatically declined to about 100 animals per year
11 between 2004 and 2007 and remains below 10 per year at present. Imported animals originated
12 primarily from Australia (84%) with the rest being sourced from Asia (the Philippines, South Korea,
13 Thailand, Japan, Indonesia, and Singapore), Canada, and Denmark. The majority of import records in the
14 Global Trade Atlas do not include the animal species. According to the territorial veterinarian, no
15 livestock have been imported to Guam over the last 5 years (Poole 2009). Additionally, according to
16 published reports, no cattle have been imported in the last two decades (Duguies et al. 2000). Swine
17 semen has been imported in the past, but no records were found to indicate recent importations (Poole
18 2009).

19 Importation of poultry breeding stock to Guam is restricted and subject to U.S. federal regulations; most
20 poultry breeding stock have been imported from the continental United States and Hawai'i. During fiscal
21 years 1991 to 1996, most of the imported birds were day-old chicks, with some roosters and few hens

1 (Figure A2-3). The number of bird imports declined following the imposition of restrictions on transit of
 2 birds after the outbreak of West Nile fever in the continental United States. According to a GCQA 2002
 3 report on animal imports, no chicks or hens were imported in 2002 (GovGuam 2002). Global Trade
 4 Information Services reported one shipment of 14,000 live chickens from Denmark in 2003 (GTIS 2010).
 5 No data are available from GCQA on animal importations after 2002 (Campbell 2010a). Current demand
 6 for poultry breeding stock is partially met by GDOA, which runs an experimental farm that hatches and
 7 raises poultry for local farmers. We were not able to identify data specific to the number of hatching
 8 eggs and day-old chicks imported, but nearly all of these imports are from Hawai'i and the continental
 9 United States (USDA-APHIS-PPQ 1997; GovGuam 2002; DNRL 2003; Dela Cruz 2009; Poole 2009).

10 **Figure A2-3: Trends in the Importation of Live Birds to Guam, FY 1991 to FY 1996**

11

12 Source: USDA-APHIS-PPQ 1997

13 The GCQA 2002 report documents animal imports and indicates that on average, 9,400 roosters were
 14 imported annually during the 1990s. These numbers have declined, starting shortly after the West Nile
 15 fever outbreak in the continental United States. Only 12 roosters were imported to Guam in 2002 from
 16 CNMI (GovGuam 2002). While more current data are not available from GCQA, there is reason to believe
 17 that the trend reversed shortly after, with increasing numbers of roosters brought in and used to supply
 18 a burgeoning cock fighting industry (Poole 2009). In unpublished reports, Guam Animals In Need
 19 indicated that approximately 6,000 roosters were imported between 2003 and 2005; these increasing
 20 numbers of rooster imports are also consistent with the increasing popularity of cock fighting on Guam
 21 as discussed in a 2008 Honolulu newspaper article (Boylan 2008). However, in 2002, a federal law was
 22 implemented that prohibits the interstate transit of birds used for fighting, and United Airlines recently
 23 banned the air freight transportation of adult poultry (Huemer 2007), suggesting the trend will be
 24 reversed once again with far fewer roosters imported.

25 In the past, the annual number of pet birds imported ranged from 42 to 6,505 (FY 1991 to FY 1996)
 26 (USDA-APHIS-PPQ 1997). These numbers drastically declined after the implementation of importation
 27 and quarantine requirements designed to prevent the introduction of West Nile virus (WNV) from the

1 continental United States. Based on the last available Guam-specific animal import data, there are no
2 records of pet birds having been imported into Guam in 2002 (GovGuam 2002). Since GCQA took over
3 inspection responsibilities in 2003, animal import numbers have not been reported. However, according
4 to the territorial veterinarian on Guam the approximate number of pet birds coming to Guam is
5 currently less than a dozen per year (Poole 2009).

6 The number of dogs and cats imported into Guam annually is low, with estimates ranging from 10 to 100
7 animals a year (Poole 2009). In the GCQA 2002 animal report, 113 dogs and 29 cats were imported to
8 Guam in 2002 (GovGuam 2002). The majority of imports originated from the continental United States
9 and Australia, with a few animals imported from Japan and CNMI (USDA-APHIS-PPQ 1997).

10 Most food imports originate in the continental United States. In FY 2009, imports from the rest of the
11 United States accounted for more than 85% of meat products, 98% of egg products, and 75% of dairy
12 products imported into Guam. Data for imports of animal products and byproducts from foreign sources
13 over the period 2005 to 2009 were obtained from the Global Trade Atlas (GTIS 2010) and are
14 categorized by the harmonized schedule (HS) codes. The volume of foreign meat imports increased from
15 2005 to 2009, mostly due to a steady annual increase in the volume of imported pork over the last 5
16 years as shown in Table A2-24, and in Figure A2-4 and Figure A2-5.

17

1 **Table A2-24: Annual Percent Volume of Foreign Meat Imports to Guam, 2005-2009**

HS code	Commodity	Year					Countries or regions of origin
		2005	2006	2007	2008	2009

5

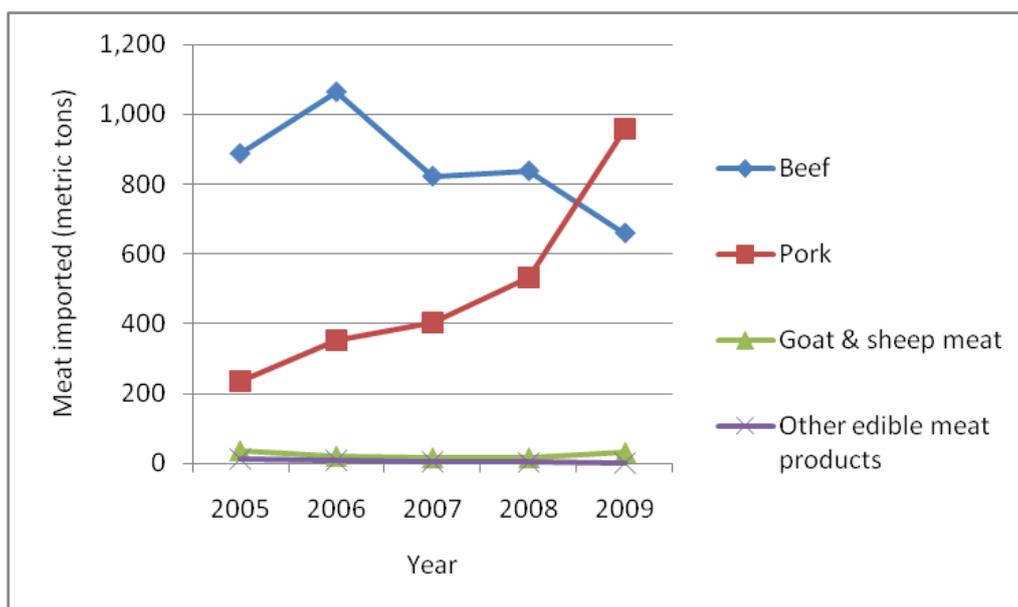

1 **Figure A2-4: Foreign Meat Imports To Guam By Continent of Origin, 2005-2009**

2
3 Source: Official trade data for partner countries exporting to Guam; GTIS 2010
4

5 Volumes of beef imports decreased from 2006 to 2009 (GTIS 2010). No foreign imports of poultry
6 products were recorded, indicating that all or nearly all poultry products were sourced from the United
7 States. Meat from goats and sheep constituted less than 5% of total meat imports and was imported
8 exclusively from Australia and New Zealand. Other edible preparations, including preserved or prepared
9 meat, blood, sausages, and similar products, represented 24% of total meat imports for 2009. Most
10 foreign-origin meat was imported from Denmark (58%), Australia (21.8%), and New Zealand (19.9%),
11 with less than 1% imported from elsewhere (the Philippines, Japan, and Taiwan) (Table A2-25). Imports
12 of beef came primarily from New Zealand and Australia (99%) and less than 1% from Japan.

1 **Figure A2-5: Annual Volumes of Foreign Meat Imports to Guam, 2005-2009**

 7

8 Each year from 2005 to 2009, New Zealand and Australia supplied more than 95% by weight of all dairy
 9 imports to Guam from foreign origins. During the same time period, 1% or less of all dairy imports were
 10 from each of several other regions, including the Philippines, Japan, Taiwan, and Canada (Table A2-26).

11 **Table A2-26: Annual Percent Volume Dairy Imports to Guam By Country and Continent of**
 12 **Origin, 2005-2009**

 14 ^a Due to rounding, not all totals equal 100.

1 From 2005 to 2009, 80% to 90% of dairy imports were non-sweetened and non-concentrated dairy
 2 products; the rest were cheeses and sweetened or concentrated milk products (Table A2-27).
 3 Sweetened and concentrated milk products and cheese represented on average 12 and 4% of imports
 4 from Asia respectively.

5 **Table A2-27: Foreign Dairy Product Imports to Guam, 2005-2009**

HS code	Commodity	Year					Countries of Origin
		2005	2006	2007	2008	2009

8
 9 In the last 5 years, all foreign imports of egg products have come from Asia (Thailand, Japan, and
 10 occasionally from Taiwan) with the volume of imported egg products oscillating between 20 and 30
 11 metric tons. In 2005, almost 80% of foreign imports of egg products were from Japan (Table A2-28).
 12 However, from 2007 to 2009 an increasingly large proportion of egg product imports have come from
 13 Thailand (Table A2-28).

14 **Table A2-28: Percent of Egg Product Imports to Guam by Country of Origin, 2005-2009**

Reporting country or region	Year				
	2005	2006	2007	2008	2009
Percent of egg product imports, by weight ^a					
Thailand	21	22	61	81	100
Japan	79	75	31	19	0
Taiwan	0	3	7	0	0

16 ^a Due to rounding, not all totals equal 100. The volumes of egg product imports for years with no
 17 reported imports are assumed to equal zero.

18
 19 Limited veterinary services throughout Micronesia and lack of inspection for slaughter activities
 20 preclude the possibility of commercial trade of locally produced animal products, including meat, eggs,
 21 and milk.

1 **A2.4.3.1** *Animal Product Imports by the U.S. Armed Forces*

2 The Defense Commissary Agency provides groceries to military personnel, retirees, and their
3 dependents (Melton 2009). All perishable food products procured by the Defense Commissary Agency,
4 including meat, eggs, and fresh dairy products, come into Guam from other parts of the United States.
5 All meat products procured by the Defense Commissary Agency require USDA certification (Melton
6 2009). Military food comes into the military port where it is inspected by military veterinarians prior to
7 distribution. These food commodities are inspected to assure the product matches the paperwork, and
8 for quantity and approved source. Most of the distributors are based in California.

9 Currently there are over 200 domestic and foreign sources of food for which the U.S. Army Veterinary
10 Corps must provide inspection services for the military bases on Guam (VETCOM 2009). In 2010, there
11 will be an increase in the number of approved foreign sources. Some of the new suppliers will be located
12 in Vietnam and China. Locally sourced food items are limited to some fruits and vegetables and are
13 provided by less than 20 local retailers or businesses. Animal products are not sourced from local
14 suppliers. Most suppliers of locally procured food products are located in CNMI (Saipan and Rota) (DeCA
15 2009; Melton 2009).

16 To accommodate the expected increase in the number of military personnel on Guam, the Defense
17 Commissary Agency expects to increase business operations to 7 days a week and increase the
18 quantities of imported products procured from current suppliers (Melton 2009). It is important to note
19 that the Defense Commissary Agency does not resupply the Carrier Group, which is expected to harbor
20 in Guam for up to 120 days each year. However, the commissary would be available to military
21 personnel disembarking from these ships.

22 **A2.4.3.2** *Animal Byproducts*

23 The value of hide and skin imports to Guam has increased significantly during the last decade, with most
24 products coming from Europe and Asia (Table A2-29). The highest import value was recorded in 2003
25 from Colombia. All imports were of treated products. The importation of leather and treated hides,
26 skins, and capes is permitted without restriction (Poole 2009, 9 CFR § 95).

27

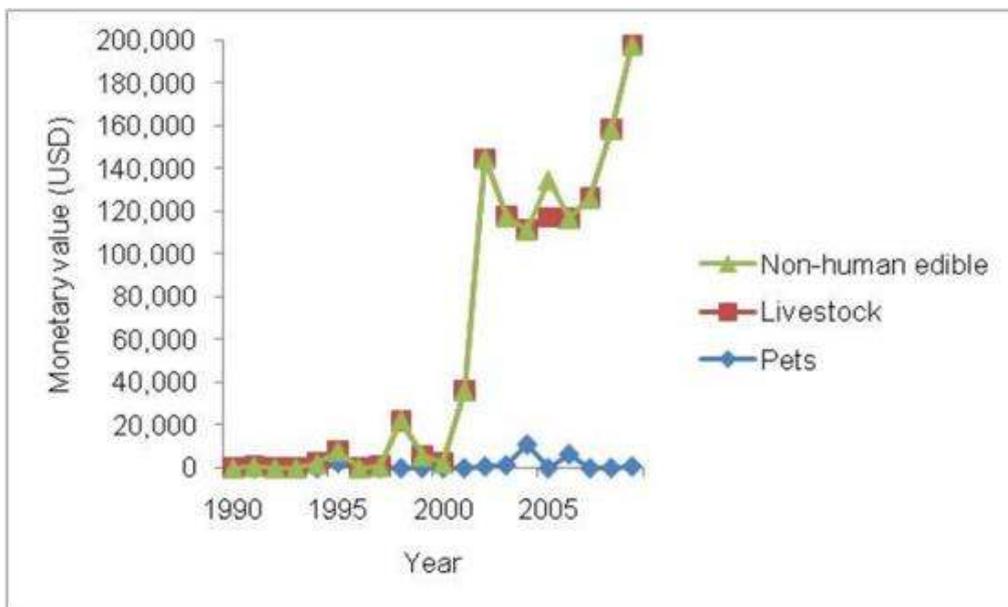

1 **Table A2-29: Value (USD) Foreign Imports of Raw Hides, Skins, and Leathers**
 2 **to Guam, 1997-2008**

 4 Data restricted to the years for which importations were recorded; HS codes for the commodities included in
 5 this list are 4113 (leather of other animals, no hair); 4114 (chamois leather, patent, laminated, and metallized
 6 leather); 4106 (goat or kidskin leather, no hair); 4107 (leather of bovine/equine, no hair). HTSTUS, chapter 41:
 7 raw hides, skins, and leather.
 8

9 Most commercial pet food and livestock feed sold in Guam is produced in the United States and is a
 10 domestic import (Poole 2009). Only a small portion is imported from foreign sources. In Figure A2-7, we
 11 present the amounts, in U.S. dollars, of animal feed and intermediary products imported to Guam for
 12 the last two decades.

13 **Figure A2-7: Annual Value of Imported Animal Feed and Intermediary Products**
 14 **to Guam, 1990-2009**

15 Source: Global Trade Atlas (GTIS 2010)

16 Most foreign imports of pet food and animal feed during the last 5 years were preparations for animals
 17 other than dogs and cats. Commercial food for dogs and cats and animal products unfit for human
 18

1 consumption represent less than 0.1% of the total volume of foreign feed imports from 2000 to 2009,
 2 with the exception of 2005 where they accounted for approximately 15%. Foreign imports of dog and
 3 cat food started in 2002, but dropped after 2005, reflecting a preference for U.S.-produced feed. Taiwan
 4 was the main foreign source for dog and cat food, with one importation each from the Philippines
 5 (2003) and Australia (2004).

6 **A2.4.4 Animals and Animal Products: Domestic Production and Exports**

7 The livestock inventory for Guam was obtained from the U.S. Census of Agriculture (2007) (USDA NASS
 8 2009a). Over the last decade, both the number of farms and the total number of livestock have
 9 declined. The biggest declines have been in the pig and goat populations with reductions of 70% and
 10 30%, respectively. Cattle and carabaos (water buffalo) are less important as production animals and
 11 their populations have always been relatively small (Table A2-30). Swine are the most important
 12 production animal for Guam, with around 600 domestic pigs on the island.

13 **Table A2-30: Guam Livestock Inventory, 1998-2007**

Livestock	1998		2002		2007		Percent change 1998 to 2007	
	Farms	Animals	Farms	Animals	Farms	Animals	Farms	Animals

16 ^b N/A indicates data withheld and thus unavailable for calculation.

17
 18 Semi-feral and feral pigs are distributed island-wide with greater numbers found in the secondary
 19 limestone forests of the north and ravine forest of the south (Conry 1988a). The estimated feral pig
 20 density in Northwest Field on Andersen AFB was 110 pigs/square kilometer (km²) in 1987 (0.44
 21 pigs/acre) (Conry 1988a), and had not significantly changed by the late 1990s (Lujan and Wiles 1997).

22 Approximately 300 wild carabaos inhabit Guam (U.S. Navy 2009f). To control the carabao population,
 23 the Navy, in cooperation with the U.S. Geological Survey and the Wildlife Defense Fund, has in the past
 24 used a contraceptive drug and supported an adoption program, and the Navy culled 126 animals (U.S.
 25 Navy 2009f). Other wildlife species include the Philippine deer. Recent surveys estimate deer density
 26 15.3 deer/km² at the Naval Magazine and around the Andersen munitions storage area, respectively
 27 (Brooke 2009).

28 In the Micronesia Region, most poultry farming consists of small commercial or backyard operations
 29 (Duguies et al. 2000). Guam limits residents to no more than 20 birds in residential areas (GCA 2010c).
 30 Chickens comprise the largest poultry population on Guam (Table A2-31). Most poultry for human
 31 consumption is imported from the continental United States (Jimenez et al. 2009). Small flocks of feral

1 chickens are commonly seen on Guam. The number of feral chickens is high, although there are no
 2 precise estimates of population size (USDA-APHIS WS 2009).

3 **Table A2-31: Numbers of Poultry and Poultry Farms in Guam, 1998-2007**

Poultry	1998		2002		2007		Percent change, 1998 to 2007	
	Farms	Animals	Farms	Animals	Farms	Animals	Farms	Animals

5 Note that data referred to as 1998 data were for the 12-month period of July 1, 1997, through June 20, 1998.

6 ^a (D): data withheld to avoid disclosing data for individual farms. Data indicated by dashes were not reported.

7 ^b N/A indicates data withheld and thus unavailable for calculation.

8
 9 No published reports exist on the number of pet bird owners or pet birds on Guam. Based on American
 10 Veterinary Medical Association estimates for areas of similar size, there may be approximately 4,000 pet
 11 birds on Guam (AVMA 2007). We could not find estimates for the number of pet dogs and cats on
 12 Guam, nor could we find estimates of the current size of the stray population. The number of stray dogs
 13 and cats on Guam was last estimated in 1967 as between 20,000 and 60,000 (Glosser and Yarnell 1970).

14 The numbers of livestock and poultry in CNMI in 1998 to 2007 were larger than those in Guam. They are
 15 summarized in Table A2-32 and Table A2-33.

16 **Table A2-32: Numbers of Livestock and Livestock Farms in CNMI, 1998-2007**

Livestock	1998		2002		2007		Percent change, 1998 to 2007

Note that data referred to as 1998 data were for the 12-month period of July 1, 1997, through June 30, 1998.

4

^a Data for other poultry were not available in the 1998 census.

5

^b N/A: data were not available for 1998 and thus not available for calculation of the percent change for the period 1998 to 2007.

6

7

8 A2.5 CONSTRUCTION**9 A2.5.1 Equipment**

10 Equipment in excess of what is currently available will be needed on Guam to complete construction of
 11 new military facilities, civilian infrastructure, and port improvement and expansion. Approximately 50
 12 logistics elements (bulldozers, trucks, and forklifts, for example) will be transported to Guam to support
 13 relocation and post-relocation activities (U.S. Navy 2009h) A range of equipment will be imported for
 14 commercial port improvements (Table A2-34); some of this equipment is currently available and some
 15 will be moved onto Guam.

16

Table A2-34: Equipment Needed for the Commercial Port Improvements

Type	Quantity
Container quay cranes	4
Top picks	5
Yard tractors	22
Yard chassis	50
Side picks (empties)	6
Break bulk ship cranes	2
Mafi trailers	8
Forklifts, 30 ton	1
Forklifts, 10 ton	1
Forklifts, 7.5 ton	2
Forklifts, 5 ton	6

17

Source: PB International 2008

18

19 Grading equipment, trucks, cranes, and specialty hopper trucks used to move cement will likely be
 20 imported to accomplish land clearing and construction goals (U.S. Navy 2009h). Specifically, equipment

1 will be needed for clearing, grading, grubbing, and demolition of existing road pavement, earthwork,
2 and landscaping (U.S. Navy 2009f). In addition to equipment used for clearing land, equipment will also
3 be needed for building construction.

4 **A2.5.2 Housing**

5 Housing demand estimates we consider here represent an approximation of the number of housing
6 units required for the Guam civilian population (U.S. Navy 2009h) under the proposed action. We
7 assume temporary foreign construction workers will live in the dormitory housing provided by
8 contractors and active-duty military personnel will be housed on base or on ships (U.S. Navy 2009i).

9 The forecast housing demand for the relocation is large. One source suggests that housing demand will
10 significantly increase during the relocation, to 11,893 units by 2014, and decrease to 3,205 units after
11 construction ceases in 2017 (U.S. Navy 2009i). At an earlier date, Guam was thought to have available
12 housing (approximately 2,800 units) to offset some of this anticipated housing demand, which was
13 thought to be sufficient for private-sector housing needs during 2010 (U.S. Navy 2009i). If additional
14 housing is developed, large quantities of excess housing may be realized when the construction phase is
15 completed (U.S. Navy 2009i).

16 For much of the construction for the proposed relocation, foundations, walls, and roofs would be
17 primarily made from concrete (U.S. Navy 2009h). Concrete batch plants may be established on large
18 construction sites for cast-in-place construction, although precast facilities at additional sites may also
19 be utilized (U.S. Navy 2009h). Some wall construction may use concrete masonry units, which would be
20 produced at an offsite facility and subsequently moved to the construction sites (U.S. Navy 2009h). For
21 family housing (presumably military), one source suggests that the military may favor the use of precast
22 concrete panels that will be transported to Guam as needed for new housing units (PB International
23 2008).

24 **A2.5.3 Apra Harbor**

25 Approximately 1.1 million cubic yards of dredged material will need to be removed from Apra Harbor to
26 accommodate military vessels (U.S. Navy 2009h). As part of the overall construction process for the
27 harbor, some fill could be mixed with stone that could be used to support the shoreline and the wharf
28 piles (U.S. Navy 2009h). In addition, the Port Authority of Guam recently proposed filling several acres of
29 currently submerged land to provide space for port expansion (U.S. Navy 2009b). Should this expansion
30 project be conducted, the U.S. Navy has a memorandum of agreement with the Port Authority of Guam
31 to provide fill from proposed dredging projects, dependent on material suitability and logistics (U.S.
32 Navy 2009h). Nonetheless, due to concerns over the potential of liability from this material, the
33 preferred use of dredged material has been proposed to have it be stored on DoD lands (U.S. Navy
34 2009d).

35 **A2.6 MAIL**

36 The U.S. Postal Service (USPS) provides public mail service to the Micronesia Region. Mail sent between
37 the United States, Guam, CNMI, RMI, Palau, and FSM is considered domestic (USPS 2009).

1 Approximately 95% of Guam’s incoming mail is domestic (Berthoud 2009) originating from Hawai’i and
2 the mainland United States (Ericksen 2010). Several private shipping companies also operate in the
3 Micronesia Region. These companies consider mail traveling between the United States and the
4 Micronesia Region to be international mail.

5 Guam’s main post office, located in Barrigada, is the service hub for USPS mail in the Micronesia Region.
6 Surface mail and airmail destined for the Micronesia Region are sorted at this facility for Guam, CNMI,
7 RMI, Palau, and FSM. The majority of international mail destined for Guam arrives from Japan and the
8 Philippines. All domestic mail from the mainland United States and most international mail destined for
9 the Micronesia Region is processed in Honolulu, Hawai’i, before being sent to Guam (Ericksen 2010).

10 Military personnel stationed in Guam receive mail through one of the four USPS post office branches
11 that are located within military installations (Law-Byerly 2010a). Military mail is sent to Army Post Office
12 (APO) or Fleet Post Office (FPO) addresses through the USPS distribution network and through the
13 Military Postal Service Agency (MPSA) 2010).

14 In 2008, approximately 1,104 metric tons (2,433,903 pounds) and 4,111 metric tons (9,063,204 pounds)
15 of mail were sent from and received in Guam, respectively (BSP 2009a). Approximately 20,000 to 30,000
16 packages arrive in Guam each week, and the majority of parcels are addressed to businesses in Guam
17 (Ericksen 2010). The USPS does not keep records of mail volumes for any of the other locations in the
18 Micronesia Region (USPS 2010a), but these locations likely receive and send much smaller volumes of
19 mail. For example, RMI received 0.238 metric tons (525 pounds) of mail during the 2008 fiscal year
20 (Marshall Islands Journal 2008). The APO/FPO addresses in Okinawa currently receive about 1,587.5
21 metric tons (3,499,838 pounds) of mail total per year from the United States and Japan (Berthoud 2009).
22 Mail volumes on Guam are expected to greatly increase as a result of the military relocation; an
23 additional 18,000 packages per week, or 900,000 packages per year, may be delivered to the Naval Base
24 alone (Ericksen 2010).

25 **A2.7 REGULATED GARBAGE AND SOLID WASTE**

26 To protect against the introduction of exotic animal and plant pests and diseases, importation of
27 garbage from all foreign countries except Canada into the United States is prohibited. Movement of
28 garbage from Hawai’i, Puerto Rico, American Samoa, CNMI, FSM, Guam, the U.S. Virgin Islands, RMI, and
29 Palau to any other state is prohibited with few exceptions. As discussed below, the term “garbage”
30 refers to all waste material that is derived in whole or in part from fruits, vegetables, meats, or other
31 plant or animal (including poultry) material, and other refuse that has been associated with any such
32 material. The term “agricultural waste” refers to byproducts generated by the rearing of animals and the
33 production and harvest of crops or trees. Animal waste, a large component of agricultural waste,
34 includes waste (feed waste, bedding and litter, and feedlot and paddock runoff, for example) from
35 livestock, dairy, and other animal-related agricultural and farming practices (9 CFR § 94).

36 Garbage is regulated if it is on or removed from a conveyance that has been in any port outside the
37 United States and Canada within the previous 2 years. Garbage generated during international or

1 interstate transit including food scraps, table refuse, galley refuse, food wrappers or packaging
2 materials, and other waste material from stores, food preparation areas, passengers' or crews' quarters,
3 or dining rooms, is regulated; this also includes meals and other food that were available for
4 consumption by passengers and crew on an aircraft but were not consumed (9 CFR § 94).

5 All regulated garbage must be contained in tight, covered, leak-proof receptacles during storage on
6 board a conveyance while in the territorial waters, or while otherwise within the territory of the United
7 States. Per Presidential Proclamation 5928 (1988), territorial seas extend 12 nautical miles offshore,
8 while the Submerged Lands Act places state property boundaries 3 miles offshore for most states. Given
9 the unique relationship between the United States, Guam, and countries within the Micronesia Region,
10 alternate interpretation of these different boundaries may occur. If unloaded, regulated garbage must
11 be moved under the direction of an inspector to an approved facility for incineration, sterilization, or
12 grinding into an approved sewage system. Any person or entity engaged in the business of handling or
13 disposing of regulated garbage must first enter into a compliance agreement with APHIS unless the
14 regulated garbage is handled under the direct supervision of an APHIS inspector (9 CFR § 94).

15 Garbage management practices can affect the likelihood that pests in waste will escape into the
16 environment, or that the waste will serve as a source of disease transmission (Novak 1995; Gale 2004;
17 Auclair et al. 2005; Gould and Huamán Maldonado 2006; McCullough et al. 2007; Wichuk and
18 McCartney 2007; Graiver et al. 2009; Jacobson et al. 2009). Garbage management options at sea include
19 disposal at sea, incineration, shredding, compaction, and storage for disposal on land (Nawadra et al.
20 2002). Within the Micronesia Region, port demand for waste reception facilities is highest in Guam
21 (Nawadra et al. 2002). Most of this demand is accounted for by domestic inter-island passenger and
22 cargo vessels, tourist boats, and commercial fishing boats. Waste, including regulated garbage, from
23 large merchant vessels is generally not accepted in Guam, and the commercial port generally does not
24 accept waste from international vessels. At the commercial port, commercial marinas, and fisheries
25 wharves in Guam, waste is collected by private waste collection companies under compliance
26 agreements with APHIS and is subject to Port Authority and government policies and regulations. In
27 general in the Micronesia Region, waste from international vessels that contains food waste is treated as
28 quarantine garbage. In Guam, regulated garbage and rejected cargo seized from international vessels
29 are incinerated.

30 Solid waste generated on land can be broadly categorized as municipal, commercial, or industrial.
31 Detailed, reliable data regarding the composition of each of these waste streams in the Micronesia
32 Region, and waste generation rates for each stream, are not available. However, domestic solid waste
33 generated on Pacific islands, including islands of the Micronesia Region, has been estimated to include
34 large proportions of packaging waste, food waste, and garden waste (WHO 1996). Municipal,
35 commercial, and industrial waste in Guam is disposed of at Ordot Dump, an unlined, uncapped landfill
36 that is scheduled to be closed in 2011 (GSWRIC 2010). A new landfill is under construction. The civilian
37 solid waste management system includes waste collection services, three waste transfer stations, and
38 two landfills for disposal of demolition debris (U.S. Navy 2010a). Household food waste is fed to pigs

1 and chickens, or used as fertilizer (Nawadra et al. 2002). Quarantine and hospital waste is incinerated
2 (Nawadra et al. 2002).

3 DoD waste is disposed of at the Navy Sanitary Landfill located on the Navy base, or at the landfill located
4 at Andersen AFB (U.S. Navy 2010a). At both of these landfills, waste is buried daily. Wood, such as
5 crates, and other green waste at the Andersen AFB landfill is shredded; the shredded waste is used for
6 landscaping on and off base. Waste from Navy ships berthed at Apra Harbor is disposed of at the Navy
7 Sanitary Landfill.

8 The U.S. Navy is responsible for all waste reception and disposal at the naval port. Commercial garbage
9 skips are used for waste reception, and the naval facility has its own landfill for all garbage. All items
10 must be disposed of in accordance with U.S. federal laws (7 CFR § 330.400). Garbage is separated for
11 recycling at the ports and all items for recycling are stored separately at the military landfill site (located
12 on the base) and, in general, are shipped off island on military vessels. Oil, metals, plastics, batteries,
13 and paper wastes are recycled. Toxic wastes are stored while awaiting removal from the island.

14

1 **A3 PLANT PESTS**

2 This section of Micronesia Biosecurity Plan—Methods and Strategies to Manage Invasive Species
3 Impacts to Agriculture, Natural Resources, and Human Health and Safety Project—was prepared by
4 APHIS-PPQ, Center for Plant Health Science and Technology; APHIS Policy and Program Development,
5 Environmental and Risk Analysis Services; and North Carolina State University. The suggested citation for
6 this section is: Meissner, H., R. Ahern, T. Culliney, A. Lemay, A. Hiser, L. Kohl, O. Lenahan, A. Suazo, and
7 Y. Takeuchi. 2010. Plant pests. In *Terrestrial plant and animal health risks associated with the U.S.*
8 *military relocation in the Micronesia Region.* United States Department of Agriculture, Animal and Plant
9 Health Inspection Service. Washington, D.C.

10 **A3.1 SUMMARY**

11 Our objective was to evaluate the risk of exotic plant pest introduction into the Micronesia Region as a
12 result of the planned military relocation on Guam, identify safeguarding gaps, and provide suggestions
13 for improved safeguarding. We evaluated pest risk based on pathways of introduction. The pathways
14 discussed are: people; containers, conveyances, and equipment; wood packaging material (WPM);
15 construction materials; plant propagative material; mail; agricultural commodity imports; and garbage.

16 Our evaluation is qualitative. Due to an overall lack of quantitative data, we did not consider it
17 scientifically justifiable to rate risk, even in semi-quantitative terms (e.g., by assigning “high”, “medium”,
18 and “low” ratings). Such ratings are only meaningful when they are clearly defined and assigned with
19 legitimate confidence. If these conditions cannot be met, such ratings are likely to mislead the reader
20 and promote poor decision-making.

21 We do not expect the military relocation to lead to a fundamental change in the types of pests
22 introduced into the Micronesia Region. Similar types of pests to those that currently enter the Region
23 could potentially be introduced more frequently and may thus establish sooner than they would have
24 otherwise.

25 **A3.2 INTRODUCTION**

26 The introduction of exotic plant pests can have enormous economic and ecological consequences. Exotic
27 plant pests may destroy crops, change landscapes, and drive native species to extinction. Not only
28 agricultural production but also forestry, tourism, and even local climate can be impacted by exotic
29 species. Most exotic species introductions have been facilitated by humans, either inadvertently or
30 deliberately (Baker 1986b; Mack et al. 2000; Ruiz et al. 2000; Mack and Lonsdale 2001; Naylor et al.
31 2001; Reichard and White 2001; Fuller 2003; Kraus 2003).

32 Agriculture is not a particularly large economic sector in Guam or the rest of the Micronesia Region, but
33 many subsistence farmers rely on crop production and various plant species have great cultural value.
34 Most notable among these plants are coconut, numerous varieties of banana, taro, papaya, avocado,
35 breadfruit, and mango. The introduction of pests affecting any of these plant species may have a serious
36 impact on the people and the culture of the Region.

1 Guam has undergone extensive development, particularly over the last 60 years. Numerous exotic
2 species have been introduced over the years and have taken their toll on Guam’s native fauna and flora.
3 The rest of the Micronesia Region, however, possesses a more intact natural environment, with
4 numerous indigenous plant and animal species existing on many of the islands. Guam serves as a
5 gateway to the Micronesia Region, and any exotic species introduced into Guam may from there reach
6 other parts of the Region.

7 The objective of this section was to assess the risk of exotic plant pest introductions into the Micronesia
8 Region associated with the planned military relocation on Guam. In the context of this section, we
9 define plant pests as all terrestrial invertebrates, plant pathogens, and weeds that affect plants of
10 economic, ecological, or cultural significance. Thus, plant pests include arthropods, mollusks,
11 nematodes, fungi, viruses, viroids, bacteria, phytoplasmas, and weeds.

12 **Approach**

13 This is a qualitative risk assessment, organized by pathways of introduction through which plant pests
14 may enter the Micronesia Region. While it was not feasible to address every possible pathway, we
15 discuss those of likely importance, as identified through expert solicitation and preliminary literature
16 research. The pathways discussed are movement of people; containers, conveyances, and equipment;
17 WPM; construction materials; plant propagative material; mail; agricultural commodity imports; and
18 garbage. Soil contamination (on containers, vehicles, etc.), while a very important and common means
19 of spreading plant pests, was not considered an independent pathway, but was instead discussed in the
20 context of the other pathways. For each of these pathways, we describe pest risk in general terms and
21 then evaluate the additional pest risk created as a direct or indirect result of the military relocation
22 (both during and after the relocation activities).

23 For the evaluation of pest risk, we used information from a variety of sources, including published
24 scientific literature, public and government-internal databases, expert interviews, and our personal
25 observations during site visits to the Micronesia Region. In general, relevant data were scarce, especially
26 data specific to the Micronesia Region and data suitable for quantitative analysis. Because of this lack of
27 information, we did not consider it meaningful to formally employ a quantitative or semi-quantitative
28 rating system to categorize any components of pest risk (likelihood of introduction, likelihood of
29 establishment, severity of impact).

30 Based on our assessment of pest risk and biosecurity challenges associated with each pathway, we offer
31 a list of suggested safeguarding measures. The purpose of these suggestions is not to provide detailed
32 operational guidance but, rather, to contribute insights as a basis for developing a comprehensive
33 biosecurity plan.

34 Due to the large number of plant pests potentially threatening the Micronesia Region, it was not feasible
35 to discuss each individual pest in detail. Instead, we present an annotated list of potential pest threats
36 (Section A7). While we identified the most obvious potential invaders, it is important to note that the
37 universe of plant pests that may enter the Micronesia Region is largely unknown.

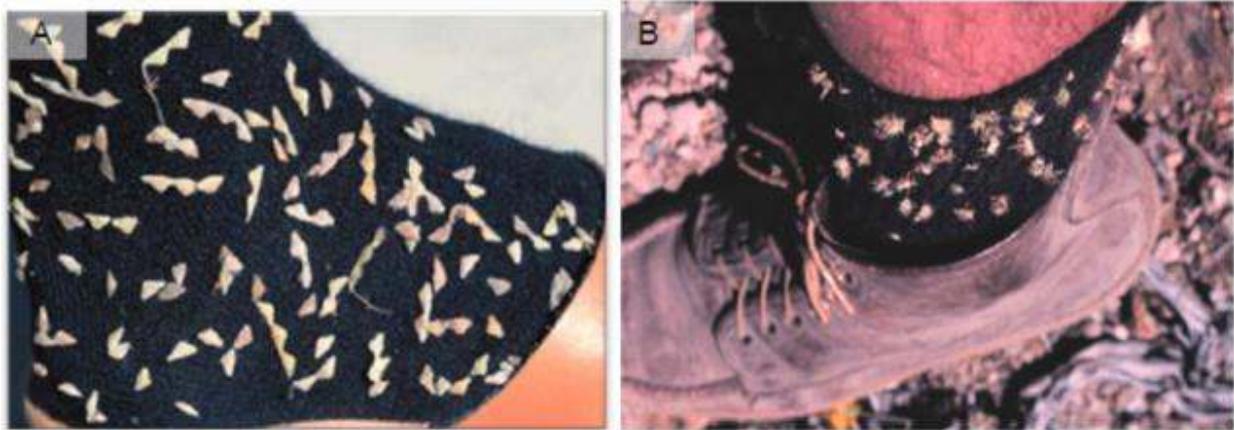

1 **A3.3 RISK ASSESSMENT**

2 **A3.3.1 Pathway: People**

3 The likelihood of pest introduction increases with the number of visitors to a location (Lonsdale 1999).
4 People may spread plant pests by unknowingly carrying pests on themselves, their clothing, or their
5 shoes; by inadvertently transporting pests on objects such as household items, handicrafts, or
6 agricultural products; or by moving pests deliberately. A large number of people will enter the
7 Micronesia Region as a result of the proposed military relocation (Figure A3-1), increasing the frequency
8 of plant pest introductions. Specifically, DoD estimates that the number of people on Guam from off-
9 island will increase eight-fold to almost 80,000 by 2014 . While some of these people will leave again
10 after the relocation phase, an estimated 33,000 will remain on the island permanently (Table A3-1).
11 Because the majority of these people will be military and their dependents, there will be a turnover of
12 people approximately every 2 years. This turnover has a potential multiplying effect on pest pressure.

13 Plant pathogens are easily transported on clothing and boots (Wellings et al. 1987; Cushman and
14 Meentemeyer 2008), where they can remain viable for several months (Norman and Strandberg 1997).
15 Young et al. (2007) reported a large number of fungi and bacteria in soil on air passengers' shoes. Soil on
16 shoes can facilitate the spread of nematodes (Boag 1985), mollusks (Cowie 2001), and weeds (DiTomaso
17 2000; Wichmann et al. 2009). Many plant seeds are adapted to adhere to the fur of animals (Bullock and
18 Primack 1977); these adaptations also facilitate adherence to clothing (Vibrans 1999) (Figure A3-1).
19 Whinam et al. (2005) list 981 propagules (seeds and fruits) and five moss shoots representing 90 plant
20 species from 15 families that were transported to overseas locations on the clothing and equipment of
21 44 Australian expeditioners; clothing and outdoor items with Velcro® fasteners were identified as the
22 highest risk items. Mount and Pickering (2009) also found seeds adhering to uncovered socks, boots,
23 and laces. Some of the most aggressive introduced grasses on Guam, *Cenchrus echinatus*, *C. browneri*,
24 *Paspalum conjugatum*, and *Triumfetta semitriloba* (Space and Falanruw 1999; Motooka et al. 2003), are
25 thought to have spread throughout Guam and CNMI on military personnel' clothing during World War II
26 (Fosberg 1960).

4
5
6 Military training exercises, as well as popular outdoor activities like hiking and bicycling, facilitate pest
7 spread by bringing people into close contact with the natural environment. Military training exercises
8 are of special concern as they often cause movement of relatively large numbers of people over
9 extensive areas, involve frequent changes of location, and extend over relatively long time periods. In
10 addition, military exercises tend to create large areas of disturbed land, which may facilitate the
11 establishment of introduced species. Studies of disturbed military training sites have shown that exotic
12 plant species can rapidly colonize these areas (Lozon and MacIsaac 1997; Hirst et al. 2003; Leis et al.
13 2005; Yager et al. 2009). Space et al. (2000) list 69 species of invasive plants that are present on Guam
14 but not on Tinian. Tinian is the main site for planned military exercises, and propagules of these plants
15 could potentially be carried there by military personnel.

16 People often transport plant pests or plant materials deliberately, although usually without being aware
17 of the potential biological consequences of their actions. For example, seeds, plants, and flower bulbs
18 are frequently intercepted in airline passenger baggage (Liebhold et al. 2006; McCullough et al. 2006;
19 USDA-APHIS-PPQ 2010a). These items may themselves be pests (if they are invasive plants), or they may
20 be infested with pests. Table A3-1 lists quarantine pests intercepted from the baggage of commercial
21 airline passengers traveling to Hawai'i from Japan, South Korea, and the Philippines, among the main
22 origins of visitors to Guam and CNMI. Table A3-2 lists interceptions from the baggage of airline
23 passengers traveling to Hawai'i from within the Micronesia Region (USDA-APHIS-PPQ 2010a),
24 demonstrating the possibility of pest introductions to Hawai'i from Micronesia. Among the intercepted
25 pests were organisms that would almost certainly have severe negative impacts if introduced into the
26 Micronesia Region, such as certain ants and fruit flies. Agricultural materials have also been found in the
27 duffle bags of military personnel traveling to Guam (Jimenez et al. 2009).

People moving to new areas often bring plants with them to provide a sense of familiarity and home. Plants and other organisms may also be brought along to maintain a customary diet (McNeely 2001). In countries such as Japan and the Philippines, insects are commonly reared as pets (Kabuto 1997; Endo 1998) and may be very valuable. For example, four live giant rhinoceros beetles, *Trypoxylus dichotomus* (Coleoptera: Scarabaeidae) intercepted in Portland, Oregon, in passenger baggage from Japan (Figure A3-2) were valued at about U.S.\$2,500 each (Nelson 2010).

Figure A3-2: Live Giant Rhinoceros Beetles, *Trypoxylus dichotomus* (Coleoptera: Scarabaeidae) Intercepted in Portland, Oregon, in Passenger Baggage from Japan

Source: Customs and Border Protection

Personal effects that will be brought to Guam by the military and the civilian workforce may be contaminated with pests or pest-containing soil, especially items that have been stored or used outdoors, for example barbecue grills, outdoor furniture, bicycles, boats, cars, trailers, motorcycles, outdoor play sets, or yard decorations (USDA-APHIS 2007a). In addition, wooden objects such as outdoor furniture can harbor wood-boring pests (Mauldin 1984; Brown et al. 2004), which easily escape detection and cannot be removed by standard sanitation procedures, such as power washing.

Handicrafts such as baskets, floor mats, figurines, and hats, made from natural materials (e.g., coconut and Pandanus fibers or local woods) may be infested with pests. Wood-boring pests have been found in decorative wood carvings (Haugen and Lede 2001), and the red palm mite, *Raoiella indica* (Acari: Tenuipalpidae), was brought from the Dominican Republic to Florida on palm frond hats purchased by cruise ship passengers (Apgar 2007; Welbourn 2009). Hats are of particular concern because people may wear them during their travels and thus may spread plant pests between locations.

1 The proposed military relocation in Guam will move an estimated 11,000 permanent military personnel
2 along with 10,000 dependents to Guam by 2014 (U.S. Navy 2009h) . These people will arrive on Guam
3 with their baggage and household items, including outdoor equipment and vehicles (cars, motorbikes,
4 etc.). Up to 8,164 kg (18,000 pounds) of household items are allowed per person (DoD 2010b). The
5 associated potential for introducing pests is significant. Standard practice in military relocations is to
6 allow military personnel to complete their assignment in their current location, and then have their
7 replacement report to the new duty station (Fiedler 2010). This means there will not be a mass
8 movement of military personnel from Okinawa to Guam; rather, most military personnel to be stationed
9 on Guam will move there from the United States (including Hawai'i). Therefore, any pests brought along
10 in the baggage or personal effects of arriving military personnel will more likely originate in the United
11 States than in Japan or other foreign countries.

12 DoD currently relies on individual military personnel to clean and inspect their own clothing and
13 personal property in order to prevent the introduction of plant pests (U.S. Navy 2009j; DoD 2010f;
14 Houston 2010). While military personnel receive some information about the risks of moving plant pests
15 into Guam and around the Micronesia Region, this information may not be sufficient. For example,
16 military personnel do not generally receive training in pest detection, and thus may not know how to
17 search for pests, nor to recognize pests if found. A DoD guide for military personnel relocating to Guam
18 does not make any mention of plant pests (DoD 2010b). In addition, no oversight, compliance checks, or
19 quality control processes seem to exist to ensure that military personnel are following guidelines and
20 that procedures are effective in removing pests (Meissner et al. 2010).

21 GCQA inspects some portion of civilian and military passenger baggage for prohibited items, including
22 agricultural items; however, opening and searching every bag is not feasible, and functional x-ray
23 machines are not always available to screen passenger baggage (Meissner et al. 2010). In addition, as for
24 similar agencies elsewhere, drugs and weapons take priority over agricultural threats for GCQA.

25 **Expected impact of military relocation.** Apart from the additional military personnel stationed on
26 Guam, military exercises will lead to movement of military personnel within the Micronesia Region and a
27 temporary influx of foreign and U.S. Armed Forces for joint operations. Approximately 200 to 400
28 Marines are expected to train for 1 week at a time, 12 times per year on the island of Tinian (CNMI) (U.S.
29 Navy 2009g). In addition, the Japan Self Defense Forces plan to send 500 to 3,000 military personnel to
30 train on Guam, Tinian, and Pagan for 1 to 4 weeks, one to six times per year (U.S. Navy 2009c). While
31 USDA-APHIS has in the past set up cleaning operations on Tinian for military equipment returning to
32 Guam, no comparable phytosanitary efforts have been carried out for equipment moving from Guam to
33 Tinian or other locations within the Micronesia Region.

34 In addition to military personnel arriving on Guam, approximately 20,000 temporary workers are
35 expected to enter Guam for employment in construction (U.S. Navy 2009h), and approximately 17,000
36 workers will be hired for jobs in other fields such as healthcare (GMANews.TV 2009; U.S. Navy 2009h).
37 More than 20,000 dependents are expected to accompany these workers. The majority of the workers
38 will likely come from the Philippines, with smaller percentages coming from other Asian countries, from
39 elsewhere in the United States, and from within the Micronesia Region (U.S. Navy 2009h).

1 While these people are unlikely to bring large amounts of personal belongings, there are few safeguards
2 in place to ensure that what they do bring is free of pests. An overall elevated demand for specialty
3 ethnic items has the potential to increase the amount of plants and plant pests smuggled into the
4 Micronesia Region. Additionally, some of the temporary workers moving to Guam from within the
5 Micronesia Region may travel home regularly to visit family and friends, potentially facilitating the
6 spread of plant pests throughout the Micronesia Region. No processes are in place for educating
7 incoming workers about biosecurity and the potential impacts of introducing plant pests (Martinez
8 2010).

9 The effects the military relocation will have on tourism are unknown. Currently, Guam receives more
10 than a million tourists annually, mainly families and young couples from Japan. While the majority of the
11 temporary workforce on Guam would not be very likely to engage in tourist activities outside of Guam, a
12 small part of the workforce may travel around the Micronesia Region or visit Hawai'i on the way to the
13 U.S. mainland. In addition, military personnel stationed on Guam may be visited by friends and family
14 who would not otherwise travel to Micronesia. At the same time, it is possible that an increased military
15 presence on Guam may make Guam less attractive to its traditional visitors.

16 **A3.3.2 Pathway: Conveyances, Containers, and Equipment**

17 Many types of organisms can be inadvertently transported as contaminating pests on or in conveyances
18 (aircraft, maritime vessels, personal vehicles) and shipping containers, as well as on equipment and
19 machinery. Plant pests may get onto or into a conveyance, container, or piece of equipment either
20 accidentally (e.g., weed seeds blown in by the wind) or because they are attracted by certain conditions.
21 For example, flying insects may be attracted by lights during nighttime loading (Caton et al. 2006; Fowler
22 et al. 2008), and arthropods or mollusks may find shelter on or in cargo containers. In addition, pests
23 that were originally associated with an agricultural commodity may be left behind in a container or
24 conveyance after unloading. Conveyances and containers tend to be relatively unmitigated and
25 unregulated as pathways for plant pests, in part because they are notoriously difficult to inspect and to
26 clean. Guam is the major hub for cargo and passengers entering and leaving the Micronesia Region.
27 Most cargo arrives from the U.S. mainland and Hawai'i, China, Korea, and Japan.

28 **A3.3.2.1 Pests on Aircraft**

29 Live pests have been intercepted in aircraft cabins and cargo holds (Evans et al. 1963; Rainwater 1963;
30 Russell et al. 1984; Goh et al. 1985). Aircraft cargo holds may be cooled to accommodate perishable
31 cargo, such as fruits, vegetables, and live plants, but these temperatures are not lethal to most plant
32 pests. Russell (1987) reported very high survival rates of mosquitoes, *Culex quinquefasciatus* (Diptera:
33 Culicidae); house flies, *Musca domestica* (Diptera: Muscidae); and flour beetles, *Tribolium confusum*
34 (Coleoptera: Tenebrionidae) in unpressurized wheel bays of a Boeing 747B at altitudes greater than
35 10,500 meters. Caton (2003) reported an average of two flights daily arriving in Miami from Central and
36 South America with quarantine pests in their cargo holds, estimating that one pest species per year may
37 become established in Florida as a result of this pathway. A large proportion of the interceptions were
38 species attracted to light. Dobbs and Brodel (2004) estimated that pest contamination occurs in about
39 10% of cargo aircraft arriving at Miami International Airport (MIA), Florida; this percentage accounts for

1 live pests found in aircraft cockpits, galleys, compartments, and the surfaces of cargo. Between 2006
2 and 2009, U.S. Customs and Border Protection (CBP) officers intercepted almost 1,500 live insects from
3 82 taxonomic families from aircraft cargo stores, quarters, or holds, demonstrating the large variety of
4 pests that are associated with this pathway (USDA-APHIS-PPQ 2010a).

5 **A3.3.2.2 Pests on Maritime Vessels**

6 Ships are not usually inspected for pest organisms; thus, most pest organisms present on ships remain
7 undetected. Nevertheless, close to 1,000 live plant pests, mostly insects, were intercepted from ships at
8 U.S. ports of entry between 2006 and 2009 (USDA-APHIS-PPQ 2010a). We do not know how many ship
9 inspections were carried out during this time, nor how they were performed. In July of 2010, a ship
10 arriving in Guam from Korea with cargo supporting the military relocation was found to be infested with
11 thousands of exotic spiders belonging to at least two different species (University of Guam ANRP 2010).

12 While data regarding the prevalence of plant pests on maritime vessels are very limited, several
13 characteristics of maritime vessels make it likely that they play a role in spreading plant pests: maritime
14 vessels often move or anchor close to shore, allowing an exchange between ship and land of flying
15 insects and organisms blown in the wind; maritime vessels may be loaded with huge amounts of diverse
16 cargo, presenting ample opportunity for plant pests to enter or leave the ship; movement of crew and
17 passengers between vessel and land provides a pathway for pests; and, because of the immense size
18 and complex shape of maritime vessels, pests are very difficult or impossible to detect.

19 **A3.3.2.3 Pests on Shipping Containers**

20 Like conveyances, shipping containers may harbor plant pests. The type of shipping container used
21 depends on the mode of transportation. Standard 20- and 40-foot metal containers (Figure A3-3) are
22 used in maritime shipping and have a long documented history of carrying pests. Air cargo containers
23 can be specialized to fit a particular type of aircraft and are typically smaller (Figure A3-4); however,
24 some aircraft can accommodate standard 20- or 40-foot containers.

25 **Figure A3-3: Shipping Containers Stored at Maritime Ports in Kosrae (A, B) and in Palau (C)**

26
27 Containers stored on bare ground and weeds growing close by increase the chance of contamination
28 with plant pests.

1

Figure A3-4: Air Cargo Containers

2

3

4 In a survey of the exterior sides (not the top or bottom) of maritime containers arriving in New Zealand,
5 soil was the main external contaminant and was found on about 4% of loaded and 1% of empty
6 containers (Border Management Group 2003). Gadgil et al. (2000) also inspected the exterior of
7 maritime containers arriving in New Zealand. The amount of contaminating soil found was low (10 to 50
8 grams [0.3 to 2 ounces]) in 63%, medium (50 to 500 grams [2 to 18 ounces]) in 29%, and large (greater
9 than 500 grams [18 ounces]) in 8% of all contaminated containers. Fungi of taxa containing plant
10 pathogens were isolated from 83%, and nematodes were isolated from 81% of the soil samples. Foliage
11 and woody material were also common contaminants. Overall, quarantinable contaminants
12 (contaminants containing plant pests, plant parasitic nematodes, or fungi of genera that contain plant
13 pathogens) were found on 23% of the containers. Containers from the Pacific Islands had one of the
14 highest contamination rates (47.5%); containers from Korea, Taiwan, and Japan had a contamination
15 rate of 13.7%. The authors concluded that the nature and frequency of contaminants on shipping
16 containers represents a pest risk to New Zealand.

17 Contamination of the interior (soil, seeds, live arthropods, plant material) was found in approximately
18 21% of loaded and 18% of empty sea cargo containers; live insects were present in 15% of loaded and
19 7% of empty containers (Border Management Group 2003). In another study, plant pathogenic bacteria
20 were isolated from soil on sea cargo containers entering New Zealand (Godfrey and Marshall 2002).

21 In contrast to sea cargo containers, only about 1% of air cargo containers arriving in New Zealand were
22 contaminated on the outside. However, 24% of these containers had contaminants on the inside, mostly
23 fresh plant materials such as leaves and twigs. Potentially quarantinable organisms (live fungi belonging
24 to genera that include plant pathogens, or live insects) were found in 13% of the containers. The
25 detection of fresh plant material containing pests, coupled with the fact that newly introduced pests
26 have been found in close vicinity to airport sheds, led the authors to conclude that air cargo containers
27 may provide a pathway by which exotic organisms can become established (Gadgil et al. 2002).

28 Between 2006 and 2009, insects belonging to 14 families, mollusks belonging to three families, and
29 weeds belonging to two families were intercepted on or in cargo containers entering the United States.
30 The refrigeration units on temperature-controlled containers are frequently contaminated with weed

1 seeds. For example, seeds of cogongrass, *Imperata cylindrica* (Poaceae), an introduced invasive
2 throughout much of the Micronesia Region, have been intercepted on the refrigeration components of
3 containers entering the United States (CBP 2010a). Terrestrial mollusks are frequently intercepted on
4 civilian and military cargo containers worldwide (Cofrancesco Jr. et al. 2007) (Figure A3-5).

5 **Figure A3-5: Snails on a Maritime Container**

6 Source: David Robinson

7
8

9 The Argentine ant, *Linepithema humile* (Hymenoptera: Formicidae), was brought to Hawai'i on military
10 equipment (Krushelnycky 2009), and species of *Solenopsis* and *Linepithema* have been intercepted at
11 U.S. ports of entry on maritime vessels (USDA-APHIS-PPQ 2010a). These and other ant species are an
12 important concern to the Micronesia Region, as they quickly colonize new areas, causing significant
13 ecological, human health, and economic impacts (Sherley and Lowe 2000; PIAG 2004).

14 **A3.3.2.4 Pests on Equipment, Machinery, and Personal Vehicles**

15 Weed seeds, insects, mollusks, and soil frequently become attached to equipment and vehicles in the
16 course of military operations, and are difficult to remove (Moerkerk 2006). Between 2006 and 2009,
17 pests belonging to the insect families Cerambycidae, Cochlicellidae, Lymantriidae, Miridae,
18 Pentatomidae, and Scarabaeidae; the mollusk family Hygromiidae; and the plant families Poaceae and
19 Asteraceae were intercepted at U.S. ports of entry on equipment and vehicles. Cogongrass is believed to
20 have been introduced into the Micronesia Region on heavy equipment (Hawley et al. 2006), and the
21 Argentine ant, *Linepithema humile*, was introduced into Hawai'i with military equipment (ISSG 2010).
22 Vehicles and equipment imported into New Zealand were found to be contaminated with soil containing
23 viable plant pathogenic fungi and nematodes (Biosecurity New Zealand 2007); of used vehicles
24 inspected, almost half were found to be contaminated with soil, some of it containing intact plant
25 material. In another study, soil 132 kilograms (kg) (291 pounds) was removed from wheels, tracks, body
26 work, and attachments of four construction vehicles, and an estimated 40,000 seeds were found in that
27 soil, in addition to bacteria, fungi, and intact plants (Hughes et al. 2010). The spread of the plant
28 pathogen *Phytophthora lateralis* (Oomycetes: Pythiales) in Oregon has been linked to vehicular
29 movement, including equipment used in logging activities (Jules et al. 2002). Ecologically disturbed sites,

1 such as those caused by military and construction activities, tend to provide good establishment
2 opportunities for pests, and especially weeds (Hobbs and Huenneke 1992).

3 **A3.3.2.5** *Safeguards*

4 Per a compliance agreement with USDA, GCQA has the authority to inspect any incoming containers,
5 equipment, and conveyances for pests. However, some disagreement exists about naval ships, and it is
6 not clear whether GCQA officers (rather than only federal officers) will be permitted by the DoD to
7 conduct inspections (U.S. Navy 2009k). Regardless, thorough inspection for pests on containers and
8 conveyances very rarely occurs. This is due to the logistical difficulty and the time intensiveness of such
9 inspections and is consistent with the situation at most other U.S. ports of entry.

10 In addition, because of limited space at the maritime port in Guam, inspection of incoming sea cargo
11 does not take place at the port itself, but at various off-site locations (Meissner et al. 2010). It is unclear
12 if these off-site locations are sufficiently equipped to prevent the escape of pests (Jimenez et al. 2009). It
13 is also unknown what safeguards, if any, are in place to prevent the escape of pests during transit
14 between port and off-site locations. While Guam’s commercial air and maritime ports have sealed
15 surfaces, reducing the likelihood that containers become contaminated with soil and other pests, off-
16 site locations and other ports in the Region may not.

17 DoD protocols require equipment and machinery to be cleaned prior to entry (AFPMB 2008; DoD 2009b)
18 (Figure A3-6). DoD protocols also instruct Marines to clean their own personal vehicles and equipment
19 (such as bikes and lawnmowers) before moving them into Guam (DoD 2010b, c). However, DoD does
20 not seem to have a functioning quality control program in place on Hawai’i and Micronesia installations
21 to ensure compliance with and effectiveness of these protocols, and no records of pests or
22 contaminations detected are available (Meissner et al. 2010). It also appears there may be differences in
23 the interpretation and application of DoD guidelines, as pointed out in a study on the transfer of exotic
24 species on U.S. Armed Forces equipment from U.S. bases in foreign countries to the United States,
25 which found that not all military bases cleaned outgoing material and equipment or inspected and
26 cleaned incoming material and equipment (Cofrancesco Jr. et al. 2007)

6 **A3.3.2.6 *Expected Impact of Military Relocation.***

7 Given that the number of pest interceptions is positively correlated with traffic volumes (Liebhold et al.
8 2006), expected increases in the number of incoming airplanes, maritime vessels, cargo containers,
9 military and construction equipment, and personal vehicles and equipment will lead to more frequent
10 exotic pest introductions.

11 In 2009, close to 100,000 containers were processed at Guam's maritime port; during the peak year of
12 the military relocation, the number of arriving containers is expected to be twice that number (see Table
13 A2-14 and Table A2-16) (PB International 2008). If approximately one quarter of arriving sea cargo
14 containers are contaminated with pest organisms (based on Gadgil et al. 2000; Border Management
15 Group 2003), we estimate that between 2010 and 2025, one quarter of a million contaminated sea
16 cargo containers will arrive in Guam as a direct or indirect result of the military relocation (Table A3-3).
17 The proportion of containers accounted for by the military sector is expected to increase from currently
18 15% to 50% during the peak of the military relocation, and to remain at between 30% and 40% after the
19 relocation (PB International 2008). Data regarding container traffic at other maritime ports in the
20 Micronesia Region were unavailable.

21 The number of air cargo containers entering Guam's international airport will rise to accommodate the
22 projected annual 7% increase (in metric tons) of air cargo from 2008 to 2023 (Tagawa and Torres 2007).
23 While we do not know the exact numerical increases in airplanes, maritime vessels, equipment, and
24 vehicles entering Guam and the Micronesia Region as a result of the military relocation, there is little
25 doubt that the increases will be considerable.

1 **Table A3-3: Estimated Number of Sea Cargo Containers and of Sea Cargo Containers With**
 2 **Contamination (Pests, Pathogens, Soil, Weeds) entering Guam⁵**

Year	Containers	Contaminated Containers ^a	Contaminated containers by type			Contaminated containers due to military relocation ^c
			Transshipment ^b	DoD	Non-DoD	
2010	129,000	30,186	2,760	8,970	17,940	8,019
2011	149,000	34,866	2,530	13,340	18,400	12,699
2012	172,000	40,248	2,530	17,940	19,090	18,081
2013	178,000	41,652	2,530	18,630	19,780	19,485
2014	182,000	42,588	2,530	19,550	19,780	20,421
2015	190,000	44,460	2,530	20,470	20,700	22,293
2016	180,000	42,120	2,530	17,480	21,390	19,953
2017	152,000	35,568	2,530	10,580	21,850	13,401
2018	146,000	34,164	2,760	8,740	22,080	11,997
2019	148,000	34,632	2,760	8,740	98,000	12,465
2020	150,000	35,100	2,760	8,740	23,000	12,933
2021	151,000	35,334	2,760	8,740	23,230	13,167
2022	153,000	35,802	2,760	8,740	23,690	13,635
2023	155,000	36,270	2,760	8,740	24,150	14,103
2024	157,000	36,738	2,760	8,740	24,610	14,571
2025	158,000	36,972	2,760	8,740	24,840	14,805

3 ^a Estimated based on a 0.23 container contamination rate (Gadgil et al. 2000).

4 ^b Transshipped containers enter a country only to be loaded onto a different vessel and then shipped to a
 5 different country.

6 ^c Calculated by subtracting the number of containers in 2009 from the forecast number and multiplying by
 7 the contamination rate (0.23). The 2009 container traffic volume is assumed to represent what the
 8 traffic volume would have been in Guam if there was no military relocation; thus, increases in container
 9 traffic are assumed to be due to the military relocation and do not take into account regular growth in
 10 trade. Source: PB International 2008. Contaminated container values are based solely on historical
 11 contamination rates and do not consider change in inspection protocols, personnel, or technology.
 12

13 **A3.3.3 Pathway: Wood Packaging Material**

14 WPM such as pallets, crates, and dunnage is widely used for shipping a large variety of cargo, including
 15 military cargo. WPM is a known pathway for exotic species introductions (Pasek 2000; Allen and Humble
 16 2002). In addition to wood-boring pests found inside WPM, a broad range of plant pests are routinely
 17 detected as contaminants on WPM, including arthropods, nematodes, mollusks, weed seeds, and fungi
 18 (Gu et al. 2006; USDA-APHIS-PPQ 2010a).

19 WPM is a circulating product, routinely reused, reconditioned, and reimported (Bush et al. 1997); thus,
 20 the origin of WPM often differs from the origin of the commodity with which it is being moved. To
 21 reduce the pest risk associated with WPM worldwide, the International Plant Protection Convention
 22 (IPPC) developed the International Standards for Phytosanitary Measures (ISPM) No. 15, “Guidelines for
 23 Regulating Wood Packaging Material in International Trade” (IPPC 2009), which prescribes either

⁵ Ibid.

1 fumigation or heat treatment according to specific treatment schedules for all WPM entering a country.
2 Treated WPM must display a specified ISPM No. 15 stamp in a visible location to facilitate compliance
3 checks at ports of entry. There is no requirement to repeat the treatment each time the WPM is re-
4 used. The United States began enforcement of regulations in accordance with ISPM No. 15 on July 5,
5 2006 (USDA-APHIS-PPQ 2006). However, even though ISPM No. 15 stipulates that the wood used for the
6 WPM be debarked, U.S. regulations do not require debarking for WPM entering the United States
7 (USDA-APHIS 2007b).

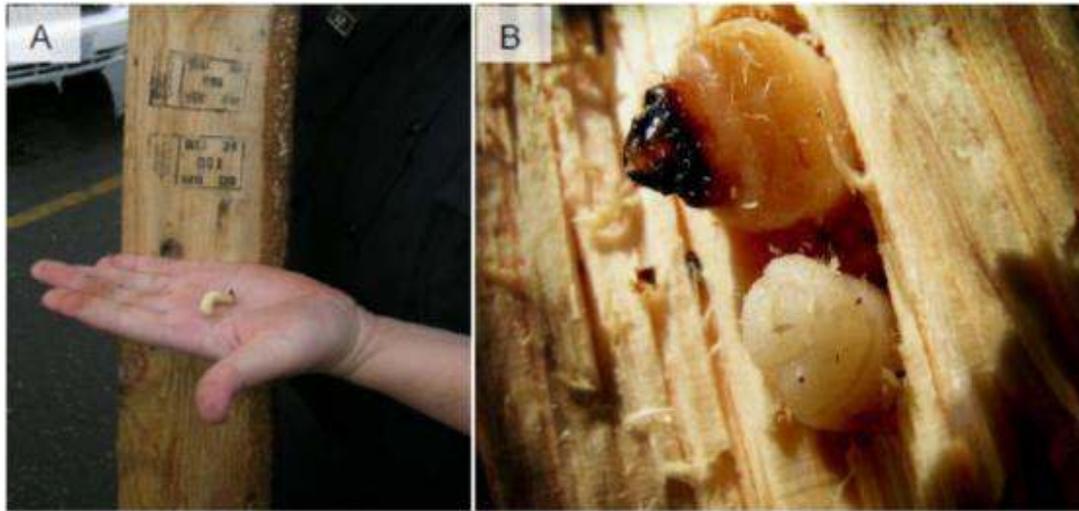

8 U.S. regulations apply to WPM imported from foreign origins into Guam, FSM, CNMI, and American
9 Samoa, in addition to the 50 U.S. States, Puerto Rico, and the U.S. Virgin Islands. However, movement of
10 WPM between the above-mentioned states and territories is considered domestic and is thus not
11 subject to these regulations (USDA-APHIS 2007b). Because the majority of cargo entering Guam is from
12 domestic locations (GovGuam 1995; 1999; 2000; 2002), this represents a potentially significant gap in
13 safeguarding. Palau and RMI are not following ISPM No. 15. In Palau, WPM is “subject to inspection and
14 treatment as prescribed, re-shipment or destruction at the expense of the importer or agent”; in
15 addition, packing materials that have been previously used for the transport of plant or animal materials
16 are not allowed to enter (Palau BAMR 1999). It is not known to what degree these regulations are
17 enforced or even can be enforced (ALSC 2010).

18 Beyond what is imposed by U.S. regulations, DoD stipulates that all new WPM under DoD contracts or
19 otherwise acquired by DoD must meet ISPM No. 15 requirements for shipments both inside and outside
20 of the United States (DSCC 2008). In addition, companies providing WPM to DoD are required to comply
21 with a quality control program administered by the American Lumber Standard Committee, Inc.,
22 through an agreement with APHIS (ALSC 2010). The purpose of this program is to ensure proper
23 treatment application and record keeping through audits and oversight.

24 While this is a laudable policy, DoD has large amounts of stores inside and outside of the United States
25 packaged on or in old WPM not compliant with ISPM No. 15. We do not know if this WPM will be moved
26 to Guam and other parts of the Micronesia Region; we also do not know if and how this WPM is
27 inspected by DoD. Regardless, a certain percentage of WPM—both military and commercial shipments—
28 will always bypass existing regulations and guidelines. While we do not know how large this percentage
29 is, random inspections carried out by USDA revealed that approximately 1% of the WPM accompanying
30 maritime shipments and approximately 5% of the WPM in air shipments arrived without the required
31 ISPM No.15 stamp (Meissner et al. 2009).

32 It is generally assumed that WPM marked with the ISPM No. 15 stamp is compliant with ISPM No. 15
33 requirements. However, treatments may be applied incorrectly or treatment stamps may be used
34 fraudulently. For example, in 2008, CBP found live wood borers in the ISPM No. 15-stamped WPM
35 accompanying 14 separate shipments from a single shipper and concluded that the shipper was using
36 the stamp fraudulently (CBP 2008) (Figure A3-7).

1 **Figure A3-7: ISPM No. 15-stamped WPM with live cerambycid larvae (A) and *Monochamus***
2 **sp. detected in dunnage (B)**

3
4 Source: Photo A courtesy of CBP. Photo B courtesy of M. Hitchcox

5 There is general agreement that non-compliant WPM carries a considerable pest risk. For example, in a
6 USDA pest risk assessment, Pasek (2000) rated 19 insects and fungi known to be associated with WPM
7 and assigned a high pest risk potential to 17 of them. A New Zealand Ministry of Agriculture and
8 Forestry review of sea containers prior to the implementation of ISPM No.15 found that of 5,000
9 containers with WPM, about 30% contained WPM infested with pests (Border Management Group
10 2003). Before China implemented regulations according to ISPM No. 15, a survey focusing on
11 nematodes, conducted between 2000 and 2005, found that batches of WPM imported into China from
12 Japan, the United States, Korea, and the European Union exhibited infestation with various species of
13 nematodes of 21, 17, 24, and 17%, respectively; 6% of batches were infested with species of
14 *Bursaphelenchus* (Nematoda: Aphelenchoididae)—serious plant pests known for their longevity in dead
15 wood (Gu et al. 2006). Finally, Allen and Humble (2002) examined dunnage entering Canada from
16 Norway and recovered over 2,500 adult insects representing more than 40 species of bark beetles,
17 wood borers and their associated parasitoids, predators and scavengers, blue-stain fungi, and
18 nematodes from 29 log bolts. These studies underscore the significant pest risk associated with non-
19 compliant WPM that may enter Guam.

20 In addition to the pest risk presented by non-compliant WPM, live pests are also found on a regular
21 basis on WPM bearing the ISPM No. 15 stamp. Subsequent to implementing ISPM No.15, the Australian
22 Quarantine and Inspection Service sampled close to 20,000 pieces of WPM and found about 0.5%
23 infested with live, wood-boring insects and 0.5% had fungi and/or mold (Biosecurity Australia 2006). A
24 survey carried out at several U.S. ports of entry concluded that 0.1% of all WPM marked with the ISPM
25 No.15 stamp was infested with live wood-boring insects (Haack 2006). Apart from the possibility of
26 incorrectly applied treatments and fraudulent use of the seal, pests may be present in the WPM because
27 the prescribed treatments are not completely effective against all pests (Qi et al. 2005), especially plant
28 pathogens, and because WPM may be re-infested by pests after treatment (ALSC 2009; Haack and
29 Petrice 2009).

1 Pest interception records from routine port-of-entry inspections are not statistically rigorous enough to
2 be used for quantifying pest risk, but they can provide qualitative information on the types of pests
3 found on WPM. Pests intercepted on WPM at U.S. ports of entry between July 5, 2006 (date of full
4 enforcement of ISPM No.15) and February 26, 2010, include a large variety of taxa. More than 2,200
5 specimens were collected in about 1,000 interceptions. The majority of the interceptions were insects,
6 most frequently cerambycid and curculionid woodborers. Many other taxa were also found. Overall, 80
7 families of insects from seven different orders, seven families of mollusks, seeds of 27 plant families, as
8 well as mites, spiders, and a scorpion were intercepted (USDA-APHIS-PPQ 2010a); most of the
9 intercepted specimens were not identified to the family level. The pest taxa intercepted no doubt
10 represent a subset of the taxa actually present in the WPM. Some groups of organisms may be
11 overlooked because of their small size and lack of extraction and identification methods. For example,
12 no nematodes or fungi were intercepted, but these pests are likely to be present on WPM, as shown by
13 Braasch, Gu et al. (2007) and Biosecurity Australia (2006). Similarly, no plant pathogenic bacteria or
14 viruses have been reported from WPM, but it is possible that these types of organisms would also be
15 present.

16 It is important to note that not all species present on WPM truly infest the wood. Many are
17 contaminating pests, which means that they are on the WPM but have no biological association with it.
18 For example, mollusks may seek shelter in WPM, weed seeds may get stuck on WPM, pests may fall
19 from agricultural commodities transported on WPM, and nematodes and soil-borne pathogens may be
20 present in soil on WPM. Outdoor storage of WPM, a common practice at many shipyards and
21 warehouses, facilitates pest infestation, especially if the WPM is stored in direct contact with the soil, if
22 weeds are growing close by, and if nighttime lighting attracts flying insects to the site. Contaminating
23 pests can settle on WPM after treatment and thus may not be affected by ISPM No. 15 measures.

24 Almost any pest species may potentially be present on WPM, and WPM may originate from or may have
25 been in almost any country. To identify species that may present a threat to the Micronesia Region, we
26 compiled a list of species that have been found associated with WPM, are absent from all or some parts
27 of Micronesia, have a distribution range that includes tropical areas, and have host plants that occur in
28 the Micronesia Region. The list is based on the assumption that WPM origin cannot be determined with
29 certainty; thus it encompasses a pest universe of worldwide origin. This list contains numerous species
30 from a variety of taxonomic groups, including wood-boring beetles, ants, fungi, nematodes, and
31 mollusks.

32 While a discussion of the introduction and impact potential for each of these species is beyond the
33 scope of this report, there is little doubt that many of these species, if introduced, could cause severe
34 damage to the native fauna and flora and/or agricultural production of the Micronesia Region. In
35 particular, the introduction of certain ants is extremely worrisome because of their severe ecological
36 and human health impacts (PIAG 2004); similarly, the introduction of terrestrial mollusks, usually
37 generalist feeders, is likely to have very undesirable consequences for agriculture and biodiversity
38 (Cowie 2000); damage caused by wood-boring beetles in many parts of the world is well known; and
39 nematodes and fungi, although knowledge about their biology is very limited, are doubtlessly of
40 concern.

1 As previously stated, some amount of non-compliant WPM will enter Guam, and even compliant WPM
2 presents a pest risk. We found that port-of-entry inspection is the only means by which WPM may
3 currently be monitored, although in actuality WPM seems to be rarely inspected in Guam and the rest of
4 the Micronesia Region due to workload and logistical challenges. When inspection of WPM occurs, it is
5 often limited to a verification of the ISPM No.15 stamp rather than a thorough search for pests. This
6 seems to be true for both military and non-military shipments. If ports of entry in the Micronesia Region
7 are currently understaffed, this situation is only expected to worsen during the military relocation.

8 While port-of-entry inspection is a potentially important safeguarding measure, it is not reliable as a sole
9 measure for preventing pest entry. For a thorough inspection, cargo must be removed from a pallet or
10 crate and repackaged, presenting a considerable logistical challenge. Even thorough inspection will miss
11 many of the pests that are present. Wood-boring pests are usually hidden inside the wood and are very
12 difficult to find. For some pests, such as nematodes and fungi, special extraction methods and
13 identification expertise are needed, and port inspectors are not always sufficiently trained for the
14 detection of wood-boring pests.

15 We know neither the quantity of WPM currently entering Guam and the Micronesia Region nor the
16 quantity that will enter during the military relocation. No precise information on the amount of WPM
17 moved in trade exists, and little information is available to make any estimates.

18 Expected impact of military relocation. The military relocation will lead to a considerable population
19 increase on Guam (see Table A-12). As a result, more consumer goods and construction materials will be
20 imported, often on or in WPM. In addition, the increased workload for inspection personnel during and
21 after the military relocation may place further strain on the safeguarding system. As a result, the
22 frequency of pest introduction through the WPM pathway is likely to increase. However, we do not
23 expect a fundamental change in the types of pests introduced; rather, we expect that the same types of
24 pests will enter Guam more frequently and may thus establish sooner than they would have otherwise.
25 WPM presents a considerable pest risk and strong measures should be taken to protect the Micronesia
26 Region against pests introduced through this pathway.

27 **A3.3.4 Pathway: Construction Materials and Equipment**

28 Construction projects have been implicated in the introduction of exotic species. For example, the
29 introduction of snails into French Polynesia was linked to the construction of a hydro-electric station;
30 and road construction in the Marquesa Islands and water tank construction in the Austral Islands have
31 purportedly led to the introduction of exotic plants to these island groups (Shine et al. 2003). On Guam,
32 the coconut rhinoceros beetle, *Oryctes rhinoceros* (Coleoptera: Scarabaeidae), a devastating pest of
33 coconut palms, is thought to have been introduced on construction material from Asia (Smith and
34 Moore 2008). Seeds of cogongrass, *Imperata cylindrica*, and the giant African snail, *Achatina fulica*
35 (Gastropoda: Achatinidae), both highly invasive species in the Micronesia Region, are known to spread
36 via the movement of construction equipment (Hawley et al. 2006).

37 Apart from construction materials and equipment being a pathway for pest introduction, construction
38 activities create disturbed environments, where the establishment of exotic pests may be more likely

1 (Mulugeta and Stoltenberg 1997). For example, the highly invasive Argentine ant (*Linepithema humile*),
2 a species with potentially devastating consequences to the Micronesia Region, preferentially invades
3 disturbed sites (Mulugeta and Stoltenberg 1997, Kennedy 1998)

4 We do not have precise information on the types and amounts of construction material currently
5 entering Guam or expected to enter Guam in the future. The projected peak housing demand of
6 between 3,500 and 10,000 homes (PB International 2008, U.S. Navy 2009j) cannot be met by the
7 currently available housing on Guam. In addition, a number of utility and training facilities will be built
8 (CMTF 2007), and much of the existing infrastructure (roads, landfills, municipal and port buildings) will
9 be expanded. Significant construction is also planned at Apra Harbor (CMTF 2007). Construction at
10 Andersen AFB alone is estimated to require between 60 and 70 loads of steel weighing approximately
11 22,680 kg (50,000 pounds) per load (PB International 2008). Very few construction materials are
12 available locally on Guam. In spite of plans to reuse soil, rocks, and other materials (U.S. Navy 2009j), the
13 majority of the necessary construction materials such as timber, gravel, sand, steel, tile, granite, cement,
14 and concrete will need to be imported. Construction equipment will also be imported in large quantities.
15 Overall, it is clear that construction material and equipment imports will increase significantly as a result
16 of the relocation and then level off after construction is complete.

17 The majority of construction materials will come from the U.S. mainland (Berthoud 2009), with
18 significant portions also originating in Asian countries (PB International 2008), mainly in China and Japan
19 (Berthoud 2009). Wood has also been imported from Palau in the past (GovGuam 1995), and some
20 materials are being imported from the Philippines and Indonesia (Jimenez et al. 2009). Blocks of cement
21 and concrete currently come from FSM (Berthoud 2009). We do not know whether materials will be
22 imported from any additional countries during the military relocation.

23 Timber pests. A large variety of plant pests are associated with timber. From 2003 to 2009, 106 different
24 species were found in 194 interceptions on wood entering the United States from Asia, including
25 41 families of insects (including wood-boring beetles and ants), 6 families of weeds, 4 families of mites,
26 and 3 families of mollusks (USDA-APHIS-PPQ 2010a). Timber from U.S. locations has been found to
27 harbor pests as well, including the little fire ant, *Wasmannia auropunctata* (Hymenoptera: Formicidae)
28 (Hawley et al. 2006, Berthoud 2009). The little fire ant is currently found on Hawai'i and in other parts of
29 the United States, from where it may be introduced on timber (Hawley et al. 2006). It has demonstrated
30 an ability to establish on Pacific Islands, and is known to occur in New Caledonia, Vanuatu, Tuvalu, and
31 the Cook Islands (Wetterer 2009). Like other fire ants, the little fire ant causes painful stings and harms
32 native biodiversity (ISSG 2010).

33 Certain safeguarding measures are in place to minimize the spread of pests on timber (Table A3-4).
34 Unpeeled saw logs are prohibited from entering Guam, and peeled saw logs and lumber must be
35 inspected and found to be free of termites and wood-boring insects (GDOA 1997). Foreign timber is
36 required to have an import permit detailing the required treatment, which is fumigation (USDA-APHIS
37 2007c). As with any commodity, GDOA has the authority to quarantine, inspect, fumigate, disinfect,
38 destroy, or exclude timber infested with pests (GDOA 1997).

1 **Table A3-4: Regulations Pertaining to Construction Materials and Equipment Entering**
 2 **Guam**

Material	Treatment Requirements
Timber	Peeled saw logs (no bark material) and lumber from domestic locations are permitted to enter Guam after inspection and verification of freedom from termites and wood-boring insects (GDOA 1997); unpeeled saw logs from domestic locations are prohibited from entering Guam. Timber from foreign locations requires fumigation and an import permit, or must be debarked, heat treated or kiln-dried, permanently marked, and kept separate from other shipments (USDA APHIS 2007c). May be refused entry or subject to order to undergo phytosanitary treatment if found to be contaminated upon port-of-entry inspection (7 CFR § 330).
Tile/granite	May be refused entry or subject to order to undergo phytosanitary treatment if found to be contaminated upon port-of-entry inspection (7 CFR § 330).
Cement/concrete	May be refused entry or subject to order to undergo phytosanitary treatment if found to be contaminated upon port-of-entry inspection (7 CFR § 330).
Sand/gravel	GovGuam requires sand and gravel to be sterilized by approved methods (GEPA 1991, 2009); successful sterilization is verified through testing by the Guam Environmental Protection Agency prior to entry (GEPA 2009). May be refused entry or subject to order to undergo phytosanitary treatment if found to be contaminated upon port-of-entry inspection (7 CFR § 330).
Steel	May be refused entry or subject to order to undergo phytosanitary treatment if found to be contaminated upon port-of-entry inspection (7 CFR § 330).
Construction equipment	The DoD has specific guidelines for the inspection and washing of military equipment and removal of soil and hitchhiker pests (AFPMB 2008). Non-military construction equipment is not generally subject to any cleaning requirements; however, washing or other phytosanitary measures may be required or entry may be refused if construction material is found to be contaminated upon port-of-entry inspection (7 CFR § 330).

3
 4 However, these measures may not be sufficient to mitigate the pest risk posed by timber imports. A risk
 5 assessment determined that similar mitigation measures in New Zealand were not sufficient to prevent
 6 pest introduction (Ormsby 2003). Inspection of wood is often complicated by the size of timber products
 7 and by the fact that wood-boring pests are usually hidden inside the wood. Prescribed quarantine
 8 treatments are not completely effective against all pests, and timber may be recolonized after effective
 9 treatment. For these reasons, and because of the large diversity of pests that may be associated with
 10 timber, there is a significant risk of pest introduction to Guam through this pathway.

11 **A3.3.4.1 Contaminating Pests**

12 Contaminating pests are those that do not have a biological association with the material they are
 13 transported on. For example, a snail does not feed or otherwise depend on steel tubes, but may still be
 14 transported on them. Most construction materials have the potential to transport pests as
 15 contaminants. For example, a recent shipment of insulation and housing beams entering Guam from
 16 South Korea was found to be infested with thousands of spiders belonging to at least two different
 17 species (University of Guam ANRP 2010). From 2003 to 2009, U.S. port-of-entry inspectors intercepted
 18 355 species on some 1,300 shipments of tile and granite from Asia. These interceptions comprised 96
 19 families of insects, 25 families of weeds, 8 families of mollusks, 7 families of mites, and 1 family of plant

1 pathogens (USDA-APHIS-PPQ 2010a). Among the interceptions was the highly invasive cogongrass,
2 *Imperata cylindrica*, (USDA-APHIS-PPQ 2010a), which has become widespread on Guam, and is under
3 eradication in Palau and Yap (LaRosa 2010). While we have no interception records for cement or
4 concrete blocks, they presumably have the same types of contaminating pests associated with them as
5 tiles or granite.

6 Sand and gravel are also known to harbor pests. For example, seeds of the Siam weed, *Chromolaena*
7 *odorata* (*Asteraceae*), which is currently found in CNMI, Guam, Palau, and Yap, have been detected in
8 sand and gravel used in road construction, and can survive for long periods in this medium (Hawley et al.
9 2006). Over 130 different plant pest species were found in 394 interceptions on quarry products from
10 Asia at U.S. ports from 2003 to 2009 (USDA-APHIS-PPQ 2010a). Similarly, 55 different species were
11 found in 79 interceptions on steel and steel bars at U.S. ports of entry from 2003 to 2009, including 19
12 families of insects, 6 families of weeds, 2 families of mollusks, and 1 plant pathogen family (USDA-APHIS-
13 PPQ 2010a).

14 Construction equipment and machinery are also well-known carriers of contaminating pests (AFPMB
15 2008); several exotic species in the Micronesia Region have been introduced as contaminants on
16 construction equipment (Hawley et al. 2006). Of 271 interceptions from Asia on general equipment,
17 machinery, and vehicles at U.S. ports of entry from 2003 to 2009, there were 49 families of insects, 13
18 families of weeds, 6 families of mollusks, 3 families of plant pathogens, and 1 family of nematodes
19 (USDA-APHIS-PPQ 2010a). Weed contamination is of particular concern on construction equipment; a
20 recent Australian study found that 25% of the machinery evaluated (including tractors, graders, and
21 other equipment used for local land management) was contaminated with weed seeds (Moerkerk
22 2006).

23 No USDA regulations specifically address sand or gravel. GovGuam does have quarantine measures in
24 place for timber, sand and gravel, and construction equipment (see Table A3-4); federal regulations give
25 GCQA the authority to require phytosanitary treatment (including washing) of construction materials
26 found to be contaminated with pests or soil through port-of-entry inspection. However, it is unclear how
27 efficacious these measures are at preventing pest entry and how consistently they are applied.

28 **A3.3.4.2 Expected Impact of Military Relocation**

29 The planned military relocation on Guam will lead to a significant increase in construction activity, and
30 thus to an increase in construction material and equipment imports. These imports will increase
31 dramatically during the relocation phase and then level off after most construction is complete.
32 Imported materials will comprise a large diversity of items, many of which are likely to be contaminated
33 with plant pests. Inspection of these items is difficult and existing safeguards are not sufficient to
34 prevent pest introduction. There is little doubt that this pathway will present a significant plant pest risk
35 for the duration of the relocation phase. After the relocation, the pest risk is expected to be slightly
36 higher than its current level.

1 **A3.3.5 Pathway: Plant propagative material**

2 Propagative material used for landscaping on Guam is mainly imported from the United States
3 (GovGuam 2002, McConnell 2010). Other countries of origin include Thailand, Taiwan, Philippines, Costa
4 Rica, Ecuador, and Puerto Rico (Campbell 2010d). In addition to importing, Guam also exports plants to
5 CNMI and FSM, providing a mechanism for pest spread from Guam to other parts of the Micronesia
6 Region (GovGuam 2010).

7 **A3.3.5.1 Pathway for Plant Pests**

8 Movement of plant propagative material (whole plants, buds, bulbs, tubers, or seeds) is a primary
9 means by which plant pests invade new areas (Palm and Rossman 2003, Brasier 2008). Propagative
10 materials are usually planted in areas conducive to their growth, greatly facilitating their establishment
11 and that of any associated pests. A large variety of pests are intercepted on propagative materials
12 arriving at U.S. ports of entry (USDA-APHIS-PPQ 2010a). For example, from March 2009 to March 2010,
13 over 16,000 pest specimens were found in some 5,600 interceptions, including insects (86 families),
14 mollusks (16 families), mites (5 families), weeds (13 families), as well as viruses, fungi, bacteria, and
15 nematodes. Mites, plant pathogens, and nematodes only accounted for 23% of interceptions. However,
16 this is almost certainly not due to a low prevalence of these pests on propagative materials; rather, it is
17 likely due to the difficulty of detecting these types of pests. This is supported by a study of Childers and
18 Rodrigues (2005), who washed propagative plant materials in ethanol, and found 81 mites from 11
19 families on only 12 shipments of propagative materials arriving at Miami International Airport. By
20 comparison, routine port-of-entry inspections at the same airport detected only one species of mite in
21 over 40,000 propagative material shipments. Similarly, plant pathogens are often not detected, because
22 the infected plant material may not express noticeable symptoms and appropriate diagnostic tools do
23 not exist or are not feasible or affordable for plant quarantine purposes (Schaad et al. 2003).

24 Damaging arthropods have been or may be introduced into the Micronesia Region via the propagative
25 materials pathway. The Asian cycad scale, *Aulacaspis yasumatsui* (Homoptera: Diaspididae), was first
26 introduced into Florida through the importation of cycad plants by a botanical garden; from Florida it
27 was introduced into Hawai'i and from there into Guam through the plant trade (Moore et al. 2005). The
28 scale attacks *Cycas micronesica* (Cycadaceae), a plant endemic on Guam and the Micronesia Region.
29 Since the scale's introduction, populations of *C. micronesica* have declined to the point where the
30 situation has been described as an environmental disaster akin to that caused by the brown treesnake
31 (University of Guam 2007). Another exotic insect pest, the coconut rhinoceros beetle, *Oryctes rhinoceros*
32 (Coleoptera: Scarabaeidae), is devastating betelnut, coconut, and ornamental palms on Guam (Smith
33 and Moore 2008). While this pest was likely introduced on construction materials from Asia, movement
34 of live host plants may further spread it throughout the Micronesia Region (Smith and Moore 2008);
35 improper disposal of infested plants may also spread this pest to new locations on Guam. Movement of
36 propagative material has contributed to the dramatic spread of the red palm mite, *Raoiella indica* (Acari:
37 Tenuipalpidae), into and throughout the Caribbean region, where it attacks numerous palm species
38 (Welbourn 2009). The red palm mite is not known to occur in the Micronesia Region and could have a
39 significant impact if introduced.

1 Movement of propagative material is also linked to the spread of numerous plant pathogens, such as
2 the banana bunchy top virus (Thomas et al. 1994) and the causal agent of the citrus disease
3 Huanglongbing (Wang 2009). Finally, Cowie et al. (2008) identified the importance of the horticultural
4 trade pathway in facilitating the spread of mollusks, listing 29 non-native species of terrestrial snails and
5 slugs found during a survey of nurseries in Hawai'i. Terrestrial mollusks can damage nursery crops,
6 displace native species, and vector human and animal diseases (Cowie 2001, Cowie et al. 2009). The
7 polyphagous mollusk *Succinea tenella* (Succineidae), invasive in Hawai'i (Cowie et al. 2008), has been
8 intercepted multiple times on orchid plants at Guam ports of entry (USDA-APHIS-PPQ 2010a).

9 **A3.3.5.2 Plant Propagative Material as Invasive Species**

10 Plant propagative material may become invasive when introduced into a new location. Certain
11 characteristics that are desirable in landscape plants, such as rapid growth, high reproductive capacity,
12 and the ability to withstand a range of environmental conditions (Peters et al. 2006), also predispose
13 plants to being invasive (SPREP 2000; Richardson et al. 2004). Invasive plants can have devastating
14 effects on ecosystems by displacing native species (ISSG 2010), altering the frequency and intensity of
15 fires (Brooks et al. 2004), changing the erosion properties of soil (SPREP 2000), and clogging waterways
16 (Opande et al. 2004; FLDEP 2009; ISSG 2010), among other impacts.

17 There are many examples of plants that have become invasive after being deliberately introduced into
18 an area; in fact, most invasive exotic plant species were probably intentionally introduced. Waugh
19 (2008) reports that of the 191 invasive plants examined in the insular Caribbean, 66% were introduced
20 deliberately through the horticulture pathway; and Frank and McCoy (1995) state that approximately
21 one quarter of Florida's flora comprises non-indigenous species, almost all of them introduced
22 deliberately.

23 *Lantana camara* (Verbenaceae) was deliberately introduced into the Micronesia Region for use as an
24 ornamental plant. However, it is poisonous to livestock (McGinty and Machen 1993) and is now
25 considered a damaging invasive species (ISSG 2010). Similarly, *Miconia calvescens* (Melastomataceae)
26 was introduced into Hawai'i as an ornamental tree; because of its aggressive growth and interference
27 with watershed functions, this species is now listed as a noxious weed (Loope 1997).

28 **A3.3.5.3 Potting Media**

29 Demand for potting media, sometimes referred to as potting soil, is directly related to landscaping
30 activity. Movement of potting media, whether intentional or unintentional, is a well-known pathway for
31 a wide variety of potentially dangerous organisms.

32 In New Zealand, 25 species of exotic weeds were found in imports of coco peat, widely used as a
33 growing medium in the nursery and horticulture industries (Biosecurity New Zealand 2009b). Live
34 arthropods and weeds have been found in potting media sold at a Garden Center in Guam (Moore 2010)
35 (Figure A3-8). Similarly, Cloyd and Zaborski (2004) found a total of 1,245 arthropods in 23 of 96 bags of
36 potting media from wholesale distributors in the United States. Cartwright et al. (1995) reported that
37 commercial potting media were the source of *Pythium* infecting tobacco seedlings. Commercially

1 packaged potting media can also harbor organisms harmful to humans (Steele et al. 1990; Casati et al.
2 2009; Norcini et al. 2010).

8 **A3.3.5.4 Safeguards**

9 All plant propagative material imported into Guam, including transshipments to the CNMI, Palau, and
10 FSM, is inspected at the Plant Inspection Station operated by GDOA (Campbell 2010d).

11 Plants imported for planting must be free of soil. In addition, plants entering Guam from Hawai'i must
12 be treated with hot water drench or citric acid solution prior to shipment (mainly to prevent the
13 introduction of coqui frogs), and must be inspected for pests of concern to Guam (GDOA 2004). While
14 this regulation may help reduce the plant pest risk posed by propagative material from Hawai'i, the
15 costs associated with the required treatment have caused a shift towards imports from Florida and the
16 Caribbean (Campbell 2010d); no treatment requirements are currently in place for plants from these
17 locations.

18 Both federal and GovGuam regulations prohibit the entry of certain types of plant propagative material
19 from certain locations to prevent the introduction of specific pests of concern. For example, the
20 importation of citrus, coconut, banana, taro, and sweet potato planting material is highly restricted; the
21 same is true for certain plants from areas infested with the European corn borer, *Ostrinia nubilalis*
22 (Lepidoptera: Pyralidae) (GDOA 1997). While these regulations provide some protection against the
23 introduction of pests, the number of regulated pests pales in comparison to all pest species potentially
24 associated with propagative materials entering Guam. The invasiveness potential of the propagative
25 material itself is not considered in any of the existing regulations.

26 DoD drafted a landscape plan for Guam that includes a list of recommended plant species for military
27 lands (NAVFAC 2010). It is not clear whether compliance with this plan is mandatory and, if so, how
28 compliance will be enforced. The majority of species recommended in this landscape plan are native or

1 non-invasive and commonly used in landscapes in Guam. However, the plan also contains some species
 2 that are invasive in parts of the Micronesia Region (Table A3-5). For example, *Pseuderanthemum*
 3 *reticulatum* (Acanthaceae) is invasive in Palau, and Space et al. (2003) discourage further planting.
 4 Another species, *Cynodon dactylon* (Poaceae), is considered one of the most aggressive grasses that has
 5 been introduced into the Micronesia Region (Space and Falanruw 1999). In addition, the landscape plan
 6 lists at least 11 species that are potentially invasive. For example, *Duranta repens* (Verbenaceae) is
 7 believed to have a high potential for invasiveness in the Micronesia Region because it has established
 8 beyond its natural range in other locations (PIER 2010).

9 **Table A3-5: Plants Recommended in the DoD Landscape Plan That Are Invasive in the**
 10 **Micronesia Region or Information Is Insufficient to Determine Invasive Potential**

Scientific name	Comments on invasiveness
<i>Duranta repens</i> (syn. <i>Duranta erecta</i>)	High risk of becoming invasive (PIER 2010)
<i>Hedychium coronarium</i>	High risk of becoming invasive (PIER 2010); Space et al. (1999) suggest monitoring <i>Hedychium</i> sp. for invasive behavior; invasive or potentially invasive in Palau (Space et al. 2009)
<i>Heliconia psittacorum</i>	High risk for becoming invasive (PIER 2010)
<i>Paspalum vaginatum</i>	High risk of becoming invasive (PIER 2010)
<i>Pennisetum clandestinum</i>	High risk of becoming invasive (PIER 2010)
<i>Thevetia peruviana</i>	High risk of becoming invasive (PIER 2010); species of concern in Palau (Space et al. 2009)
<i>Alpinia purpurata</i>	Evaluation of invasiveness recommended (PIER 2010)
<i>Chrysalidocarpus lutescens</i> (syn. <i>Dyopsis lutescens</i>)	Evaluation of invasiveness recommended (PIER 2010)
<i>Clusia rosea</i>	Evaluation of invasiveness recommended (PIER 2010)
<i>Cynodon dactylon</i>	Weedy in Micronesia (Space and Falanruw 1999); Evaluation of invasiveness recommended (PIER 2010)
<i>Livistona chinensis</i>	Evaluation of invasiveness recommended (Space et al. 2009, PIER 2010)
<i>Chlorophytum bichetti</i>	Potential invasiveness unknown
<i>Cordyline fruticosa</i>	Potential invasiveness unknown
<i>Philodendron selloum</i>	Potential invasiveness unknown
<i>Pseuderanthemum reticulatum</i> (syn. <i>Pseuderanthemum carruthersii</i>)	Invasive in Palau; further planting is discouraged (Space et al. 2003)

11
 12 In addition to regulated commerce, smuggled propagative material presents a potentially serious risk. Of
 13 particular concern are live plants sent through the mail or carried in passenger baggage. Various military
 14 guidelines for relocating personnel do not mention restrictions concerning plants and plant products. A
 15 DoD website for personnel assigned to foreign duty stations explicitly states that there are “No
 16 restrictions identified” for plant movement into Guam (DoD 2010d).

17 **A3.3.5.5 Expected Impact of Military Relocation**

18 The demand for plant propagative material, particularly plants for landscaping, will likely increase during
 19 the military relocation due to landscaping needs around newly constructed civilian and military housing,
 20 hotels, and commercial businesses. Apart from plantings on DoD lands, garden centers may increase

1 their supply of ornamental plants to meet demands from a larger consumer base (including
 2 homeowners, hotels, and commercial businesses). Depending on consumer demand, garden centers
 3 may also increase their supply of novel ornamentals, including plants that have not been tested in
 4 Guam’s landscapes and that could become invasive. Increased sales of commercial potting soil may also
 5 introduce and facilitate spread of pests from the U.S. mainland on Guam (Berringer 2010a). Increases in
 6 plant propagative imports will place additional strain on existing safeguarding staff and infrastructure,
 7 limiting their ability to prevent pests from entering the Micronesia Region.

8 **A3.3.6 Pathway: Mail**

9 Mail is a known pathway for the movement of exotic organisms. Almost two decades ago, a report of
 10 the U.S. Congress specifically identified mail as a source of invasive species (OTA 1993) and pointed out
 11 concerns about the potential spread of nematodes, mites, diseases, and parasites in shipments of bee
 12 and bumble bee colonies.

13 Larvae of the Mediterranean fruit fly, *Ceratitis capitata*, the melon fly, *Bactrocera cucurbitae*, the
 14 Oriental fruit fly, *B. dorsalis*, and the Malaysian fruit fly, *B. latifrons* (Diptera: Tephritidae), among other
 15 quarantine pests were found during an examination of first-class USPS and United Parcel Service
 16 packages arriving in California in 1990 to 1991 (McDowell and Krass 1992). Prohibited materials seized in
 17 public and private mail entering the United States include seeds, fresh fruits and vegetables, propagative
 18 plant parts, nuts, live insects, and soil (USDA-APHIS-SITC 2005; 2006; 2007; DHS CBP and USDA-APHIS-
 19 SITC 2008; USDA-APHIS-SITC 2009b; c). Indeed, the relatively low cost of mailing and lax enforcement of
 20 the regulations make the mail an attractive way of moving plant products, legally or otherwise.

21 Specific information about the significance of the mail pathway in Guam and the Micronesia Region is
 22 scarce, but interceptions from mail packages sent from the Micronesia Region to Hawai’i demonstrate
 23 the possibility of pests making their way from the Micronesia Region to Hawai’i via the mail pathway
 24 (Table A3-6). Pests of betelnut, *Areca catechu*, may be of special concern, because betelnuts seem to be
 25 sent frequently in the mail.

26 **Table A3-6: Pest Insects Intercepted From Packages Mailed From the Micronesia Region**
 27 **Destined to Hawai’i between 2003 and 2008**

Country of origin	Inspected host	Pest
Guam	<i>Mangifera indica</i> (fruit)	<i>Sternochetus</i> sp. (Curculionidae)
Guam	Unknown seeds	Curculionidae, species of
Guam	<i>Areca</i> sp. (fruit)	<i>Chrysomphalus aonidum</i> (Diaspididae)
RMI	<i>Areca catechu</i> (seeds)	Pseudococcidae, species of
FSM	<i>Psidium</i> sp. (fruit)	<i>Bactrocera</i> sp. (Tephritidae)
FSM	<i>Citrus</i> sp. (fruit)	<i>Lepidosaphes beckii</i> (Diaspididae)
FSM	<i>Citrus</i> sp. (fruit)	Tarsonemidae, species of
FSM	<i>Areca catechu</i> (fruit)	Pseudococcidae, species of
FSM	<i>Areca catechu</i> (fruit)	Diaspididae, species of

1 A rise in e-commerce has caused an increase in the number of packages sent through the mail
 2 worldwide (Hafner 2006). While e-commerce is currently less utilized in the Micronesia Region than in
 3 other parts of the world, technological advancement and an influx of a large number of people from the
 4 United States, many of whom are accustomed to online shopping, may lead to increased e-commerce
 5 activity over time. Internet retailers and online auction sites are easily accessible sources of plants and
 6 other live organisms (Kay and Hoyle 2001; Derraik and Phillips 2010). Organisms sold online are often
 7 not identified to the species level or are misidentified (Walters et al. 2006; Keller and Lodge 2007), and
 8 consumers tend to be unaware of the phytosanitary risks and regulations associated with mail-order
 9 organisms.

10 In spite of steps taken by some Internet auction sites to curb the sale of invasive plants and plant pests
 11 (eBay 2009), such items, ordered online, are seized in the United States on a regular basis (Table A3-7)
 12 (USDA-APHIS-SITC 2009a, d). Seeds are the most common type of intercepted material, demonstrating
 13 the potential for exotic plant species to be mailed into the Micronesia Region from anywhere in the
 14 world; seeds and other types of mailed propagative material also pose the threat of introducing plant
 15 pests and diseases. It is worth noting that many of the plants listed in Table A3-7 are already established
 16 throughout much of Micronesia and the State of Hawai'i and most likely available from local sources (at
 17 least some varieties).

3 Mail service to Guam and the Micronesia Region is provided by the USPS and several private shipping
4 companies. Military mail is handled by the Military Postal Service Agency. The Military Postal Service
5 Agency is the single DoD point of contact with the USPS and is required to adhere to USPS rules, federal
6 laws, and various international laws and agreements for movement of military mail. The Military Postal
7 Service Agency uses USPS mail handling and distribution networks where they exist (MPSA 2010).

8 Guam's Main Post Office, located in Barrigada, is the Micronesia Region's mail service hub, serving as a
9 processing facility and staging area for civilian and military mail entering the Region (Ericksen 2010). In
10 addition to delivering mail to people on Guam, this facility processes domestic and international mail for
11 CNMI, RMI, Palau, and FSM (Murphy 1983; Jimenez et al. 2009). Mail inspection also takes place at this
12 facility. Thus, this facility's capacity directly affects the entire Region's biosecurity.

13 The Military Postal Service Agency educates military personnel about items that are prohibited in mailed
14 packages, and the Guam Post Office displays educational posters describing prohibited mail items
15 (Ericksen 2010).

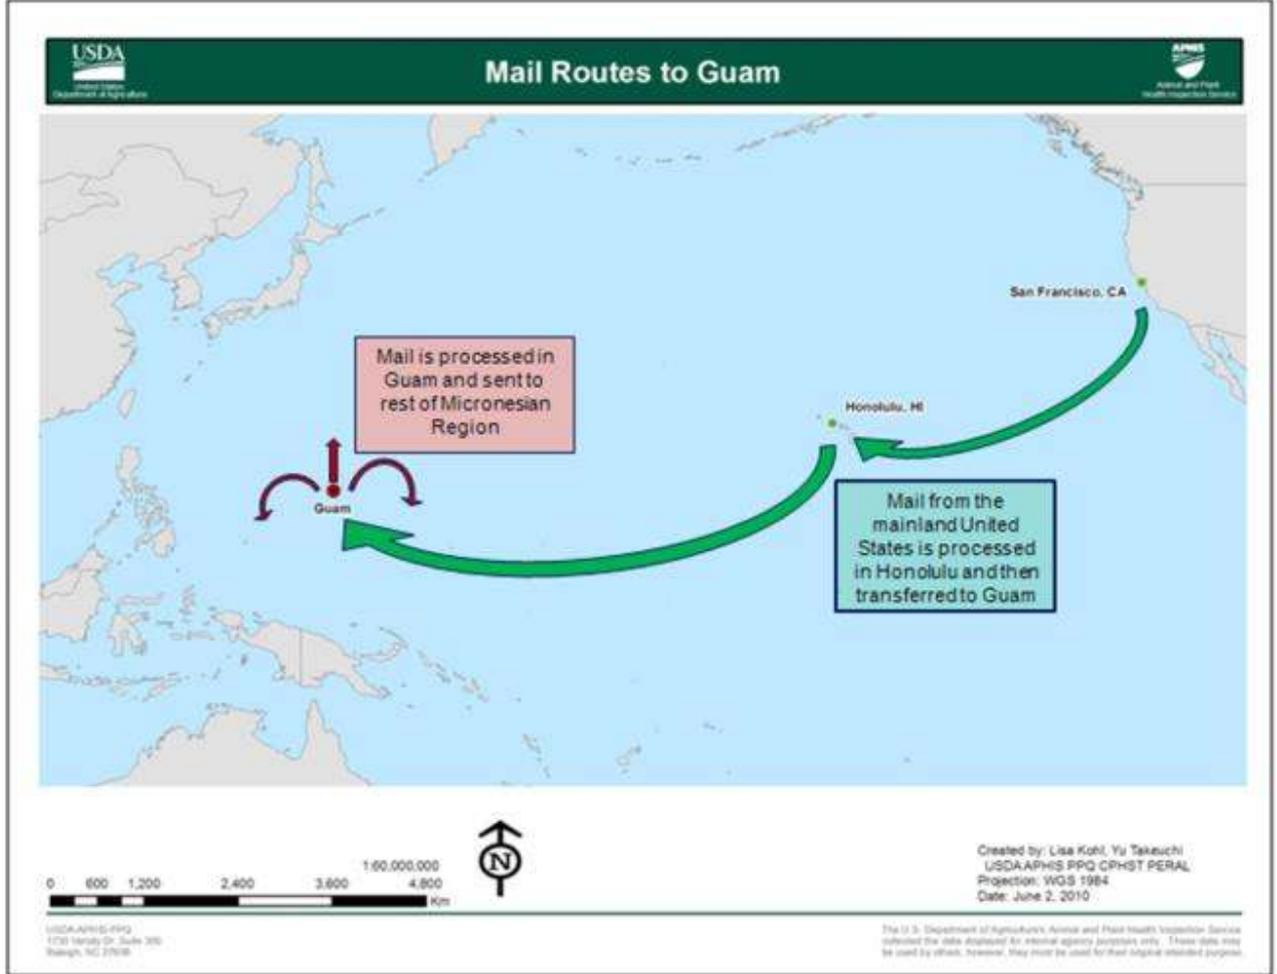

16 Mail sent between the United States, Guam, CNMI, RMI, Palau, and FSM through the USPS is considered
17 U.S. domestic mail (USPS 2009), which means that standard domestic rates apply. This makes the USPS a
18 relatively inexpensive shipping option (USPS 2010b) compared to private shipping companies, which
19 charge international rates on packages sent between the United States and areas in the Micronesia
20 Region (FedEx 2010; UPS 2010). Thus, most packages sent to the Micronesia Region from the United
21 States are sent through the USPS rather than private companies (Ericksen 2010).

1 First-class mail sent via the USPS has legal protection under the Fourth Amendment to the Constitution
2 of the United States, making it illegal to delay such mail or to open it without either a search warrant or
3 permission from the addressee (DoD 2002; USPS 2007). These protections apply also in Guam, the
4 CNMI, RMI, Palau, and FSM. However, of these locations, Guam is the only one where inspection of mail
5 takes place. In order to obtain a search warrant for inspecting first-class mail, the Postal Inspector must
6 establish probable cause. For this purpose, screening of the mail by detector dogs would be useful;
7 however, detector dogs are not being used in the Guam postal facility (Meissner et al. 2010). The actual
8 opening and inspection of the mail is carried out by GCQA officers, but a Postal Inspector must be
9 present at the time of inspection. Because the postal facility cannot legally slow down the flow of
10 domestic mail (39 CFR Title 39), the number of packages that can be inspected with the available
11 workforce is very limited.

12 In contrast to USPS first-class mail, parcels shipped through private mail are considered cargo and are
13 regulated and inspected as such. GCQA has the authority to inspect these packages, and no search
14 warrant is needed. Privately shipped mail (with the exception of diplomatic parcels) may be x-rayed by
15 GCQA (Shimizu 2010a).

16 All mail originating in the United States and most international packages destined for the Micronesia
17 Region are processed in Honolulu, Hawai'i, before being sent to Guam (Figure A3-9). The postal facility
18 of Honolulu has a compliance agreement in place that facilitates inspection of first-class USPS domestic
19 packages. However, it is unclear to what degree mail destined for Guam is actually inspected in
20 Honolulu. While Guam postal officials seem to rely on Hawai'i Department of Agriculture inspectors to
21 inspect this mail (Ericksen 2010; Shimizu 2010a), postal officials in Hawai'i seem to believe that GCQA is
22 carrying out these inspections (Gonzalez 2010). The Hawai'i Department of Agriculture recently
23 experienced a drastic decrease in agricultural inspectors due to budget cuts (Advertiser Staff 2009),
24 creating a general workforce shortage which also affects postal inspections.

1 **Figure A3-9: Route for Packages Sent from the U.S. Mainland to the Micronesia Region**

2
3 Source: Murphy 1983; Ericksen 2010

4
5 Approximately 1.5 million packages currently arrive in Guam; of these, some 100,000-150,000 packages
6 arrive from international locations, mainly Japan and the Philippines (Ericksen 2010). The remainder
7 arrives from domestic locations (Ericksen 2010). The USPS does not keep records of mail volumes for
8 anywhere else in the Micronesia Region (USPS 2010a).

9 In addition to mail arriving from outside the Region, plant pests may also be mailed from Guam to areas
10 within the Micronesia Region. Outgoing packages are not inspected on Guam, and other locations in the
11 Region do not seem to inspect incoming mail (Ericksen 2010).

12 Expected impact of the military relocation. The military relocation is expected to increase mail volumes
13 to Guam. An estimated additional 900,000 packages annually may be delivered to military personnel
14 alone (Ericksen 2010). While we have no data to determine the percentage of packages entering Guam
15 that contain plant quarantine materials, a value of 1% previously calculated based on randomly sampled
16 international mail entering the United States (Meissner et al. 2009) serves as a reasonable estimate.

1 Based on this estimate, an additional 10,000 packages containing plant quarantine material may arrive
2 annually in military mail. In addition, packages mailed to the large expected temporary workforce from
3 Southeast Asia also present a risk.

4 **A3.3.7 Pathway: Agricultural Commodity Imports**

5 Most of the agricultural commodities consumed on Guam are imported, and most of these imports
6 come from the United States. In 2002, the United States supplied 92% (based on weight) of Guam's
7 agricultural imports, and 14 other trading partners provided the remaining 8% (Table A3-8). Some 160
8 types of agricultural commodities were imported from the United States, while Korea provided 90 types,
9 and FSM provided 11 types.

10 **Table A3-8: Percentage of Agricultural Commodity Imports to Guam by**
11 **Country of Origin in 2002**

Country of origin	Percentage of imports ^a
United States	92
Korea	3
FSM	2
New Zealand	1
All other countries ^b	<1

13 ^a Fresh agricultural commodity imports exclude animal-based products.

14 ^b All other countries: Australia, China, CNMI, Japan, Malaysia, Netherlands,
15 Philippines, Singapore, Taiwan, Thailand, and Palau.
16

17 USDA regulations regarding the importation of fresh fruits and vegetables into the United States
18 (including Guam and CNMI) are detailed in 7 CFR (7 CFR § 319; 7 CFR § 318). For any fresh fruits and
19 vegetables from foreign countries, USDA requires pest risk assessments detailing the likelihood and
20 potential consequences of exotic plant pest introduction before permitting importation into the United
21 States. Guam is almost never explicitly considered in these pest risk assessments; however, all fruits and
22 vegetables approved for entry into any part of the United States are also permitted to enter Guam,
23 unless they are specifically designated as not approved (which is rare). This leaves Guam vulnerable to
24 pest introductions from foreign countries. In addition, commodities prohibited from entering Guam may
25 be imported into the continental United States and sent from there to Guam as domestic shipments.

26 Domestic shipments from Hawai'i are governed by GovGuam regulations and 7 CFR § 318 federal
27 regulations. GovGuam restricts the entry of certain agricultural commodities from domestic locations
28 (GDOA 1997); e.g., hosts of the European corn borer from infested U.S. States and hosts of the oriental
29 fruit fly, *Bactrocera dorsalis* (Diptera: Tephritidae), from infested areas in Hawai'i are prohibited.
30 However, the majority of commodities from the United States are allowed to enter Guam without any
31 phytosanitary restrictions, but subject to inspection.

32 In 2009, GDOA intercepted pests in agricultural shipments from the mainland United States (Campbell
33 2010c), including mites, aphids, thrips, beetles, flies, Hemiptera, Homoptera, Lepidoptera, fungi, and
34 mollusks. Since most of the pests were not identified to the genus level, we were unable to determine

1 their quarantine status. A wider variety of pests not known to occur or of limited distribution in the
 2 Micronesia Region have been found in agricultural shipments entering Hawai'i from the mainland
 3 United States, further demonstrating the potential of introducing pests from the mainland United States
 4 into the Micronesia Region (Table A3-9) (HDOA 2007).

1
2

3 Expected impact of the military relocation. The military relocation will lead to a considerable population
4 increase on Guam. As a result, larger amounts of agricultural commodities will be imported. The
5 increased workload for inspection personnel during and after the military relocation may place further
6 strain on the safeguarding system. As a result, the frequency of pest introduction through the
7 agricultural commodity pathway is likely to increase. However, we do not expect a fundamental change
8 in the types of pests introduced; rather, we expect that the same types of pests will enter Guam more
9 frequently and may thus establish sooner than they would have otherwise. In addition to legal imports,
10 increased smuggling of agricultural commodities into Guam may occur, especially via mail or in
11 passenger baggage.

12 **A3.3.8 Pathway: Regulated Garbage**

13 Garbage is defined as waste derived from fruits, vegetables, meats, or other plant or animal material.
14 This may include unconsumed meals, food scraps, table refuse, galley refuse, food wrappers or
15 packaging materials, and other waste material from stores, food preparation areas, passengers' or
16 crews' quarters, or dining rooms in ships or airplanes. Garbage is regulated if it is on or removed from
17 any conveyance that has been in any port outside the United States and Canada in the past 2 years (9
18 CFR § 94; 7 CFR § 330.400).

19 Regulated garbage may not be disposed of or removed from a conveyance except in accordance with
20 federal Regulations. All regulated garbage must be contained in tight, covered, leak-proof receptacles
21 during storage on board the conveyance while in the territorial waters, or while otherwise within the
22 legal jurisdiction of the United States. If unloaded, regulated garbage must be moved under the
23 direction of an inspector to an approved facility for incineration, sterilization, or grinding into an
24 approved sewage system. Any person engaged in the handling or disposing of regulated garbage must
25 first enter into a compliance agreement with APHIS (9 CFR § 94; 7 CFR § 330.400). The offloading of
26 regulated garbage from all foreign countries except Canada into the United States is prohibited. Hawai'i,
27 Puerto Rico, American Samoa, CNMI, FSM, Guam, the U.S. Virgin Islands, RMI, and Palau fall under the
28 domestic quarantine notices restricting the offloading of regulated garbage into other States or
29 territories.

30 Expected impact of the military relocation. If the above regulations are followed, regulated garbage
31 poses little to no phytosanitary risk to Guam and the Micronesia Region; thus, changes in this pathway
32 resulting from the military relocation are not likely to negatively affect the Micronesia Region.

1 **A3.3.9 Overview of Pathways and Associated Safeguarding Challenges**

Pathway	Significance of pathway	Safeguarding challenges
People	People may introduce plant pests intentionally or accidentally. Outdoor activities facilitate pest spread. More people will travel to and around the Region.	<ol style="list-style-type: none"> 1. Lack of education about phytosanitary risks and prevention measures 2. Inadequate agricultural inspection staffing and equipment 3. Insufficient agricultural training and focus (inspectors) 4. Smuggling
Personal effects of military personnel	May be contaminated with pests, especially if it has been used or stored outdoors (bicycles, barbecue grills, outdoor furniture, etc.)	<ol style="list-style-type: none"> 1. Lack of education about phytosanitary risks and prevention measures 2. Insufficient agricultural training and focus (military personnel conducting inspections) 3. Smuggling 4. Lack of compliance checks and quality assurance program
Shipping containers	External and internal contamination is common. Transported to multiple ports. Storage practices leading to recontamination. Loading practices may attract pests.	<ol style="list-style-type: none"> 1. Insufficient equipment, space, and resources for agricultural inspection 2. Inspection of containers is rare 3. Cleaning is difficult and often not feasible
Wood packaging material	Wood-boring pests, contaminating pests, and soil contamination are common. Routinely reused and recycled. Inspection is difficult and rarely occurs.	<ol style="list-style-type: none"> 1. Domestic WPM not subject to U.S. phytosanitary regulations 2. Inadequate agricultural inspection staffing and equipment 3. Recontamination due to outdoor storage
Construction materials: wood	Wood-boring pests and contaminating pests are common. Storage practices can lead to recontamination. Contact with disturbed sites facilitates pest establishment.	<ol style="list-style-type: none"> 1. Phytosanitary treatment not required for some types of timber
Construction materials: concrete, sand, steel, etc.	Frequently contaminated with pests and soil. Storage practices can lead to recontamination. Inspection is difficult and rarely occurs. Movement to disturbed sites facilitates establishment.	<ol style="list-style-type: none"> 1. Enforcement of existing regulations is lax 2. Insufficient inspection of incoming materials 3. Lack of phytosanitary procedures at construction sites

Pathway	Significance of pathway	Safeguarding challenges
Construction and other equipment	External and internal contamination with pests and soil very common. Contact with disturbed sites facilitates pest establishment.	<ol style="list-style-type: none"> 1. Enforcement of existing regulations is lax 2. Insufficient inspection of incoming equipment 3. Lack of phytosanitary procedures at construction sites
Soil contamination	Soil that contains plant pests can adhere to containers, machinery, personal effects, agricultural commodities, shoes, and construction equipment. Numerous pests can be found and can survive for a long time in contaminating soil.	<ol style="list-style-type: none"> 1. Insufficient resources for agricultural inspection staff 2. Lack of education about phytosanitary risks and prevention measures 3. Soil-cleaning procedures not in place for equipment moving from Guam to CNMI
Aircraft	Often visit multiple ports in short timeframe. Loading practices can attract pests.	<ol style="list-style-type: none"> 1. Inadequate agricultural inspection staffing and equipment 2. Pest entry and contamination during loading/storage of aircraft 3. Inspection very difficult due to large size of aircraft
Maritime vessels	Often visit multiple ports in short timeframe. Loading practices can attract pests.	<ol style="list-style-type: none"> 1. GCQA officers not allowed to board/inspect military vessels 2. Inadequate agricultural inspection staffing and equipment 3. Inspection is very difficult due to large size of ships
Propagative material	Plant material may become invasive itself or may be infested with pests. Increased landscaping needs of military and civilian population will likely increase imports of propagative materials. Landscaping activities may also facilitate further spread of already established exotic pests.	<ol style="list-style-type: none"> 1. Inadequate agricultural inspection staffing and equipment 2. No weed risk assessment is required for plant importation 3. No code of conduct for nurseries, landscaping businesses, or other entities to promote responsible phytosanitary practices 4. Lack of education about phytosanitary risks and prevention measures 5. Smuggling 6. Very few phytosanitary requirements in place for domestic imports

Pathway	Significance of pathway	Safeguarding challenges
Mail	Plant pests are frequently transported through the mail, both intentionally and accidentally. Internet sales facilitate the movement of pests in the mail. Domestic mail volumes will increase as population of Guam increases.	<ol style="list-style-type: none"> 1. Majority of domestic mail is not inspected 2. Lack of education about risks of sending agricultural materials in the mail 3. No existing mail inspection system in some parts of the Micronesia Region 4. Inadequate agricultural inspection staffing and equipment 5. Smuggling 6. Federal regulations hinder the inspection of domestic mail
Potting media	Direct contact with landscapes facilitates spread of pests.	<ol style="list-style-type: none"> 1. Enforcement of existing regulations (sterilization)
Agricultural commodities	Most of the fruits and vegetable consumed on Guam are imported; most of these imports are domestic imports from the continental United States. May be contaminated with a multitude of pests. Agricultural commodity imports will increase as the population of Guam increases.	<ol style="list-style-type: none"> 1. No phytosanitary requirements for most domestic imports.
Regulated garbage	Contamination with pests possible. Not a big phytosanitary concern if existing regulations are followed.	<ol style="list-style-type: none"> 1. Enforcement of existing regulations

1

2 **A3.3.10 Safeguarding Challenges–General Observations**

3 Based on our risk assessment, we identified a number of overarching safeguarding challenges that
4 pertain to all of the pathways discussed. Most of these challenges are not specific to Guam, but exist to
5 some degree in any location where safeguarding activities take place.

6 **A3.3.10.1 Regulations, Guidelines, and Standard Operating Procedures**

7 Within the federal regulatory framework, Guam (and CNMI) are often considered part of the United
8 States and fall under APHIS domestic quarantines (7 CFR § 318) as well as foreign quarantine regulations
9 (7 CFR § 319). For example, commodity imports into Guam are subject to the federal risk assessment
10 process; mail sent to Guam from the United States is considered domestic mail; and the movement of
11 WPM between Guam and any part of the United States is considered domestic movement. This
12 approach does not take into account Guam’s special geographic, biological, and political reality and
13 leaves Guam vulnerable to exotic pest introductions. While Guam has the authority to protect itself
14 through its own regulations, this is neither economically nor political feasible.

15 In addition, regulations do not always sufficiently address existing pest threats, in part because the
16 regulations are out of date, and in part because they are not based on an accurate assessment of pest

1 risk. Moreover, regulations usually do not provide specific guidance on safeguarding actions. For
2 example, regulations give GCQA and APHIS the authority to carry out inspections, but do not specify
3 what exactly an inspection entails or how it should be conducted. Such details must be provided by
4 separate guidelines or standard operating procedures (SOPs); however, guidelines or SOPs do not
5 always exist where they are needed. In addition, the language of some guidelines or SOPs is vague
6 enough to allow for a broad interpretation.

7 **A3.3.10.2** *Phytosanitary Inspection*

8 Inspection presents an immense challenge in a number of different ways. First, the number of incoming
9 items and the time required for their inspection do not permit thorough inspection of all incoming
10 items. Second, inspection is hindered by logistical challenges, such as the necessity to unload cargo
11 containers for thorough inspection and the lack of the necessary space and equipment for inspection.
12 Third, the detection of plant pests is inherently difficult, as these pests tend to be minute, hidden, or
13 both. Plant pathogens are practically impossible to detect if the infected plant material is asymptomatic,
14 which is frequently the case. Also, inaccurate or imprecise information provided on import manifests
15 sometimes makes it difficult for inspectors to identify shipments that contain materials of plant
16 quarantine significance. Given these shortcomings, a majority of incoming plant pests routinely escape
17 detection, and phytosanitary inspection tends to be overrated as a safeguarding tool.

18 **A3.3.10.3** *Collaboration*

19 As in other locations, various entities work together to safeguard Guam against the introduction of
20 exotic plant pests. GCQA and USDA-APHIS-PPQ collaborate not only with each other, but also with port
21 management, the USPS, various other agencies, and industry on the island. Safeguarding success
22 depends on productive and efficient collaboration, and there is considerable opportunity for improving
23 existing working relationships. Especially regarding the mail pathway, an effort towards improved
24 collaborations seems to be advisable.

25 **A3.3.10.4** *Education*

26 Education on several levels is an important component of any safeguarding system: safeguarding
27 personnel must receive the necessary training to be effective at their job (e.g., training in pest detection
28 and pest identification); military personnel must receive adequate training on the potential impact of
29 exotic plant pests and on ways to prevent their introduction and spread; similarly, the general public
30 must be made aware of the exotic species problem and of opportunities to support safeguarding efforts.

31 **A3.3.10.5** *Data*

32 Reliable data is necessary for assessing pest risk, evaluating the efficacy of safeguarding programs,
33 weighing costs and benefits of safeguarding actions, and allocating resources. Lack of reliable data is a
34 common problem in the United States; however, in Guam and the Micronesia Region this problem is
35 much more pronounced. Pest interception data are not consistently recorded; especially on the side of
36 the DoD, no pest interception records seem to exist. Import data often do not distinguish Guam from
37 the mainland United States, and reliable import data don't exist for the other Micronesian Region
38 countries. There is little information on the number of conveyances and containers processed at the

1 ports of entry, and data on mail volumes are lacking. The number and type of inspections performed is
2 generally unknown.

3 **A3.4 RECOMMENDATIONS**

4 **A3.4.1 Staffing and Infrastructure**

- 5 • Ensure sufficient staffing (e.g., plant safeguarding specialists, identifiers, surveyors) to
6 accomplish all necessary inspection and quarantine activities in the Micronesia Region.
7 Already insufficient staffing levels will become further strained as a consequence of the
8 military relocation as the workload at airports, maritime ports, the mail facility, and the
9 Plant Inspection Station increases. Quarantine officers with plant health expertise should be
10 on duty to clear cargo and conveyances whenever aircraft or maritime vessels arrive.
11 Quarantine officers must be adequately trained in all aspects of their work and should
12 receive periodic refresher training.
- 13 • Ensure availability of necessary equipment. Equipment necessary for effective safeguarding,
14 such as hand lenses, microscopes, and computers, must be available to quarantine officers.
15 X-ray machines or other appropriate scanning technology and cleaning equipment such as
16 power washers must be provided where needed. A sufficient number of lifts must be
17 available for sea cargo container inspections. All equipment must be maintained in working
18 order over the long term. APHIS manuals provide detailed guidance on necessary
19 equipment.
- 20 • Establish decontamination sites for cleaning military and other equipment. Such sites must
21 be available at all locations where military training exercises will take place and at the ports
22 of entry. Sites should contain a quarantine area for storing contaminated equipment prior to
23 cleaning. Precautions must be taken to prevent contaminated water to run off into the soil.
24 Ensure that wash systems used are effective (see Balbach et al. 2008, Flemming 2008).
- 25 • Deploy detector dogs and handlers a) to mail facility for efficient screening of mail for plant
26 pests and to establish probable cause for inspection of domestic mail, and b) to airports for
27 screening baggage for plant pests.

28 **A3.4.2 Point-of-entry Activities (Cleaning, Inspection, Treatment)**

- 29 • Conduct phytosanitary inspection of all arriving conveyances, military and non-military, for
30 contaminating plant pests. Inspection must include a thorough search for contaminating
31 pests on the exterior and the interior of the conveyance. In the case of military vessels,
32 either PPQ safeguarding specialists must be made available to inspect military vessels, or
33 GCQA officers must be allowed to inspect military vessels instead of PPQ safeguarding
34 specialists.
- 35 • Conduct phytosanitary inspection of WPM. An adequate percentage of all domestic and
36 foreign, military and non-military, WPM accompanying agricultural and non-agricultural
37 cargo must be thoroughly inspected for pests. The help of a statistician should be enlisted to
38 determine adequate sample size and inspection protocol. SOPs should be developed to

- 1 ensure consistent inspection methods. All inspections and pest interceptions should be
2 carefully documented. Pest interceptions should also be recorded in the relevant APHIS
3 database to be available for analysis that may contribute to safeguarding improvements and
4 quality control.
- 5 • Conduct phytosanitary inspection of all incoming construction materials for contaminating
6 pests, including materials that have been previously treated or cleaned (due to high chance
7 of recontamination after treatment) and including construction material from the United
8 States.
 - 9 • Clean and disinfect containers and conveyances that arrive in the Micronesia Region
10 contaminated with soil or exotic plant pests. Follow all current APHIS policies and guidelines.
11 Evaluate the effectiveness of current cleaning methods and improve effectiveness as
12 appropriate.
 - 13 • Properly clean all equipment (construction and military) according to APHIS guidelines prior
14 to entry into any part of the Micronesia Region to remove hitchhiker pests and soil
15 contaminations. Equipment must also be cleaned before moving within the Micronesia
16 Region (between countries, between islands of the same country, and, where appropriate,
17 between areas of the same island).
 - 18 • Establish an effective mail inspection system on Guam. Follow a similar model as Hawai'i to
19 use detector dogs for establishing probable cause for inspection of first-class USPS packages.
20 Use appropriate scanning technology for all other incoming mail. For mail arriving via
21 Hawai'i, either ensure adequate level of inspection in Hawai'i or else carry out inspection in
22 Guam. Establish effective working relationships to ensure that safeguarding personnel can
23 carry out their responsibilities. Safeguarding personnel must have sufficient access to the
24 postal facility.
 - 25 • Treat storage areas with molluscicides or install mollusk barriers to prevent mollusks from
26 infesting WPM and shipping containers. Remove weeds and other contaminants from
27 container and WPM storage areas. Storage areas should be hard surface or gravel.

28 **A3.4.3 Regulations, Guidelines, and Compliance**

- 29 • Strengthen existing regulations and guidelines for all jurisdictions and consider options for
30 improving pre-border activities that may assist in reducing risks.
- 31 • Require mandatory training of all construction and contracting companies used by both DoD
32 and public sector developers hired by the Military.
- 33 • Systematically review all guidelines and SOPs of phytosanitary relevance. Ensure that they
34 are clear, complete, and detailed. Develop guidelines or SOPs where they are lacking.
- 35 • Enforce full compliance with all applicable existing federal, GovGuam, and military
36 regulations, guidelines, and SOPs. Issue adequate fines for violations.

- 1 • Require treatment of all WPM according to ISPM No. 15. All domestic and foreign, military
2 and non-military, WPM entering the Micronesia Region should be required to be compliant
3 with ISPM No. 15. Even though these treatments do not fully mitigate pest risk, they help
4 reduce the presence of pests, especially wood-boring pests.
- 5 • Require phytosanitary treatment of all imported timber, including timber from domestic
6 locations in order to mitigate the risk of pest entry on this pathway. Required treatments
7 should have been scientifically shown to be effective in removing pests.
- 8 • Require weed risk assessment for the importation of exotic plant species. Prohibit the
9 importation of all plant species exotic to and not yet naturalized on Guam unless they have
10 been deemed unlikely to become invasive by a weed risk assessment. Exceptions may be
11 made for plants that have been historically imported without becoming invasive.
- 12 • Develop best management practices for contractors and construction sites. Work with
13 industry and gain their support in helping to prevent the introduction and spread of exotic
14 plant pests. Implement “clean” practices at construction sites to minimize land disturbance
15 and spread of plant pests.
- 16 • Adopt a voluntary code of conduct for nurseries, landscaping companies, hotels, and other
17 businesses as appropriate to promote the sale and use of native and non-invasive plants.
18 This code of conduct should stipulate that the businesses:
 - 19 o ensure that their staff is knowledgeable on the subject of invasive plants
 - 20 o help educate their customers about invasive plants
 - 21 o immediately report any potentially exotic pest organisms found on their premises
 - 22 o use native plants or non-invasive plants locally sourced
- 23 • Revise the DoD landscape plan by removing plant species that are or have the potential to
24 be invasive in the Micronesia Region or Hawai’i. Request technical support from the
25 University of Guam as appropriate.

26 **A3.4.4 Education and Training**

- 27 • Provide adequate education about the potential negative consequences of spreading plant
28 pests and about ways to prevent pest spread. Provide a list of enterable and prohibited
29 materials. Create awareness of the potential legal consequences of violating the law.
30 Educate people on how they can actively contribute to exotic species prevention efforts.
31 Educate military personnel and dependents; non-military workforce; tourists; the general
32 public; and private industry.
- 33 • Provide training to increase inspection and identification expertise. Safeguarding inspectors
34 (both non-military and military) should receive adequate training on a regular basis teaching
35 them the proper techniques for detecting, extracting, recognizing, and identifying pests. A

1 communication network for continuously sharing relevant new information is also
2 recommended.

- 3 • Provide specific and detailed guidance to military personnel on how to inspect clothing and
4 personal effects for plant pests.

5 **A3.4.5 Additional Safeguarding Practices**

- 6 • Implement systematic surveillance for exotic pests, following the model of the Cooperative
7 Agriculture Pest Survey. Surveillance should take place both on and outside of military lands.
8 A transparent and well-documented process of pest prioritization, surveillance, data
9 collection, and record keeping must be followed. Communication of survey results
10 throughout the Micronesia Region would be an essential part of any survey program. Early
11 detection of new pests increases the chances that these pests can be eradicated or
12 controlled. Consider employing the help of qualified volunteers, such as amateur
13 taxonomists or university students to reduce costs.
- 14 • Improve record keeping including recording types and quantities of inbound materials for all
15 jurisdictions, such as agricultural products and origins of such products.
- 16 • Conduct periodic surveys of ethnic markets and grocery stores to intercept prohibited plant
17 products, following the model of or cooperating with USDA-APHIS-PPQ Smuggling,
18 Interdiction and Trade Compliance.
- 19 • Preferentially load conveyances in a way that minimizes pest entry. For example, avoid
20 nighttime loading because lights attract insects.
- 21 • Minimize pest contamination of containers and WPM by:
 - 22 o minimizing storage outdoors
 - 23 o sealing surfaces of storage sites
 - 24 o keeping storage sites clean
 - 25 o controlling pests around storage sites
 - 26 o limiting the use of nighttime lighting around storage sites
- 27 • Re-export infested or non-compliant WPM (as opposed to chipping it). Chipped WPM may
28 present a pest risk when the chips are re-used or improperly disposed of.
- 29 • Carefully inspect plant material recovered from construction sites for plant pests prior to
30 replanting.

31 **A.3.5 ACKNOWLEDGMENTS**

32 We gratefully acknowledge the individuals listed below for their assistance during this project.

- 1 Reviewers from USDA-APHIS:
- 2 Leslie Newton, Rob McDowell, Mitch Nelson, Jim Warren, Maria Borja, and Gary Cave
- 3 We also thank the numerous people who met with us on our site visits to the Micronesia Region to
- 4 share their expertise and answer our questions.

8 the U.S. military relocation in the Micronesia Region. United States Department of Agriculture, Animal
9 and Plant Health Inspection Service. Washington, D.C.

10 **A4.1 UNINTENTIONAL PATHWAYS**

11 **A4.1.1 Summary**

12 The movement of the 3rd Marine Expeditionary Unit from Okinawa to Guam and associated actions will
13 greatly increase maritime and air traffic, cargo movement, and military training exercises. As a result,
14 the potential for the unintentional (Section A4.1) and intentional (Section A4.2) transport and
15 introduction of terrestrial vertebrate species will also increase. A high management priority is
16 preventing movement of the brown treesnake (*Boiga irregularis*) (hereafter, BTS) from Guam and
17 Saipan; hence air and seaport biosecurity measures include screening of departing aircraft and cargo
18 exports. The transport and introduction of terrestrial vertebrate species within the Micronesia Region
19 has the potential to negatively impact the region's human health and safety, economy, and ecology.

20 In this section, we conducted a pathway-based risk assessment to determine the means by which
21 terrestrial vertebrate species are unintentionally transported from one location to another in
22 association with the military relocation. We used methods developed by the National Invasive Species
23 Council and the Aquatic Nuisance Species Task Force to identify routes of transport that were related to,
24 and affected by, the military mission; these routes were organized as pathways involving air
25 transportation (the aircraft itself), water transportation (the vessel itself), cargo and cargo conveyance
26 transportation, and transportation of people and baggage. We quantitatively ranked pathways based on
27 the numbers and types of species they could transport, frequency of pathway use, species control
28 measures currently used, characteristics of the pathway or species, and regulatory procedures currently
29 in place governing the specific pathway. Each pathway was assigned to an impact category based on
30 whether the species involved could harm human health and safety, the economy, or the ecology of the
31 region.

32 Most pathways evaluated were rated as high risk because they all had the potential to transport species
33 that could harm human health and safety. Species of particular concern are BTS and rodents because
34 these species could be transported in the majority of the pathways. Pathways with the highest risks

⁶ We gratefully acknowledge the following reviewers from USDA-APHIS for their assistance during this project: Leslie Newton, Rob McDowell, Mitch Nelson, Jim Warren, Maria Borja, and Gary Cave. We also thank the numerous people who met with us on our site visits to the Micronesian Region to share their expertise and answer our questions.

1 were related to the transport of military cargo that is associated with the relocation and for use in
2 training exercises and deployment missions; military field missions and training exercises have the most
3 potential to place gear and personnel in areas where the BTS occurs or could likely establish if
4 introduced. Additionally, there are insufficient resources to meet current inspection requirements and
5 demand, and military activities are expected to exacerbate the problems of an already burdened
6 biosecurity system. For example, even if communications occur, either formal or informal, between the
7 military, customs officials, and agricultural officials on Tinian when an inspection is required, the
8 response capabilities do not exist, thereby preventing adequate inspections from occurring. Inspections
9 of aircraft and vessels are focused on preventing the movement of agricultural pests and vectors of
10 disease; therefore the likelihood of detecting terrestrial vertebrate species is decreased. Short
11 transportation durations such as on aircraft and military high-speed vessels increase the probability of
12 species survival during transport. Currently, GCQA can inspect military vessels and aircraft, unless the
13 craft is carrying classified cargo, is actively engaged in warfare, or has already been pre-cleared. The
14 least amount of risk was associated with fruits and vegetables as these are inspected closely, although
15 only a portion of each shipment gets inspected.

16 Preventing the transport and introduction of terrestrial vertebrate species in the Micronesia Region will
17 require a high degree of cooperation among agencies and increased awareness of the risks associated
18 with invasive species. Additional resources like funding and enforcement are necessary to improve
19 inspection procedures, maintain efficiency in current control measures, and allow for a higher level of
20 biosecurity for the region. It is far more cost-effective to prevent the movement of species in the first
21 place, than to implement management for the control and eradication of species that become
22 established.

23 **A4.1.2 Introduction**

24 **A4.1.2.1 *Methods***

25 The risk analysis process we used was developed jointly by the NISC Prevention Committee and the
26 Aquatic Nuisance Species Task Force (ANSTF) collaborating as the Pathways Work Team in support of
27 the NISC Management Plan (ANSTF and NISC 2007). Although some details of this risk analysis method
28 did not always fit well with data on terrestrial vertebrate invasive species, the stepwise analysis allowed
29 us to elucidate all of the potential risks. Thus, the absolute value of the risk score was not as important
30 as the relative evaluation compared to other pathways and the identification of risk factors. Our risk
31 analysis is pathway-based, meaning it focused primarily on the means by which species are transported
32 and introduced, as well the species being moved. We identified the mission-related pathways in the
33 Micronesia Region (associated with the military relocation), and then assessed those pathways based on
34 the species likely to be transported in each.

35 The risk of transporting and introducing terrestrial vertebrate species for each pathway is evaluated
36 based on a three-step nested process that assigns a risk factor based on aspects like the type of
37 pathway, the species that may be transported, and current biosecurity measures in place in the region.
38 First, mission-related pathways are identified, and each is then assessed based on a list of potentially
39 invasive species that have been, or are likely to be, transported through each pathway. Impact category

1 rating for a pathway depends upon the species that may be transported in that pathway; impacts, in
 2 descending order, are to human health and safety (Impact Category A), the economy (Impact Category
 3 B), and the ecology (Impact Category C). Thus, a species that poses a human health risk is assigned the
 4 highest category even though the number of people that are affected by the health risk is small
 5 compared to those affected economically (ANSTF and NISC 2007). Second, pathway scope level is
 6 evaluated based on the geographic area potentially affected by species transport and introduction. This
 7 ranking uses the number of incidents that may occur and how large an area may be affected. A pathway
 8 that provides for multiple invasive species across international boundaries is ranked the highest,
 9 whereas a pathway limited to a single potential event in a localized area is ranked the lowest. For
 10 example, risk could be intra-island (Pathway Scope I), inter-island (Scope II), between island groups
 11 (Scope III), between regions (Scope IV), and international (Pathway Scope V).

12 Third, the pathways are then evaluated according to a fixed set of criteria (16 questions) that capture
 13 the capacity of the pathway to transport invasive species and the likelihood that the invasive species will
 14 move through the pathway undetected in sufficient numbers to establish an incipient population. The
 15 16 questions addressed issues pertaining to a) probability of species transport, b) invasiveness of
 16 species, c) the attributes of the pathway related to species movement, and d) control-interdiction-
 17 eradication methods. Each question was rated on a whole number scale of 0-10 (0 = No Risk) (Table A4-
 18 1). Risk ratings were science based and supported by quantitative datasets, peer-reviewed scientific
 19 literature, and expert opinion and expertise (NISC 2005; ANSTF and NISC 2007). Information content was
 20 evaluated in risk assessments by criteria such as if it was out of date, scant in detail, or not available,
 21 and/or if information was lacking for a pathway, or for a species not typically targeted for detection,
 22 able to escape detection and/or interdiction methods in use, or detected incidentally and never
 23 reported. Where species- and pathway-specific information was lacking, indirect information was used
 24 to supplement assessments. Such information included temperature-monitored shipments of laboratory
 25 mice in experimental studies on survival rates during air transport, as an indication of thermal conditions
 26 experienced by a hitchhiker (Syversen et al. 2008), or experiments determining ship stowaway rates of
 27 rodents within a specific commodity (Baker 1994).

28 **Table A4-1: Whole Number Risk Level Determination Used For Assessing Each of the 16**
 29 **Evaluation Criteria**

Whole number level determination	Level descriptor
Level 0	No Risk
Level 1-2	Extremely Low Level of Risk
Level 3-4	Moderately Low Level of Risk
Level 5-6	Medium Level of Risk
Level 7-8	Moderately High Level of Risk
Level 9-10	Extremely High Level of Risk

30
 31 Critical to the evaluation process was rating uncertainty, which exists to varying degrees in any risk
 32 assessment and thus was included in the analyses (Caley et al. 2006; ANSTF and NISC 2007). If there
 33 were unknowns, we could not be 100% certain of the risks involved; therefore, ratings represented how
 34 certain we were in our assessment of risks. Uncertainty was rated on a whole number scale of 1-5 (1 =

1 slightly uncertain) (Table A4-2). A general rationale for the uncertainty rating, such as flaws in
 2 methodology (Table A4-3), was coupled with specific details to provide justification. For example, the
 3 increased use of technologically advanced military vessels and aircraft in the region is a political
 4 impediment because biosecurity resources are already taxed, and a reason for biological unknowns
 5 because pathways are new, hence they lack information such as species-interception data.

6 **Table A4-2: Whole Number Ratings of Uncertainty in Risk Assessments**

Whole Number Uncertainty Level	Uncertainty Descriptor
Level 1	≥ 95 percent confident of assessment (slightly uncertain)
Level 2	80 percent – 94 percent confident of assessment
Level 3	65 percent – 79 percent confident of assessment
Level 4	50 percent – 64 percent confident of assessment
Level 5	≤ 49 percent confident of assessment (highly uncertain)

7

8 **Table A4-3: General Basis for Uncertainty in Risk Assessment Ratings**

Basis of Uncertainty
Flaws in methodology
Lack of expertise
Lack of issue coherence
Biological unknowns
Insufficient information
Political impediments
Other–Define

9

10 Numerical scores for the 16 questions were averaged for pathway risk rank; uncertainty ratings were
 11 also averaged and factored into risk ratings. Each pathway receives a risk score based on the
 12 combination of these three steps: a risk impact category (to human health, economy, ecology), a
 13 pathway scope level (local to international), and pathway risk ranking, which were used to determine
 14 the scale of invasiveness from a tabulated scoring ranging from 1 to 200; scores below 50 were assumed
 15 to have no harmful impact, from 51 to 100 were considered to be ecologically significant, from 101 to
 16 150 economically significant, and from 151 to 200 significant to human health and safety (ANSTF and
 17 NISC 2007). The final numerical score provides a rough index to prioritize the pathways for significance.
 18 Rationale for each final risk rating was given in brief narrative format, followed by a list of specific risks
 19 identified for that pathway.

20 The Pathways Work Team grouped pathways under three umbrella categories of Transportation (T),
 21 Living Industry (L), and Miscellaneous (M). Pathways were assessed for the potential to unintentionally
 22 transport terrestrial vertebrate hitchhikers, defined as terrestrial vertebrate species unintentionally
 23 moved to a different location in cargo, packing material, or a shipping container used for transport, or
 24 on/in the conveyance of transport (Meissner et al. 2009). These pathways have been linked to the rapid,
 25 worldwide movement and spread of invasive species (Burgiel et al. 2006; Meyerson and Mooney 2007;
 26 Westphal et al. 2008; Hulme 2009; Osborn 2010). We defined an invasive species as a nonnative species
 27 whose establishment causes or is likely to cause harm to human health and safety, the economy
 28 including agriculture, or the ecology of places where they have been introduced (NISC 2005). Expected

1 increased activities in these pathways during and following the proposed military relocation further
2 increases the probability of unintentionally transporting invasive terrestrial vertebrate species
3 throughout the Micronesia Region (Westphal et al. 2008).

4 Unintentional transport of hitchhiking terrestrial vertebrate species occurs in a number of ways.
5 Hitchhiking species may initially become attracted to certain physical or chemical conditions. Examples
6 include rats (*Rattus spp.*) nesting in aircraft wheel wells (Vice 2010c), BTS sheltering inside shipping
7 containers (Fritts et al. 1999), amphibians such as coqui frog (*Eleutherodactylus coqui*) laying eggs
8 among nursery plants and associated materials (Christy et al. 2007c), and mice (*Mus spp.*) feeding on
9 grain and garbage shipments transported overseas (Baker 1994). Hitchhiking might also result when
10 intentionally transported species escape en route from cargo holds (Graglia 2003; TMG 2009). The
11 swimming ability of some hitchhiking species, like rats and lizards, enables them to jump ship in
12 favorable scenarios, such as when the vessels are close to shore (Perry et al. 2006; Russell et al. 2007;
13 Peacock 2010).

14 Species lists were generated using those species known to be successful invaders. Only those species
15 present at the origin site but not present at the destination site were used except for rodents, which can
16 be exposed to a disease present at the origin site that is absent at the destination site, and therefore
17 have the potential to spread disease if they reach the destination site. Species presenting a human
18 health impact are considered high priority. Species of snakes, particularly BTS, and rodents like rats were
19 included due to their impacts on human health, economic interests, and the ecology (Brennan 1980;
20 Baker 1994; Stenseth et al. 2003; Kurle et al. 2008; Vidal 2008; CDC 2010e).

21 A primary management objective in the Micronesia Region is to prevent the spread of BTS from Guam
22 (Vice et al. 2009). The risk assessment accounted for the potential to transport and spread BTS within
23 the Micronesia Region (Engeman et al. 1998b; Fritts et al. 1999; Wiles et al. 2003; Rödder and Lötters
24 2010; Shwiff et al. 2010). BTS presents a unique circumstance in terms of biosecurity; whereas most
25 customs and quarantine inspections occur upon arrival and importation of goods into a country, BTS
26 inspections take place upon departure and export of goods (Vice et al. 2009). Many of the small
27 amphibians and lizards that could also be potentially transported can also become a prey base for BTS
28 (Pitt et al. 2005, Christy et al. 2007a, Christy et al. 2007c).

29 Information is gravely lacking on the science of species survival, or the physical environment
30 experienced by species during varying transport situations, primarily because the science of biological
31 invasions is relatively new (Wonham 2006), the research of species survival is complex in considering
32 myriad factors and their combinations (Meyerson and Mooney 2007), and because the global
33 movement of species is increasing faster than our ability to understand the consequences (Hulme 2009).
34 Assessment of species movement was associated with pathway and species aspects such as the
35 conduciveness of a pathway to transport species, the probability of species survival during transport,
36 probability of survival in the introduced ecosystem, and the biosecurity measures in place. For example,
37 species survival during transport depends upon several factors, including the type of species, an
38 individual's fitness, the duration of transport, and the thermal environment experienced by the
39 hitchhiker (Syversen et al. 2008; Vice and Pitzler 2008). The type of species and its fitness will determine

1 the animal's ability to deal with stressors like temperature extremes, starvation, and dehydration, as
2 observed in a cat (*Felis catus*) that survived 17 days in a goods container shipped overseas from Israel to
3 Britain (Associated Press 2006). Reptiles can endure long durations without food and water, as
4 evidenced by a BTS that survived 7 months in a crate of household goods on a cargo ship from Guam to
5 Texas (USGS 2005a).

6 Temperature variations and extremes during transport influence species survival. For ocean transport,
7 thermal fluctuations and extremes are more likely in surface-shipped freight than for freight transported
8 below decks out of the elements, the latter being more conducive to species survival (Vice and Pitzler
9 2008). Monitored air shipments of laboratory mice indicated that temperature variations and extremes
10 were more common during international versus domestic flights, when freight handlers used
11 commercial over private aircraft, and on transport routes with stopovers (Syversen et al. 2008). Survival
12 also depends upon the availability of food and shelter during transport. For example, feral mice can
13 stow away in garbage, hay, grain, household goods, dog food, mattresses, and tires (Baker 1994). A
14 combination of these factors likely influences the probability of species survival (Vice and Pitzler 2008).

15 Several of the species listed in this risk assessment have characteristics that would allow them to survive
16 during transport, e.g., the ability to survive periods without food or water, or endure varying thermal
17 environments during transport, such as the cold temperatures of aircraft cargo holds. House mice can
18 survive short durations without food, and can adapt to gradual, rather than sudden, decreases of water
19 intake (Haines et al. 1973; Newsome et al. 1976). In laboratory experiments, musk shrews (*Suncus*
20 *murinus*) survived 32 hours of fasting and lived up to 25 days on 25% of their normal daily food
21 consumption (Wayne et al. 1991; Yasuhara et al. 1991).

22 For the frog species *Hyla cinerea* (American green tree frog), the presence of a cutaneous barrier
23 prevents excessive water loss (Wygoda and Williams 1991; Wygoda and Garman 1993); in laboratory
24 experiments, this species endured a week of starvation and a 37% loss of body water (Layne Jr. et al.
25 1989). Arboreal frogs of the genus *Litoria* have lower rates of evaporative water loss than arboreal frogs
26 in North America, also due to a cutaneous lipid barrier (Main and Bentley 1964; Buttemer 1990;
27 Christian and Parry 1997). For *Rana sylvatica* (wood frog), a terrestrial hibernator, the ability to survive
28 temperatures ranging from 1.5°C to 15°C and withstand long periods submerged in ice water (Light
29 1991; Muir et al. 2007) demonstrates the variable thermal environments tolerated by this species during
30 transport.

31 The green anole (*Anolis carolinensis*) can also endure periods of starvation. In one laboratory
32 experiment, the species was able to withstand up to 12 days of starvation (Windell and Sarokon 1976;
33 Brown and Griffin 2005), and in another, they survived a very restrictive food intake regime for 4 weeks
34 (Speedy and Mumme 1994). Other laboratory studies indicate green anoles are able to acclimate to and
35 withstand temperatures ranging from 10°C to 35°C (Ragland et al. 1981; Art and Claussen 1982). In
36 response to conditions of low humidity, the green anole can decrease the rate of cutaneous evaporative
37 water loss, possibly through the deposition of lipids in the skin (Kobayashi et al. 1983; Kattan and
38 Lillywhite 1989). In laboratory experiments, BTS were able to survive temperatures as low as -5°C for 1
39 hour, with half of those surviving temperatures up to 39°C (Christy et al. 2007b). Boa constrictors (*Boa*

1 *constrictor*) were able to survive up to 168 days without food in the laboratory (McCue 2008). Southern
2 ringneck snakes (*Diadophis punctatus*) withstood temperatures ranging from 3°C to 36°C, but could not
3 survive for extended periods of time at 36°C (Henderson 1970). Burmese pythons (*Python molurus*
4 *bivittatus*) can go up to a year without eating (Starck and Beese 2001, 2002). Red-sided garter snakes
5 (*Thamnophis sirtalis parietalis*) survived for a month without food at 25°C in the laboratory (Starck and
6 Beese 2002). Two species of habu (*Trimeresurus elegans* and *Trimeresurus flavoviridis*) have been
7 reported to go for 2 to 3 years without food (Kamura and Nishimura 1992).

8 We factored in the likelihood of species establishing populations at arriving destinations, or the
9 opportunity for species to establish extralimital populations in assigning risk ratings (Livo et al. 1998;
10 Christy et al. 2007c). The likelihood of species establishing populations focused on either species-related
11 or pathway-related aspects. Species-related aspects included assessments of the numbers, types, and
12 frequency rates of species being moved, the viability of transported individuals, if species are difficult to
13 detect within introduced ecosystems, if species are habitat generalists, and if species are further spread
14 by human activity. Pathway-related factors included whether introductions are possible at multiple
15 points of entry, frequency of pathway use, the types of screening procedures in practice at an entry or
16 departure point, and also whether the pathway itself was conducive to moving the species.

17 Risk assessments accounted for cumulative effects of species transport and introduction. Although the
18 cumulative effects of species introductions remain largely unknown (Baker 1994; Wonham 2006;
19 Ricciardi 2007; Caut et al. 2008; Vidal 2008), repeated releases over an extended time period will
20 increase the chance of successful invasion simply because the release “experiment” is repeated many
21 times under different biotic and abiotic conditions, including different climates and seasons, fitness
22 condition of released animals, and numbers of natural enemies present (Bomford 2008). Cumulative
23 effects include invasive genes that spread among native populations rapidly and insidiously; invasive
24 species hybridizing with native species can have biological, aesthetic, and legal implications. For
25 example, populations of threatened California tiger salamanders (*Ambystoma californiense*) are at risk
26 of losing federal protection as a listed species and becoming genetically extinct because of the rapid
27 spread and introgression of introduced alleles from barred tiger salamanders (*A. tigrinum mavortium*)
28 (Fitzpatrick et al. 2010). Further, it is expected that global climate change will exacerbate the worldwide
29 problem of species invasions (Zhang et al. 2006b; Ward and Masters 2007; Sommer et al. 2010),
30 resulting in uncertain long-term impacts. Such influence is evident in cane toads (*Rhinella marina*)
31 introduced into Australia; the species is rapidly expanding its range in part because of changing
32 environmental and habitat conditions (Christy et al. 2007c). Range expansion by introduced species
33 allows them the ability to exert greater predation and competition pressures on natural ecosystems
34 (White et al. 2008; Greenlees et al. 2010; Martin and Pfennig 2010).

35 Because preventive measures are touted as best management practices, the risk assessment took into
36 account operational biosecurity measures in place for preventing the introduction of terrestrial
37 vertebrate species (CDF and WWF 2002; MAF 2003; VPC 2007; Bomford 2008; Australian Government
38 2009;, Biosecurity New Zealand 2009a; CDF 2009; Galapagos Conservancy 2010). Risks were highest
39 where efforts to prevent the transport of species were lowest. Risks were associated with gaps in
40 biosecurity measures resulting from factors such as insufficient port screening capabilities (staff,

1 equipment, etc.) (Wonham 2006, pg. 298), and regulatory provisions made for the military. For example,
2 although military aircraft departing Guam undergo APHIS canine inspection for BTS, for urgent or
3 medical missions aircraft may depart immediately without BTS inspection, thereby increasing the risk of
4 species transport. The risk assessment also included aspects such as whether control measures are
5 known, available, and effective, and whether control and eradication costs are feasible.

6 There were varying degrees of overlap among pathways. Overlap between military and civilian pathways
7 resulted from the common use of facilities, such as military aircraft using commercial airport facilities
8 (DeGuzman 2009). Overlap can occur when a species is able to access another pathway from the one it
9 is in currently. For example, species may escape from cargo into a craft's recesses, or vice versa, as for
10 escapees from a military aircraft carrier (vessel) to a staged aircraft (cargo). Overlap could also occur if
11 animals are being intentionally transported, such as for research or for the pet trade, or as personal
12 pets, and escape during transport (unintentionally) into a pathway.

13 Limited time and resources dictated the exclusion of some pathway assessment. We chose to focus on
14 pathways associated with the relocation that seemed most likely to unintentionally transport terrestrial
15 vertebrate invasive species. Cargo was not addressed as a single pathway because cargo and cargo
16 conveyance transportation is complex; rather, cargo and conveyances, and their transport means, were
17 addressed as they pertain to military activities in the region. Because of time constraints, not all sources
18 of cargo were considered in each pathway; e.g., for plants transported in food-related pathways, the
19 only source considered was the continental United States. Further, mail was not addressed as an
20 unintentional pathway because it was presumed species moving in mail were most likely being
21 intentionally transported, either legally or illegally; however, mail cargo and conveyance pathways are
22 considered because they are capable of transporting species that escape from other pathways.

23 **A4.1.3 Risk Assessment**

24 **A4.1.3.1 *Air Transportation***

25 The air transportation pathways focus on the aircraft itself as the mode of species transport. The term
26 'aircraft' includes both fixed and rotary-wing aircraft in military, commercial, and private sectors.
27 Different types of military, commercial, and privately owned aircraft currently visit, are home-based, or
28 routinely operate on Guam, with air transportation traffic in all three sectors expected to increase from
29 military activities during and after relocation. Plans for the relocation include training and field exercises
30 conducted on the islands of Tinian, Rota, and Saipan, which involve aircraft operations from Guam and
31 from aircraft carriers.

32 Air transportation pathways are capable of unintentionally transporting mammals, reptiles, amphibians,
33 and birds (Table A4-4). The Department of Transportation estimates that more than 2 million live
34 animals are transported each year in passenger cabins and cargo holds (DOT 2005) as pets, laboratory,
35 or medical research animals, or as a commodity in the wildlife trade, demonstrating the conduciveness
36 of air transportation pathways in moving species and supporting species survival during transport (IATA
37 2010). Military forces may be required to deploy virtually anywhere in the world, with great potential
38 for inadvertently spreading or introducing terrestrial vertebrate species (Dalsimer 2002).

1 **Table A4-4: Invasive Species Transported in the Air Transportation Pathway**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL
	<i>Kaloula pulchra</i>	Asian painted frog	ECL
	<i>Polypedates leucomystax</i>	Common tree frog	ECL
Birds	<i>Padda oryzivora</i>	Java finch	ECN
Mammals	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
Reptiles	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL

2 ^a H = health, ECN = economic, ECL = ecological.

3
 4 Terrestrial vertebrate hitchhikers have been found aboard military and commercial aircraft (Brink 1968,
 5 U.S. Navy 2001). Incidents with military aircraft include BTS, and illustrate the ability of BTS to be
 6 transported over a large geographical region on aircraft (Table A4-5) (Claiborne 1997; USGS 2005a).
 7 Hitchhikers aboard civilian aircraft include rodent pups discovered by APHIS-WS inspectors in the rear
 8 wheel well of an aircraft that had landed on Guam in March 2010 (Vice 2010c). Both live and dead mice
 9 have been found within aircraft cabins (Michaels 2005; Bodry 2008; Moriarty 2010). Java finches (*Padda*
 10 *oryzivora*) were found within an aircraft cargo hold (Vice 2009). Four, 6-inch-long pythons escaped from
 11 an “appropriate” shipping container during a domestic Qantas flight over Australia and were never
 12 found upon arrival by luggage handlers or afterwards by fumigators (TMG 2009). Birds common around
 13 airport facilities such as house sparrows (*Passer domesticus*), starlings (*Sturnus vulgaris*), pigeons
 14 (*Columba spp.*), and mynahs (*Acridotheres spp.*) attract predatory reptiles and rodents that may then
 15 enter aircraft (Brink 1968; Christy et al. 2007c; Gandhi 2009; Cohen 2010).

16 **Table A4-5: Examples of BTS Transport in Military Aircraft**

Location	Year	Number of snakes found	Aircraft type
Kwajalein Atoll	1979	1	Cargo plane
Darwin, Australia	1984	1	B-52 bomber
Kadena AFB, Okinawa	1992	1	unknown
Hickham AFB, Hawai'i	1997	1	Cargo plane

18
 19 Guam’s population is expected to increase due to the military relocation in both military and
 20 commercial sectors, thereby increasing air transportation activity throughout the region. Such activity
 21 includes military travel for training and services deployment. An increase is expected in military and
 22 civilian inter-island travel for recreation and tourism in the region, the latter necessary for regional
 23 economic growth. Travel may also increase for family visits to and from abroad. On Saipan, tourism is an
 24 economic driver alongside manufacturing. Rota boasts increasing economic development and legalized
 25 gambling, and has an emerging tourism industry that targets service members. Tinian’s primary
 26 community, San Jose, is agricultural. From 2000 to 2005, 90% of tourists visiting CNMI came from East
 27 and Southeast Asia (NOAA 2005). The expected increase in commercial air transportation traffic is
 28 evident in the scope of improvements underway at airports on Saipan, Tinian, Rota, and Guam (CPA
 29 2007a, b; Todeno 2009; Deposa 2010; Guam ABWPIA 2010; Saipan Tribune 2010). Increased air traffic
 30 will increase the risk of vertebrate invasive species being transported on aircraft.

1 **A4.1.3.1.1 Commercial Air Traffic**

2 Commercial aircraft arrive and depart Guam at A.B. Won Pat International Airport, hereafter Guam
 3 International Airport, which serves “over 300 flights per week” (Guam ABWPIA 2010). These flights
 4 consist of daily international cargo and passenger transport. Traffic consists mainly of local aviators and
 5 inter-island taxi traffic, combined and referred to herein as commuter traffic (Table A4-6). Seven
 6 international airlines and six air freight couriers operate out of the Guam International Airport (WPIAA
 7 2010b, a). Guam’s commuter airlines include Freedom Air, Cape Air, and Pacific Island Aviation. Private
 8 jet planes traveling through the area are provided with full executive jet service and maintenance
 9 through Aviation Concepts, Airport Group International, and Guam flight services. The airport has 21
 10 aircraft parking positions with 18 common use terminal gates (GEDA 2010). GCOA is available during
 11 scheduled aircraft operations and upon prior arrangement with field supervisors.

17 ^e Data unavailable.

18
 19 The Francisco C. Ada Saipan International Airport houses several major airlines and a commuter
 20 terminal. Commuter traffic makes up the majority of the flights to and from Saipan (see Table A4-6). The
 21 major airlines are Asiana, Delta, United Airlines, Northwest Airlines, China Southern, Air China, Shanghai
 22 Airlines, China Eastern, and All Nippon Airways. They provide direct flights from Guam, Japan, Korea,
 23 Hong Kong, Manila, and China. Cape Air, Star Marianas, and Freedom Air provide commuter services to
 24 Tinian, Rota, and Guam (CPA 2007b; Deposa 2010; FlightStats 2010; POI 2010). The airport operates 24
 25 hours, 7 days a week and has 24-hour availability of operating aircraft rescue personnel and equipment
 26 (CPA 2007b). Ground-handling services are provided by POI Aviation Services which is affiliated with Tan
 27 Holdings Company (POI 2010). Immigration and customs officials are available during scheduled
 28 operations, or by prior arrangements with the chief of Immigration Saipan (AirNav 2010a).

29 The majority of flights to and from Tinian are commuter flights (see Table A4-6). Tinian is serviced by
 30 Freedom Air, operating daily flights, and the privately chartered Star Marianas Air that provides services
 31 for the Tinian Dynasty Hotel & Casino customers (CPA 2005). Construction of a high-speed taxiway is

1 currently being advertised for bid and is expected to increase traffic (AirNav 2010d). Ongoing
 2 construction of a new departure terminal is slated to be finished in September 2010 (Saipan Tribune
 3 2010). The airport is equipped for night operation, with night flights from Saipan and Guam for the hotel
 4 and casino (CPA 2005). Immigration and customs officials are available during scheduled operations, or
 5 by prior arrangements with the chief of Immigration Saipan. The airport is also closed to unscheduled
 6 flights of carriers with more than 10 passenger seats without 24 hours' written notice to the airport
 7 manager (AirNav 2010d).

8 Traffic at the Rota International Airport also consists mainly of commuter flights, primarily from Saipan
 9 and Guam (see Table A4-6). Commuter airlines include Freedom Air and Cape Air, the latter a United
 10 Airlines Connection partner. Cape Air is suspending flights to Rota as of 5 October 2010 due to required
 11 scheduled maintenance on the ATR aircraft currently in service (PNC 2010). The airport is equipped for
 12 nighttime operations (CPA 2007a). Immigration, customs, and quarantine officials are available during
 13 scheduled aircraft operations and upon prior arrangements with field supervisors (AirNav 2010c).

14 United Airlines and its affiliates were selected as representative of these pathways, although other
 15 carriers provide similar services (Table A4-7) (United Airlines 2010). The flights listed in Table A4-7 are
 16 the flights that were evaluated and are by no means the only flights to and from Guam. Additionally,
 17 there are other carriers in the region other than United Airlines; however, many of their flights are
 18 similar to United's and are not listed here. From the continental United States, all other major carriers
 19 route through either Hawai'i or Japan.

20 **Table A4-7: Representative Flights to and From Guam on**
 21 **United Airlines and Its Affiliates**

Flight origin	Flight destination	Number of flights/day
Guam	Tokyo, Japan	3
Honolulu, Hawai'i	Guam	2a
Guam	FSM and RMI	1b
Guam	Palau	1
Guam	Saipan	6

22 ^a One flight is nonstop. The other flight makes five stops in Majuro (RMI), Kwajalein (RMI),
 23 Kosrae (FSM), Pohnpei (FSM), and Chuuk (FSM).

24 ^b Stops in Chuuk (FSM), Pohnpei (FSM), Kosrae (FSM), Kwajalein (RMI), and Majuro (RMI).
 25

26 **A4.1.3.1.2 Military Air Traffic**

27 Military air traffic is expected to increase during and after the relocation as personnel are moved and
 28 training exercises increase. Military activities using air transportation pathways include those by the U.S.
 29 Transportation Command which oversees the movement of military personnel and equipment via
 30 aircraft, the U.S. Air Force Air Mobility Command that provides strategic and tactical airlift support for
 31 military operations by moving personnel and cargo, and the movement of military cargo not consigned
 32 to commercial carriers that would be transported by Air Mobility Command aircraft. Aircraft arrivals at
 33 Andersen AFB on Guam include both military and civilian flights resulting from training exercises,
 34 transporting military dependents, and moving cargo. Military aircraft are used in medical or other types

1 of emergency missions, and these aircraft can depart Guam with little or no advance notice or BTS
 2 inspection. Aircraft operations for military training purposes are conducted by the Army, Marine Corps,
 3 Air Force, and Navy (U.S. Navy 2009j). Additional aircraft will be housed on Andersen AFB by the Marine
 4 Corps associated with the relocation, and additional training activities will occur (U.S. Navy 2009a).

5 On Tinian, the Marianas Island Range Complex draft EIS/Overseas EIS (U.S. Navy 2009j) identifies three
 6 range activities (strike warfare and two amphibious warfare activities) that presently include aircraft
 7 training (Table A4-8). Aircraft for these activities may come from the airfield or be staged on an aircraft
 8 carrier. The North Field on Tinian is an abandoned and unmaintained World War II era airfield with four
 9 runways. Two are abandoned and overgrown, one is used for military fixed-wing and helicopter
 10 activities, and the other is used for parachute drops and helicopter activities.

11 **Table A4-8: Range Activities on Tinian Utilizing Aircraft**

Training exercise	Type of aircraft utilized	Number of sorties/year ^a
Strike warfare (combat search and rescue)	SH-60, MH-60, HH-60, CH-53, C-17, C-130, V-22	≤ 75
Amphibious assault warfare	H-53, H-46, MV-22, UH-1, AH-1, AV-8	≤ 5
Amphibious raid warfare	H-53, H-46, MV-22, UH-1, AH-1, AV-8	≤ 2

12 ^a A sortie is defined as an operational flight by a single aircraft, as in a military operation.

13
 14 Training missions associated with various aircraft staged on a carrier are identified in the Marianas
 15 Island Range Complex draft EIS/Overseas EIS, but actual numbers are difficult to come by (U.S. Navy
 16 2009j). Should the carrier transit from Guam to CNMI, aircraft can redeploy rapidly with little time for an
 17 invasive species to leave the aircraft, particularly if this transfer occurs during daylight. Aircraft that are
 18 unloaded from the carrier while in port are considered cargo (U.S. Navy 2009b).

19 **A4.1.3.1.3 Aircraft Inspection**

20 Currently, biosecurity inspection procedures differ for military and commercial aircraft, between arriving
 21 and departing crafts, among the region’s airport security systems, and according to species of concern.
 22 Because inspections of any aircraft departing Guam, commercial or military, are primarily designed to
 23 detect BTS (BTS CEC 1996; USAF 2007), other species not specifically targeted have the potential to be
 24 missed or overlooked. Arriving military and commercial aircraft are not usually inspected for terrestrial
 25 vertebrate species by APHIS-WS unless an incident has been reported aboard (Vice 2010a).

26 **Inspections for BTS**

27 A Brown Treesnake Control and Interdiction Plan was developed by the Navy to prevent the movement
 28 of BTS off of Guam in response to Executive Order 13112, Invasive Species (The White House 1999; U.S.
 29 Navy 2005b). Executive Order 13112 made it the responsibility of all federal agencies to prevent the
 30 introduction and spread of invasive species in the United States and elsewhere. The BTS plan requires
 31 the military to cooperate fully with federal authorities during observations and inspections of cargo
 32 destined to be shipped from Guam. It also requires a close working relationship with APHIS-WS to
 33 effectively implement the plan. The plan directs the Department of the Interior and USDA to go through
 34 a rulemaking process on BTS inspections.

1 In general, all aircraft undergo similar inspection processes for BTS, regardless of the aircraft type and
2 use. Planes that are not "quick turns" (on the ground for 3 hours or less) are inspected exteriorly using
3 both detector dog and visual inspection. Very rarely are internal inspections of planes undertaken. It is
4 highly unusual for a plane door to be left open if there is not someone immediately around the aircraft.
5 If a plane is down for extended service, it is more likely to have hatches, doors, or exterior
6 compartments open for extended periods. Depending upon circumstances, an internal inspection on
7 such a plane may be done, but is not the norm (Vice 2010d). Additionally, if cargo is loaded onto a plane
8 without prior inspection, an internal inspection of the craft may be conducted. In 2008 APHIS-WS
9 inspected 88.6% of all departing commercial aircraft, and more than 98% of all departing military aircraft
10 (USDA-APHIS WS 2008a).

11 All aircraft departing Guam are required to be inspected by APHIS-WS (U.S. Navy 2005b). APHIS-WS
12 maintains dogs and equipment necessary to implement BTS control plans. During major exercises,
13 commanders are to work with both Andersen AFB and APHIS-WS personnel to develop an aircraft
14 parking plan to minimize BTS entry into aircraft. If APHIS-WS inspects an aircraft which subsequently is
15 delayed in scheduled departure (after hours of darkness), WS may require another inspection prior to
16 departure. Authority is given to APHIS-WS to stop the departure of aircraft from Guam, with some
17 exceptions, if it is suspected to be harboring BTS; e.g., BTS inspections cannot delay medical emergency
18 departures.

19 Military flight crews are instructed to keep doors of aircraft closed when the aircraft is idling to prevent
20 entry of BTS, and to be aware of the potential for BTS presence during pre-flight inspections (U.S. Navy
21 2005a). All vehicles being shipped are required to be cleaned prior to departure from Guam. High-risk
22 aircraft, such as those used in field exercises, may require additional measures. Such measures may
23 include high-pressure washing, steam-cleaning, fumigation, or other methods required by DoD policy.

24 ***Military Aircraft Inspections***

25 The Quarantine Regulations of the Armed Forces were written to allow the military to comply with the
26 regulations of the U.S. Departments of Health and Human Services, Agriculture, Treasury, Homeland
27 Security, Interior, and Commerce (DoD 1992). This was superseded by OPNAVINST 6210.2. The
28 regulations are designed to prevent the introduction and spread of disease agents (human, animal, and
29 plant), arthropod vectors, and pests of health or agricultural importance. The documents state that the
30 military is to cooperate with the agencies listed above to comply with regulations. Inspectors from these
31 agencies are authorized to board and inspect aircraft. However, inspectors from foreign countries are
32 not allowed aboard aircraft, even to observe an inspection. In these cases, commanding officers certify
33 compliance with the quarantine regulations of the foreign country to foreign officials. Certification may
34 include a general description of the measures taken to be in compliance.

35 Section II, Subsection B of the Quarantine Regulations of the Armed Forces and Section 9b of
36 OPNAVINST 6210.2 specifically govern aircraft (DoD 1992). Measures are to be taken prior to departure
37 to minimize movement of human disease vectors and arthropod vectors of medical importance. Aircraft
38 commanders are to comply with the medical and agricultural quarantine regulations of the destination
39 country that are published in the U.S. Air Force Foreign Clearance Guide (AFR 8-5 and OPNAVINST

1 3710.2E). Aerosol disinfectants are required when leaving areas known to harbor yellow fever, malaria,
2 or plague, unless a World Health Organization (WHO)- or DoD-approved disinfectant has been used and
3 the aircraft contains certification to that effect. Commanding officers at the point of departure
4 (embarkation) are required to determine whether mosquitoes or other vectors and pests of medical
5 importance are near the airport. In addition, officers are required to undertake pest control measures to
6 eliminate such pests, and minimize their access to aircraft. Commanding officers at the point of entry
7 (debarkation) are required to eliminate breeding places that could be readily accessible to vectors or
8 pests of medical importance, and to conduct routine surveillance for such pests.

9 Section II, Subsection C of the Quarantine Regulations of the Armed Forces and Section 10 of
10 OPNAVINST 6210.2 cover the USDA requirements. These sections govern the movement of animal and
11 plant diseases and pests. Aircraft moving between Hawai'i, Guam, Puerto Rico, the U.S. Virgin Islands,
12 and the continental United States are required to undergo USDA inspection by a USDA inspector or
13 representative. GCQA officers collaborate with USDA-APHIS to enforce federal regulations and have the
14 authority to board military aircraft, provided cargo is not classified and the aircraft are not actively
15 engaged in warfare (Taijeron 2010c), despite recent military questioning of the authority of GCQA to
16 conduct inspections of military aircraft and ships (Delgado 2009, U.S. Navy 2009k). The disinfection
17 measures currently available target primarily disease organisms and insects and may not be effective on
18 many of the invasive species transported in aircraft. Subsection C requires surveillance aboard aircraft
19 that includes spot checking and routine collection and identification of pest organisms.

20 The Defense Transportation Regulations, Part V establishes the requirements for agricultural cleaning
21 and inspection, and the assignment of DoD personnel as agricultural and customs inspectors for pre-
22 clearance programs. USDA-APHIS is responsible for providing DoD with guidance, information, and
23 training to perform pre-clearance inspections (DoD 2009a). APHIS remains the final authority on the
24 pest risk status of material or equipment. Stores and in-flight meals may not enter the United States and
25 garbage must be placed in tight, leak-proof, covered containers and disposed of according to port
26 procedures (DoD 2009a).

27 To facilitate redeployment operations, DoD can request pre-clearance inspections by CBP and USDA for
28 cargo and equipment returning to the Customs territories of the United States (CTUS) (DoD 2009c). Pre-
29 clearance inspections may be requested for redeployment from major exercises or contingencies, and
30 are performed at the point of origin. Requests for pre-clearance inspections must be submitted no later
31 than 75 days prior to when the inspection is needed. Requests must contain the following information:
32 dates, times, and place of departure from a foreign country; date, time, and place of arrival in the CTUS;
33 number and type of aircraft; identification of all stops between the point of departure and arrival; and
34 whether the border clearance integrity of the aircraft will be maintained during en route stops.
35 Examples of clearance integrity being breached are the addition or removal of cargo or passengers at
36 any stop, crew member changes, off-loading of crew and passengers, or the aircraft remaining in a
37 location overnight. Such breaches of integrity will void the pre-clearance authority.

38 Both CBP and USDA provide and approve training of Customs Border Clearance Agents for the military
39 (DoD 2009c). When the planned destination is in the CTUS, Customs Border Clearance Agents inspect

1 aircraft to ensure it is free of plants, animals, or plant and animal products. Equipment must be stored in
2 a way that prevents re-infestation by pests. In addition, CBP can establish a Military Customs
3 Inspectors–Excepted program at a DoD installation (DoD 2009d). Such a program allows DoD personnel
4 to perform the same functions as CBP agents in connection with arriving military or military-chartered
5 aircraft from overseas areas. Inspection duties of the DoD personnel under this program include
6 customs, immigration, and agricultural inspections or functions.

7 The Armed Forces Pest Management Board published Technical Guide Number 31 to cover the cleaning
8 and inspection procedures used in conjunction with retrograde washdowns (AFPMB 2008). Large aircraft
9 that remain on the flightline are to have protected areas, such as wheel wells and around cargo and
10 passenger doors, cleaned. A visual inspection of cargo and the flight deck is performed to determine
11 whether further cleaning is needed. For fixed and rotary wing aircraft, the following areas are cleaned:
12 cabin area, cockpit, wheels, wheel wells, skid/runner bars, under deck plates, panels, in flap wells, and
13 all other areas where debris may lodge. Cleaning may consist of a water wash or steam as determined
14 by the inspector on site. Washing and inspection of aircraft may only occur during daylight hours. We
15 had hoped to see the cleaning of aircraft performed while we were on Guam, and specifically requested
16 this, but were unable to schedule a demonstration.

17 ***Commercial Aircraft Inspections***

18 The CFR provides some guidance on aircraft inspection and disinfection as it pertains to movement of
19 regulated articles from Hawai'i and the territories, and movement of animals or animal parts. The
20 pertinent portions are Title 7 (regulated articles from Hawai'i and the territories), Title 9 (movement of
21 animals and animal parts), and Title 42 (public health). Title 7 (Subtitle B, Volume 5, Chapter 3, Part
22 3A.13-9 and Part 330.111) requires inspectors be notified prior to departure or arrival of aircraft on
23 Guam, giving ample opportunity for the inspection process to occur. Title 9 (Volume 1, Chapter 1,
24 Subchapter D, Part 93) allows the inspection of any aircraft from foreign locations without a warrant to
25 determine whether the aircraft is carrying any animal or animal part subject to disposal to prevent the
26 spread of disease. If the aircraft is found to be contaminated, the operator of the aircraft is responsible
27 for disinfection. Title 9 (Volume 1, Chapter 1, Subchapter D, Part 95) also requires the disinfection of an
28 aircraft if it has transported restricted items that were not contained in leak-proof containers. The
29 method of cleaning prescribed in Title 9 (Part 95) includes the collection of litter and refuse, and
30 disposal of that refuse by incineration or other approved method. This is to be followed by cleaning of
31 the areas of the aircraft that were exposed to the contaminant and saturation of the contaminated
32 surface with an approved disinfectant. The approved disinfectants are sodium carbonate solutions,
33 sodium hydroxide solutions, or liquefied phenol. These disinfectants are specifically designed to target
34 foot-and-mouth disease, rinderpest, and ticks. Title 42 (Part 71, Subpart E, Section 71.41) of the CFR
35 states that carriers arriving at U.S. ports are subject to sanitary inspections to look for rodent, insect, or
36 vermin infestation that may spread disease.

37 The APHIS-PPQ Manual for Agricultural Clearance contains information on the inspection of aircraft
38 (USDA-APHIS-PPQ 2013). The manual instructs inspectors to look for "hitchhiking pests" on the aircraft,
39 but does not specify whether this only refers to insects or also includes vertebrates. Inspectors are to

1 board the aircraft after passengers have deplaned but prior to airline personnel, such as caterers and
2 cleaners, to conduct their inspections. The areas to be inspected are the galley area and areas where
3 stores are kept, passenger and crew areas, and cargo holds for cargo and military flights. The manual
4 specifically instructs inspectors to look for hitchhiking insects in cargo holds, but does not mention
5 vertebrate invasive species. Cargo holds are also to be inspected for plant and animal contamination and
6 soil. If contamination or live pests are found, the aircraft must be disinfected. Disinfection procedures
7 for animal contamination include treatment with Virkon®S or sodium carbonate with sodium silicate.
8 Disinfection procedures for live pests are to be determined by a CBP Agricultural Specialist according to
9 the APHIS-PPQ Treatment Manual. The treatment manual only contains guidance for treatment when
10 khapra beetles, fruit flies, and soft bodied insects are found (USDA-APHIS-PPQ 2008). State aircraft are
11 exempt from inspection unless there is a specific agreement in place that allows inspection. State
12 aircraft are aircraft that have been given Diplomatic Overflight and Landing Clearance by the
13 Department of State, Bureau of Political-Military Affairs, and Office of International Security Operations.

14 On July 18, 2007, the United States became a party to the International Health Regulations adopted by
15 the WHO to mitigate public health risks associated with international travel (WHO 2005b). In 2009, the
16 WHO published an updated guideline for hygiene and sanitation practices in aviation to protect
17 passengers from serious illnesses (WHO 2009b). These regulations prescribe measures for routine
18 cleaning of aircraft and procedures to be used when specific disinfection is required due to a known or
19 suspected infected person traveling aboard the aircraft. All procedures in this guideline are focused on
20 the spread of human disease primarily by humans or contaminated food and water.

21 ***Guam***

22 GCQA officers clear aircraft, passengers, and cargo at the airport (Taijeron 2010a). There are seven
23 officers at the airport to inspect air freight and 16 officers to process passengers (Taijeron 2010a). In
24 addition to enforcing local regulations, GCQA officers collaborate with USDA-APHIS to enforce federal
25 regulations (Taijeron 2010c). Inspections by the seven GCQA officers are focused on the interior of the
26 plane and its compartments specifically to search for smuggled contraband, live animals, cargo with a
27 manifest, agriculture violations, and abandoned agricultural items (Taijeron 2010b). In addition, GCQA
28 ensures that garbage aboard aircraft meet local and federal requirements. If pests are found aboard the
29 aircraft, the aircraft doors are shut, and appropriate measures are taken to handle the infestation (Reyes
30 2010).

31 ***Commonwealth of the Northern Mariana Islands***

32 Aircraft from foreign countries arriving in Saipan are cleared by two separate agencies, Saipan Customs
33 and Saipan Quarantine. In CNMI, the Customs Service is under the jurisdiction of the Department of
34 Finance, whereas the Quarantine Service is under the Department of Lands and Natural Resources. All
35 commercial aircraft arriving at the airport in Saipan from Guam are inspected by a BTS detector dog
36 team (Pangolinean 2010). No other inspections are made. There are 14 quarantine officers assigned to
37 operate 24 hours a day, 7 days a week. If a BTS is detected in an aircraft or cargo, Saipan Division of Fish
38 and Wildlife is notified. In addition, if any animals or insects are found, the container is closed and
39 APHIS-PPQ is notified. The Department of Land and Natural Resources, Division of Fish and Wildlife is in

1 charge of training BTS detector dogs (Onni 2010). It takes 1 to 2 months to train a dog training 1 day per
2 week. To be a certified BTS detector dog, dogs must be able to find 80% of the BTS present. Currently,
3 there are four BTS detector dogs on Saipan, and one on Tinian. Funding has been obtained to place a
4 BTS detector dog on Rota. There are 50 BTS traps at the airport, operated by the Division of Fish and
5 Wildlife which currently must breed their own mice for the traps, that are serviced twice a week.

6 Currently, the BTS handler on Tinian only has a snake skin to train the single detector dog. Therefore,
7 the dog is accustomed to finding a dead BTS as opposed to a live BTS. Additionally, because there is only
8 one skin, the dog is used to finding only a single snake (Castro 2010). Additional training is provided off
9 island, but it has been difficult to obtain matching funds from CNMI agencies to send personnel to the
10 training. Personnel must breed their own mice for BTS traps, and recently some traps have been
11 removed due to a lack of mice. The mouse colony on Tinian collapsed due to disease, and personnel did
12 not have the resources to purchase new mice. On Tinian there are two issues; first, customs officials
13 there are not always notified when aircraft bound for Tinian depart Guam without a BTS inspection, and
14 second, even when notified, there is little or no response capability. Customs officials need
15 approximately 12 hours prior notice to enable them to conduct the necessary inspections (Ferrell 2010).

16 ***Federated States of Micronesia***

17 According to FSMC Title 18, Chapter 2 § 206, any aircraft entering FSM is subject to inspections by
18 customs, immigration, agriculture, and administrative personnel. We were unable to find any
19 information regarding exactly what these inspections entail. The immigration regulations of FSM state
20 that all aircraft will be inspected for stowaways, presumably human (FSM ORC 2005). FSM developed a
21 National Biosecurity Strategy and Action Plan in 2002 (FSM 2002), and each of the four FSM states
22 (Kosrae, Pohnpei, Chuuk, and Yap) provided input for the plan. Overall coordination and support is
23 provided through the Environmental Management and Sustainable Development Council and the
24 Department of Economic Affairs.

25 ***Republic of the Marshall Islands***

26 Aircraft entering or leaving RMI are subject to inspections by immigration, customs, agriculture, public
27 health, or administrative personnel as stated in Title 43, Chapter 2, Section 205 of the Marshall Islands
28 Revised Code (PacLII 2003). According to Title 8, Chapter 1, Section 110 of the Marshall Islands Revised
29 Code, aircraft known or suspected to be harboring insects or agricultural pests are to be sprayed with an
30 insecticide (PacLII 2004a). Any employee of the RMI Ports Authority may enter an aircraft for the
31 purpose of inspection according to Title 22, Chapter 1, Section 153 of the Marshall Islands Revised Code
32 (PacLII 2004c).

33 ***Palau***

34 No information could be accessed regarding inspections of aircraft in Palau.

35 ***Japan***

36 No information could be accessed regarding inspections of aircraft in Japan.

1 **Hawai'i**

2 Aircraft inspections follow the procedures outlined above for commercial aircraft inspections. There is a
3 toll-free pest hotline to call if a BTS or other suspected alien pest is sighted, and various agencies and
4 offices throughout Hawai'i have trained responders available.

5 Summary of Findings

6 All aircraft pathways were considered high risk because they can transport BTS and other IAS. In
7 addition, rodent damage, such as gnawing aircraft electrical wiring, can have dangerous consequences
8 (WHO 1995, pg. 7; Song et al. 2003; Moriarty 2010). Risk increased as the probability of species survival
9 during transport increased. Higher risk was associated with planes on routes with few or no stops that
10 travel over relatively short distances and/or durations, due to the increased probability of survival.

11 Risk also increased based on several factors related to the process of inspection. For military aircraft,
12 risks were higher for conveyances not inspected, such as those departing on urgent missions, which are
13 not delayed for BTS (or other terrestrial vertebrate) inspections. The risk of inspectors missing an
14 invasive species increased as time constraints and equipment unavailability (broken or nonexistent
15 equipment) increased, or the number of inspectors decreased. Risk rankings also reflected increased
16 commercial air traffic without adequate increases in biosecurity needs, such as additional staffing for
17 inspections and enforcement, updated equipment and facilities, continued training, and easier reporting
18 capabilities.

19 **A4.1.3.1.4 Specific Risk Factors**

20 The specific risk factors we found to be associated with the air transportation pathways are as follows:

21 **Common Risk Factors**

- 22 • BTS inspections may not address the movement of other potentially invasive species.
- 23 • No rapid response program or formal reporting network exists for introductory detections
24 of vertebrate species other than alien snakes, albeit, the region does utilize informal
25 networking to report potential alien species encounters and to ilicite support from a variety
26 of internal and external resources. Formal reporting mechanisms with jurisdictional and
27 regional coordinating offices established and utilized would be preferable.
- 28 •
- 29 • Agricultural inspections at the port of entry may not adequately detect a vertebrate invasive
30 species moving in aircraft.
- 31 • There are limited control measures for frogs and snakes that could be moved in aircraft
32 pathways.
- 33 • There are no rapid lethal control methods for use to control reptile or amphibian
34 infestations on aircraft.

1 ***Risk Factors Associated With Commercial Aircraft***

- 2 • Inadequate financial resources exist in the CNMI, FSM, RMI, and Palau to maintain
3 expensive control programs.
- 4 • Staffing is inadequate to meet current quarantine demands. Guam needs a total of 100 staff
5 to meet anticipated demands of the relocation (Campbell 2010c). Saipan presently has 14
6 inspectors, and needs a total of 28 to meet demands (Pangolinean 2010). Tinian presently
7 has 4 inspectors, and needs a total of 12 to meet demands (Berringer 2010c).
- 8 • Airports lack adequate screening equipment and facilities for effective and comprehensive
9 inspections.

10 ***Risk Factors Associated With the Military***

- 11 • The retrograde washdown and inspection process (AFPMB 2008) is focused on preventing
12 the transport of agriculturally significant pests on vehicles and may not be effective for
13 preventing the transport of vertebrate invasive species.
- 14 • Aircraft used in urgent missions such as search and rescue and medical evacuations are not
15 delayed for BTS (or other terrestrial vertebrate) inspections.
- 16 • Communication is inadequate between the military and officials on Tinian to allow for
17 proper inspections of aircraft associated with military training to occur, and even when
18 notified, there is little or no response capability.

19 **A4.1.3.2 *Water Transportation***

20 The water transportation pathways focus on the vessel itself as the mode of species transport, and
21 include military, commercial, and private sector vessels. Types of vessels are numerous, including but
22 not limited to rigid inflatable boats, long-line fishing boats, sailboats, amphibious landing craft, high-
23 speed catamarans, cruise ships, container ships, cargo ships (bulk, break-bulk, roll-on/roll-off), aircraft
24 carriers, landing craft utility vessels, barges, inter-island ferries, cruise ships and shuttles, platforms, and
25 hovercraft. Different types of military, commercial, and privately owned vessels currently visit, are
26 home-based, or routinely operate on Guam with water transportation traffic in all three sectors
27 expected to increase from military activities during and after relocation. Plans for the relocation include
28 the construction and use of training ranges for field exercises and activities on the islands of Tinian,
29 Rota, and Saipan, which involves water transport of materials, equipment, and vehicles for range
30 construction, operation, and field exercises. Assessment of these pathways excludes evaluating items
31 carried on a ship such as cargo.

32 Water transportation vessels pose several risks in transporting terrestrial vertebrate species. The wide
33 diversity of vessels operating in the Micronesia Region, along with the current and expected increase in
34 vessel traffic due to military relocation, offer a variety of transport opportunities to hitchhiking
35 terrestrial vertebrate pests. For example, on high-speed catamarans with long-distance capabilities in
36 use by the military (Tack 2010), the probability of species survival during rapid transit times is increased,
37 along with the chance for far-ranging spread and dispersal, whereas the same hitchhiker in the hold of a

1 commercial cargo ship would typically experience longer transit durations that decrease survival
 2 probability en route; however, the global trade via the water transportation industry still facilitates the
 3 widespread movement and dispersal of pest species (Burgiel et al. 2006; Meyerson and Mooney 2007;
 4 Westphal et al. 2008; Hulme 2009; Osborn 2010). Vessels that are in direct contact with the ground,
 5 such as vessels in dry storage; are within shipyard facilities; or have technological advances such as
 6 military amphibious vessels, are vulnerable to species access. Vessels vary in their capacity for harboring
 7 species, depending upon the vessel's physical size and configuration. For example, a bulk cargo ship
 8 typically has fewer areas for harboring terrestrial vertebrate species than a break-bulk cargo ship, but
 9 both will have more discrete hiding places than a barge. All of these aspects increase the probability of
 10 successful species transport, including their myriad possible combinations.

11 Rodents have a history of hitchhiking in water transportation pathways (AQIS 2010), and are therefore
 12 considered a concern. Rats are a particular concern because rat species have reached about 80% of the
 13 world's islands and are among the most successful invasive mammals (Caut et al. 2008; Peacock 2010).
 14 Marine port facilities with rodent infestations have a higher likelihood of introducing them into the
 15 water transportation pathways (2005). As much as one-quarter of Chinese seaports have rodent
 16 infestations (Song et al. 2003). Rodent infestations around port facilities can occur from improper
 17 garbage handling and waste disposal and employees feeding the wildlife, combined with inadequate
 18 resources to control or eradicate detected populations or educate port staff (WHO 2007b, 2010h).
 19 Detection systems for rat introductions are lacking overall (Jarrad et al. 2010). Rodents, such as rats, are
 20 capable of swimming to and from shore in favorable scenarios (Peacock 2010). Other species are also
 21 capable of being transported in water transportation pathways (Table A4-9). Because rodents are well-
 22 known vectors of disease and are often well established at ports, this makes their presence on ships a
 23 special concern (WHO 2007b; Meerburg et al. 2009; WHO 2010h). Due to their confined nature, ships
 24 are conducive to spreading disease among passengers and crew (WHO 2007b, 2010h). This, combined
 25 with global travel, presents a risk of spreading infectious diseases to other ports.

26 **Table A4-9: Invasive Species Transported in the Water Transportation Pathway**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Bufo gargarizans</i>	Asiatic toad	ECL
	<i>Kaloula picta</i>	Slender-digit chorus frog	None foundb
	<i>Rana catesbeiana</i>	American bullfrog	ECN, ECL
	<i>Rhinella marina</i>	Cane toad	H, ECN, ECL
Birds	<i>Columba livia</i>	Rock dove	H, ECN, ECL
	<i>Dicrurus macrocercus</i>	Drongo	ECL
	<i>Padda oryzivora</i>	Java sparrow	ECN
	<i>Passer domesticus</i>	House sparrow	H, ECN, ECL
	<i>Passer montanus</i>	Tree sparrow	ECN
	<i>Pycnonotus jocosus</i>	Red-whiskered bulbul	ECN, ECL
	<i>Streptopelia bitorquata dusimieri</i>	Philippine turtle dove	ECL
Mammals	<i>Herpestes javanicus</i>	Small mongoose	H, ECN, ECL
	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL

Class	Scientific name	Common name	Risk type ^a
	<i>Rattus rattus</i>	Black rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Anolis carolinensis</i>	Green anole	ECL
	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL
	<i>Dinodon rufozonatum</i>	Red banded snake	None found
	<i>Elaphe carinata</i>	Taiwan stink snake	None found
	<i>Elaphe taeniura friesi</i>	Taiwan beauty snake	None found
	<i>Gehyra mutilata</i>	Mutilating gecko	None found
	<i>Gekko gekko</i>	Tokay gecko	ECL
	<i>Hemidactylus frenatus</i>	Common house gecko	ECL
	<i>Lepidodactylus lugubris</i>	Mourning gecko	None found
	<i>Naja kaouthia</i>	Monocled cobra	H
	<i>Trimeresurus elegans</i>	Sakashima habu	H
	<i>Trimeresurus flavoviridis</i>	Habu	H
	<i>Trimeresurus mucrosquamatu</i>	Taiwan habu	H
	<i>Xenochrophis piscator</i>	Asiatic water snake	None found

a H = health, ECN = economic, ECL = ecological.

b No impacts found in the literature, but undocumented impacts may exist.

Both commercial and military maritime traffic are expected to increase due to the relocation, thereby increasing the risk of moving invasive species. Commercial maritime traffic plays a significant role in transporting a majority of commodities moved throughout the Micronesia Region, and maritime traffic in general will transport a majority of the cargo associated with the relocation on Guam (U.S. Navy 2009j, pages 97-112). Military maritime traffic will significantly impact the potential to transport vertebrate invasive species to Guam and CNMI. The complex set of training activities following the relocation on Guam and Tinian combined with the technically advanced types of military vessels used in the region pose significant opportunities for the movement of vertebrate invasive species (U.S. Navy 2009a, j). Vessels calling on the Port of Guam do so at Apra Harbor, which comprises both an outer harbor area (Outer Apra Harbor) and an inner harbor area (Inner Apra Harbor). Most of Outer Apra Harbor and the entire Inner Apra Harbor are under the jurisdiction of the Navy.

Species may stow away in a vessel's hold or on the superstructure of the ship. Five classes of vessels were evaluated: commercial container ships, commercial barges, commercial fishing vessels, cruise ships, military vessels, and privately owned and operated vessels.

A4.1.3.2.1 Commercial Maritime Traffic

The Jose D. Leon Guerrero Commercial Port of Guam is located at the northern end of Apra Harbor, with commercial and recreational facilities located in the outer harbor. The commercial port has six berths associated with the main cargo terminal that provide port access to vessels with different draft and cargo container handling requirements. The berths are characterized in the Port of Guam Master Plan (PB International 2008). Commercial shipping activity and annual container traffic, as well as estimated

1 increases due to the military relocation, are also included for both shipping activities and container
2 traffic elsewhere in this document.

3 Guam also has two marinas, Hagatna Marina (Gregorio D. Perez Marina) and Agat Marina, that are
4 administered by the Port Authority of Guam (PB International 2008). Both marinas have chainlink fences
5 on their perimeter, but the fences are in generally poor condition, thereby allowing terrestrial
6 vertebrate species access to port areas and vessels. Private vessels used for recreation, such as fishing,
7 utilize these marinas. There are at least three major recreational fishing events associated with these
8 marinas. These include the Guam Marianas International Fishing Derby, the Fisherman’s Festival, and
9 the Annual Marianas Underwater Fishing Federation Competition (Allen and Bartram 2008). The fishing
10 derby averages around 70 boats and 300 fishermen (Allen and Bartram 2008). A total of 75 teams
11 participated in the derby departing from both the Agat Marina and the Hagatna Marina in 2009. The
12 underwater fishing competition had 13 teams from Guam and two from Saipan in 2005 (Allen and
13 Bartram 2008).

14 The majority of cargo vessels in the region are operated by Matson Navigation Company and Horizon
15 Lines (Horizon Lines 2010b, c, d, a; Matson 2010a, b). The Kyowa Shipping Company also operates in the
16 area, shipping from the ports in Busan, South Korea and Yokohama, Japan into the port on Saipan
17 (Kyowa Shipping Company 2010a, b). Kyowa Shipping is the transshipment service provider for Horizon
18 in the region (PB International 2008). Shipping routes are shown in Figure A2-2 (Section A2). Regional
19 shipping from the ports on Guam and Saipan throughout the region are handled by feeder services
20 provided by Kyowa, Seabridge Marine, and Micronesia Express Service (PB International 2008). Major
21 islands serviced by these providers in the region include Guam; Saipan and Tinian (CNMI); Majuro (RMI);
22 Pohnpei, Chuuk, Kosrae, and Yap (FSM); and Palau. Regional shipping via Seabridge or Matson has a
23 transit time between Guam and Saipan of approximately 12 hours according the Port Authority of Guam
24 Master Plan Update (PB International 2008). We did not attempt to capture every possible shipping
25 route in our analysis, but focused instead on the major routes. Therefore, routes from charter vessels,
26 fuel vessels, and smaller shipping companies are not captured in the analysis.

27 The shipping companies contract with each other and other regional carriers to provide transshipment
28 services throughout the region (PB International 2008). The interconnections between the different
29 international and regional transshipment services make determining actual transit time for a given
30 container difficult to predict. For example, it is possible for a container to be loaded in a port in Asia, be
31 unloaded in Busan, reloaded on a regional ship and shipped to Saipan or transshipped further, on the
32 same vessel to a port “downstream” of Saipan. A more complex route would have a container loaded on
33 a ship in a port on the west coast of the United States, transshipped via Hawai’i to Guam, loaded on a
34 Kyowa vessel and transshipped out of Guam to another port in the region. However, some estimates of
35 shipping times are shown in Table A4-10 (PB International 2008; Horizon Lines 2010b, c, d, a; Kyowa
36 Shipping Company 2010a, b; Matson 2010a, b).

37 **Table A4-10: Estimates of Time in Transit for Various Shipping Companies and Routes**

Carrier	Origination site	Destination site	Estimated transit time (days)
---------	------------------	------------------	-------------------------------

Horizon, Matson	U.S. west coast	Hawai'i	4
Horizon, Matson	Hawai'i	Guam	8
Horizon	China	Oakland, California	21
Matson	China	Los Angeles, California	18
Kyowa, Seabridge, Micronesia Express	Busan, Korea	Saipan, CNMI	10
Kyowa, Seabridge, Micronesia Express	Saipan, CNMI	Guam	<1
Kyowa, Seabridge, Micronesia Express	Guam	Chuuk, FSM	3
Kyowa, Seabridge, Micronesia Express	Chuuk, FSM	Pohnpei, FSM	2
Kyowa, Seabridge, Micronesia Express	Pohnpei, FSM	Kosrae, FSM	3
Kyowa, Seabridge, Micronesia Express	Pohnpei, FSM	Yap, FSM	4
Kyowa, Seabridge, Micronesia Express	Yap, FSM	Koror, Palau	2

A4.1.3.2.2 Military Maritime Traffic

3

The Marianas Island Range Complex is a major naval training area and includes Guam, as well as the islands of Saipan, Tinian, Rota, Farallon de Medinilla, and the training area W-517 (U.S. Navy 2009j). It includes 501,872 square nautical miles of sea space for naval training, as well as 10,074 hectares (24,894 acres) of land range. Navy ships that may operate in the area during any major training exercise include nuclear aircraft carriers, cruisers, frigates, landing craft utility vessels, high-speed transport vessels, and amphibious support and assault vessels (U.S. Navy 2009j). Exercises involve 3 to 30 ships and last 5 to 21 days. Training events may occur 1 to 5 times per year. The types of ships currently operating in the area attached to the U.S. Navy Military Sealift Command include tanker ships and ships carrying break bulk and containers (U.S. Navy MSC). The southern end of Apra Harbor on Guam has four major wharves available for docking ships: Victor Wharf, Sierra Wharf, Polaris Point, and Kilo Wharf. Navy waterfront facilities are located in both the outer harbor and the inner harbor. Waterfront facilities for the U.S. Coast Guard are located in the inner harbor.

15

A4.1.3.2.3 Ship Inspection Procedures

16

World Health Organization Regulations

17

On July 18, 2007, the United States became a party to the International Health Regulations adopted by the WHO to mitigate public health risks associated with international travel (WHO 2005b). Article 27 of these regulations states that if a source of contamination or infection is found or suspected on board a ship, authorities are allowed to decontaminate the ship which may include deratting. Article 28 states that, if an infected ship wishes to enter a port that is not equipped to deal with the infection, the port authorities may order the ship to proceed to the nearest suitable port for inspection. Port authorities are required to notify the next known port of entry of the infection.

24

Article 39 of the International Health Regulations governs Ship Sanitation Control Certificates and Ship Sanitation Control Exemption Certificates. Formerly, these certificates were referred to collectively as a

25

1 Deratting/Deratting Exemption Certificate. With the publication of the 2005 International Health
2 Regulations, these certificates were changed to include all public health risks, not just those pertaining
3 to rodents (WHO 2007a). Certificates are only valid for 6 months, after which inspection is required for
4 renewal. If a port is unable to perform an adequate inspection at the time of renewal, the certificate
5 may be renewed for up to 1 month to allow the necessary inspection to be performed. Inspections for
6 certification are to be conducted when the ship and holds are empty. Ship Sanitation Control Exemption
7 Certificates are issued when an inspection reveals no evidence of a public health risk, and authorities are
8 satisfied the ship is free of contamination or disease vectors (WHO 2007a). A Ship Sanitation Control
9 Certificate is issued when an inspection reveals evidence of a public health risk or sources of
10 contamination and appropriate control measures have been undertaken. If appropriate control
11 measures cannot be performed at the port of inspection, this is to be noted on the Ship Sanitation
12 Control Certificate and the next port of call notified; this does not guarantee response by officials
13 receiving notification.

14 The third edition of the International Health Regulations Guide to Ship Sanitation was published in
15 October 2007. The guide contains both general and specific recommendations to be considered in the
16 construction of ship facilities, as well as measures that can be undertaken to minimize problems in ships
17 that have already been constructed (WHO 2007b, 2010c). Section 10.7 of the ship sanitation guide
18 contains specific recommendations for controlling insect and rodent disease vectors. Essentially, any
19 openings larger than 1.25 centimeters (cm) (0.5 inches [in]) should be obstructed with rat-proof
20 materials. Insulation that is thicker than 1.25 cm (0.5 in) must also be protected against gnawing by rats.
21 The rat-proof materials mentioned in the guide include steel plates, sheet iron or steel, sheet aluminum
22 or metal alloy, perforated sheet metal, expanded metal, flattened expanded metal, wire mesh, or
23 hardware cloth. These materials must not contain openings greater than 1.25 cm (0.5 in). Non-rat-proof
24 materials may be used in rat-proof areas as long as boundaries and gnawing edges are protected. Rat-
25 proof material is defined as a material having surfaces and edges that are resistant to gnawing by rats. A
26 rat-proof area is defined as an area that is completely isolated from other areas by means of rat-proof
27 material. Examples of rat-proof areas include galleys, pantries, cargo holds, storage spaces, and
28 shaftways. A rat-tight area is an area bounded by material that contains no hole large enough for the
29 passage of rats, and is sufficient only in more frequented areas where rats cannot gnaw undisturbed.
30 Examples of rat-tight areas include quarters, dining rooms and mess rooms, and public spaces such as
31 lounges, radio rooms, and wheelhouses.

32 The ship sanitation guide also recommends delegating at least one person on board a ship to be
33 responsible for a rodent trapping program. Traps are to be set after leaving a port where rats could
34 possibly have come on board directly or with cargo. If, after 2 days, no rats are caught, the traps can be
35 removed. Otherwise, traps are to be left in place until no more rats are caught. Records of when and
36 where traps were set along with catch records should be recorded in the ship's log to be available for
37 port health inspectors. In addition to trapping, regular inspections should be performed to look for
38 evidence of rats, such as droppings. In particular, these inspections should focus on areas where food is
39 prepared and garbage is stored, as well as any place rats might potentially hide. Port authority officials
40 conduct inspections of the ship to ensure the ship has adequately assessed and addressed potential

1 health risks. For larger ships that have monitoring and management programs in place, inspection at the
2 port may consist only of auditing records to ensure compliance. Ships that have had an outbreak of
3 disease or pests will be inspected by authorities to determine the cause.

4 The U.S. government does not require ships to hold a Ship Sanitation Control Certificate or Ship
5 Sanitation Control Exemption Certificate (CDC 2009). The authority for compliance with the
6 International Health Regulations in the United States is the U.S. Department of Health and Human
7 Services. Most of the responsibilities associated with the International Health Regulations are assigned
8 to the Centers for Disease Control and Prevention. The United States currently does not provide ship
9 sanitation inspections of commercial cargo carriers, and is awaiting further guidance from the WHO
10 regarding these inspections (CDC 2009; WHO 2010e).

11 ***Federal Regulations***

12 The CFR provides some guidance on ship inspection and disinfection. The pertinent portions are Title 7
13 (regulated articles from Hawai'i and the territories), Title 9 (movement of animals and animal parts), and
14 Title 42 (public health). Title 7 (Subtitle B, Volume 5, Chapter 3, Part 3A.13-9 and Part 330.111)
15 specifically requires notification of inspectors prior to departure or arrival of ships on Guam, giving the
16 inspector the opportunity to conduct an inspection. Title 9 (Volume 1, Chapter 1, Subchapter D, Part 93)
17 allows the inspection of any ship from foreign locations without a warrant to determine whether the
18 ship is carrying any animal or animal part subject to disposal to prevent the spread of disease. If the ship
19 is found to be contaminated, the operator of the ship is responsible for disinfection. Title 9 (Volume 1,
20 Chapter 1, Subchapter D, Part 95) also requires the disinfection of a ship if it has transported restricted
21 items that were not contained in leak-proof containers. The method of cleaning prescribed in Title 9
22 (Part 95) includes the collection of litter and refuse, and disposal of that refuse by incineration or other
23 approved method. This is to be followed by cleaning of the areas of the ship that were exposed to the
24 contaminant and saturation of the contaminated surface with an approved disinfectant. The approved
25 disinfectants are sodium carbonate solutions, sodium hydroxide solutions, or liquefied phenol. These
26 disinfectants are specifically designed to target foot and mouth disease, rinderpest, and ticks. Title 42
27 (Part 71, Subpart E, Section 71.41) of the CFR states that carriers arriving at U.S. ports are subject to
28 sanitary inspections to look for rodent, insect, or vermin infestation that may spread disease.

29 The APHIS-PPQ Manual for Agricultural Clearance contains information on the inspection of ships
30 (USDA-APHIS-PPQ 2013). The manual provides a table for determining whether a ship needs to be
31 boarded on arrival, boarding can be deferred, or the ship only needs to be monitored. Ships that need to
32 be boarded on arrival are generally from known infected areas, have a history of violations, or are
33 foreign ships. Ships in the deferred boarding category are usually U.S. Armed Forces vessels not boarded
34 on arrival, U.S. flag ships, private ships, or ships that frequent the port and have a low pest risk. Ships
35 are monitored on an unannounced, spot-check basis for compliance with garbage regulations and
36 adequate safeguarding of stores. Ships that were not previously boarded are monitored when feasible,
37 and at least 50% of ships that were previously boarded will also be monitored.

38 There are three factors that determine the focus and extent of ship inspections (USDA-APHIS-PPQ 2013),
39 the location of the port, where the ship has traveled and taken on cargo, and whether the ship is on a

1 watch list for previous violations or known pest outbreaks. The areas to be inspected include the galley
2 and stores, quarters, and deck. These areas are inspected for fresh fruits and vegetables, evidence of
3 pests, and compliance with garbage regulations. The manual specifically instructs inspectors to focus
4 their inspections of barges on the deck areas. If live or dead animals, contamination, or leaking garbage
5 is found, the area is to be cleaned and disinfected. Disinfection procedures for animal contamination
6 include treatment with Virkon®S or sodium carbonate with sodium silicate. Disinfection procedures for
7 live pests are to be determined by a CBP Agricultural Specialist according to the APHIS-PPQ Treatment
8 Manual. The treatment manual only contains guidance for treatment when khapra beetles, fruit flies,
9 and soft bodied insects are found (USDA-APHIS-PPQ 2008).

10 CBP published a Vessel Inspection Guide in 2009. However, this guide does not contain information on
11 inspection of ships per se. The guide contains instructions for checking the paperwork of crew members
12 and passengers, signs of human trafficking, and how to handle human stowaways (CBP 2009).

13 ***Commercial Vessel Inspections***

14 The Centers for Disease Control and Prevention published a Vessel Sanitation Program Operations
15 Manual in 2005. This manual also provides guidance to the cruise ship industry on methods to minimize
16 public health risks (CDC NCEH 2005). Compliance with the program is voluntary. However, the U.S.
17 Public Health Service has the authority under the Public Health Service Act (Title 42, Part G) to make
18 regulations and take actions to prevent the spread of communicable diseases (FDA 1999a, b). Title 42 of
19 the CFR also gives the Public Health Service the authority to conduct sanitary inspections. The National
20 Center for Environmental Health at the Centers for Disease Control and Prevention became responsible
21 for administering the program in 1986. A fee is charged for the service depending on the size of the ship.
22 The manual contains guidance on keeping food areas free of rodents and other pests, such as using
23 tight-fitting lids on garbage containers. Incoming food supplies are to be inspected for signs of insect,
24 rodent, or other pest infestation. Areas of the ship that are inspected include medical facilities, potable
25 water systems, swimming pools, whirlpools, galleys, dining rooms, child activity centers, hotel
26 accommodations, ventilation systems, and common areas. The manual recommends that any vessel
27 with a foreign itinerary carrying more than 13 passengers be inspected twice yearly for food safety and
28 environmental sanitation. However, inspections do not occur every 6 months (WHO 2010e). These are
29 to be unannounced inspections if the vessel is available. Inspection reports or summary reports are
30 published on the Vessel Sanitation Program website.

31 ***Military Vessel Inspections***

32 The Quarantine Regulations of the Armed Forces were written to allow the military to comply with the
33 regulations of the U.S. Departments of Health and Human Services, Agriculture, Treasury, Homeland
34 Security, Interior, and Commerce (DoD 1992). This was superseded by OPNAVINST 6210.2. The
35 regulations are designed to prevent the introduction and spread of disease agents (human, animal, and
36 plant), arthropod vectors, and pests of health or agricultural importance. The documents state that the
37 military is to cooperate with the agencies listed above to comply with regulations. Military vessels are
38 exempt from inspections by foreign officials, although they must meet the quarantine requirements of
39 each entry port that are published in the U.S. Air Force Foreign Clearance Guide (AFR 8-5 and

1 OPNAVINST 3710.2E). Commanding officers may certify compliance to foreign health officials, which
2 may include a general description of the measures taken to be in compliance. Foreign officials are not
3 allowed to board a U.S. Armed Forces ship, even to observe inspections.

4 Section II, Subsection A of the Quarantine Regulations of the Armed Forces and Section 9a of
5 OPNAVINST 6210.2 specifically govern vessels (DoD 1992). Measures are to be taken prior to departure
6 to minimize movement of human disease vectors, including insects and rats. As soon as a vessel is
7 berthed at a pier, and for the remainder of its stay at the pier, certain preventive measures must be
8 taken to minimize the likelihood of rats gaining access to the ship. Ships must be moored at least 6 feet
9 from the pier. Gangways and other access points to the ship are to either be well lit and guarded, or
10 separated from the shore. Cargo nets or similar devices extending between the ship and the shore will
11 be raised or removed unless actually in use. All connecting lines are to be fitted with rat guards. The
12 International Health Regulations no longer require the use of rat guards on mooring lines unless the ship
13 is berthed in a port where plague is endemic. However, commanding officers or medical department
14 representatives can still require their use in ports with a large rodent population. Cargo is only to be
15 loaded after it has either been found to be free of rodents or has been treated to remove all rodents.
16 Before the ship departs the port, it must be inspected for fleas and rodents and treated to remove these
17 pests if found.

18 All naval ships are required to have current Ship Sanitation Control or Ship Sanitation Control Exemption
19 certificates because they can be deployed anywhere in the world on short notice (U.S. Navy 2001).
20 These may be issued either by the U.S. Public Health Service or by a Public Health Service designated
21 military quarantine representative (DoD 1992; OPNAVINST 6210.2). According to BUMED 6210, the
22 primary medical personnel that are authorized to issue ship sanitation certificates are Navy preventive
23 medicine technicians (U.S. Navy 2010b), and inspectors are not allowed to inspect or issue a ship
24 sanitation certificate for a vessel where they are part of the ship's company (U.S. Navy 2001, 2010b).
25 Navy medical personnel are authorized to issue ship sanitation certificates for Navy, Army, Military
26 Sealift Command, Coast Guard, and National Oceanic and Atmospheric Administration vessels. Qualified
27 inspectors are issued an official seal from the U.S. Public Health Service to be used in the issuance of
28 ship sanitation certificates (U.S. Navy 2010b). According to BUMED 6250.14A, rodent inspections for
29 ship sanitation certificates are to be conducted during daylight hours with an empty hold or a hold
30 containing only material unattractive to rodents (U.S. Navy 2010b). If rodents are found, BUMED
31 6250.14A instructs personnel to continue to conduct control operations for 3 to 5 days after signs of an
32 active infestation have ceased before requesting a re-inspection. Deratting should be conducted when
33 holds are empty if possible. Ship sanitation certificates are to be issued in duplicate, with one copy going
34 to the ship and the medical department retaining the other. Specifications and directions for rat guards
35 are also given in BUMED 6250.14A.

36 Section II, Subsection C of the Quarantine Regulations of the Armed Forces and Section 10 of
37 OPNAVINST 6210.2 cover the USDA requirements. These sections govern the movement of animal and
38 plant diseases and pests. Ships moving between Hawai'i, Guam, Puerto Rico, the U.S. Virgin Islands, and
39 the continental United States are required to undergo USDA inspection by a USDA inspector or
40 representative. GCQA officers collaborate with USDA-APHIS to enforce federal regulations (Tajjeron

1 2010c). The disinfection measures currently available target primarily disease organisms and insects and
2 may not be effective on many of the invasive species transported in ships. Subsection C requires
3 surveillance aboard ships that includes spot checking and routine collection and identification of pest
4 organisms.

5 The Defense Transportation Regulations, Part V establishes the requirements for agricultural cleaning
6 and inspection, and the assignment of DoD personnel as agricultural and customs inspectors for pre-
7 clearance programs. USDA-APHIS is responsible for providing DoD with guidance, information, and
8 training to perform pre-clearance inspections (DoD 2009a).

9 To facilitate redeployment operations, DoD can request pre-clearance inspections by CBP and USDA for
10 vessels returning to the CTUS (DoD 2009c). Pre-clearance inspections may be requested for
11 redeployment from major exercises or contingencies, and are performed at the point of origin. Requests
12 for pre-clearance inspections must be submitted no later than 75 days prior to when the inspection is
13 needed. Requests must contain the following information: dates, times, and place of departure from a
14 foreign country; date, time, and place of arrival in the CTUS; number and type of ships; identification of
15 all stops between the point of departure and arrival; and whether the border clearance integrity of the
16 ship will be maintained during en route stops. Examples of clearance integrity being breached are the
17 addition or removal of cargo or passengers at any stop, crew member changes, or off-loading of crew
18 and passengers. Such breaches of integrity will void the pre-clearance authority. Both CBP and USDA
19 provide and approve training of Customs Border Clearance Agents for the military (DoD 2009c). When
20 the planned destination is in the CTUS, Customs Border Clearance Agents inspect ships to ensure they
21 are free of plants, animals, or plant and animal products. Equipment must be stored in a way that
22 prevents re-infestation by pests.

23 The Armed Forces Pest Management Board published Technical Guide Number 31 to cover the cleaning
24 and inspection procedures used in conjunction with retrograde washdowns (AFPMB 2008). Decks of
25 ships that held vehicles or equipment are required to be thoroughly cleaned. In particular, recessed
26 areas, underneath shelving, corners, and hard to reach places should be cleaned to remove soil.
27 Causeways on naval vessels are to be washed with either fresh or salt water during back loading.
28 Vessels, such as the Captain's launch or a liberty launch, are not required to be cleaned unless they are
29 contaminated. Although the guide recommends that operators of these vessels conduct a thorough
30 inspection, it does not require it.

31 NAVMED P-5010-8 is the Naval Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest
32 Control Technology (U.S. Navy BMS 2004). This manual covers the use of preventive measures and oral
33 bait stations and anticoagulants for rodent control. The species of concern that are listed in the manual
34 are the Norway rat (*Rattus norvegicus*), roof rat (*Rattus rattus*), and house mouse (*Mus musculus*). Some
35 general characteristics of each are described to aid in identification. Measures that are mentioned to
36 control and prevent rodent infestations include the elimination of food and shelter, rodent proofing
37 when feasible, rodenticides, snap traps, and glue boards. The manual contains a specific section on
38 controlling and preventing rodents aboard ships which include proper sanitation, pierside inspections,
39 rat guards, illumination and movement restrictions, glue boards, and snap traps. Pierside inspections for

1 signs of rodents (droppings, hair, gnawing) should be conducted on all subsistence items and cargo. Rat
2 guards are required to be a minimum of 91 cm (36 in) in diameter and be mounted at least 1.8 m (6
3 feet) from shore or 0.6 m (2 feet) from the ship. Access points to the vessel, such as gangways, are to be
4 separated from the shore by at least 1.8 m (6 feet), and cargo nets or similar devices extending between
5 ship and shore are to be raised or removed when not in use. Vessels departing from ports where certain
6 diseases such as yellow fever, malaria, and plague are endemic or epidemic in the port area must be
7 disinfected.

8 The U.S. Navy Shipboard Pest Control Manual, NAVMED P-5052-26, provides guidance on inspection and
9 deratting procedures to be carried out on ships (U.S. Navy 2008). This manual also lists the Norway rat,
10 roof rat, and house mouse as the most common rodents of concern. The commanding officer of a ship is
11 to ensure that medical department personnel are trained and certified in shipboard pest control. The
12 medical department representative ensures that there is an ongoing pest control program on board the
13 ship. This includes maintaining current ship sanitation certificates, conducting inspections, and keeping
14 records of pest control activities. Records of activities include pierside and onboard inspection records,
15 ship sanitation certificates, and pesticide use records.

16 According to the U.S. Navy Shipboard Pest Control Manual, inspections occur pierside for incoming food,
17 and surveillance on a ship is to occur at least every 2 weeks (U.S. Navy 2008). If control measures are
18 implemented, they should be followed up with surveillance to determine efficacy. Rodent signs to look
19 for during inspections include runways and rub marks, tracks, gnawing, droppings, urine, and hairs.
20 Prevention measures listed are similar to those provided in NAVMED P-5010-8. In addition to the rat
21 guard requirements listed in NAVMED P-5010-8, the pest control manual requires rat guards to have a
22 cone angle of 30 degrees and be made of 18 gauge steel or aluminum. Gaps are to be plugged with rags
23 that are tightly secured to prevent rodents from pulling them apart. Stray lines are to be kept out of the
24 water, and if two lines are close to each other, they are either to be installed through the same rat guard
25 or have rat guards installed side by side to prevent rats from jumping from line to line. The U.S. Navy
26 Shipboard Pest Control Manual also reiterates the guidelines in the CFR listed above.

27 In addition to the U.S. Navy Shipboard Pest Control Manual, MIL-STD-904B provides guidance on the
28 detection, identification, and prevention of pest infestations. This standard is provided in full in
29 Appendix G of the U.S. Navy Shipboard Pest Control Manual (U.S. Navy 2008). The standard applies not
30 only to insects and rodents, but to birds and other animals as well. For preventing cross-contamination
31 of pathways (cargo to vessel), the standard requires samples be taken of subsistence items that have a
32 history of contamination or infestation or items that have been stored near contaminated or infested
33 items. Samples should be taken from the area most likely to be infested, such as the outermost
34 containers of a stack, or the area closest to the contaminated or infested items. Closed packages are to
35 be inspected for holes made by insects, and rodent, bird, or other animal contamination or damage. If
36 signs of contamination or damage are found, the package is to be opened. Opened packages weighing
37 less than 4.5 kg (10 pounds) are to be inspected in their entirety. If the opened package weighs more
38 than 4.5 kg (10 pounds), a 1.4 kg (3 pounds) sample is to be taken from the top and bottom of the unit
39 and adjacent to tears or holes. Subsistence items shipped from tropical environments are to be paid
40 special attention and inspected thoroughly. Stored subsistence items are to be inspected at least once

1 monthly, as are storage areas. Items are to be stored off the floor on pallets or shelves and be at least
2 0.5 m (18 in) from the wall to minimize hiding areas available to rodents, birds, and other animals.

3 ***Guam***

4 Commercial ships providing a ship sanitation certificate that arrive in the Port of Guam will have
5 acquired it from a previous port of call on the identified list of ports identified by the WHO (Ames 2010).
6 Guam is listed in the WHO International Health Regulations Authorized Ports List as being able to issue
7 ship sanitation certificates (WHO 2010e). All vessels tying up at the dock must place rodent barriers on
8 mooring lines (Merfalen 2010). All commercial cargo is subject to inspection and is selected based on
9 the manifest associated with the shipment (Merfalen 2010). The process for inspecting the vessel will
10 follow the guidelines established in the International Health Guidelines interim technical advice, but will
11 vary procedurally by the country of issuance (WHO 2007a). Title 10 Chapter 37 of the Guam Code
12 requires docks and wharves to be constructed so as to prevent rodents from gaining access to them
13 during low and high tides. Food stored at docks and wharves must be stored in such a manner to
14 prevent access by rodents. The Director of Public Health and Social Services is to enforce international
15 quarantine regulations for controlling rodents for all vessels and watercraft arriving on Guam (GCA).
16 Perimeter fencing supports traps for BTS (PB International 2008).

17 ***Commonwealth of the Northern Mariana Islands***

18 Privately owned vessels returning to Saipan are inspected by CNMI Customs and Quarantine officers for
19 rodents and BTS by the detector dog teams. The BTS detector dog teams are part of the CNMI Division
20 of Fish and Wildlife, which is a separate agency from the CNMI Customs and CNMI Quarantine agencies.
21 Customs personnel accompany the dog detector team aboard the vessel (Guerrero 2010). Saipan is
22 listed in the WHO International Health Regulations Authorized Ports List as being able to issue ship
23 sanitation certificates (WHO 2010e). We observed perimeter fencing supporting traps for BTS during our
24 site visit to the Port of Saipan in January 2010. The Port of Tinian receives cargo ships routed from
25 Saipan or Guam and inter-island ferry traffic. We observed perimeter fencing supporting traps for BTS
26 during our site visit to the Port of Tinian in January 2010. During the site visit on Tinian there were no
27 mice available to use in BTS traps due to collapse in the species' population on the island, and
28 insufficient funding to purchase new mice (Castro 2010).

29 ***Federated States of Micronesia***

30 According to FSMC Title 18, Chapter 2 § 206, any ship entering FSM is subject to inspections by customs,
31 immigration, agriculture, and administrative personnel. We were unable to find any information
32 regarding exactly what these inspections entail. The immigration regulations of FSM state that all ships
33 will be inspected for stowaways, presumably human (FSM ORC 2005). FSM is a party to the WHO, and
34 therefore is bound by the International Health Regulations.

35 ***Republic of the Marshall Islands***

36 Vessels entering or leaving RMI are subject to inspections by immigration, customs, agriculture, public
37 health, or administrative personnel as stated in Title 43, Chapter 2, Section 205 of the Marshall Islands
38 Revised Code (PacLII 2003). According to Title 8, Chapter 1, Section 110 of the Marshall Islands Revised

1 Code, vessels known or suspected to be harboring insects or agricultural pests are to be sprayed with an
2 insecticide (PacLII 2004a). Any employee of the RMI Ports Authority may enter a vessel for the purpose
3 of inspection according to Title 22, Chapter 1, Section 153 of the Marshall Islands Revised Code (PacLII
4 2004c). RMI is a party to the WHO, and therefore is bound by the International Health Regulations.

5 ***Palau***

6 No information could be accessed regarding ship inspections in Palau. However, Palau is a party to the
7 WHO, and therefore is bound by the International Health Regulations.

8 ***China***

9 China is a member state of the WHO, and therefore is bound by the International Health Regulations,
10 and according to the WHO International Health Regulations Authorized Ports List, can issue ship
11 sanitation certificates (WHO 2010e). Chapter 4 of the Rules for the Implementation of Frontier Health
12 and Quarantine Law of the People’s Republic of China covers seaport quarantine (Chinese Ministry of
13 Public Health 1989). Both entry and exit quarantine inspections are conducted, although what these
14 inspections actually entail is not explained. Article 29 states that inspections will occur between sunrise
15 and sunset only, unless the port is equipped for night navigation. Inspections will not occur at night if
16 the ship is from an area with a known infestation. Ship Sanitation Control Certificates are required for
17 entry to ports in China according to Article 30.

18 ***Korea***

19 Korea is not listed as a member state of the WHO, and therefore may not follow the International Health
20 Regulations. However, the Republic of Korea is listed in the WHO International Health Regulations
21 Authorized Ports List as being able to issue ship sanitation certificates (WHO 2010e). No information
22 could be accessed regarding ship inspections in Korea.

23 **A4.1.3.2.4 *Summary of Findings***

24 All water transportation pathways were considered high risk due to their ability to transport species,
25 such as BTS and rodents, with potential impacts to human health. Risk increased as the probability of
26 species survival during transport increased, such as for high-speed vessels and vessels transiting short
27 distances. Risk also increased based on several factors related to the process of inspection. Risk
28 increased in ports where the International Health Regulations are not enforced. The risk of inspectors
29 missing an invasive species increased as time constraints and equipment unavailability (broken or
30 nonexistent equipment) increased, or the number of personnel decreased. Risks basically reflected an
31 increase in commercial ship traffic without adequate increases in biosecurity needs, such as additional
32 staffing for inspections and enforcement, updated equipment and facilities, continued training, and
33 easier reporting capabilities.

34 **A4.1.3.2.5 *Specific Risk Factors***

35 The specific risk factors we found to be associated with the water transportation pathways are as
36 follows:

1 **Common Risk Factors**

- 2 • Rat guards may not be required or used for prevention in all ports of call on vessels
3 transiting to Guam or the Micronesia Region.
- 4 • Rat guards may not prevent BTS from accessing the ship by crawling up a mooring line.
- 5 • The ability of the canine inspection to locate BTS in a complex environment may be
6 compromised.
- 7 • An inspection/management program focused on preventing introduction of an agricultural
8 pest may not detect or prevent the movement of a vertebrate invasive species to another
9 pathway.
- 10 • Regulations pertaining to ships are primarily focused on insects, rodents, and the prevention
11 of spreading human disease. Invasive species that do not fall under one of these categories,
12 such as amphibians, may be missed during inspections.
- 13 • Inadequate financial resources exist in CNMI, FSM, RMI, and Palau to maintain expensive
14 control programs.

15 **Risk Factors Associated With Commercial Maritime Traffic**

- 16 • Commercial carrier vessels from the major shipping lines are cleared rapidly (approximately
17 30 minutes) by customs and quarantine officers (Merfalen 2010). Emphasis is on regulated
18 waste inspections and reviewing cargo manifests.
- 19 • Cruise ships are not required to comply with the Vessel Sanitation Program and only need to
20 supply ship sanitation certificates if it is required for a port at which the vessel is docking.
- 21 • Staffing on Guam and CNMI is inadequate to meet current quarantine demands.

22 **Risk Factors Associated With Military Maritime Traffic**

- 23 • Retrograde washdown procedures primarily target soil and may not remove invasive species
24 hidden in areas not targeted for washing.
- 25 • Captain’s launches and liberty launches are not required to be inspected or cleaned upon
26 return to a ship unless they are contaminated, increasing the likelihood of moving invasive
27 species undetected.

28 **A4.1.3.3 Military Cargo and Vehicles Used In Training Exercises**

29 The pathways we evaluated in this analysis are focused on the risk of moving invasive species on cargo
30 associated with military training. Cargo includes equipment, gear, vehicles, vessels, aircraft, and supplies
31 used in training exercises. Current training activities are presented in the Marianas Island Range
32 Complex draft EIS/Overseas EIS (U.S. Navy 2009j). Future training activities following the relocation of
33 the 3rd Marine Expeditionary Unit from Okinawa to Guam are presented in the second and third
34 chapters of Volume 2 of the draft EIS/Overseas EIS (U.S. Navy 2009f, Vol 2, Chap 2, 2009g, Vol 2, Chap
35 3).

1 Various species can be moved in cargo (Table A4-11). The Marianas Island Range Complex EIS specifically
 2 lists tent and camp setup as activities that will occur during field training and force protection exercises
 3 at Northwest Field and Andersen South (U.S. Navy 2009j). There have been documented reports of the
 4 transport of invasive species of concern in cases of munitions (Vice et al. In preparation). Therefore, we
 5 evaluated munitions being brought to Guam and spent munitions being shipped from Guam as a result
 6 of training. Vehicles, such as trucks and tanks, amphibious assault and support vessels, and high-speed
 7 vessels will be used in training exercises to transport troops and supplies (U.S. Navy 2009j, f).

8 **Table A4-11: Invasive Species Transported In Military Cargo and Equipment**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Bufo gargarizans</i>	Asiatic toad	ECL
	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL
	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL
	<i>Fejervarya cancrivora</i>	Crab-eating frog	ECL
	<i>Fejervarya limnocharis</i>	Asian cricket frog	ECL
	<i>Kaloula pulchra</i>	Asian painted frog	ECL
	<i>Litoria fallax</i>	Dwarf tree frog	ECL
	<i>Microhyla pulchra</i>	Marbled pygmy frog	ECL
	<i>Polypedates leucomystax</i>	Common tree frog	ECL
	<i>Polypedates megacephalus</i>	Spot-legged tree frog	ECL
	<i>Rana catesbeiana</i>	American bullfrog	ECN, ECL
	<i>Rana guentheri</i>	Guenther's frog	H, ECL
	<i>Rhinella marina</i>	Cane toad	H, ECN, ECL
Birds	None likely	None likely	
Mammals	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
	<i>Rattus rattus</i>	Black rat	H, ECN, ECL
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Anolis carolinensis</i>	Green anole	ECL
	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL
	<i>Dinodon rufozonatum</i>	Red banded snake	None found ^b
	<i>Elaphe carinata</i>	Taiwan stink snake	None found
	<i>Elaphe taeniura friesi</i>	Taiwan beauty snake	None found
	<i>Gehyra mutilata</i>	Mutilating gecko	None found
	<i>Gekko gekko</i>	Tokay gecko	ECL
	<i>Hemidactylus frenatus</i>	House gecko	ECL
	<i>Lepidodactylus lugubris</i>	Mourning gecko	None found
	<i>Naja kaouthia</i>	Monocled cobra	H
	<i>Trimeresurus elegans</i>	Sakashima habu	H
	<i>Trimeresurus mucrosquamatu</i>	Taiwan habu	H
	<i>Xenochrophis piscator</i>	Asiatic water snake	None found

^a H = health, ECN = economic, ECL = ecological.

^b No impacts found in the literature, but undocumented impacts may exist.

10
11

1 **A4.1.3.3.1 *Military Cargo and Vehicle Inspection***

2 A Brown Treesnake Control and Interdiction Plan was developed by the Navy to prevent the movement
3 of the BTS off of Guam in response to Executive Order 13112, Invasive Species (The White House 1999;
4 U.S. Navy 2005b). Executive Order 13112 made it the responsibility of all federal agencies to prevent the
5 introduction and spread of invasive species in the United States and elsewhere. The BTS plan requires
6 the military to cooperate fully with federal authorities during observations and inspections of cargo
7 destined to be shipped from Guam. It also requires a close working relationship with APHIS-WS to
8 effectively implement the plan. The plan directs the Department of the Interior and USDA to go through
9 a rulemaking process on BTS inspections.

10 The plan requires that 100% of all outbound cargo is to be inspected for BTS using canine detection
11 methods; however, the plan also states that military commanders and APHIS-WS personnel must jointly
12 decide the extent of inspections based on the nature of the training exercise and the volume of cargo to
13 be transported. On Guam, APHIS-WS maintains dogs and equipment necessary to implement BTS
14 control plans. APHIS-WS may recommend holding a cargo carrier from departing Guam if it is suspected
15 to harbor BTS, and allow commanders to make the decision whether to release the cargo (Vice 2010a).

16 Prior to establishing bivouac sites on Guam, APHIS-WS personnel are to be consulted so they can
17 recommend areas that have a lower BTS risk. Cargo shipped to Tinian from Guam is tagged following
18 inspection and clearance by APHIS-WS and this tag is subject to confirmation by CNMI Quarantine
19 inspectors. Untagged cargo may be refused entry and reloaded aboard the conveyance for return to
20 Guam. Vehicles are to be cleaned and inspected prior to being moved to an approved cargo staging
21 area. Vehicles and equipment that are considered to be higher risk for BTS infestation may be required
22 to undergo additional cleaning measures such as high pressure washing, steam-cleaning, or fumigation.
23 Once cargo is cleaned and inspected, it is to be immediately loaded onto a vessel or aircraft. If a delay
24 will occur between inspection and loading, cargo may be placed in a APHIS-WS approved staging area
25 and re-inspection may be required. Cargo staging areas are to be chosen to minimize the likelihood that
26 BTS can access cargo. APHIS-WS is to be given complete access to staged cargo and equipment for the
27 purposes of BTS inspections. Prior to breaking camp, all personal belongings and tents used in a bivouac
28 area are to be inspected by APHIS-WS for the presence of BTS.

29 Inspections of baggage and personnel are focused on preventing the movement of drugs, firearms, plant
30 and animal products, and undeclared items (DoD CBCPP 2009c). All DoD cargo is to be made available
31 for inspection by CBP upon entry to the United States. It is up to the discretion of CBP personnel to
32 determine what level of inspection is required.

33 To facilitate redeployment operations, the DoD can request pre-clearance inspections by CBP and USDA
34 for cargo and equipment returning to the CTUS (DoD 2009c). The Defense Transportation Regulations,
35 Part V establishes the requirements for agricultural cleaning and inspection, and the assignment of DoD
36 personnel as agricultural and customs inspectors for pre-clearance programs. USDA-APHIS is responsible
37 for providing the DoD with guidance, information, and training to perform pre-clearance inspections
38 (DoD 2009a). APHIS remains the final authority on the pest risk status of material or equipment.

1 Pre-clearance inspections may be requested for redeployment from major exercises or contingencies,
2 and are performed at the point of origin. Requests for pre-clearance inspections must be submitted no
3 later than 75 days prior to when the inspection is needed. Requests must contain the following
4 information: dates, times, and place of departure from a foreign country; date, time, and place of arrival
5 in the CTUS; amount and type of cargo; identification of all stops between the point of departure and
6 arrival; and whether the border clearance integrity of the aircraft or ship will be maintained during en
7 route stops. Examples of clearance integrity being breached are the addition or removal of cargo or
8 passengers at any stop, crew member changes, off-loading of crew and passengers, or an aircraft
9 remaining in a location overnight. Such breaches of integrity will void the pre-clearance authority.

10 Both CBP and USDA provide and approve training of Customs Border Clearance Agents for the military
11 (DoD 2009c). When the planned destination is in the CTUS, CBP agents inspect cargo to ensure it is free
12 of plants, animals, or plant and animal products. Equipment must be stored in a way that prevents re-
13 infestation by pests. In addition, CBP can establish a Military Customs Inspectors–Excepted program at a
14 DoD installation (DoD 2009d). Such a program allows DoD personnel to perform the same functions as
15 CBP agents in connection with arriving military or military-chartered aircraft from overseas areas.
16 Inspection duties of the DoD personnel under this program include customs, immigration, and
17 agricultural inspections or functions. Inspectors under the Military Customs Inspection Excepted
18 program may not conduct searches of personnel.

19 Chapter 511 of the Defense Transportation Regulations Part V states that all cargo entering Guam,
20 regardless of origin, is subject to inspection by GCQA. GCQA requires a packing list for all containers, and
21 will conduct inspections of containers. What these inspections entail is not described, other than to say
22 that inspectors must make sure departing containers are free of BTS. Coordination of inspection
23 activities between the military and foreign governments falls to the U.S. Transportation Command (DoD
24 CBCPP 2009b). Part II of the Defense Transportation Regulations covers cargo, but contains little
25 information regarding inspections (DoD 2008a).

26 OPNAVINST 6210.2 states that USDA-APHIS-PPQ personnel may inspect cargo to prevent the
27 introduction of plant and animal pests or diseases. No cargo is to be loaded in foreign countries unless it
28 is free of soil or pests. Cargo is to be cleaned to remove soil and pests, and packed in such a way as to
29 prevent access of pests to cleaned cargo. The Quarantine Regulations of the Armed Forces states that
30 cargo is subject to inspection by a representative of USDA to prevent the introduction or spread of
31 animal and plant diseases or pests (DoD 1992). For the purposes of these regulations, Guam is
32 considered part of the United States. The CFR provides some guidance on military cargo inspection and
33 disinfection as it pertains to movement of regulated articles from Hawai'i and the territories, and
34 movement of animals or animal parts. Title 7 (Subtitle B, Volume 5, Chapter 3, Parts 3A.13-8 and 3A.13-
35 10) states that cargo moving between Guam, CNMI, Hawai'i, and the continental United States is subject
36 to agricultural inspection.

37 The Armed Forces Pest Management Board published Technical Guide Number 31 to cover the cleaning
38 and inspection procedures used in conjunction with retrograde washdowns (AFPMB 2008). Washing and
39 inspection of vehicles and equipment shipped as cargo may only occur during daylight hours. Prior to

1 arriving at a washdown area there are several preparations that must take place on vehicles. Vehicles
2 are to be prepared by having the cab and all storage and tool compartments swept or vacuumed. The
3 battery and battery box should be removed, cleaned, and reinstalled. Outside dual tires and spare tires
4 should be removed and placed in the back of the vehicle. Payloads, seat cushions, detachable
5 sideboards, canvas dies/tops, and person gear are to be removed and left at the mobile staging area for
6 cleaning. Vegetation, insects, or other debris should be removed from the radiator. Trucks that are
7 equipped with collapsible sides should have the sides disengaged, and all recessed areas and ledges
8 cleaned. Engine packs should be removed from tanks and Bradley fighting vehicles prior to washing.
9 Once at the washdown area, vehicles are exposed to either high pressure (minimum 90 psi) fresh water
10 or steam.

11 After vehicles are washed, they are inspected to ensure all soil has been removed (AFPMB 2008).
12 Common areas to be inspected include top and bottom access points, paying particular attention to
13 crevices. Top access points are floor boards; battery boxes; storage and tool compartments; wheels and
14 tires; windshield bases; front and rear bumper hollows and braces; radiator front; and truck beds.
15 Bottom access points are fender wells; rocker panels; fore and aft frames; coil spring wells; transmission
16 support beams; rear suspension A-frames; pivot points; and drain holes; trailer hitch bolt recesses; front,
17 side, and rear body lips; drive shaft tunnels; power take-offs; axle brackets; fuels tanks; transaxle
18 brackets; leaf springs; and air tank braces.

19 The troop compartment, crew area, and the crew's personal equipment on amphibious vehicles are
20 required to be cleaned. All soil packed into the treads, around the rubber cleats, in the tread connectors,
21 and between and behind tread guides and roller supports on tracked vehicles must be removed. The
22 interior of tracked vehicles, including the battery box, must also be free of soil. Bilges can contain some
23 sand as long as it is mixed with salt water and is not being transported on an aircraft. Tracked vehicles
24 can only be cleaned on shore as long as they can be reloaded without recontamination of the treads,
25 otherwise they must be cleaned on the ship's well deck. The problem areas of specific vehicles are
26 shown in the Appendices of Technical Guide Number 31 (AFPMB 2008).

27 Hand brooms, rags, compressed air, and other non-water methods can be used to clean supplies and
28 equipment such as mount-out boxes/Hardigg-like cases, field desks, and communications equipment
29 (AFPMB 2008). In particular, attention should be paid to cracks, crevices, and recesses. Pallets are to be
30 cleaned of soil and vegetation. Tents and canvas should be spread out on a pest free surface and swept
31 down on both sides, paying particular attention to the seam and flaps. No water should be used to clean
32 tents and canvas, but compressed air may be used to aid in the cleaning process.

33 **A4.1.3.3.2 Summary of Findings**

34 With the exception of transporting hazardous waste from the naval base on Guam to the continental
35 United States, all pathways were considered to be high risk due to their potential to transport species
36 that can harm human health and safety. The hazardous waste pathway was only likely to vertebrate
37 species and species that could be transported in this pathway only had ecological effects. Inspections of
38 cargo departing Guam are primarily focused on BTS and pests with agricultural risks; thus, inspections
39 may miss some vertebrate invasive species. Detection of BTS relies on a large degree of cooperation

1 among agencies, particularly APHIS-WS and the military. Resources are limited in CNMI to maintain
 2 expensive prevention and control programs for BTS, increasing the risk that the BTS could become
 3 established there.

4 **A4.1.3.3.3 Specific Risk Factors**

5 The specific risk factors we found to be associated with transport of military cargo used in training
 6 exercises are as follows:

- 7 • BTS inspections may not address the movement of other potentially invasive species.
- 8 • Tent cleaning and inspection processes emphasize agricultural pest risks and may not
 9 adequately address the risk of transporting an invasive vertebrate species.
- 10 • The emphasis on preventing the movement of invasive species associated with tent cities is
 11 on departure from Guam and BTS. No emphasis is placed on the risk of bringing new
 12 invasive species to Guam.
- 13 • No contact networks exist for species other than BTS. This network may be used when other
 14 invasive species are located or captured, but this is not always the case.
- 15 • Agricultural inspections of cargo at the port of entry may not adequately detect a vertebrate
 16 invasive species moving in vehicles, cargo or equipment.
- 17 • There are limited control measures for frogs, toads, lizards, and snakes that could be
 18 transported with military cargo.
- 19 • The retrograde washdown and inspection process is focused on preventing the transport of
 20 agriculturally significant pests on vehicles and may not be effective for preventing the
 21 transport of vertebrate invasive species.
- 22 • Inadequate financial resources exist in CNMI to maintain expensive prevention and control
 23 programs.
- 24 • Communication is inadequate between the military and officials on Tinian, and response
 25 capabilities are lacking on Tinian, to allow for proper inspections of cargo associated with
 26 military training to occur.

27 **A4.1.3.4 Cargo and Container Conveyances**

28 Movement of invasive vertebrate species in containerized cargo and on the container conveyance itself
 29 is a significant pathway, capable of moving many types and a large number of species (Table A4-12).
 30 There is an anticipated increase in the amount of containerized cargo that will be shipped to Guam to
 31 support the relocation and the provisioning of increased military personnel.

32 **Table A4-12: Invasive Species Transported in the Cargo Container Pathway**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Bufo melanostictus</i>	Asian common toad	None found ^b
	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL

Class	Scientific name	Common name	Risk type ^a
	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL
	<i>Hyla cinerea</i>	American green tree frog	ECL
	<i>Kaloula pulchra</i>	Asian painted frog	ECL
	<i>Limnodynastes tasmaniensis</i>	Spotted grass frog	ECL
	<i>Litoria aurea</i>	Green and golden bell frog	H, ECL
	<i>Litoria caerulea</i>	Australian green tree frog	ECL
	<i>Litoria chloris</i>	Red-eyed tree frog	None found
	<i>Litoria ewingii</i>	Whistling tree frog	ECL
	<i>Litoria fallax</i>	Eastern dwarf tree frog	ECL
	<i>Osteopilus septentrionalis</i>	Cuban tree frog	H, ECN, ECL
	<i>Polypedates leucomystax</i>	Common tree frog	ECL
	<i>Pseudacris regilla</i>	Pacific tree frog	ECL
	<i>Rana sylvatica</i>	Wood frog	ECL
Birds	None likely	None likely	
Mammals	<i>Didelphis marsupialis</i>	American opossum	H, ECN, ECL
	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Myotis lucifugus</i>	Little brown bat	H, ECN
	<i>Pipistrellus javanicus</i>	Javan pipistrelle	H, ECN
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
	<i>Rattus rattus</i>	Ship rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN, ECL
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Agama agama</i>	Common agama	None found
	<i>Anolis cristatellus</i>	Common Puerto Rican anole	ECL
	<i>Anolis distichus</i>	Hispaniolan gracile anole	ECL
	<i>Anolis extremus</i>	Barbados anole	ECL
	<i>Anolis porcatius</i>	Cuban green anole	ECL
	<i>Anolis sagrei</i>	Cuban brown anole	ECL
	<i>Boa constrictor</i>	Boa constrictor	H, ECN, ECL
	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL
	<i>Calotes versicolor</i>	Eastern garden lizard	ECL
	<i>Chondrodactylus bibronii</i>	Bibron's thick-toed gecko	ECN
	<i>Cnemidophorus lemniscatus</i>	Rainbow lizard	ECL
	<i>Cryptoblepharus carnabyi</i>	Spiny-palmed snake-eyed skink	None found
	<i>Cryptoblepharus peecilopleurus</i>	Mottled snake-eyed skink	ECL
	<i>Cryptoblepharus plagioccephalus</i>	Péron's snake-eyed skink	None found
	<i>Cryptoblepharus virgatus</i>	Cream-striped shinning-skink	None found
	<i>Cyrtopodion scabrum</i>	Rough-tailed gecko	ECL
	<i>Elaphe taeniura friesi</i>	Taiwan beauty snake	None found
	<i>Elgaria multicarinata</i>	Southern alligator lizard	None found
	<i>Emoia cyanura</i>	Bluetail emo skink	ECL
	<i>Eulamprus tenuis</i>	Bar-sided forest skink	None found
	<i>Gehyra mutilata</i>	Mutilating gecko	None found

Class	Scientific name	Common name	Risk type ^a
	<i>Gekko gekko</i>	Tokay gecko	ECL
	<i>Gonatodes albogularis</i>	Yellow-headed gecko	None found
	<i>Hemidactylus frenatus</i>	Common house gecko	ECL
	<i>Hemidactylus garnotii</i>	Indo-Pacific gecko	None found
	<i>Hemidactylus platyurus</i>	Flat-tailed house gecko	None found
	<i>Hemidactylus turcicus</i>	Mediterranean house gecko	ECL
	<i>Hemiphyllodactylus typus</i>	Common dwarf gecko	None found
	<i>Lampropholis delicata</i>	Delicate skink	ECL
	<i>Lepidodactylus aureolineatus</i>	Golden scaly-toed gecko	None found
	<i>Lepidodactylus lugubris</i>	Mourning gecko	None found
	<i>Lipinia noctua</i>	Moth skink	None found
	<i>Lycodon aulicus</i>	Common wolf snake	ECL
	<i>Mabuya multifasciata</i>	Rough mabuya	None found
	<i>Python molurus bivittatus</i>	Burmese python	H, ECN, ECL
	<i>Ramphotyphlops braminus</i>	Blind snake	None found
	<i>Sceloporus occidentalis</i>	Western fence lizard	None found
	<i>Sphaerodactylus argus</i>	Ocellated gecko	None found
	<i>Sphaerodactylus elegans</i>	Ashy gecko	None found
	<i>Tarentola mauritanica</i>	Common wall gecko	None found
	<i>Tiliqua scincoides</i>	Common bluetongue	None found
	<i>Trimeresurus flavoviridis</i>	Habu	H
	<i>Uta stansburiana</i>	Northern side-blotched lizard	None found

^a H = health, ECN = economic, ECL = ecological.

^b No impacts found in the literature, but undocumented impacts may exist.

Cargo and its conveyances originate from numerous sources, and the actual points of origination for much of this traffic have not been identified. The major shipping companies for containerized cargo transport in the Micronesia Region are Horizon, Matson, Kyowa, and Marianas Express Lines (PB International 2008). Information from these companies was used to determine the routes by which cargo is likely to be shipped. The shipping pathways are taken from the current schedules posted on the websites for Horizon, Horizon Lines of Guam, Kyowa, Mariana Express Lines, and Matson (Horizon Lines 2010b, c, d, a; Kyowa Shipping Company 2010a, b; Mariana Express Lines 2010a, b; Matson 2010a, b).

Shipping routes were chosen to capture the risks associated with the movement of containerized cargo in the region with emphasis on the most likely sources for material associated with the relocation. We focused on containerized cargo coming from Asia, specifically that shipped through South Korea by Kyowa, and from the continental United States via the West Coast and Hawai'i to Guam by Matson and Horizon.

A4.1.3.4.1 Cargo Container Inspections

International and Federal Regulations

The International Health Regulations contain guidance regarding containers and cargo with respect to public health concerns (WHO 2005b). Chapter 4, Article 34, governs containers and loading areas. Container shippers are responsible for ensuring that containers are kept free of vectors and reservoirs of

1 disease and contamination during the packing process. Loading areas are also to be kept free of disease
2 vectors and reservoirs. If containers are used for multiple types of cargo, shippers must ensure that
3 cross-contamination does not occur. Countries may determine, at their discretion, that a container is
4 sufficiently large to require a sanitary inspection for disease vectors and reservoirs; no guidance is given
5 on what “sufficiently large” means. Inspection facilities are to be available at container loading areas if
6 practical. Chapter 5, Article 23, allows any country to require inspections of cargo and containers prior
7 to departure and arrival if deemed necessary for public health reasons.

8 The CFR provides guidance on cargo and cargo container inspection and disinfection as it pertains to
9 movement of regulated articles from Hawai’i and the territories, and movement of animals or animal
10 parts. Title 7 (Subtitle B, Volume 5, Chapter 3, Parts 3A.13-8 and 3A.13-10) states that cargo moving
11 between Guam, CNMI, Hawai’i, and the continental United States is subject to agricultural inspection.
12 Title 9 (Volume 1, Chapter 1, Subchapter D, Part 93) allows the inspection of any shipping containers on
13 aircraft or ships from foreign locations without a warrant to determine whether the aircraft or ship is
14 carrying any animal or animal part subject to disposal to prevent the spread of disease. If the container
15 is found to be contaminated, the operator of the aircraft or ship is responsible for disinfection. Title 9
16 (Volume 1, Chapter 1, Subchapter D, Part 95) also requires the disinfection of a container if it has
17 transported restricted items that were not contained in leak-proof containers. The method of cleaning
18 prescribed in Title 9 (Part 95) includes the collection of litter and refuse, and disposal of that refuse by
19 incineration or other approved method. This is to be followed by cleaning the areas of the container that
20 were exposed to the contaminant and saturation of the contaminated surface with an approved
21 disinfectant. The approved disinfectants are sodium carbonate solutions, sodium hydroxide solutions, or
22 liquefied phenol. These disinfectants are specifically designed to target foot and mouth disease,
23 rinderpest, and ticks.

24 The APHIS-PPQ MAC instructs inspectors to inspect cargo if it is of agricultural interest (USDA-APHIS-PPQ
25 2013). Cargo of agricultural interest will contain either plant or animal material and is inspected
26 primarily for agricultural pests or diseases. The APHIS-PPQ Treatment Manual contains procedures for
27 treating cargo with fumigants, phosphine, methyl bromide, aerosols, or micronized dust (USDA-APHIS-
28 PPQ 2008).

29 ***BTS Inspections***

30 A Brown Treesnake Control and Interdiction Plan was developed by the Navy in response to Executive
31 Order 13112, Invasive Species (The White House 1999, U.S. Navy 2005b), to prevent the movement of
32 BTS off of Guam. Executive Order 13112 made it the responsibility of all federal agencies to prevent the
33 introduction and spread of invasive species in the United States and elsewhere. The BTS plan requires
34 the military to cooperate fully with federal authorities during observations and inspections of cargo
35 destined to be shipped from Guam. It also requires a close working relationship with APHIS-WS to
36 effectively implement the plan. APHIS-WS maintains dogs and equipment necessary to implement BTS
37 control plans. The plan directs the Department of the Interior and USDA to go through a rulemaking
38 process on BTS inspections.

1 The plan requires that 100% of all outbound cargo be inspected by BTS detector dog teams. However,
2 the plan also states that military commanders and APHIS-WS personnel must jointly decide the extent of
3 inspections based on the nature of the training exercise and the volume of cargo to be transported.
4 Cargo shipped to Tinian is tagged following inspection and clearance by APHIS-WS, and this tag is subject
5 to confirmation by CNMI Quarantine inspectors; however, the limited resources on Tinian hamper these
6 confirmation inspections. Untagged cargo may be refused entry and reloaded aboard the conveyance
7 for return to Guam. Once cargo is cleaned and inspected, it is to be immediately loaded onto a vessel or
8 aircraft. If a delay will occur between inspection and loading, cargo may be placed in an APHIS-WS
9 approved staging area and re-inspection may be required. Cargo staging areas are to be chosen to
10 minimize the likelihood that BTS can access cargo. APHIS-WS is to be given complete access to staged
11 cargo and equipment for the purposes of BTS inspections.

12 ***Military Regulations***

13 All DoD containerized cargo is to be made available for inspection by CBP upon entry to a U.S. port of
14 entry. It is up to the discretion of CBP personnel to determine what level of inspection is required.
15 Inspections are focused on preventing the movement of drugs, firearms, plant and animal products, and
16 undeclared items (DoD CBCPP 2009c). When the planned destination is in the CTUS, CBP agents inspect
17 cargo to ensure it is free of plants, animals, or plant and animal products. Technically, Guam is not
18 considered a CTUS.

19 To facilitate redeployment operations, DoD can request pre-clearance inspections by CBP and USDA for
20 containerized cargo and equipment returning to the CTUS (DoD 2009c). The Defense Transportation
21 Regulations, Part V, establish the requirements for agricultural cleaning and inspection and the
22 assignment of DoD personnel as agricultural and customs inspectors for pre-clearance programs. USDA-
23 APHIS is responsible for providing DoD with guidance, information, and training to perform pre-
24 clearance inspections (DoD 2009a). Both CBP and USDA provide and approve training of Customs Border
25 Clearance Agents for the military (DoD 2009c; DoD CBCPP 2009a, c). In addition, CBP can establish a
26 Military Customs Inspectors–Excepted program at a DoD installation (DoD 2009d). Such a program
27 allows DoD personnel to perform the same functions as CBP agents in connection with certain cargo as
28 laid out in a memorandum of understanding between the installation commander and the local CBP port
29 director. Inspection duties of the DoD personnel under this program include customs, immigration, and
30 agricultural inspections or functions.

31 According to the requirements for agricultural cleaning and inspection (Part 5, Chapter 505), no cargo is
32 to be loaded in a foreign country unless it is free from plant and animal contamination or pest
33 infestations (DoD 2009a). Pre-clearance inspections may be requested for redeployment from major
34 exercises or contingencies, and are performed at the point of origin (DoD 2009c). Requests for pre-
35 clearance inspections must be submitted no later than 75 days prior to when the inspection is needed.
36 Requests must contain the following information: dates, times, and place of departure from a foreign
37 country; date, time, and place of arrival in the CTUS; amount and type of cargo; identification of all stops
38 between the point of departure and arrival; and whether the border clearance integrity of the aircraft or
39 ship will be maintained during en route stops. Examples of clearance integrity being breached are the

1 addition or removal of cargo or passengers at any stop, crew member changes, off-loading of crew and
2 passengers, or an aircraft remaining in a location overnight. Such breaches of integrity will void the pre-
3 clearance authority. APHIS remains the final authority on the pest risk status of material or equipment.

4 Chapter 511 of the Defense Transportation Regulations Part V states that all containerized cargo
5 entering Guam, regardless of origin, is subject to inspection by GCQA. GCQA requires a packing list for all
6 containers, and will conduct inspections of containers. What these inspections entail is not described,
7 other than to say that inspectors must make sure containers are free of BTS. Coordination of inspection
8 activities between the military and foreign governments falls to the U.S. Transportation Command (DoD
9 CBCPP 2009b). Part II of the Defense Transportation Regulations covers cargo, but contains little
10 information regarding inspections (DoD 2008a).

11 OPNAVINST 6210.2 states that USDA-APHIS-PPQ personnel may inspect containerized cargo to prevent
12 the introduction of plant and animal pests or diseases. For the purposes of these regulations, Guam is
13 considered part of the United States. No military cargo is to be loaded in foreign countries unless it is
14 free of soil or pests. Cargo is to be cleaned to remove soil and pests and packed in such a way as to
15 prevent access of pests to cleaned cargo. The Quarantine Regulations of the Armed Forces states that
16 cargo is subject to inspection by a representative of USDA to prevent the introduction or spread of
17 animal and plant diseases or pests (DoD 1992).

18 ***Australia***

19 The Australia Customs and Border Protection Service operates Container Examination Facilities at
20 seaports, which were established to address border risks such as narcotics and terrorism (ACBPS 2009a,
21 b). The Australia Customs and Border Protection Service conducts risk assessments for incoming cargo,
22 and conducts inspections of all high risk cargo using x-ray machines in combination with physical
23 examinations. Containers are x-rayed upon arrival at the port, and a determination is made whether the
24 cargo requires an examination. Those requiring examination are physically inspected.

25 The Australian Quarantine and Inspection Service also conducts inspections of cargo containers.
26 Inspections are designed to exclude exotic pests and diseases, and examine the external and internal
27 cleanliness of containers. Containers from areas where the giant African snail (*Achatina fulica*) is found
28 undergo a mandatory inspection. Containers are also examined for the presence of soil, plant material,
29 and animal products.

30 ***China***

31 China Customs and the Ministry of Agriculture are responsible for import and export inspections. The
32 best information that we could obtain for cargo inspections by China Customs is related to inspection of
33 goods. This information was used because goods may be packaged as cargo in containers. All inspections
34 are conducted by two or more officers in a Customs control area. Goods are inspected to ensure that
35 they match what is listed on the customs declaration. Customs officers have the discretion to determine
36 what level of inspection is required. Inspections may be either thorough or selective, and may take place
37 by either manual inspection, machine inspection, or both. Manual inspection may be of the exterior of
38 packages, the interior of packages, or both (Xinsheng 2005; GAC 2007). Containers may also be

1 inspected under the Import and Export Animal and Plant Quarantine Regulations by Ministry of
2 Agriculture officials (People’s Republic of China State Council 1982). No details could be found as to
3 what quarantine inspections entail.

4 ***Commonwealth of the Northern Mariana Islands***

5 The Saipan Customs Division looks for undeclared items, non-English labeled items, drugs, and weapons
6 during its inspections of cargo (Sabian 2010). Saipan Customs has an x-ray machine for container
7 inspections at the Port of Saipan. There is a BTS barrier at the Port of Saipan for containers, but Customs
8 does not currently have a protocol for using it. Cargo that does not come from the continental United
9 States is put in the barrier area for a minimum of 3 days. Personnel from the Department of Land and
10 Natural Resources place traps around the barrier, and inspect the exterior of the containers with BTS
11 detector dogs (Guerrero Jr. 2010). If a BTS detector dog alerts to a container, the container will stay
12 within the barrier longer than 3 days for further inspection. Detector dog inspections are usually only
13 conducted in the morning because the metal of the containers gets too hot during the middle of the day
14 for the dogs. The BTS detector dog teams are part of the Division of Fish and Wildlife, which is a
15 separate agency from the CNMI Customs and CNMI Quarantine agencies. Customs officials at the Saipan
16 Airport receive training and certification for clearing exports (Pangolinean 2010). Staffing is currently
17 inadequate at the airport, and Customs officials lack the necessary safety equipment to conduct
18 inspections. The x-ray machine that was in use at the airport is nonfunctional because it is so old that
19 replacement parts can no longer be obtained.

20 There is also a BTS barrier at the Port of Tinian (Ferrell 2010). Any containers that come from Guam get
21 put into the barrier until the BTS detector dog can inspect it. Another BTS barrier is needed at the Tinian
22 airport where the military C-130s unload their cargo. The military does not always inform Tinian
23 Quarantine when they are coming with cargo; therefore, not all cargo gets inspected. Further, even
24 when notification does occur, Tinian lacks the necessary response capabilities. Agricultural inspections in
25 CNMI are overseen by APHIS-PPQ.

26 ***Federated States of Micronesia***

27 FSMC Title 54, Chapter 2, Subchapter 3 gives Customs officials the right to examine goods. All cargo
28 entering at an FSM port is required to be reported to FSM Customs within 1 day of arrival. No
29 information could be found regarding Customs inspections of cargo. FSMC Title 22, Chapter 4, governs
30 agricultural inspections of cargo, but no information is contained regarding what inspections entail.

31 ***Guam***

32 Containerized cargo import inspections are to be conducted at designated ports unless otherwise
33 authorized by the Director of GCQA (GCA 2010a). Seals on cargo and containers are not to be broken
34 except by GCQA officials. There are 78 container freight stations on Guam (Merfalen 2010). Because of
35 the volume of traffic, not all containers are selected for inspection. It is unknown how many arriving
36 containers are opened and inspected for vertebrate invasive species. However, GCQA does not routinely
37 open containers unless they lack proper documentation or are from a country Guam has deemed a
38 country of concern (Merfalen 2010). Countries may be considered a concern for a variety of reasons,

1 including whether they harbor an agricultural pest of concern, have had a disease outbreak, or have had
2 previous customs violations.

3 The container freight station at the Guam International Airport currently only has one, two-man team.
4 The freight station needs at least two teams to handle the relocation. GCQA has a new facility at the
5 airport that will be able to handle the increased cargo flow from the relocation once it is fully
6 operational. However, GCQA at the airport is currently understaffed and will need at least 31 additional
7 personnel to handle the increased cargo flow due to the relocation (Shimizu 2010b). Guam Customs has
8 two x-ray machines at the airport; they were inoperable at the time this was document was written and
9 are awaiting replacement RapidScan machines (Berringer 2010b). GCQA relies on a paper trail to identify
10 containers likely to require inspection. For example, in the Port of Guam, a container identified as
11 requiring an inspection will be tagged by a Guam Customs and Quarantine Agent. This container may
12 then be released to a consignee for movement from the port to a container freight station until
13 inspection.

14 ***Hong Kong***

15 Containerized cargo export examination is carried out by the Hong Kong Customs and Excise
16 Department. Selection for examination is done in such a way as to minimize disruption of the shipping
17 process. Hong Kong allows shippers to submit either a paper or an electronic cargo manifest. No specific
18 information could be accessed regarding cargo examination procedures (Hong Kong CED 2010). We
19 were unable to find any information regarding agricultural inspections of cargo.

20 ***Indonesia***

21 No information could be found regarding inspections of cargo in Indonesia.

22 ***Japan***

23 Exporters in Japan must obtain an export permit from Japan Customs, and goods are physically
24 examined (Japan Customs and Tariff Bureau , MoF). Cargo is also subject to agricultural inspections by
25 personnel from the Ministry of Agriculture, Forestry, and Fisheries. We could not obtain information
26 regarding what inspections entail.

27 ***Korea***

28 In order to promote foreign trade, the Korea Customs Service utilizes a paperless system for exporters
29 to file paperwork. Technically, exported goods are exempt from inspection; however, Customs officials
30 use risk selection criteria to select a certain percentage of exported containers to inspect. The risk
31 selection criteria include shippers with past violations and forged goods or documents (MSF 2009). We
32 were unable to find any information regarding agricultural inspections of cargo. The United States
33 military has a manual specifically for customs inspections of military cargo in Korea (USFK CLE 2010).
34 Military inspectors are to coordinate with the Korea Customs Service to conduct inspections and to
35 ensure violations are reported and investigated. Military cargo imports are inspected on a case by case
36 basis, with the emphasis placed on preventing military property from entering the black market. In light

1 of this emphasis, cargo with a high black market value is considered high risk and is targeted for
2 inspection.

3 ***Malaysia***

4 No information could be found regarding inspections of cargo in Malaysia.

5 ***New Zealand***

6 The Ministry of Agriculture and Forestry is responsible for agricultural inspections of cargo, and the New
7 Zealand Customs Service is responsible for customs inspections. The only guidance concerning
8 agricultural inspections of cargo and cargo containers we could find is related to import requirements
9 for companies shipping to New Zealand. The interior of containers is to be inspected prior to being
10 packed for animals, insects and other invertebrates, insect egg casings, animal materials, plant
11 materials, water, and soil (MAF). During loading, containers are not to be contaminated with soil by
12 forklifts or footwear, and are to be loaded on a hard, sealed surface. Containers are not to be left open
13 for extended periods of time or overnight to prevent entry by pests. The exterior of containers are to be
14 inspected for egg masses, grass, insects, pests, nests, seeds, snails, soil, and webs. Importers must file a
15 Quarantine Declaration form that includes information about any treatments the container has
16 received; otherwise it will be considered high risk. It is unknown if exported cargo must meet the same
17 requirements.

18 The New Zealand Customs Service has an online declaration website that exporters can use to clear their
19 exports with Customs. Shippers using this service must first be approved by customs officials as a
20 registered user of the site. No information could be found regarding whether containers and cargo are
21 inspected, how containers and cargo are selected for inspection, or what inspections entail.

22 ***Palau***

23 The Bureau of Agriculture is the NPPO of Palau and maintains the legal authority from the Plant and
24 Animal Quarantine Regulations (1999) as amended in 2008 to inspect containers and their contents for
25 plant pests. The Palau NPPO is not responsible for the issuance of phytosanitary regulations or arranging
26 for phytosanitary certification with the objective of ensuring that exported plants, plant produces,
27 regulated articles, and consignments are in conformity with the certifying statement that the shipment
28 is in compliant IPPC standards (Werner 2012).

29 ***Philippines***

30 The Philippine Bureau of Customs regulates exports, but no information could be found regarding
31 inspections for cargo other than paperwork requirements. Imported cargo agricultural products are
32 inspected by the Bureau of Customs (BOC) control. A cargo manifest for both incoming vessels and
33 airways are shared with the Plant and Animal Quarantine to inform of incoming products. As per
34 agreement in different ports of entry all attached government agencies involved in regulating the
35 imported agricultural products provide clearance prior to BOC release. Upon arrival of agricultural
36 products, BOC notifies plant and animal quarantine section to facilitate inspection and clearance. All
37 documentation have to pass and satisfy both agencies prior to release. For export products, all

1 agricultural products for export has to comply with the import requirement of the importing countries.
2 Plant quarantine will issue a phytosanitary certificate for plants and plant products and international
3 veterinary certificate for animals and animal products along with the inspection, treatment and
4 compliance to any bilaterally agreed protocol required by the importing country. Documentation and
5 treatment requirements of all cargoes with agricultural commodities for export are being done in the
6 exporter's premises prior to transport to the port. For hand-carry baggage and small consignments,
7 there are plant and animal quarantine inspection booths present in all ports of departure to inspect
8 outgoing agricultural products and issue export certifications.

9 ***Republic of the Marshall Islands***

10 The Marshall Islands Revised Code (Title 48, Chapter 2, Section 216) gives Customs officials the authority
11 to examine goods carried on ships and aircraft (PacLII 2004b). No information is given regarding what
12 examinations entail. The Marshall Islands Revised Code (Title 8, Chapter 1, Section 106) authorizes
13 agricultural inspections of cargo to enforce plant and animal quarantine regulations (PacLII 2004a). No
14 detail is given as to what agricultural inspections entail.

15 ***Singapore***

16 Cargo that is to be exported requires a Customs permit and is cleared by Singapore Customs officials
17 (Singapore Customs 2007a, b). No information was available as to what the clearance procedures entail.
18 We were unable to find any information regarding agricultural inspections of cargo.

19 ***Taiwan***

20 The Directorate General of Customs (DOGC) is the authority to regulate cargo container inspections for
21 both imports and exports for non-agriculture items. Importers are required to provide documents that
22 can prove the authenticity of country of origin, eg. certificate of origin, contract of conveyance, the
23 information of manufacturing factory, export goods declaration form, etc. DOGC will check all the
24 related documents for each cargo to ensure that they match with each other. However, physically
25 examination on cargos are randomly sampled. The number of samples is determined based on entities,
26 types, packages, and quantities of commodities. If dangerous cargo is suspected, then police agencies
27 will jointly inspect the cargo with DOGC. Imported fresh fruit and vegetables, live animals, and plants
28 may be exempted from inspection by DOGC. DOGC do not inspect these items for export. The Bureau of
29 Animal and Plant Health Inspection and Quarantine (BAPHIQ), Council of Agriculture, is the authority
30 responsible for both imports and exports of agricultural inspections of cargo. Food and Drug
31 Administration, Department of Health and BAPHIQ are the authorities responsible for inspection of
32 meat for human consumption.

33 ***United States***

34 United States regulations are covered above under federal regulations.

35 ***Vietnam***

36 Vietnam Customs is responsible for government inspections related to national security issues and
37 inspects both imported and exported cargo (Vietnam Customs 2008a, b). Shippers who have been

1 importing goods for 2 years without customs violations are exempt from inspection. It is unknown if this
2 exemption also applies to exporters. In addition, there are certain types of goods that are exempt from
3 inspection such as equipment and machinery. Ten percent of the cargo containers that do not meet one
4 of these two requirements are inspected. Those shippers that have had three or more customs
5 violations in the past 2 years will have the entire shipment of cargo inspected. We were unable to find
6 any information regarding agricultural inspections of cargo.

7 **A4.1.3.4.2 Summary of Findings**

8 All pathways were considered high risk due to their ability to transport species that can harm human
9 health and safety. The primary risk associated with this pathway is that current inspection procedures
10 do not include inspection for vertebrate invasives because they have an agricultural pest or national
11 security emphasis. In addition, containers are generally not opened unless they lack proper
12 documentation or are from a country with a history of transporting invasive species or other violations.
13 Such directed inspections, as opposed to true random inspections, make it more likely vertebrate
14 invasive species could get missed. However, the optimal container selection strategy is a topic of current
15 research (Eiswerth and Johnson 2002, Horan et al. 2002, Batabyal and Beladi 2006, Batabyal and Lee
16 2006, Surkov et al. 2009, Batabyal and Herath 2010).

17 **A4.1.3.4.3 Specific Risk Factors**

18 The specific risk factors we found to be associated with the cargo container pathways are as follows:

- 19 • Customs agencies are constrained by resources to only inspect a portion of containers.
20 These inspections tend to be of material that has insufficient documentation or is from a
21 country of concern.
- 22 • The paperwork associated with arriving containers is not automated which does not allow
23 for more rapid selection of containers for screening.
- 24 • Documentation is lacking with regard to interception of vertebrates in or on cargo
25 containers. Often a species is identified as moving in cargo but the specifics are not
26 available.
- 27 • Container scanners are not available on Guam. They are available on Saipan but not used
28 due to funding limitations.
- 29 • Not all cargo from Asia is required to be inspected prior to export.

30 **A4.1.3.5 Wood Packaging Material**

31 Wood packaging material can be a commodity shipped, used in the shipping process as packing material,
32 and the conveyance used in packing, such as wooden crates. Wood packaging materials are used in
33 almost all major shipments of cargo, and are known pathways for plant pest and pathogen introductions
34 (USDA-APHIS 2003, FAO 2006e). Risk assessments to date have focused primarily on the movement of
35 plant pests and pathogens; however, the WPM pathway can also move terrestrial vertebrates (Table A4-
36 13).

1

Table A4-13: Invasive Species Transported in the Wood Packaging Material Pathway

Class	Scientific name	Common name	Risk type ^a	
Amphibians	<i>Bufo melanostictus</i>	Asian common toad	None found ^b	
	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL	
	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL	
	<i>Hyla cinerea</i>	American green tree frog	ECL	
	<i>Kaloula pulchra</i>	Asian painted frog	ECL	
	<i>Limnodynastes tasmaniensis</i>	Spotted grass frog	ECL	
	<i>Litoria aurea</i>	Green and golden bell frog	H, ECL	
	<i>Litoria caerulea</i>	Australian green tree frog	ECL	
	<i>Litoria chloris</i>	Red-eyed tree frog	None found	
	<i>Litoria ewingii</i>	Whistling tree frog	ECL	
	<i>Litoria fallax</i>	Eastern dwarf tree frog	ECL	
	<i>Osteopilus septentrionalis</i>	Cuban tree frog	H, ECN, ECL	
	<i>Polypedates leucomystax</i>	Common tree frog	ECL	
	<i>Pseudacris regilla</i>	Pacific tree frog	ECL	
	<i>Rana sylvatica</i>	Wood frog	ECL	
	<i>Rhinella marina</i>	Cane toad	H, ECN, ECL	
	Birds	None likely	None likely	
	Mammals	<i>Didelphis marsupialis</i>	American opossum	H, ECN, ECL
		<i>Mus musculus</i>	Common mouse	H, ECN, ECL
		<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
<i>Rattus norvegicus</i>		Norway rat	H, ECN, ECL	
<i>Rattus rattus</i>		Ship rat	H, ECN, ECL	
<i>Suncus murinus</i>		Musk shrew	H, ECN, ECL	
Reptiles	<i>Agama agama</i>	Common agama	None found	
	<i>Anolis cristatellus</i>	Common Puerto Rican anole	ECL	
	<i>Anolis distichus</i>	Hispaniolan gracile anole	ECL	
	<i>Anolis extremus</i>	Barbados anole	ECL	
	<i>Anolis porcatius</i>	Cuban green anole	ECL	
	<i>Anolis sagrei</i>	Cuban brown anole	ECL	
	<i>Boa constrictor</i>	Boa constrictor	H, ECN, ECL	
	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL	
	<i>Calotes versicolor</i>	Eastern garden lizard	ECL	
	<i>Chondrodactylus bibronii</i>	Bibron's thick-toed gecko	ECN	
	<i>Cnemidophorus lemniscatus</i>	Rainbow lizard	ECL	
	<i>Cryptoblepharus carnabyi</i>	Spiny-palmed snake-eyed skink	None found	
	<i>Cryptoblepharus peocilopleurus</i>	Mottled snake-eyed skink	ECL	
	<i>Cryptoblepharus plagioccephalus</i>	Péron's snake-eyed skink	None found	
	<i>Cryptoblepharus virgatus</i>	Cream-striped shinning-skink	None found	
	<i>Cyrtopodion scabrum</i>	Rough-tailed gecko	ECL	
	<i>Elaphe taeniura friesii</i>	Taiwan beauty snake	None found	
	<i>Elgaria multicarinata</i>	Southern alligator lizard	None found	
	<i>Emoia cyanura</i>	Bluetail emo skink	ECL	
	<i>Eulamprus tenuis</i>	Bar-sided forest skink	None found	
	<i>Gehyra mutilata</i>	Mutilating gecko	None found	
	<i>Gekko gekko</i>	Tokay gecko	ECL	
	<i>Gonatodes albogularis</i>	Yellow-headed gecko	None found	

Class	Scientific name	Common name	Risk type ^a
	<i>Hemidactylus frenatus</i>	Common house gecko	ECL
	<i>Hemidactylus garnotii</i>	Indo-Pacific gecko	None found
	<i>Hemidactylus platyurus</i>	Flat-tailed house gecko	None found
	<i>Hemidactylus turcicus</i>	Mediterranean house gecko	ECL
	<i>Hemiphyllodactylus typus</i>	Common dwarf gecko	None found
	<i>Lampropholis delicata</i>	Delicate skink	ECL
	<i>Lepidodactylus aureolineatus</i>	Golden scaly-toed gecko	None found
	<i>Lepidodactylus lugubris</i>	Mourning gecko	None found
	<i>Lipinia noctua</i>	Moth skink	None found
	<i>Lycodon aulicus</i>	Common wolf snake	ECL
	<i>Mabuya multifasciata</i>	Rough mabuya	None found
	<i>Python molurus bivittatus</i>	Burmese python	H, ECN, ECL
	<i>Ramphotyphlops braminus</i>	Blind snake	None found
	<i>Sceloporus occidentalis</i>	Western fence lizard	None found
	<i>Sphaerodactylus argus</i>	Ocellated gecko	None found
	<i>Sphaerodactylus elegans</i>	Ashy gecko	None found
	<i>Tarentola mauritanica</i>	Common wall gecko	None found
	<i>Tiliqua scincoides</i>	Common bluetongue	None found
	<i>Trimeresurus flavoviridis</i>	Habu	H
	<i>Uta stansburiana</i>	Northern side-blotched lizard	None found

^a H = health, ECN = economic, ECL = ecological.

^b No impacts found in the literature, but undocumented impacts may exist.

1
2
3
4 WPM encompasses such things as crates, pallets, dunnage, packing blocks, drums, cases, load boards,
5 pallet collars, skids, veneer peeler cores, sawdust, wood wool, wood shavings, raw wood cut into thin
6 pieces, and cable spools. Because WPMs differ and are not likely to transport the same types of
7 terrestrial vertebrates, they were grouped into three broad categories for the risk analysis depending on
8 what they were likely to transport. Cable spools, cases, crates, drums, and pallets were grouped
9 together as being likely to transport a variety of amphibians, mammals, and reptiles because of the
10 availability of hiding places. Dunnage, load boards, packing blocks, pallet collars, raw wood cut into thin
11 pieces, skids, and veneer peeler cores were grouped together because they most likely will only
12 transport tree frogs, geckos, and skinks as these species are capable of clinging to various surfaces.
13 Finally, sawdust, wood shavings, and wood wool were grouped together as being likely to only transport
14 rodents that might be attracted to the material as bedding or nesting habitat.

15 Because of the paucity of documentation specifically relating to the movement of invasive species in
16 WPM, species that were listed as having been moved in cargo were used to generate the species lists,
17 and further, only those that were deemed likely to use a particular type of packing material based on
18 biological information were used. Species selection was based on criteria such as body size, presence of
19 toe pads on amphibians and lizards, ability to walk on vertical surfaces and upside down, whether a
20 species tends to be arboreal or terrestrial, and the resting or nesting sites typically utilized. Many
21 species are listed as having been moved in cargo, but no specific information is given as to where in the
22 cargo they were found. They may have been clinging to the inside of the cargo container itself, clinging
23 to WPM such as dunnage, or have found their way inside packing material such as sawdust. There is
24 likely to be overlap between the species listed in these pathways and those listed in the cargo container

1 pathway. Because no good data exist, there is some uncertainty inherent in the list of species for this
2 pathway.

3 Information from the major shipping companies servicing the Micronesia Region was used to determine
4 the routes by which cargo is likely to be shipped. This information was used because no information
5 exists explicitly on the transport of WPM, and WPM is likely to be used with specific cargo. The major
6 shipping companies used for cargo delivery in the Micronesia Region and their routes are covered
7 elsewhere in this document.

8 **A4.1.3.5.1 Wood Packaging Material Inspections**

9 Wood packaging material can be shipped as cargo to companies that then use those materials in the
10 packing and shipping of cargo goods. The United States began fully enforcing treatment of WPM being
11 shipped as cargo according to the ISPM on July 5, 2006 (USDA-APHIS 2007b). Wood packaging materials
12 themselves are subject to ISPM regulations listed in ISPM 15 that were developed by the IPPC (FAO
13 2006e). The IPPC is an international agreement regarding plant health and the prevention of the
14 movement of plant pests. Currently, it has 173 signatories, making the majority of the countries involved
15 in this pathway subject to ISPM 15 regulations (IPPC 2010). These regulations do not apply to WPM used
16 in the packing and shipping of cargo goods.

17 The regulations allow manufacturers and shippers two options: heat treatment or treatment with
18 methyl bromide. For materials to receive the ISPM 15 quality mark, materials being shipped as cargo
19 must be inspected by an agency accredited by either the American Lumber Standard Committee for heat
20 treatment (ALSC 2009), or the National Wood Pallet and Container Association for methyl bromide
21 fumigation (NWPCA 2009). Inspection procedures by both agencies must follow ISPM 15 regulations.
22 The regulations were developed to prevent the movement of plant pests such as insects, rather than
23 vertebrate invasives. These regulations only apply to pallets, dunnage, crates, packing blocks, drums,
24 cases, load boards, pallet collars, and skids that are transported as cargo and not as a conveyance (FAO
25 2006e). Materials such as veneer peeler cores, sawdust, wood wool, wood shavings, and raw wood cut
26 into thin pieces are not considered pathways of introduction for quarantine pests and thus are not
27 regulated (FAO 2006e). These regulations do not apply to movement within the United States or to
28 export to U.S. Trust Territories (USDA-APHIS 2008a). Also exempt is WPM used in DoD cargo shipments
29 of WPM that are imported for use by the DoD or its contractors, although some contractors may choose
30 to implement ISPM procedures (CBP 2010c).

31 Although heat treatment and methyl bromide may eliminate many insect and plant pests, both
32 treatments are utilized during the manufacturing stage only, and terrestrial vertebrate species may
33 enter treated WPM during the packing process. Heat treatment consists of heating wood until the
34 minimum wood core temperature is 56°C for at least 30 minutes (FAO 2006e). The methyl bromide
35 fumigation procedure is temperature and dosage dependent, but the minimum temperature is not to be
36 less than 10°C and the minimum exposure time is not to be less than 24 hours. Minimum monitoring of
37 the methyl bromide concentration should be conducted at 2, 4, and 24 hours (FAO 2006e).

1 Customs agents clearing WPM imported as cargo rely on quality marks, the labeling required by ISPM 15
2 for WPM. Quality marks allow for clear and easy identification of material that has been properly
3 treated and its country of origin. The country of origin is identified by a two letter ISO (International
4 Organization for Standardization) country abbreviation (FAO 2006e). Quality marks include information
5 such as a trademark, facility identification, and treatment used. The trademark identifies who made the
6 inspection, and is an identifying symbol, logo, or name of the accredited agency that provided inspection
7 services. The facility identification gives the product manufacturer name, brand, or assigned facility
8 number. The treatment used is symbolized as HT for heat treatment and MB for methyl bromide. The
9 quality mark contains an approved international symbol for compliant WPM, and an indication of
10 whether the material is used as dunnage; dunnage can either be spelled out or abbreviated. Dunnage
11 imported as cargo may be specifically singled out for marking because it can be made from wood that
12 has or has had bark on it, or it may be recycled and used to build crates or pallets; therefore, it needs to
13 be especially clear that it has been treated to avoid movement of insect pests (FAO 2006e). Wood
14 packaging material cargo that is recycled must be re-certified and re-marked to ensure that no new
15 pests, particularly insects, have entered the material prior to recycling (FAO 2006e).

16 Accredited inspection agencies periodically audit WPM manufacturer facilities and provide the quality
17 mark to the manufacturer. Audits typically include an inspection of records to ensure compliance with
18 ISPM 15, and may or may not include an inspection of the manufacturing floor or operational
19 procedures. It is incumbent upon the individual manufacturer to maintain proper records and quality
20 assurance procedures. Generally, only representative samples from random lots of material are
21 inspected (ALSC 2009, NWPCA 2009). An obvious invasive species might get detected during this
22 process, but most invasives listed in this pathway are small and may go undetected. In addition, most
23 vertebrate invasives are most likely to enter this pathway when the materials are used post-
24 manufacture to cushion other cargo during transport. This screening does nothing to prevent a species
25 from entering the material while it is being used in the packing process, post-manufacturing.

26 CBP inspects WPM shipped as a commodity for compliance with ISPM 15 and the presence of quality
27 marks indicating inspections were completed by an accredited agency (CBP 2010b). CBP does not
28 validate quality marks which is the jurisdiction of USDA, but it does check to ensure marks are legible
29 and permanent (SAL). Most of the countries involved in this pathway are parties to the IPPC, and require
30 adherence to ISPM 15 regulations (USDA-APHIS 2009b).

31 Title 7 of the CFR governs the treatment and inspection of WPM being shipped as a cargo commodity.
32 Part 305 of Title 7 covers phytosanitary treatments and states that treatments are to occur at APHIS
33 certified facilities and are to be monitored by APHIS officials. Part 319 of Title 7 of the CFR defines
34 regulated WPM as dunnage, crating, pallets, packing blocks, drums, cases, and skids. All regulated WPM
35 are required to have the IPPC quality mark, unless they are a DoD shipment. Regulated WPM is to be
36 inspected at the first port of entry. If pests are found, the shipment can either be cleaned and treated or
37 refused entry. A minimum of 7 days' advance notice to the APHIS officer in charge is required for all
38 regulated WPM coming into a port in the United States.

1 The APHIS-PPQ Manual for Agricultural Clearance directs inspectors to check whether regulated WPM is
2 compliant or non-compliant, but gives no other information on inspections (USDA-APHIS-PPQ 2013).
3 Dunnage on barges is a particular concern because it is more susceptible to becoming flotsam. The
4 APHIS-PPQ Treatment Manual contains specific instructions for the treatment of regulated WPM with
5 heat or methyl bromide (USDA-APHIS-PPQ 2008).

6 The APHIS Miscellaneous and Processed Products Manual contains inspection guidance that also applies
7 to Guam and CNMI (USDA-APHIS-PPQ 2010d). Inspectors are instructed to look specifically for timber
8 pests, other insects, and unspecified hitchhikers. If the WPM came from the United States, including U.S.
9 territories, or from the DoD, it is to be released but may be inspected. Wood packaging material coming
10 from foreign locations is inspected for the proper ISPM 15 quality mark and for timber pests, other
11 insects, and hitchhikers. Inspection is defined in the manual as a review of documentation and articles to
12 determine compliance with regulations. Logs, lumber, wood crating, and dunnage have special
13 inspection instructions that are related to the safety of the inspector. When no special inspection
14 instructions exist, 2% of the shipment is inspected. In addition, these articles are inspected for beetles,
15 borers, nematodes, termites, and weevils. A list of 28 items that routinely use WPM that should be paid
16 special attention to are given in this manual. These include such items as cast iron products, equipment,
17 pottery, and stoneware.

18 It is unknown how many containers are opened and the WPM used in the packing and shipping process
19 are inspected for terrestrial vertebrate invasive species, or the thoroughness of inspections. GCQA does
20 not routinely open containers unless they lack proper documentation or are from a country Guam has
21 deemed a concern (Shimizu 2010b). Countries of concern for Guam tend to be in Asia and on smaller
22 Micronesian islands that have little or no resources for biosecurity, because these were identified as
23 points of origin for cargo and related packing materials, or have had previous violations. Inspection
24 protocols similar to Guam's are in place on Saipan and Tinian (Ferrell 2010; Sabian 2010). We were
25 unable to find information specifically relating to the inspection of WPM by the other countries listed as
26 moving cargo and WPM.

27 **A4.1.3.5.2 Summary of Findings**

28 All pathways were considered high risk because of their ability to transport species that could harm
29 human health and safety. The primary risk associated with this pathway is that current inspection
30 procedures do not include inspection for terrestrial vertebrate species, nor do they prevent the entry of
31 these species into the material during the packing process. Inspections driven solely by proper
32 documentation and country of origin, as opposed to true random inspections, make it more likely to
33 miss terrestrial vertebrate species inadvertently being transported. Risk increased as the resources of
34 customs agencies decreased. The required ISPM 15 quality marks have been counterfeited or
35 fraudulently used (Brindley 2010; WPA 2010). More data are needed on the interception of vertebrates
36 found specifically in WPM upon arrival with cargo.

37 **A4.1.3.5.3 Specific Risk Factors**

38 The specific risk factors we found to be associated with the WPM pathways are as follows:

- 1 • The inspection process for WPM applies to pre-packaged material manufactured at the plant of
- 2 origin and does not apply to vertebrates that have entered the material while it is being used
- 3 post-manufacturing as packing material for cargo shipments.
- 4 • Customs agencies are constrained by resources such as time and finances, to inspect only a
- 5 portion of arriving containers, and may exclude any WPM within.
- 6 • It is unclear how thorough inspection of containers is with regard to WPM.
- 7 • ISPM 15 quality marks may be counterfeited or fraudulently used.
- 8 • Documentation is lacking with regard to interception of vertebrates found in WPM.

9 **A4.1.3.6 Relocation: Household Goods and Personal Vehicles Related to Relocation**

10 In general, household goods and vehicles are well-known pathways for the movement of invasive
11 species (Long 2003, Vice and Pitzler 2008, Kraus 2009). This type of cargo is capable of transporting BTS
12 and rodents among other species (Table A4-14). A large number of military personnel and their
13 dependents will be relocating to Guam as a result of the military relocation (see Section 0). Personnel
14 will be bringing household goods and personal vehicles, increasing the risk of moving vertebrate invasive
15 species. Additionally, military and civilian household goods and vehicles are routinely shipped
16 commercially throughout the Micronesia Region.

17 Military personal property is shipped by the U.S. Transportation Command, who can transport the cargo
18 on a military conveyance or book a commercial contract carrier (DoD 2008b, 2010a). To the extent
19 possible, personal property is shipped using the services of the Air Mobility Command or the Military
20 Sealift Command. Property is commonly packed commercially and moved off base by commercial
21 channels as freight (Vice and Pitzler 2008). Additionally, when service members are relocated they are
22 entitled to have one vehicle transported to their new duty station at government expense (DoD 2009e).
23 Other vehicles may be transported at the service member's expense.

24 Regionally, Guam is a commercial center for the Micronesia Region for commodities such as small
25 appliances, furniture, and other household goods that are often shipped regionally from Guam
26 throughout the region for both private and military purposes. This type of cargo may be containerized or
27 palletized. Personally owned vehicles, particularly used vehicles, are also shipped from Guam, often as
28 bulk cargo.

29 Three major routes for this type of cargo shipment were considered in the analyses: Okinawa to Guam,
30 Guam to the continental United States, and Guam to other parts of the Micronesia Region via Saipan.
31 Household goods and personally owned vehicles can be shipped commercially from Okinawa via Miike
32 Harbor, Japan, once a week. The shipping company is Hueng-A Shipping Company, Limited, and their
33 agents for the Okinawa to the Port of Miike route are either Kaniyaku Corporation or Minami Nihon
34 Kisen (Port of Miike). Containerized cargo can then be transshipped via Busan by Kyowa to Guam or via
35 a port in China to Guam by Matson or Horizon. Arrangements can be made through a freight forwarding
36 company. Cargo shipped commercially off Guam by Matson or Horizon to the continental United States
37 is transshipped through Asia prior to returning to the continental United States (Matson 2006; Horizon

1 Lines 2008). Regional shipping from the ports on Guam and Saipan throughout the Micronesia Region is
 2 handled by feeder services provided by Kyowa, Seabridge Marine, and Micronesia Express Service (PB
 3 International 2008).

4 **Table A4-14: Invasive Species Transported in the Household Goods and Personal Vehicles**
 5 **Pathways**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL
	<i>Kaloula picta</i>	Slender-digit chorus frog	None found ^b
	<i>Kaloula pulchra</i>	Asian painted frog	ECL
	<i>Litoria fallax</i>	Dwarf tree frog	ECL
	<i>Polypedates leucomystax</i>	Common tree frog	ECL
	<i>Rhinella marina</i>	Cane toad	H, ECN, ECL
Birds	None likely	None likely	
Mammals	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
	<i>Rattus rattus</i>	Black rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN, ECL
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Anolis carolinensis</i>	Green anole	ECL

	<i>Gekko gekko</i>	Tokay gecko	ECL
	<i>Lepidodactylus lugubris</i>	Mourning gecko	None found

6 ^a H = health, ECN = economic, ECL = ecological.

7 ^b No impacts found in the literature, but undocumented impacts may exist.

8

9 **A4.1.3.6.1 Inspection of Household Goods and Personal Vehicles**

10 **Military Regulations**

11 Shipping of military household goods and personally owned vehicles is covered in Part 4 of the Defense
 12 Transportation Regulations. Other regulations that pertain to these items are covered in Section 0.
 13 Personnel are counseled prior to a move as to what is required of them, and they are required to sign
 14 form DD 1797 stating they have been counseled as to moving requirements (DoD). Household goods
 15 that contain engine power driven equipment must be free of dirt and grease (DoD 2010b). Personal
 16 property items are also to be free of soil and pest infestations, such as gypsy moths or BTS (DoD 2010b,
 17 c). Any item that can be scratched, broken, or otherwise damaged during shipment is individually
 18 wrapped (DoD 2010e). Household goods packed on Guam are inspected by APHIS-WS detector dog
 19 teams for BTS during packing for households with more than an estimated 1,814 kg (4,000 pounds) of
 20 personal property (Vice and Pitzler 2008). During fiscal year 2008, approximately 70% of all packed
 21 household goods were inspected by APHIS-WS BTS detector dogs at Andersen AFB, 80% at the naval
 22 base, and 87% at the commercial ports (USDA-APHIS WS 2008a).

1 Shipment of personally owned vehicles is covered in Chapter 408 and Attachment K3. Personnel are
2 responsible for ensuring that all exterior surfaces and the undercarriage of the vehicle are free of soil
3 and foreign matter (DoD 2009e, f). The vehicle processing center at the naval base on Guam advises
4 vehicle owners to make sure their vehicles are free of plants, leaves, seeds, soil, dirt, mud, food,
5 beverages, insects, rodents, and animals (Pepka 2010). An inspection is performed of the vehicle by
6 personnel at the vehicle processing center to note any damage prior to shipping and to ensure the
7 cleanliness of the vehicle (DoD 2009e, f). On Guam, USDA personnel inspect the engine, engine
8 compartment, radiator grill, hood, trunk, hatch, door compartments, wheels, wheel areas, and
9 undercarriage areas (Pepka 2010), and APHIS-WS BTS detector dogs inspect the vehicles prior to
10 shipping. If destined for the United States, vehicles are inspected again upon arrival. GCQA inspects
11 vehicles coming from foreign locations, but does not inspect vehicles coming from the continental
12 United States. During fiscal year 2008, 100% of all vehicles were inspected by APHIS-WS BTS detector
13 dogs at Andersen AFB and the naval base, and 99% at the commercial ports (USDA-APHIS WS 2008a).

14 ***Japan***

15 Exporters of military household goods and personal vehicles in Japan must obtain an export permit from
16 Japan Customs, and goods are physically examined. Cargo is also subject to agricultural inspections by
17 personnel from the Ministry of Agriculture, Forestry, and Fisheries. We could not obtain information
18 regarding what inspections entail.

19 ***Guam***

20 Cargo and vehicles arriving in Guam shipped as commercial freight would be subject to GCQA inspection
21 (Merfalen 2010). Cargo inspections are to be conducted at designated ports unless otherwise authorized
22 by the Director of GCQA (GCA 2010a). Seals on cargo are not to be broken except by GCQA officials.
23 There are 78 container freight stations on Guam where selected containers are moved from the point of
24 entry and staged for inspection (Merfalen 2010). Because of the volume of traffic, not all containers are
25 selected for inspection. It is unknown how many arriving containers are opened and inspected for
26 vertebrate invasive species. However, GCQA does not routinely open containers unless they lack proper
27 documentation or are from a country Guam has deemed a country of concern (Merfalen 2010).
28 Countries may be considered a concern for a variety of reasons, including whether they harbor an
29 agricultural pest of concern, have had a disease outbreak, or have had previous customs violations.

30 The container freight station at the Guam International Airport currently only has one two-person team.
31 The freight station needs at least two teams to handle the relocation. GCQA has a new facility at the
32 airport, which will spatially be able to handle the increased cargo flow from the relocation once it is
33 adequately staffed and equipped and fully operational. Currently, GCQA at the airport is currently
34 understaffed, and will need at least 31 additional personnel to handle the increased cargo flow due to
35 the relocation (Shimizu 2010b). Guam Customs has two x-ray machines at the airport; they were
36 inoperable at the time this was document was written and are awaiting replacement RapidScan
37 machines (Berringer 2010b). GCQA relies on a paper trail to identify containers likely to require
38 inspection. For example, in the Port of Guam, a container identified as requiring an inspection will be

1 tagged by a Customs and Quarantine Agent. This container may then be released to a consignee for
2 movement from the port to a container freight station until inspection.

3 ***Commonwealth of the Northern Marianas Islands***

4 The Saipan Customs Division looks for undeclared items, non-English labeled items, drugs, and weapons
5 during its inspections of household imports (Sabian 2010). Saipan Customs has an x-ray machine for
6 containerized cargo import inspections at the Port of Saipan. There is a BTS barrier at the Port of Saipan
7 for containers, but Customs does not currently have a protocol for using it. Cargo that does not come
8 from the continental United States is put in the barrier area for a minimum of 3 days. Personnel from
9 the Department of Land and Natural Resources place traps around the barrier, and inspect the exterior
10 of the containers with BTS detector dogs (Guerrero Jr. 2010). If a BTS detector dog alerts to a container,
11 the container will stay within the barrier longer than 3 days for further inspection. Detector dog
12 inspections are usually only conducted in the morning because the metal of the containers gets too hot
13 during the middle of the day for the dogs. Customs officials at the Saipan Airport receive training and
14 certification for clearing exports (Pangolinean 2010). Staffing is currently inadequate at the airport, and
15 Customs officials lack the necessary safety equipment to conduct inspections. The x-ray machine that
16 was in use at the airport is nonfunctional because it is so old that replacement parts can no longer be
17 obtained.

18 There is also a BTS barrier at the Port of Tinian (Ferrell 2010). Any containers that come from Guam get
19 put into the barrier until the BTS detector dog can inspect it. Another BTS barrier is needed at the Tinian
20 airport where the military C-130s unload their cargo. The military does not always inform Tinian
21 Quarantine when they are coming with cargo; therefore, not all cargo gets inspected; however, when
22 information is relayed, there is typically little or no response capability to perform inspections.
23 Agricultural inspections in CNMI are overseen by APHIS-PPQ.

24 **A4.1.3.6.2 *Summary of Findings***

25 All pathways were considered high risk due to their ability to transport species that could harm human
26 health and safety. Household goods that are individually wrapped and/or packed are associated with
27 lower risk of transporting vertebrate invasive species because the packing process makes detection
28 more likely (Vice and Pitzler 2008). However, the probability of detecting BTS by canine inspection
29 teams is greatly decreased once household goods are sealed inside containers or wooden crates (Vice
30 and Pitzler 2008). Short shipment times, particularly those within the Micronesia Region, increase the
31 probability of species survival during transport (Vice and Pitzler 2008). Higher risk ratings also resulted
32 because resources for implementing biosecurity measures were inadequate to meet even current
33 demands.

34 **A4.1.3.6.3 *Specific Risk Factors***

35 The specific risk factors we found to be associated with the household goods and personal vehicles
36 pathways are as follows:

- 37 • BTS inspections may not address the movement of other potentially invasive species.

Class	Scientific name	Common name	Risk type ^a
	<i>Rana sylvatica</i>	Wood frog	ECL
Birds	None likely	None likely	
Mammals	<i>Didelphis marsupialis</i>	American opossum	H, ECN, ECL
	<i>Herpestes javanicus</i>	Small Indian mongoose	H, ECN, ECL
	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
	<i>Rattus rattus</i>	Ship rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN, ECL
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Agama agama</i>	Common agama	None found
	<i>Anolis cristatellus</i>	Common Puerto Rican anole	ECL
	<i>Anolis distichus</i>	Hispaniolan gracile anole	ECL
	<i>Anolis extremus</i>	Barbados anole	ECL
	<i>Anolis porcatius</i>	Cuban green anole	ECL

3

4 Construction materials are items used in the building process and can consist of packed or containerized
5 cargo goods, and break-bulk items like lumber, wood and metal paneling, molding, plumbing pipes, and
6 fixtures. Construction equipment is items and tools used for building, like generators, compressors,
7 table saws, nail guns, ladders and scaffolding, and machinery parts and accessories. Construction
8 vehicles include earth moving machinery like bulldozers, excavators, and bobcats, as well as forklifts,
9 concrete mixers and their pumps, dump trucks, and all-terrain vehicles. Estimates of construction
10 material, equipment, and vehicle needs were partly based on a projection of the amount of land that
11 would need to be cleared to accommodate military relocation on Guam (Section 0).

12 Construction material shipped as break-bulk cargo is items that exceed the dimensions of a standard
13 cargo container. The carriers Matson and Horizon transport these materials on a 40-foot flat rack system
14 (Matson 2006; Horizon Lines 2008). Cargo that exceeds the dimensions of a flat rack can be
15 accommodated by these carriers by special arrangement. Kyowa uses a similar system but will ship
16 smaller break-bulk cargo as well (Kyowa Shipping Company 2010a).

17 The actual points of origination for much of the construction materials, equipment, and vehicles have
18 not been identified. We assessed risks posed by construction cargo brought to Guam from elsewhere in
19 the United States or Asia. Construction cargo entering the Micronesia Region is shipped in by boat to the
20 Port of Guam or flown in by air to Guam International Airport (commercial) or Andersen AFB (military).
21 The major shipping companies for cargo in the Micronesia Region are Horizon, Matson, Kyowa, and
22 Mariana Express Lines (PB International 2008). Information from these companies was used to
23 determine the routes by which cargo is likely to be shipped (Horizon Lines 2010b, c, d, a; Kyowa Shipping
24 Company 2010a, b; Mariana Express Lines 2010a, b; Matson 2010a, b). All of these companies provide
25 containerized and bulk cargo transport.

26 **A4.1.3.7.1 Inspection of Construction Materials, Equipment, and Vehicles**

27 Because construction supplies and some equipment will be shipped as either containerized or break-
28 bulk cargo, the cargo regulations provided in Section 0 apply. Details of each regulation can be found in
29 that section. Most cargo undergoes both customs and agricultural inspections upon arrival. The
30 International Health Regulations govern inspections related to human health concerns (WHO 2005b).
31 The CFR gives authority for cargo inspections and disinfection in Titles 7 and 9 (7 CFR 318, 9 CFR). The
32 Brown Treesnake Control and Interdiction Plan makes it the responsibility of all federal agencies to
33 prevent the movement of BTS, and covers inspection of cargo (U.S. Navy 2005b). The military is bound
34 to conduct inspections of cargo by Parts 2 and 5 of the Defense Transportation Regulations, the
35 Quarantine Regulations of the Armed Forces, and OPNAVINST 6210.2 (DoD 1992, DoD 2009b). The

1 APHIS-PPQ Manual for Agricultural Clearance contains a chapter on clearing cargo (USDA-APHIS-PPQ
2 2013).

3 Construction vehicle inspections emphasize agricultural risks for transporting invasive plants, insects, or
4 agriculturally significant diseases vectored in soil. Inspection scrutiny increases with equipment arriving
5 from an origin of concern that may pose an agricultural risk. Agricultural inspections are overseen in
6 Guam and CNMI by APHIS-PPQ. Additionally, construction vehicles shipping from Guam are inspected
7 for the presence of the BTS by an APHIS-WS detector dog team (Vice 2010a). Because construction
8 vehicles are so large, searches by BTS detector dogs may not be as effective as for smaller vehicles.
9 Construction vehicles arriving in CNMI will be placed in a BTS barrier and inspected for BTS (Pangolinean
10 2010).

11 **A4.1.3.7.2 Summary of Findings**

12 All pathways were considered to be high risk due to their ability to transport species capable of harming
13 human health and safety. The primary risk associated with this pathway is that current inspection
14 procedures do not include inspection for vertebrate invasives because they have an agricultural pest or
15 human health risk emphasis. Inspections are directed at cargo arriving from an origin of concern or
16 cargo that may pose an agricultural risk. Containers likely to be inspected will have a manifest
17 identifying the cargo as an agricultural product. Bulk cargo containing wood or transported on/in wood
18 conveyances such as pallets will be inspected to ensure the wood complies with ISPM 15 requirements
19 (FAO 2006e). Because almost no specific information could be obtained regarding the needs and
20 acquisition of construction cargo for the military relocation on Guam and CNMI, the risk assessment is
21 incomplete.

22 **A4.1.3.7.3 Specific Risk Factors**

23 The specific risk factors we found to be associated with the construction materials, equipment, and
24 vehicles pathways are as follows:

- 25 • Customs agencies are constrained by resources to inspect only a portion of cargo or
26 vehicles. These inspections tend to be of material that has insufficient documentation, is
27 from a country of concern, or contains agricultural material.
- 28 • The paperwork associated with arriving construction cargo needs to be automated to allow
29 for more rapid selection of cargo to be screened.
- 30 • Documentation is lacking with regard to interception of vertebrates in or on break-bulk
31 cargo, construction materials, and construction vehicles. Often a species is identified as
32 moving in cargo or in a vehicle, but the specifics are not available.
- 33 • X-ray container scanners are not available on Guam. They are available on Saipan but not
34 used due to funding limitations.
- 35 • The actual origin of much of the break-bulk cargo and construction materials associated
36 with the relocation has not been identified.

1 **A4.1.3.8 Plant Pathways: Plant Materials and Plant and Nursery Trade**

2 The plant pathways are well-known routes for the transport and introduction of species such as
 3 amphibians like the coqui and greenhouse frogs to Hawai'i. Soil may transport anuran eggs, and anurans
 4 can be difficult to detect in certain plants such as bromeliads (Kraus et al. 1999; Christy et al. 2007c). The
 5 rapid shipment of live plants, and the cool, moist environment plants are shipped in, make survival of
 6 invasive species more likely (Christy et al. 2007c). Importation of ornamental plants for landscaping and
 7 nursery plants and materials is expected to increase due to the military relocation on Guam. Examples of
 8 the types of plants currently imported into Guam are given in Section O. Although risk assessments to
 9 date have focused primarily on insects and diseases of concern to plants, vertebrate invasives also have
 10 the potential to be spread by this pathway (Table A4-16). The plant pathway covers growing mediums,
 11 fertilizer, and potting soil; bedding and sod; above-ground plant parts; and below-ground plant parts. A
 12 contaminating or hitchhiking pest is carried by a commodity and, in the case of plants and plant
 13 products, does not infest those plants or plant products.

14 **Table A4-16: Invasive Species Transported in the Plant Pathways**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL
	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL
	<i>Osteopilus septentrionalis</i>	Cuban tree frog	H, ECN, ECL
	<i>Pseudacris regilla</i>	Pacific frog	ECL
Birds	None likely	None likely	
Mammals	<i>Clethrionomys rutilus</i>	Northern red-backed vole	H, ECL
	<i>Microtus californicus</i>	California vole	H, ECN, ECL
	<i>Mus musculus</i>	Common house mouse	H, ECN, ECL
Reptiles	<i>Anolis distichus</i>	Hispaniolan gracile anole	ECL
	<i>Anolis sagrei</i>	Cuban brown anole	ECL
	<i>Calotes versicolor</i>	Eastern garden lizard	ECL
	<i>Diadophis punctatus</i>	Southern ringneck snake	None found ^b
	<i>Elaphe guttata</i>	Red corn snake	None found
	<i>Gekko hokouensis</i>	Kwangsi gecko	None found
	<i>Hemidactylus frenatus</i>	Common house gecko	ECL
	<i>Hemidactylus garnotii</i>	Indo-Pacific gecko	None found
	<i>Hemiphyllodactylus typus</i>	Common dwarf gecko	None found
	<i>Lampropholis delicata</i>	Delicate skink	ECL
	<i>Saproscincus mustelina</i>	Weasel skink	None found
	<i>Tarentola mauritanica</i>	Common wall gecko	None found
	<i>Thamnophis spp.</i>	Unknown	None found

15 ^a H = health, ECN = economic, ECL = ecological.

16 ^b No impacts found in the literature, but undocumented impacts may exist.

17
 18 Growing media like potting soils and fertilizers are likely to transport amphibians and their eggs, and the
 19 blind snake, *Ramphotyphlops braminus* (Nussbaum 1980; Crombie and Pregill 1999; Christy et al. 2007c).
 20 *Ramphotyphlops braminus* was not included in the analysis because it is already present in Guam, CNMI,
 21 FSM, and Palau. Although not currently reported to be present in CNMI, fossil records show that it was
 22 once a naturally occurring part of the herpetofauna (Pregill 1998). Sod is not typically imported to
 23 Guam, although grass stolons are (Campbell 2010b). Bedding material is likely to transport a variety of

1 amphibians, mammals, and reptiles, but little of this material is “imported” to Guam because it comes
2 mainly from the continental United States (Campbell 2010b). Above-ground plant parts can transport a
3 variety of amphibians and reptiles (Christy et al. 2007c; Berringer 2010a; Campbell 2010d). Below-
4 ground plant parts are likely to transport primarily mice, and corn snakes.

5 **A4.1.3.8.1 Inspection Procedures**

6 ***International Standards for Phytosanitary Measures***

7 The IPPC is an agreement among countries on plant health and measures taken to prevent the
8 introduction and spread of pests. One of its products is the publication of the ISPM. Several of these are
9 particularly pertinent to the movement of plant materials. Principles outlining how countries should
10 implement phytosanitary measures are discussed in ISPM 1 (FAO 2006f). Thailand began full
11 implementation in 1995, and China began full implementation of ISPM 1 in 2001 (FAO 2006g, j). Japan
12 has mostly implemented this standard (FAO 2007a). New Zealand, the Philippines, and South Korea
13 report that they have fully implemented this standard, but do not give a date when full implementation
14 began (FAO 2006h, i, 2009). No information on the implementation of ISPM 1 in the other countries
15 could be found. However, of the countries listed, only Hong Kong and Taiwan are not signatories to the
16 IPPC.

17 A glossary of phytosanitary terms is given in ISPM 5 (FAO 2010b). Some definitions of particular
18 importance to this pathway are given in the following paragraphs. Thailand began full implementation in
19 1995, and China began full implementation of ISPM 5 in 2005 (FAO 2006g, j). Japan, New Zealand, the
20 Philippines, and South Korea have fully implemented the standard, but give no date when
21 implementation began (FAO 2006h, i, 2007a, 2009). No information on the implementation of ISPM 5 in
22 the other countries could be found.

23 Bulbs and tubers refer to the dormant underground parts of plants intended for planting, and include
24 corms and rhizomes. Commodities refer to types of plants, plant products, or other articles being moved
25 for trade or other purpose. Cut flowers and branches refer to the fresh parts of plants intended for
26 decorative use and not for planting. A growing medium is any material in which plant roots are growing
27 or intended for that purpose. Plants refer to living plants and parts thereof, including seed and
28 germplasm. A regulated article is any plant, plant product, packaging, conveyance, container, soil and
29 any other organism, object or material capable of harboring or spreading pests, deemed to require
30 phytosanitary measures, particularly where international transportation is involved. Seeds refer to a
31 commodity class of seeds for planting or intended for planting and not for consumption or processing.

32 Preventative measures taken within the plant pathways include various treatment methods. Treatment
33 is an official procedure for the killing, inactivation, or removal of pests, or for rendering pests infertile or
34 for devitalization. Fumigation is treatment with a chemical agent that reaches the commodity wholly or
35 primarily in a gaseous state. Heat treatment is a process in which a commodity is heated until it reaches
36 a minimum temperature for a minimum period of time according to an official technical specification.
37 Irradiation is treatment with any type of ionizing radiation.

1 Further preventative measures include screening procedures and regulatory compliance. Clearance
2 refers to the verification of compliance with phytosanitary regulations. An inspection is an official visual
3 examination of plants, plant products, or other regulated articles to determine if pests are present
4 and/or to determine compliance with phytosanitary regulations. A visual examination is the physical
5 examination of plants, plant products, or other regulated articles using the unaided eye, lens,
6 stereoscope, or microscope to detect pests or contaminants without testing or processing.

7 Imports through these pathways are subject to regulations. A certificate is an official document that
8 attests to the phytosanitary status of any consignment affected by phytosanitary regulations. The
9 country of origin is the country where the plants were grown or where regulated articles were first
10 exposed to contamination by pests. An import permit is an official document that authorizes the
11 importation of a commodity in accordance with specified phytosanitary import requirements. A point of
12 entry is an airport, seaport, or land border point officially designated for the importation of
13 consignments, and/or entrance of passengers. A re-exported consignment is a consignment that has
14 been imported into a country from which it is then exported.

15 Equivalence of phytosanitary measures refers to situations where different phytosanitary measures
16 achieve a contracting party's appropriate level of protection for a specified pest risk. Phytosanitary
17 import requirements refer to specific phytosanitary measures established by an importing country
18 concerning consignments moving into that country. A phytosanitary measure is any legislation,
19 regulation, or official procedure having the purpose to prevent the introduction and/or spread of
20 quarantine pests, or to limit the economic impact of regulated non-quarantine pests. A phytosanitary
21 procedure is any official method for implementing phytosanitary measures including the performance of
22 inspections, tests, surveillance, or treatments in connection with regulated pests.

23 An outline for the development of a national system for issuing phytosanitary certificates is described in
24 ISPM 7 (FAO 2006a). Thailand began full implementation in 1997, and China began full implementation
25 of ISPM 7 in 1998 (FAO 2006g, j). Japan, New Zealand, the Philippines, and South Korea all fully
26 implement the standard, but give no date when full implementation began (FAO 2006h, i, 2007a, 2009).
27 Guidelines for preparing and issuing phytosanitary certificates and phytosanitary certificates for re-
28 export are given in ISPM 12 (FAO 2001). Thailand began full implementation in 2001, and China began
29 full implementation of ISPM 12 in 2003 (FAO 2006g, j). Japan, New Zealand, the Philippines, and South
30 Korea all fully implement the standard, but give no date when full implementation began (FAO 2006h, i,
31 2007a, 2009). ISPM 23 outlines the guidelines for conducting inspections of plant materials (FAO 2006c).
32 Both China and Thailand began full implementation of ISPM 23 in 2005 (FAO 2006g, j). Japan, New
33 Zealand, the Philippines, and South Korea all fully implement the standard, but give no date when full
34 implementation began (FAO 2006h, i, 2007a, 2009).

35 Guidelines to assist countries in determining the equivalence of phytosanitary measures is given in ISPM
36 24 (FAO 2006d). China began full implementation of ISPM 24 in 2005, and Thailand began partial
37 implementation in 2008 (FAO 2006g, j). Thailand rates the relevance of ISPM 24 to its phytosanitary
38 procedures as low. Japan, New Zealand, and South Korea fully implement the standard, but give no date
39 when full implementation began (FAO 2006i, 2007a, 2009). The Philippines does not implement ISPM

1 24, and rates its relevance as low (FAO 2006h). The selection of an appropriate sampling scheme for
2 inspection is discussed in ISPM 31 (FAO 2008). No information could be obtained on implementation of
3 ISPM 31 in any of the countries.

4 ***Australia Export Regulations***

5 In Australia, goods that are to be exported have to be free of pests as determined by inspection, and
6 cannot be exported without an export permit. These goods cannot then be loaded after inspection into
7 containers unless the containers are free from pests. Likewise, goods cannot be loaded after inspection
8 with other goods that could cross-infect the prescribed goods (Australia OLDP 2007). A notice of intent
9 to export goods must be given not less than three working days prior to export by ship or in sufficient
10 time to obtain an export certificate for export by aircraft. The notice must contain the following
11 information:

- 12 • Name and address of the consignor and consignee
- 13 • Intended port of loading of the goods
- 14 • Intended ship and voyage number or airline flight number
- 15 • Intended date of departure
- 16 • Intended port of discharge of the goods
- 17 • Country of origin if it is not Australia
- 18 • Country of intended final destination of the goods
- 19 • Place where goods can be inspected
- 20 • Date on which goods can be inspected
- 21 • State or Territory in which application for a certificate with respect to the goods, if sought,
22 will be made
- 23 • Number allotted to the registered establishment in which processing last occurred
- 24 • Shipping or other identifying marks relating to the goods
- 25 • Identification number appearing on a container system unit that will contain the goods if
26 available
- 27 • Number and kind of packages (if different from the number passed for export, list the
28 number passed for export; if all passed for export, the phrase “as submitted”)
- 29 • True description of the goods
- 30 • Quantity of goods available for inspection
- 31 • Any other information required by the Secretary

- 1 • Declaration by the exporter that the orders that apply to the goods have been complied
2 with, information contained in the notice is true and correct, and conditions in the
3 importing country have been complied with

4 If goods do not pass inspection and a treatment exists, the treatment must be applied prior to the
5 issuance of a phytosanitary certificate. Currently, Australia treats plants for export for invertebrate pests
6 rather than vertebrate pests. Only certain plants likely to carry particular invertebrate pests, such as the
7 green snail, are treated (South Australia 2010). Such plants are treated with methyl bromide, a
8 steam/air mixture at 60°C for 30 minutes, or fumigation with Basamid. Only plants that are within 25 km
9 (15.5 miles) of a known green snail infestation are subject to treatment.

10 After inspection, the authorized officer must make sure the identification number appearing on a
11 container system unit is entered on the notice of intent to export if not already present. The officer
12 must also arrange for the number of the official mark, if applied to the container system unit, to be
13 entered on the notice of intent to export next to the number of the container unit. A phytosanitary
14 certificate will also be issued containing the following information:

- 15 • Name of an approved inspector
- 16 • Written declaration of disinfestation or disinfection treatments carried out by the exporter if
17 not supervised by an approved inspector, or ruling out of the appropriate area on the form
18 to indicate such treatments are not required
- 19 • Additional declarations such as free of weed seeds, specific pests, or pest or fumigation
20 treatment applied; if no such declarations are needed, this must be indicated on the
21 certificate
- 22 • Signature of authorized officer and the Departmental seal
- 23 • Description of the consignment (container system unit numbers, import and export permit
24 numbers if known, approved officer has to check off each column entry prior to signing the
25 certificate; if the back of the certificate or an additional sheet is used, it must contain the
26 number of the certificate and name of the exporter and be signed by the officer)
- 27 • Common and botanical name of the goods, or a general term or description if a botanical
28 name is not appropriate
- 29 • Consignee's name and address if known, or "to order" otherwise
- 30 • Point of entry, or actual port of importation if known

31 ***China Export Regulations***

32 Any material exported from China is subject to a quarantine inspection by Ministry of Agriculture
33 personnel. The shipper has to submit, prior to export, an application for quarantine inspection. Plants
34 are quarantined by the port animal and plant quarantine office until an inspection can be performed.
35 Once inspection is passed (or an unspecified suitable treatment applied), material is allowed to leave the
36 country. Customs officials release the shipment on the basis of quarantine certificates or stamps on the

1 customs declaration forms from the port animal and plant quarantine office. Transport of plant material
2 for export is expected to comply with regulations on plant quarantine and epidemic prevention (China
3 2009).

4 After inspection, a phytosanitary certificate is issued to the shipper. The phytosanitary certificate
5 contains the following information:

- 6 • Name and address of both the consignor and consignee
- 7 • Botanical and common names of the products
- 8 • Quantity of product
- 9 • Number and type of packages
- 10 • Place of origin
- 11 • Port of destination
- 12 • Mode of conveyance
- 13 • Date of inspection
- 14 • Any disinfestation or disinfection treatments applied
- 15 • Place and date where the certificate was issued

16 Interception records and patterns indicate a weak enforcement for for export criteria in China.

17 ***Commonwealth of the Northern Mariana Islands Export Regulations***

18 No regulations pertaining to plant export requirements or treatment of plants and plant propagative
19 material could be accessed.

20 ***Federated States of Micronesia Export Regulations***

21 No regulations pertaining to plant export requirements or treatment of plants and plant propagative
22 material could be accessed.

23 ***Guam Export Regulations***

24 The only information that could be found regarding plant exportation from Guam pertains to shipments
25 of nursery stock. The Guam Administrative Rules and Regulations (GARR) state that GDOA certifies
26 nursery stock shipments for export when required, but does not give information regarding what the
27 certification process involves. GDOA issues nursery stock certificates to nurseries complying with their
28 inspection regulations, although these are also not stipulated (GDOA 2007a).

29 ***Hong Kong Export Regulations***

30 No regulations pertaining to plant export requirements or treatment of plants and plant propagative
31 material could be accessed.

1 ***Japan Export Regulations***

2 Exporters must prepare an export declaration for Japan Customs describing the nature, quantity, and
3 value of the goods to be exported. The Plant Protection Station (PPS) conducts inspections of plant
4 material after an application by the shipper for an export inspection. Inspections are carried out at the
5 PPS located at the airport or seaport of export. What these inspections cover depends on the
6 requirements of the importing country. After a physical examination of the goods, an export permit and
7 phytosanitary certificate must be obtained by the shipper. Phytosanitary certificates contain the
8 following information:

- 9 • Name and address of consignor and consignee
- 10 • Number and description of packages
- 11 • Distinguishing marks
- 12 • Place of origin
- 13 • Means of conveyance
- 14 • Declared point of entry
- 15 • Name of produce and quantity declared
- 16 • Botanical name if applicable
- 17 • Disinfestation or disinfection treatment if applied

18 It is unknown whether inspections and phytosanitary certificates apply to plant propagative material.
19 Treatment of infected material is dependent on the pest found in the material. Several of the approved
20 treatments are as follows: hydrogen cyanide fumigation, methyl bromide fumigation, and phosphine
21 fumigation. No information could be found on treatment of plant propagative material prior to export
22 from Japan.

23 ***Korea Export Regulations***

24 The National Plant Quarantine Service conducts export inspections of plant materials and issues
25 phytosanitary certificates in South Korea. Plants being exported to countries not requiring a
26 phytosanitary certificate are not inspected. Inspections and phytosanitary certificates conform to the
27 requirements of the importing country (KNQS 2008). South Korea uses methyl bromide fumigation,
28 chemical treatments, cold, heat, and irradiation to treat plant materials. No information could be
29 accessed for North Korea.

30 ***Netherlands Export Regulations***

31 The Ministry of Agriculture, Nature, and Food Quality transferred responsibility for inspections to four
32 horticultural inspection bodies on September 1, 2007. These agencies are as follows: Netherlands
33 General Inspection Service for Agricultural Seed and Seed Potatoes; Netherlands Inspection Service for
34 Horticulture; Flower Bulb Inspection Service; and Quality Control Bureau for Vegetables and Fruit. These

1 four agencies are responsible for inspecting exported plants for diseases (NMA 2007). No additional
2 information could be found on further export requirements or treatments for plant materials.

3 ***New Zealand Export Regulations***

4 Exporters in New Zealand must meet the phytosanitary requirements of the country to which they wish
5 to ship material. Biosecurity New Zealand delegates authority for export inspections to authorized
6 Independent Verification Agencies (PMACI 2006; Biosecurity New Zealand 2009b). Shipments for export
7 are inspected in accordance with the requirements of the importing country and a phytosanitary
8 certificate is issued. Random samples of homogeneous lots are inspected, with samples being large
9 enough to provide a minimum 95% confidence level that pests do not exceed a specified threshold.
10 Inspections include both the product and the packaging. If pests are found, treatment may be applied
11 prior to shipment (Biosecurity New Zealand 2006). New Zealand uses several different treatments
12 depending on the plant material and the pest involved. These include methyl bromide fumigation, hot
13 water or chemical treatment for dormant material, or chemical treatment with either a spray or a dip
14 (Biosecurity New Zealand 2010).

15 Suppliers are required to maintain inspection records that include the following information:

- 16 • Product type inspected
- 17 • Line/grower/packing period
- 18 • Time of sampling
- 19 • Lot size
- 20 • Sample size
- 21 • Date of inspection
- 22 • Number and type of quarantine pest found per sample
- 23 • Country/crop maximum pest limit, or combination (as appropriate) used in the decision-
24 making process resulting from the inspection
- 25 • Action taken as a result of the inspection
- 26 • Inspector's name and validation

27 In addition, suppliers must maintain records of equipment calibrations where applicable, security checks
28 undertaken while plant products are stored in registered facilities, and non-approved organizations that
29 are supplied with plant products eligible for phytosanitary certification. These records must be
30 maintained for a minimum of 2 years (Biosecurity New Zealand 2006).

31 ***Palau Export Regulations***

32 In Palau, an exporter may request an export inspection that will be conducted according to the
33 guidelines of the importing country. Inspectors may apply official seals to inspected packages, and issue
34 a phytosanitary certificate for plants produced in Palau (Palau BAMR 1999). Phytosanitary certificates

1 are modeled after the guidelines produced by the IPPC in ISPM 12 (FAO 2001). Any plant material
2 transiting through Palau must be clearly marked as intended for re-export. Inspectors will issue a re-
3 export phytosanitary certificate for such material provided there is a valid phytosanitary certificate from
4 the country of origin and the material is as described on the certificate (Palau BAMR 1999). The only
5 decontamination measure mentioned in Palau's Quarantine Manual is methyl bromide treatment
6 (Chambers and Englberger 1998).

7 ***Philippines Export Regulations***

8 Exporters wishing to export plant material from the Philippines must submit an application for
9 inspection to a Plant Quarantine Service Office at least 48 hours prior to shipment. However, if the
10 inspection is to be conducted on the exporter's premises, it must be submitted 3 to 7 days prior to
11 export. Inspectors require additional documentation at the time of the inspection, which includes an
12 import permit from the importing country if required, Convention on International Trade in Endangered
13 Species (CITES) permits if needed, and an application for a phytosanitary certificate. Inspectors perform
14 the inspection in accordance with the requirements of the importing country. A random sample
15 consisting of 10% of the total shipment is used for inspection. Both visual and laboratory inspections are
16 made of the random samples. If the material passes the inspection, a phytosanitary certificate will be
17 issued. Only the Bureau of Plant Inspection/Plant Quarantine Service is authorized to issue
18 phytosanitary certificates in the Philippines. The Bureau only issues re-export phytosanitary certificates
19 if they are required by the importing country. The Philippines has modeled its export certification and
20 phytosanitary certification systems on guidelines established by the IPPC (FAO 2001, 2006a).

21 If the shipment fails inspection, the exporter has the option of applying an internationally approved
22 treatment to rid the shipment of infestation. Treatment can be waived if it is not required by the
23 importing country. Treatment can be performed either at Plant Quarantine Service facilities or by a
24 private firm that is licensed to operate fumigation facilities. If performed by a private firm, the entire
25 operation must be supervised by a plant quarantine officer (Philippine PQS). Specific treatments are not
26 mentioned.

27 ***Puerto Rico Export Regulations***

28 No regulations pertaining to plant export requirements or treatment of plants and plant propagative
29 material could be accessed.

30 ***Singapore Export Regulations***

31 Exporters in Singapore are responsible for knowing the import requirements of the importing country.
32 The Singapore Agri-Food and Veterinary Authority will provide a phytosanitary certificate based on the
33 requirements of the importing country. An application for a phytosanitary certificate must be filled out
34 prior to inspection (Singapore SRS 2005). Exporters may become members of an Accredited Certification
35 Scheme that allows them to assume the inspection function for their own goods. To participate,
36 members must implement and document an Agri-Food and Veterinary Authority approved quality
37 assurance system to ensure the export product is free of pests. The Agri-Food and Veterinary Authority
38 conducts regular audits of members to ensure compliance. Under this arrangement, exporters are

1 issued phytosanitary certificates as long as they submit an application for a phytosanitary certificate and
2 provide documentation ensuring the material is pest free. Documentation can include an import permit,
3 regulations of importing countries, fumigation certificates, and test reports.

4 Pest control agencies in Singapore are required to obtain accreditation if they are performing
5 phytosanitary treatments. Registration under this accreditation scheme allows pest control operators to
6 perform phytosanitary treatments and issue certificates of treatment on behalf of the Singapore Agri-
7 Food and Veterinary Authority. Treatments mentioned in the official document covering pest control
8 agencies in Singapore are methyl bromide fumigation and heat treatment (Singapore SRS 2003). These
9 agencies must specify the types of treatments they intend to perform and for which plant materials.
10 They must describe in detail a quality assurance system that will ensure products have been properly
11 sanitized. The agencies are subject to audits by the Singapore Agri-Food and Veterinary Authority.

12 ***Taiwan Export Regulations***

13 No regulations pertaining to plant export requirements or treatment of plants and plant propagative
14 material could be accessed.

15 ***Thailand Export Regulations***

16 It is unclear from Thai regulations whether phytosanitary certificates for export are required unless
17 required by the importing country. However, to obtain a phytosanitary certificate, an inspection by a
18 plant quarantine official is required. Plants that are considered by the Minister of Agriculture as being
19 likely to export plant pests are considered controlled plants and must be accompanied by a
20 phytosanitary certificate. Exporters can request registration of their facilities with the Department of
21 Agriculture to have plant quarantine officials inspect their facilities and make recommendations
22 regarding pest control. The only information that could be obtained regarding treatment of plants in
23 Thailand referred to fumigation or treatment with chemicals by means of spraying without giving
24 specifics.

25 ***United States (California, Florida, and Hawai'i) Export Regulations***

26 Phytosanitary certificates and export certification are not required to export plants and plant
27 propagative material from the United States, but are issued if the importing country requires them.
28 Exporters requiring a phytosanitary certificate may request an export inspection. Only authorized
29 government officials and accredited agencies may perform export inspections. The exporter is
30 responsible for providing the import requirements of the destination country to inspectors if they are
31 different from what PPQ currently has (USDA-APHIS). These may be in the form of an official
32 communication or an EXCERPT. An EXCERPT is a publication containing phytosanitary requirements. The
33 entire shipment must be sampled in order for a phytosanitary certificate to be issued. Samples must be
34 of sufficient size and must be representative of the entire shipment. If a shipment is not considered high
35 risk (not defined), the sample size is 2% of the inspectional unit. An inspectional unit can be a box, bag,
36 tray, or similar unit. If inspection of 2% of the material is not practical, the sample size may be
37 determined from the hypergeometric table published in the export manual. Inspection of nursery stock
38 is to be 100%, or as close to 100% as practical. At a minimum, a visual inspection is performed. A

1 laboratory analysis may be required by the importing country. No specific information could be found
2 for screening procedures used for soil, fertilizer, or growing media. If treatment is required and
3 available, it must be applied prior to issuance of the phytosanitary certificate (USDA-APHIS-PPQ 2010b).

4 The APHIS-PPQ Treatment Manual describes the use of authorized fumigants, which are methyl
5 bromide, sulfuryl fluoride, and phosphine. Methyl bromide concentrations above 5 parts per million
6 require the use of a self-contained breathing apparatus by the operator; therefore, it can be assumed it
7 would be toxic to animals. Both sulfuryl fluoride and phosphine can be toxic to humans and animals. In
8 addition, the treatment manual describes the use of aerosols and micronized dusts. Non-chemical
9 treatments that are described are hot water immersion, steam, vapor heat, forced hot air, cold
10 treatment, and irradiation. Steam, dry heat, freezing, incorporation of granular pesticides, and methyl
11 bromide fumigation are all mentioned for treating soil (USDA-APHIS-PPQ 2008). It is unknown whether
12 these treatments are required for other plant propagative materials such as growing media or fertilizer.

13 ***California***

14 The California Department of Food and Agriculture currently inspects nurseries using county
15 commissioners as often as needed to ensure compliance with nursery stock regulations regarding pests.
16 Any entity that produces or sells nursery stock in California is required to comply with the cleanliness
17 standards outlined in the Nursery Inspection Procedure Manual. Cleanliness is defined in the manual as
18 follows: “Commercially clean shall mean that pests are under effective control, are present only to a
19 light degree, and that only a few of the plants in any lot or block of nursery stock or on the premises
20 show any infestation or infection, and of these none show more than a few individuals of any insect,
21 animal or weed pests, or more than a few individual infestations of any plant disease” (CA DFA
22 2001a, b).

23 ***Florida***

24 The Division of Plant Industry under the Florida Department of Agriculture and Consumer Services
25 requires nursery registration and currently inspects nurseries several times a year. Nurseries cannot
26 advertise in newspapers unless they can provide documentation that they are registered with the state
27 (FDACS, 2004; Florida Legislature 2009). Inspection tags are required on every container in a shipment
28 (Division of Plant Industry 2008).

29 ***Hawai'i***

30 The Hawai'i Department of Agriculture provides plant inspection, plant fumigation, and plant and
31 nursery certification services. Plants to be exported from Hawai'i are required to be brought to a plant
32 inspection station where an inspection is performed according to the regulations of the importing
33 country. Once plant material passes inspection, it is packed, sealed, and stamped at the plant inspection
34 station, and a phytosanitary certificate is issued. Nurseries can bypass the inspection at the plant
35 inspection station if they obtain certification. Nursery certification requires that plants are grown
36 according to a specific set of conditions agreed to by the nursery and the Hawai'i Department of
37 Agriculture. Compliance inspections are conducted once every 6 months. Each certified nursery receives

1 an official certification stamp with a unique identifying number (Hawai'i Department of Agriculture
2 1981).

3 ***Idaho***

4 The Idaho State Department of Agriculture licenses and inspects Christmas tree nurseries. Idaho state
5 regulations require a producer to be issued a permit prior to shipping trees. The producer must acquire
6 a phytosanitary certificate and have valid nursery license prior to exporting the trees (ID DoA 2010).

7 ***Oregon***

8 The Oregon Department of Agriculture Plant Division, Nursery and Christmas Tree Program performs
9 inspection of Christmas tree producers in Oregon. Christmas tree producers must be licensed by the
10 state and are required to obtain a phytosanitary certificate for trees to be exported to destinations that
11 require them. The requirements for each phytosanitary certificate depend on the destination market for
12 the trees. Fee-based inspection services are available for both production and harvest. Regulations
13 governing phytosanitary requirements are detailed in Oregon Regulations Chapter 571 (Oregon State
14 Legislature 2009).

15 ***Washington***

16 The Department of Agriculture of the State of Washington is required to license all commercial
17 Christmas tree producers that harvest more than 100 trees per year for sale to the public. All producers
18 are subject to phytosanitary inspection by state inspectors and failure to grant access may result in
19 revocation of the license (Chapter 15.13 RCW) (Washington State Legislature 2010). The Plant Services
20 Program provides phytosanitary inspection permits for trees on a fee basis for licensed producers. All
21 licensed producers are inspected for compliance with Washington State regulations.

22 ***Commonwealth of the Northern Mariana Islands Import Regulations***

23 No regulations pertaining to plant import requirements or treatment of plants and plant propagative
24 materials could be accessed.

25 ***Federated States of Micronesia Import Regulations***

26 No regulations pertaining to plant import requirements or treatment of plants and plant propagative
27 materials could be accessed.

28 ***Guam Import Regulations***

29 Guam requires a phytosanitary certificate for the importation of rooted plants and seedlings; cuttings
30 and grafts of woody plants, ornamental plants, horticultural plants; cut flowers; flower bulbs, corms,
31 tubers, rhizomes, and other vegetative plant propagating materials; and seeds meant for propagation
32 purposes. The phytosanitary certificate has to have been issued within 14 days of shipment and be in
33 English. If the material is not coming directly from the country of origin, it needs to be accompanied by a
34 certificate from the country of origin and a re-export certificate from the country of dispatch (GDOA
35 1997).

1 An import permit is required by anybody receiving plant materials in Guam. Immediately upon arrival in
2 Guam, GDOA must be notified in writing of the materials and given the following information:

- 3 • Way-bill number
- 4 • Container number
- 5 • Name and address of both the consignor and consignee
- 6 • Marks
- 7 • Number of packages
- 8 • Description of the contents of each package
- 9 • Port at which laden
- 10 • Any additional information necessary to locate and identify the shipment

11 The only approved ports of entry into Guam are air- and sea ports and the post office. Any package
12 coming in must be plainly and legibly marked in English with the name and address of the shipper and
13 receiver; name of country, state, or territory and locality therein where the product was grown; and a
14 description of the contents of the package (GDOA 2007a).

15 Guam requires a phytosanitary certificate for the importation of soil, but it is not known if this applies to
16 other types of plant propagative material (GDOA 1997). An import permit is also required for anybody
17 receiving soil. The definition of soil in Guam is as follows: "Soil means that part of the upper layer of
18 earth in which plants can grow; this material may or may not contain organic matter and includes such
19 planting media as deteriorated peat, except clean coral, sand, pottery and industrial clay, volcanic
20 cinders and other similar soil-free material." Soil itself may only be imported in limited quantities for
21 research, unless it is commercially manufactured and packaged potting soil (GDOA 2007a; Berringer
22 2010a). No specific information could be found for screening procedures for plant propagative material.

23 Guam requires that imported Christmas trees be mechanically shaken prior to netting for shipping
24 (Oregon Department of Agriculture 2010).

25 After inspection, the inspector places a tag, label, or stamp indicating the package has been inspected
26 and has passed inspection. Guam currently inspects 100% of all declared plant material entering the
27 country at its Plant Inspection Facility. All FedEx and United Parcel Service shipments are subject to
28 inspection without a search warrant because they are private companies. However, any packages
29 coming into Guam through the U.S. Mail that are not properly labeled as containing plants or plant
30 propagative material will not be inspected. United States Mail coming into Guam is considered domestic
31 and requires a search warrant to inspect (Shimizu 2010a).

32 The advent of e-commerce has made it much easier to buy plant parts online. Although this material is
33 required to be clearly marked so that it undergoes inspection upon entry into Guam, material may not
34 always be properly labeled either willfully, or through ignorance of the regulations. The person receiving

1 the shipment is also required to have an import permit (GDOA 1997). Plants shipped to Guam must be
2 free of soil. Persons buying plants online may be unaware of this regulation. This could potentially allow
3 plant material to bypass the inspection process, allowing entry of vertebrate invasives.

4 ***Palau Import Regulations***

5 Any person entering Palau with plant material or any entity importing plant material into Palau must
6 notify the proper officials of the arrival of the material. For individuals entering Palau, this would be the
7 Customs agent. For importers, Customs officials and the Chief of Agriculture must be notified. Import
8 permits are required for any material being imported. Permits must include the following information:

- 9 • Name and address of both the shipper and exporter
- 10 • Origin of the goods
- 11 • Quantity
- 12 • Common and scientific names
- 13 • Mode of transport
- 14 • Point-of-entry
- 15 • Approximate date of arrival

16 All imported plants are required to be free from soil, and only approved packing material (e.g., sterile
17 peat moss, sphagnum moss, perlite, vermiculite, sawdust, shredded paper, or inert material) can be
18 used around the roots of imported live plants. All plant material requires a phytosanitary certificate.
19 Imported material is inspected for the presence of soil and pests. A subsample of each shipment of cut
20 flowers that consists of four or more containers is taken for inspection, and every stem in the sample is
21 inspected. Shipments of three or fewer containers are all inspected. Quarantine officials are supposed to
22 inspect 100% of imported nursery stock (Chambers and Englberger 1998; Palau BAMR 1999). No specific
23 information could be found for screening procedures used for soil, fertilizer, or growing media. The only
24 treatment measures mentioned for imported material in Palau are spraying, methyl bromide
25 fumigation, immersion in glyphosate, or quarantine (Palau BAMR 1999).

26 **A4.1.3.8.2 *Summary of Findings***

27 The primary difference in risk rankings is related to the types of species transported and whether they
28 are associated with health, economic, or ecological impacts. These pathways are considered high risk
29 because they are likely to transport and introduce species such as mice that can negatively impact
30 human health, and amphibian species that will cause impact to the region's economy and ecology.
31 Material intentionally moved in these pathways that harbor hitchhikers unintentionally presents a
32 primary risk in that inspections of these commodities focus on insects and plant diseases, and terrestrial
33 vertebrate species are likely missed, particularly when hiding in places not normally inspected for
34 insects. Due to the large volume of material that may be shipped, inspections can only cover a small
35 portion of the total shipment, increasing the likelihood that a vertebrate invasive will be missed (Christy
36 et al. 2007c). Although some differences in inspection procedures do exist among the various countries

1 for which regulations could be obtained, the general procedure used is the same. Further, there is a high
2 risk for intentional transport of plants to bypass inspection processes. For example, packages coming
3 into Guam through the U.S. Mail that are not properly labeled as containing plants or plant propagative
4 material will not be inspected; U.S. Mail coming into Guam is considered domestic and requires a search
5 warrant to inspect. This is important because the Internet allows individuals to order plants and plant
6 propagative materials and have them shipped directly to themselves. If such material is not clearly
7 marked, it may not undergo inspection.

8 **A4.1.3.8.3** *Specific Risk Factors*

9 The specific risk factors we found to be associated with the plant pathways are as follows:

- 10 • Australia does not treat plants being exported unless they come from within 25 km (15.5
11 miles) of an area that is infested with the green snail or pests are detected during the export
12 inspection process. Current treatments target invertebrates rather than vertebrates.
- 13 • Some countries tailor their export inspections to the requirements of the importing country,
14 and therefore, may be likely to miss vertebrate invasives.
- 15 • Singapore relies on the exporter to supply inspection officials with the requirements of the
16 importing country before conducting export inspections.
- 17 • The United States relies on the exporter to supply inspection officials with the requirements
18 of the importing country if they are different from what PPQ currently has.
- 19 • Intentional transport of material entering Guam through the U.S. Mail that is not clearly
20 marked as containing plant material will not be inspected as this requires a search warrant
21 and poses a high risk of unintentionally transporting and introducing terrestrial vertebrate
22 pest species.
- 23 • The Internet allows individuals to order plants and plant propagative materials and have
24 them shipped directly to themselves. If such material is not clearly marked, it may not
25 undergo inspection.
- 26 • New Zealand uses authorized independent verification agencies to conduct export
27 inspections of plant material for Biosecurity New Zealand. These agencies are only audited
28 once per year by Biosecurity New Zealand to ensure compliance with accreditation
29 standards (Biosecurity New Zealand 2009b).
- 30 • Exporters in the Philippines have the option to waive treatment of plants if it is not required
31 by the importing country.
- 32 • Exporters in Singapore may become members of an accredited certification scheme that
33 allows them to assume the inspection function for their own goods. The Agri-Food and
34 Veterinary Authority conducts regular audits of members to ensure compliance.

- 1 • Exporters in Thailand are not required to have a phytosanitary certificate unless required by
2 the importing country or the plant is deemed by the Minister of Agriculture to be likely to
3 export plant pests.
- 4 • Currently, Hong Kong and Taiwan are not signatories to the IPPC.
- 5 • Export inspections generally look for insects and signs of plant disease, which may miss
6 vertebrate invasives.
- 7 • Due to the large volume of many shipments, generally only a sample of each shipment will
8 be inspected. Sampling schemes are designed to detect insects and plant disease, rather
9 than vertebrate invasives.
- 10 • Counterfeit phytosanitary certificates have been used. Phytosanitary certificates can be
11 purchased on eBay, with no way for the buyer to know whether they are authentic. Some of
12 these can be purchased in the absence of a plant purchase (eBay 2010).

13 **A4.1.3.9 Aquaculture**

14 Aquaculture is a well-known pathway for the introduction of anurans as shown by the list of species in
15 Table A4-17 (Christy et al. 2007c; Kraus 2009). Regulations regarding aquaculture and invasive species
16 pertain to the prevention of introducing exotic fish rather than anurans into an ecosystem. The
17 shipments of commodity fish that are of concern with respect to the introduction of anurans are
18 freshwater fish (Brown 2010b). In the Micronesia Region, this typically means tilapia and catfish.

19 **Table A4-17: Invasive Species Transported in the Aquaculture Pathway**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Fejervarya cancrivora</i>	Crab-eating frog	ECL
	<i>Fejervarya limnocharis</i>	Asian cricket frog	ECL
	<i>Microhyla pulchra</i>	Marbled pygmy frog	ECL
	<i>Polypedates megacephalus</i>	White-lipped tree frog	ECL
	<i>Rana catesbeiana</i>	American bullfrog	ECN, ECL
	<i>Rana guentheri</i>	Guenther's frog	H, ECL
	<i>Rana nigromaculata</i>	Dark-spotted frog	H
Birds	None likely	None likely	
Mammals	None likely	None likely	
Reptiles	None likely	None likely	

20 ^a H = health, ECN = economic, ECL = ecological.

22 **A4.1.3.9.1 Aquaculture Regulations**

23 The United Nations Food and Agriculture Organization developed a working definition of aquaculture,
24 which is as follows (Maryland DoA and NASAC 1995): "...the farming of aquatic organisms including fish,
25 mollusks, crustaceans and aquatic plants. Farming implies some form of intervention in the rearing
26 process to enhance production, such as regular stocking, feeding, protection from predators, etc." Most
27 countries use regulations that would affect other industries to regulate aquaculture, such as regulations
28 pertaining to clean water and endangered species.

1 **China**

2 The Bureau of Fisheries under the Ministry of Agriculture regulates aquaculture in China (FAO and Spreij
3 2010a). The only regulation that could be found pertaining directly to aquaculture in China is the
4 Fisheries Law of the People’s Republic of China. This mainly formalizes the investment of the country in
5 the development of aquaculture (SCNPC 2004). This regulation does stipulate that aquaculture licenses
6 are granted, but these only give a person or entity the right to use water surfaces and tidal flats. Export
7 of fish is covered under plant and animal export regulations, but these do not mention inspections other
8 than to say that material must be free of quarantine pests (People's Republic of China 1991).
9 Presumably, these inspections look primarily for diseased fish.

10 **Indonesia**

11 The aquaculture industry in Indonesia is regulated by the Ministry of Marine Affairs and Fisheries
12 through the Directorate General of Aquaculture Development (FAO and Skonhoft 2010a). The
13 Indonesian Fisheries Act No. 31 2004 is similar to China’s Fisheries Law (Republic of Indonesia 2004; FAO
14 and Skonhoft 2010a). Fish that are to be exported are checked to ensure they are not infected with
15 quarantine pests or diseases, and that they are accompanied by the proper documents. Any fish to be
16 exported from Indonesia has to be accompanied by a health certificate if required by the importing
17 country (Wardoyo 1990). Unless prohibited by the importing country, carriers of fish quarantine pests
18 and diseases are not subject to quarantine actions. If a quarantine pest or disease is detected, the fish
19 are treated specifically for that pest or disease, but no particular treatments are mentioned. If no pests
20 or diseases are detected, a certificate of release is issued.

21 **Malaysia**

22 Regulation of aquaculture in Malaysia falls under the Ministry of Agriculture and Agro-based Industry
23 (FAO and Skonhoft 2010b). Export of live fish from Malaysia requires a permit from the Director General
24 of Fisheries (Malaysia CLR 2006). The Director General has the discretion to add provisions to the permit
25 to ensure communicable fish diseases are not spread and that non-indigenous species of fish are not
26 released. Nothing is stated regarding export inspections or what these might entail.

27 **Philippines**

28 Aquaculture regulation falls under the Department of Agriculture’s Bureau of Fisheries and Aquaculture
29 Resources in the Philippines (FAO and Spreij 2010b). The Philippines Fisheries Law governs leases for
30 aquaculture, and directs the Department of Agriculture to develop a code of aquaculture practice. It also
31 provides for aquaculture facilities to be covered by insurance, and prohibits the prevention of human or
32 fish movement because of aquaculture facilities. The law prevents the exportation of live fish unless
33 they were produced in accredited hatcheries and ponds, although nothing is mentioned regarding
34 accreditation requirements. A permit is required for export, but no specifics are given for permit
35 requirements. An export inspection for fish diseases and pests must be performed and fish must meet
36 quality standards if they are known carriers of pests or disease. No details are given on what the
37 standards entail, other than that they should be internationally accepted (Republic of the Philippines
38 1998). A health certificate will be issued if required by the importing country (Philippine Department of

1 Agriculture 2009). The code of practice stipulated in the Fisheries Law gives guidelines on site selection,
2 facility design and construction, water use and discharge, use of drugs, stocking practices, feed, and fish
3 health (Philippine Department of Agriculture 2001).

4 ***United States***

5 Aquaculture in the United States is mainly regulated by the Food and Drug Administration, the
6 Department of Health and Human Services, USDA, and the Environmental Protection Agency. Other
7 federal agencies involved in aquaculture regulation include the National Oceanic and Atmospheric
8 Administration, the Joint Subcommittee on Aquaculture, the Food and Drug Administration Center for
9 Veterinary Medicine, APHIS, and the USFWS. In addition, each State has its own regulations regarding
10 aquaculture. Exporters must keep records for a minimum of 3 years that fish meet the requirements of
11 the Federal Food, Drug, and Cosmetic Act and comply with the requirements of the importing country. If
12 a health certificate is required by the importing country, it will be issued by APHIS (FAO and King 2010).
13 The National Aquaculture Act of 1980 was designed to promote and develop aquaculture in the United
14 States by developing a national plan (United States Congress 2002). Hawai'i has regulations that cover
15 quality, use and discharge of water; areas where aquaculture can be developed; activities in coastal
16 zones; historic sites; and construction of facilities (Maryland DoA and NASAC).

17 ***Taiwan***

18 No information could be found on any requirements for the exportation of fish or regulation of
19 aquaculture in Taiwan.

20 ***Guam***

21 Guam requires an excavation permit, plan review and building permit, clearing and grading permit, well
22 permit, water quality certificate permit, wetland permit, and a U.S. Army Corps of Engineers permit. In
23 addition, Guam has regulations covering the construction of wastewater systems and the discharge of
24 storm water and dredged material. Fish coming into Guam are required to have an import permit if
25 coming from elsewhere in the United States, and a certificate of origin if coming from a foreign source.
26 In addition, a health certificate is required stating the fish are free from disease (Maryland DoA and
27 NASAC). The University of Guam aquaculture facility does not import much stock, but ships stock all over
28 the world. To minimize the risk of anurans being transported with stock, the facility ships in 34 parts per
29 trillion salinity deep well water and individually hand packs the animals (Brown 2010b).

30 ***Commonwealth of the Northern Mariana Islands***

31 Importation of fish into CNMI requires an import permit from the Division of Fish and Wildlife, an animal
32 quarantine entry permit from the Department of Agriculture, and an import license from the USFWS.
33 International sources for the purpose of permitting in CNMI include Palau, RMI, and FSM. In addition, a
34 USFWS-Designated Port Exception Permit is required. International shipments arriving in CNMI have to
35 be cleared by the USFWS at the port of first entry into the United States. USFWS only has nine ports in
36 the United States that are designated to approve fish and wildlife shipments, and these are in the
37 continental United States and Hawai'i. The Designated Port Exception Permit is required if Guam or

1 CNMI is the first port of entry for a fish shipment. Shipments may or may not be physically inspected,
2 and may require a federal wildlife inspector to come from Guam (CTSA 2003).

3 **A4.1.3.9.2 Summary of Findings**

4 Pathways were considered high risk when they were capable of transporting *Rana nigromaculata* or
5 *Rana guentheri*, both of which are capable of harming human health and safety. Pathways were
6 considered a moderate risk when they transported *Rana catesbeiana* which can cause economic damage
7 to aquaculture facilities by preying on fish fry. Information on treatments and screening procedures
8 related to ensuring that shipments of aquaculture stock are pure could not be found, other than
9 information from the University of Guam. One major risk in this pathway is the difficulty in
10 distinguishing tadpoles from fish fry (Brown 2010c). Another major risk of this pathway is that
11 jurisdiction for aquaculture is spread across several agencies, and regulations can vary at the State level
12 (United States Congress 2002). Very few, if any, permits exist that are specific to aquaculture transport.
13 Most permits apply to other industries such as agriculture or industries that impact the environment.
14 Permits generally cover water use, waste discharge, and endangered species (Maryland DoA and NASAC
15 1995; CTSA 2003).

16 **A4.1.3.9.3 Specific Risk Factors**

17 The specific risk factors we found to be associated with the aquaculture pathways are as follows:

- 18 • It is difficult to distinguish tadpoles from fish fry.
- 19 • Anurans may have access to areas where aquaculture stock is being raised.
- 20 • Packing procedures for most aquaculture facilities are unknown.
- 21 • Inspections of aquaculture stock are geared to look for signs of fish diseases and pests on
22 fish.
- 23 • Jurisdiction for aquaculture is often diluted across various agencies.
- 24 • Laws governing aquaculture are often not specific to aquaculture, but pertain to various
25 industries as a whole.
- 26 • *Fejervarya limnocharis* tadpoles can withstand salinity up to 13 parts per trillion, and may
27 survive fish fry shipments packaged in lower salinity water.

28 **A4.1.3.9.4 Plants and Plant Parts as Food**

29 The importation of produce has been identified as a potential pathway for the introduction of
30 amphibians into Guam (Vice et al. In preparation). In addition to amphibians, mammals and reptiles may
31 also be transported in produce (Table A4-18). The importation of vegetables and fruit into Guam is
32 heavily regulated; however, the emphasis is on preventing the importation of plants infested with
33 insects or diseases of agricultural significance (GDOA 1997). The Aquatic Nuisance Species Task Force
34 and National Invasive Species Council document used as a template for this risk assessment lists plants
35 used as food as a pathway of major concern (ANSTF and NISC 2007). The amount of produce imported

1 into Guam is expected to increase in association with the military relocation. An example of the types
 2 and amounts of produce imported into Guam is given elsewhere in this document. The only pathway
 3 analyzed was food being shipped from the continental United States to Guam.

4 **Table A4-18: Invasive Species Transported in Plants and Plant Parts Used as Food**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Eleutherodactylus coqui</i>	Coqui frog	ECN, ECL
	<i>Hyla cinerea</i>	Green tree frog	ECL
	<i>Pseudacris regilla</i>	Pacific tree frog	ECL
Birds	None likely	None likely	
Mammals	<i>Clethrionomys rutilus</i>	Northern red-backed vole	None found ^b
	<i>Microtus californicus</i>	California vole	H, ECN
	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
Reptiles	<i>Rattus rattus</i>	Black rat	H, ECN, ECL
	<i>Anolis cristatellus</i>	Common Puerto Rican anole	ECL
	<i>Calotes versicolor</i>	Eastern garden lizard	ECL
	<i>Chondrodactylus bibronii</i>	Bibron's thick-toed gecko	ECN

5 ^a H = health, ECN = economic, ECL = ecological.

6 ^b No impacts found in the literature, but undocumented impacts may exist.

7
 8 **A4.1.3.9.5 Inspection Procedures**

9 **Federal Inspection Regulations**

10 **Fruits and Vegetables Import Manual.** The APHIS-PPQ Fruits and Vegetables Import Manual contains
 11 guidance for PPQ and CBP inspectors regarding shipments of fresh fruits and vegetables (USDA-APHIS-
 12 PPQ 2010c). Inspectors first review the documentation accompanying a shipment of produce to
 13 determine whether the produce has restrictions placed on its entry. Next, a sample of the shipment is
 14 taken for inspection. In general, 2% of the shipment is taken as a sample for inspection. The size of the
 15 sample may be adjusted depending on the size of the shipment and past history with the shipper.
 16 Samples are to be representative of the whole shipment to avoid being misled by shippers placing the
 17 cleanest samples at the front of containerized shipments. If produce has been loaded in bulk, samples
 18 are to be taken at a minimum from the top 15.2 cm (6 in) of the shipment. Samples are inspected for
 19 plant pests such as insects, mites, mollusks, nematodes, noxious weeds, pathogens, plant debris, and
 20 soil. Depending on the type of commodity, there may be additional inspection procedures to be
 21 followed, and these are listed in the manual. The following paragraphs describe some general guidelines
 22 for broad categories of produce.

23 The entire surface of fleshy or pulpy fruits and vegetables is inspected for pests or signs of pest boring or
 24 feeding. Fruits and vegetables are to be sliced open to look for internal pests, such as larvae. The top
 25 and bottom of the fruit or vegetables are to be inspected closely as these are areas that are known to
 26 harbor insects. Signs of disease include discolored spots, lesions, and surface irregularities. Fruits and
 27 vegetables are also inspected for contaminants such as soil and plant parts, as these are not admissible.
 28 An example of a plant part contaminant is leaves still attached to an apple.

1 The surface of leafy herbs and vegetables is inspected for snails and slugs, or signs of their presence
2 such as slime trails. Leaf surfaces are to be examined for insect larvae or signs of their presence, such as
3 holes in the leaves, discolored paths under the leaf surface, and powdery insect excrement. If paths are
4 found under the leaf surface, the end of the path is pricked with a knife or probe to look for larvae. Leafy
5 vegetables that grow close to the ground are to be inspected for soil.

6 The pods and seeds of legumes are inspected for holes, as this may be a sign that insects or larvae are
7 present. In particular, legumes from Mexico, Central America, South America, and the West Indies may
8 contain significant pests. Legumes are also inspected for signs of disease such as discoloration, surface
9 irregularities, or malformed pods and seeds.

10 Root crops and bulbs are inspected for signs of insect boring. If holes are found, the root or bulb is cut to
11 look for insects. Both adults and larvae may be present in root crops, whereas bulbs most commonly
12 harbor larvae. Root crops and bulbs are also inspected for signs of nematodes such as surface
13 discoloration, surface blisters, depressions, or other irregularities. A cross section of the root is
14 examined under a hand lens or dissecting microscope for nematodes. Root crops and bulbs are also
15 inspected for soil that may be attached, or for loose soil present in the containers. Species found during
16 inspection are addressed using the following documentation as protocols and guidelines.

17 **Treatment Manual.** Chapter 5 of the APHIS-PPQ Treatment Manual contains the treatment schedule for
18 fruit, nuts, and vegetables (USDA-APHIS-PPQ 2008). The treatments listed in the schedule include
19 methyl bromide fumigation, water treatment, high temperature forced air, irradiation, vapor treatment,
20 cold treatment, and quick freeze. Treatments are listed either by commodity or by pest. Each particular
21 commodity has its own treatment schedule.

22 **Manual for Agricultural Clearance.** Cargo manifests are reviewed to determine whether it contains
23 items of agricultural interest such as fruits and vegetables (USDA-APHIS-PPQ 2013). Cargo of agricultural
24 interest is to be held until it can be cleared by CBP. Clearance of fruits and vegetables may be done by
25 an inspection of the paperwork, an inspection of the commodities, or both. Inspections may be random,
26 routine, or targeted. Guidance for inspections is provided in the APHIS-PPQ Fruits and Vegetables Import
27 Manual (USDA-APHIS-PPQ 2010c).

28 **Code of Federal Regulations.** Title 7 Part 319 of the CFR governs the importation of fruits and
29 vegetables. All fruits and vegetables are required to have an APHIS import permit. Fruits and vegetables
30 are subject to inspection upon arrival. Inspectors are to examine shipments for unauthorized plant
31 parts, plant pests, and noxious weeds. Disinfection is required if these are found in the shipment. If the
32 shipment is known to have been associated with another shipment that was infested, treatment may
33 also be required. A shipment may be refused entry if the commodity is prohibited, lacks the proper
34 documentation, or is infested in such a way that disinfection cannot be adequately accomplished. Part
35 319.56-7 contains a list of fruits and vegetables that can be imported into Guam without treatment
36 unless required in Part 319.56-3(d).

1 **Guam Regulations**

2 Title 8 (Division 2, Chapter 10) of the Guam Administrative Rules and Regulations governs the
3 importation of plants and plant products into Guam (GDOA 1997). Import permits and phytosanitary
4 certificates are required to ship regulated articles into Guam. The phytosanitary certificate must have
5 been issued from the country of origin. Shipments of plants are subject to inspection upon arrival.
6 Specific restrictions on certain commodities are given in this regulation. For example, commodities that
7 could be infested with the European corn borer are required to have been fumigated prior to shipment
8 and have documentation showing fumigation was conducted.

9 **A4.1.3.9.6 Summary of Findings**

10 This pathway was considered high risk because of its ability to transport rodents that may harm human
11 health. One of the primary risks for this pathway is that inspections tend to be focused on insects and
12 plant disease. Because of this, vertebrate invasives may get missed, particularly when hiding in places
13 not normally inspected for insects. Due to the large volume of material that may be shipped, inspections
14 can only cover a small portion of the total shipment, increasing the likelihood that a vertebrate invasive
15 will be missed (Vice et al. In preparation). This is particularly true for commodities shipped in bulk where
16 only the top layer may get inspected.

17 **A4.1.3.9.7 Specific Risk Factors**

18 The specific risk factors we found to be associated with the plants and plant parts as food pathways are
19 as follows:

- 20 • Import inspections generally look for insects and signs of plant disease, which may miss
21 vertebrate invasives.
- 22 • Insufficient agricultural inspection staff and other resources are available on Guam.
- 23 • Only the top portion of bulk shipments may get inspected.
- 24 • Inspectors may be misled by shippers if samples are not representative of the entire
25 shipment. For example, a shipper may place the lowest risk commodities at the front of a
26 container.

27 **A4.1.3.10 Ecosystem Disturbance**

28 Natural spread and ecosystem disturbance have the ability to move invasive species into locations they
29 previously did not inhabit (Table A4-19). In addition, ecosystem disturbance may poise invasive species
30 near locations where they can easily enter the transportation pathway, increasing the likelihood of their
31 introduction elsewhere (Engeman et al. 2002). The Aquatic Nuisance Species Task Force and National
32 Invasive Species Council document used as a template for this risk assessment lists natural spread and
33 ecosystem disturbance as major pathways of concern (ANSTF and NISC 2007). A formal risk analysis was
34 not conducted for the natural spread of populations because of the low likelihood this would move
35 invasive species off of Guam. However, the general risks are discussed below, particularly as they
36 pertain to the maintenance of the BTS population on Guam.

1 **Table A4-19: Invasive Species Moved in the Ecosystem Disturbance Pathway**

Class	Scientific name	Common name	Risk type ^a
Amphibians	<i>Eleutherodactylus planirostris</i>	Greenhouse frog	ECL
	<i>Litoria fallax</i>	Eastern dwarf tree frog	ECL
	<i>Polypedates megacephalus</i>	Hong Kong whipping frog	ECL
	<i>Rana guentheri</i>	Guenther's frog	H, ECL
	<i>Rhinella marina</i>	Cane toad	H, ECN, ECL
Birds	<i>Dicrurus macrocercus</i>	Drongo	ECL
	<i>Francolinus francolinus</i>	Black francolin	ECL
	<i>Lonchura malacca</i>	Black-headed mannikin	ECN
	<i>Streptopelia bitorquata dusimieri</i>	Philippine turtle dove	ECL
Mammals	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Polynesian rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL
	<i>Rattus rattus</i>	Black rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN, ECL
	<i>Suncus murinus</i>	Musk shrew	H, ECN, ECL
Reptiles	<i>Anolis carolinensis</i>	Green anole	ECL
	<i>Boiga irregularis</i>	Brown treesnake	H, ECN, ECL
	<i>Carlia ailanpalai</i>	Curious skink	ECL
	<i>Pelodiscus sinensis</i>	Chinese soft-shelled turtle	H, ECL
	<i>Trachemys scripta</i>	Red-eared slider	H, ECL

^a H = health, ECN = economic, ECL = ecological.

2
3

4 **A4.1.3.10.1 Natural Spread of Established Populations**

5 Natural dispersal of invasive species currently on Guam can occur due to increases in population size
6 forcing the dispersal of individuals. Species with high reproductive rates (r selected) tend to have an
7 advantage as an invasive species (Sax and Brown 2000). As a population increases and more dispersal
8 occurs, more populations will become established. This increase is of concern because of the potential
9 for several of the species listed to act as a prey base for BTS. These include *Eleutherodactylus*
10 *planirostris*, *Litoria fallax*, *Polypedates megacephalus*, and *Rana guentheri* (Christy et al. 2007a). An
11 increase in the prey base would allow the BTS population to persist, or perhaps even increase (Christy et
12 al. 2007a). Reducing the prey base has been suggested as a means of controlling BTS population on
13 Guam (Gragg et al. 2007).

14 In large part, the likelihood of migration off Guam to neighboring islands is negligible. The closest island
15 to Guam is Rota, which is approximately 80 km (50 miles) away. Of the bird species listed, only the
16 drongo (*Dicrurus macrocercus*) is documented to have migrated this distance, having migrated from
17 Rota to Guam sometime after 1935 (Lever 1987). The only other possible method of migration off the
18 island is the transport of animals on flotsam or swimming. None of the species listed are likely to swim
19 the distances required to reach neighboring islands, although it has been suggested that anoles may be
20 able to float for short periods of time (Schoener and Schoener 1984). *Anolis sagrei* was able to remain
21 afloat for at least 24 hours in the laboratory in a seawater wave tank, suggesting floatation may be
22 responsible in part for its success at long distance dispersal (Schoener and Schoener 1984). Anoles may

1 be able to survive in seawater longer than previously expected (Heatwole and Levins 1973, Schoener
2 and Schoener 1984). *Rhinella marina* may have reached Cayo Santiago from Puerto Rico on flotsam
3 (Heatwole et al. 1963; Heatwole and Levins 1972). Green iguanas (*Iguana iguana*) were able to reach
4 Anguilla on flotsam produced by a hurricane (Censky et al. 1998).

5 **A4.1.3.10.2 Man-made and Natural Disturbances**

6 The relocation of the Marines onto Guam will create man-made ecosystem disturbances in the form of
7 construction of facilities and utilities, roadway projects, land clearing, and landscaping (U.S. Navy
8 2009h). In addition to man-made ecosystem disturbance, Guam is prone to typhoons and earthquakes.
9 Although typhoons are more likely to be of a magnitude to cause widespread ecosystem disturbance,
10 the possibility of a large-magnitude earthquake cannot be ruled out. In addition, fire sometimes creates
11 ecosystem disturbance.

12 One of the characteristics of a successful invasive species is that it is often found in association with
13 disturbed or man-made habitats (Lozon and MacIsaac 1997; Sax and Brown 2000; Ineich 2010). Many of
14 these species are commensal with humans, such as the common mouse (*Mus musculus*) and rats (*Rattus*
15 species). Environments that are prone to invasion by invasive species are often disturbed naturally or
16 have a high amount of human activity (Lozon and MacIsaac 1997; Sax and Brown 2000). Although
17 unclear as to exactly why disturbance facilitates invasion, one hypothesis is that more opportunities
18 exist in disturbed habitats for human-mediated introductions (Simberloff 1989).

19 Typhoons play an important role in invasive species movement and establishment. Damage from
20 typhoons is due to several factors such as storm velocity, storm diameter, and storm severity (Tanner et al.
21 1991). During a typhoon, most of the methods of BTS detection are inoperable. Mice must be
22 removed from traps, and traps may be taken down altogether. The typhoon itself can damage traps, the
23 habitat the traps are placed in, and the barrier fences used to exclude BTS (Vice and Engeman 2000).
24 Because emergency equipment is being shipped from Guam to neighboring islands during this time, the
25 likelihood of transporting BTS increases dramatically. Defoliation of trees by typhoons or high winds can
26 cause long-term alterations to the microhabitat that include a reduction in humidity and higher
27 temperatures near the forest floor (Reagan 1991; Waide 1991; Greenberg 2001). These changes tend to
28 be detrimental to amphibians that require moisture, but beneficial to some reptiles reliant on warmer
29 temperatures for egg incubation and hatchling development (Reagan 1991, Waide 1991, Greenberg
30 2001). The sheer impact of the typhoon, and associated rain and moving objects, can cause mass
31 mortality of amphibians (Schriever et al. 2009), birds (Waide 1991), and reptiles (Woolbright 1991;
32 McCoid 1996; Spiller et al. 1998). Habitat specialist lizards were more prone to mortality than were
33 habitat generalist lizards in the Marianas (McCoid 1996).

34 Typhoons may facilitate overwater dispersal of lizards and lizard eggs (Censky et al. 1998; Schoener et al.
35 2001). Green iguanas (*Iguana iguana*) arrived on Anguilla in the Caribbean on a mat of logs and
36 uprooted trees a month after Hurricane Luis (Censky et al. 1998). Results of genetic examination of
37 Anolis lizards in the Caribbean suggest island colonization followed prevailing ocean currents, providing
38 evidence for overwater dispersal (Calsbeek and Smith 2003). Lizard eggs and lizards appear to be more

1 resilient to exposure to seawater than previously thought. Eggs that are hard-shelled remained viable
 2 for at least 11 days during exposure to salt water (Brown and Alcala 1957). *Anolis sagrei* eggs remained
 3 viable in saltwater for 3 to 6 hours, which was predicted to be the length of the storm surge during
 4 Hurricane Floyd (Losos et al. 2003).

5 Typhoons can readily facilitate the movement of pests within individual islands or between closely
 6 located neighboring islands. On Guam typhoons typically create mountains of debris and this debris
 7 ultimately may get moved around the island and may in fact transport pest species such as the little fire
 8 ant and the coconut rhinoceros beetle, potentially ultimately assisting in the spread of these and other
 9 pests. Protocols for dealing with these types of situations need to be established both for civilian and
 10 military authorities.

11 **A4.1.3.10.3 Specific Risk Factors**

12 The specific risk factors we found to be associated with the ecosystem disturbance pathways are as
 13 follows:

- 14 • Most BTS control measures are inoperable during a typhoon, leaving detector dogs the
 15 primary line of defense.
- 16 • Emergency equipment is shipped from Guam to neighboring islands during typhoons,
 17 increasing the likelihood of transporting BTS.
- 18 • Man-made disturbances may increase the risk of invasive species entering the
 19 transportation pathway.

20 **A4.1.3.11 Garbage**

21 Movement of invasive vertebrate species in garbage is a significant pathway, moving primarily rodents
 22 (Table A4-20). Although other species besides rodents can be moved in garbage, only rodents were
 23 analyzed because they are the primary species moved and are a significant health concern. The Aquatic
 24 Nuisance Species Task Force and National Invasive Species Council document used as a template for this
 25 risk assessment lists garbage as one of the major pathways of concern (ANSTF and NISC 2007). Ships and
 26 aircraft arriving on Guam and CNMI unload regulated garbage upon arriving. Additionally, with the
 27 relocation of the 3rd Marine Expeditionary Unit from Okinawa to Guam there is an anticipated increase
 28 in the amount of training that will occur on Tinian. Garbage generated during these training activities is
 29 to be shipped back to Guam for disposal (U.S. Navy 2009g). This analysis also includes garbage that is
 30 generated during transit for both aircraft and ships.

31 **Table A4-20: Invasive Species Moved in the Garbage Pathway**

Class	Scientific Name	Common Name	Risk Type ^a
Amphibians	None likely	None likely	
Birds	None likely	None likely	
Mammals	<i>Mus musculus</i>	Common mouse	H, ECN, ECL
	<i>Rattus exulans</i>	Pacific rat	H, ECN, ECL
	<i>Rattus norvegicus</i>	Norway rat	H, ECN, ECL

	<i>Rattus rattus</i>	Ship rat	H, ECN, ECL
	<i>Rattus tanezumi</i>	Asian house rat	H, ECN, ECL
Reptiles	None likely	None likely	

^a H = health, ECN = economic, ECL = ecological.

A4.1.3.11.1 Garbage Regulations

Garbage is defined in 7 CFR § 330.400 and 9 CFR § 94.5 as waste material derived in whole or in part from fruits, vegetables, meats, or other plant or animal material (7 CFR § 330.400, 9 CFR § 94). Any other refuse that has been associated with such materials is also considered garbage. Incineration is defined as reducing garbage to ash by burning. Sterilization is the cooking of garbage at an internal temperature of 212°F (100°C) for 30 minutes. Garbage is considered regulated if the means of conveyance it is on has been outside the United States and Canada within the previous 2-year period. Garbage is also considered regulated if the means of conveyance the garbage is on has been moved within the last year between the continental United States, U.S. territory, U.S. possession, or Hawai'i. Non-regulated garbage that has been commingled with regulated garbage is also considered to be regulated. Regulated garbage is monitored to prevent the movement and dissemination of pests and diseases of plants and livestock. Tightly covered, leak-proof containers must be used to store regulated garbage. These containers must be kept inside the guard rail on a ship. Garbage may only be moved from a conveyance for disposal if it is stored in the proper container, and can only be moved under the direction of an inspector to an approved garbage handling facility.

The APHIS-PPQ Treatment Manual gives a choice of three treatments for destroying garbage that may be infested with insects pests or pathogens (USDA-APHIS-PPQ 2008). Garbage may be incinerated to ash, or ground up and discharged into an approved sewage system. An approved sewage system is one in which effluents are not discharged onto land or stationary waters, and prevents dissemination of plant pests and livestock diseases. Garbage may also be heated with steam or dry heat to an internal temperature of 212°F (100°C) for 30 minutes, followed by burial in a landfill.

The APHIS-PPQ Manual for Agricultural Clearance provides guidance on handling foreign regulated garbage (USDA-APHIS-PPQ 2013). The primary concern is preventing the spread of plant pests and animal diseases. Entities that handle garbage must be approved by USDA and either have a compliance agreement with, or be directly supervised by, CBP and/or APHIS personnel. The approved methods of disposing of garbage listed in the Manual for Agricultural Clearance are the same as those given in the APHIS-PPQ Treatment Manual (USDA-APHIS-PPQ 2008). Garbage may only be removed from a ship if USDA-approved garbage facilities exist at the port. Arrangements for disposal of the garbage must be made in advance with CBP. In this case, the only approved methods of garbage disposal are incineration or sterilization by heating to an internal temperature of 212°F (100°C).

The APHIS-PPQ Manual for Agricultural Clearance also instructs inspectors to monitor garbage handling on ships while they are in port (USDA-APHIS-PPQ 2013). This may involve monitoring visually from shore or boarding the vessel. Inspectors monitor garbage handling to ensure it is not disposed of in an unauthorized manner, garbage containers are not leaking and are covered, and garbage containers are not placed outside the ship's railing. Garbage chutes and containers built into the railings are sealed

1 while in U.S. territorial waters. All garbage is regulated when ships are traveling between the continental
2 United States and foreign countries. Garbage aboard military vessels is handled in the same manner as
3 garbage aboard private or commercial vessels.

4 Garbage from commercial and military craft can only be unloaded if the port or military base facility is
5 given the approval to handle garbage by APHIS-PPQ (USDA-APHIS-PPQ 2013). On Guam, Naval Facilities
6 Engineering Command (NAVFAC) Marianas at the Apra Harbor Naval Station and Pacific Environmental
7 Resources Incorporated at Andersen AFB are approved to handle garbage. Compliance enforcement
8 visits to ensure garbage is being handled and disposed of properly should be conducted quarterly at a
9 minimum.

10 The responsibility for monitoring the garbage handling activities of airports, caterers, cleaners, cruise
11 ships, fixed base operators, hauling/cartage firms, marinas, military facilities, storage facilities, and
12 transfer stations falls to CBP (USDA-APHIS-PPQ 2013). APHIS-PPQ is responsible for monitoring the
13 activities of all non-military processing facilities that incinerate or sterilize regulated garbage. Garbage
14 handlers are responsible for ensuring that birds, rodents, and other vermin do not have access to
15 garbage.

16 The Quarantine Regulations of the Navy (OPNAVINST 6210.2) state that garbage must be placed in leak-
17 proof, covered containers. Garbage may only be disposed of following authorized port procedures under
18 the supervision of a PPQ representative. The only approved methods of disposal are incineration or
19 sterilization. Disposal of garbage from foreign flights in a landfill is not an approved method. The
20 Quarantine Regulations of the Armed Forces defines garbage as being derived in whole or in part from
21 fruits, vegetables, other plant products, animals, meat, meat products, or animal products (DoD 1992).
22 These regulations also state that garbage cannot be disposed of in a landfill unless it has first been
23 sterilized by heating to an internal temperature of 212°F (100°C). The Naval Supplemental Publication
24 486 contains similar guidance (NAVSUP 2004).

25 Both Guam and CNMI have their own customs and quarantine procedures with respective agencies for
26 enforcement. Customs officers on Guam focus ship inspections on compliance with regulated garbage
27 regulations (Merfalen 2010). Commercial transport companies handle the waste streams from
28 commercial vessels in the ports of Guam, Tinian, and at the airports on Guam and CNMI (Merfalen 2010,
29 Pangolinean 2010). Regulated garbage is incinerated on both Guam and CNMI.

30 **A4.1.3.11.2 Summary of Findings**

31 All pathways were considered high risk because they could harm human health due to their association
32 with the transport of rodents. Provided regulated garbage is handled properly, rodents should have
33 limited access to garbage or to other pathways from garbage containers. Garbage that is considered
34 non-regulated with respect to movement between Guam and CNMI does not contain plant or animal
35 parts. However, it could still harbor rodents because it contains items, such as cardboard, that provide
36 bedding material. Disposal of this type of garbage in a landfill is associated with the risk of introducing or
37 spreading non-native rodents.

1 **A4.1.3.11.3 *Specific Risk Factors***

2 The specific risk factors we found to be associated with the garbage pathways are as follows:

- 3 • Customs agencies focus on cleanliness and container integrity.
- 4 • Documentation is lacking with regard to interception of vertebrates in regulated trash.
- 5 • Processes for handling garbage generated during training exercises on Tinian may not
- 6 preclude the transport of a significant invasive vertebrate species.
- 7 • Non-regulated garbage may transport rodents that could be missed during inspections of
- 8 regulated garbage and during transport.

9 **A4.1.3.12 *Discussion and Conclusions***

10 The Aquatic Nuisance Species Task Force and National Invasive Species Council document used as a
11 template for this risk assessment was designed for risk analyses in the United States. It also contained
12 frames of reference more applicable to insects and aquatic species. As a result, portions of the process
13 needed to be modified to be more amenable to a risk analysis for vertebrate invasive species in a larger
14 region of the world. Although this assessment attempts to be as objective as possible in assigning risk
15 rankings, the process is inherently subjective. Despite these difficulties, the process allowed us to
16 identify pathways and gaps in security measures that could increase the likelihood of transporting
17 vertebrate invasive species.

18 We were not able to access all the information needed to accurately assess the risk of transporting
19 vertebrate invasive species associated with each pathway. For example, customs procedures for various
20 countries in Asia were often lacking or scant in nature. We did not have interception data for the
21 numbers and types of species transported in each specific pathway. For some pathways, such as WPM,
22 species lists were generated using reports of species that have been moved in cargo. Often reports
23 could be found of species being moved in cargo with no information on what type of cargo or where in
24 the cargo the species was found. Although some of the species are well known, others have little
25 biological information available. One of the key pieces of information that was lacking in this regard was
26 ability of a species to utilize various habitat types. Another critical piece of information concerned the
27 ability of a species to establish new populations in previously uninhabited areas through natural
28 dispersal. Therefore, this risk analysis should be re-evaluated as more information becomes available.

29 The pathways associated with the most risk of transporting invasive species were cargo and vehicles
30 used for military training exercises and military maritime and air transportation. This is due in part to the
31 fact that military ships and aircraft can be mobilized on a moment's notice for emergency missions that
32 preclude pre-departure inspections. There is a memo of understanding between PPQ and GCQA which
33 charges GCQA with the authority to inspect military ships and aircraft.

34 Commercial maritime and air traffic, as well as cargo containers, were also associated with a high degree
35 of risk for transporting invasive species. One of the primary factors is the current lack of adequate staff,
36 equipment, and funding in the Micronesia Region to conduct inspections. Volume will increase with the

1 military relocation in each of these pathways. Unless adequate resources become available, risk of
2 transporting vertebrate invasive species will also increase. Inspections are often limited to ships, aircraft,
3 and cargo arriving from a destination that harbors an agricultural pest or disease vector, or has had
4 previous violations. Additionally, inspections are focused on preventing the movement of agricultural
5 pests, and inspectors may not be looking for amphibians and reptiles. These limited inspections increase
6 the likelihood a vertebrate invasive species could be transported undetected.

7 Construction materials and equipment can be considered containerized cargo and bulk cargo, and are
8 associated with the same risks listed in the previous paragraph. Construction vehicles may undergo an
9 agricultural inspection for soil and plant parts to prevent the movement of plant pests and diseases.
10 APHIS-WS in Guam inspects construction vehicles for BTS, but the efficacy of these inspections may be
11 questionable due to the size and complexity of the vehicles themselves.

12 Although WPM is heavily regulated by international phytosanitary standards, inspections do little to
13 prevent the movement of vertebrate invasive species. Vertebrate invasive species are most likely to
14 enter WPM in the post-manufacturing phase when it is being used as packing material for cargo.
15 Although customs agencies do inspect WPM in cargo, they are limited by time and resources to inspect
16 only WPM present in the portion of the cargo selected for inspection. Due to the somewhat non-
17 random nature of the selection process as described above, vertebrate invasive species could go
18 undetected.

19 Plants are inspected for plant pests and diseases rather than vertebrate invasive species. Amphibians
20 may hide in areas inspectors might not be likely to inspect. Due to the large volume of plants and plant
21 materials arriving in any particular shipment, only a sample of the plants can be inspected. Inspectors
22 rely on phytosanitary certificates from the country of origin, and these can be counterfeited. As with
23 other types of cargo, the process of selecting a sample for inspection may not be entirely random,
24 leading to a greater likelihood that vertebrate invasive species might not be detected. In terms of
25 preventing the establishment of pests, much of the plant industry is self-regulating. For example,
26 nurseries can be certified to be free of certain pests.

27 Regulated garbage, when properly handled, presents a relatively low level of risk of transporting
28 vertebrate invasive species. Because regulated garbage is to be stored in leak-proof containers with
29 tightly fitting lids, animals should have very little access. Additionally, it cannot be disposed of without
30 first being incinerated or heated to 212°F (100°C) for 30 minutes, making species survival impossible.
31 The largest risk is associated with non-regulated garbage. Garbage that is considered non-regulated with
32 respect to movement between Guam and CNMI does not contain plant or animal parts. Because non-
33 regulated garbage does not contain plant or animal parts, it is not required to be stored in leak-proof
34 containers with tightly fitting lids. Such garbage may contain materials that can be used as bedding or
35 nesting material, and may attract rodents. Non-regulated garbage can be disposed of in a landfill
36 without undergoing any kind of treatment, making it more likely rodents could survive.

37 Household goods are packed indoors and are often individually handled. This decreases access for
38 vertebrate invasive species and makes detection highly likely. However, if household goods are packed

1 outside or left in an open container outside, animals could gain access. Personally owned vehicles are a
2 larger risk for the relocation pathway. Although vehicles owned personally by military personnel are
3 inspected closely for plant material, soil, and animals, vehicles in the private sector may not undergo the
4 same level of scrutiny. Additionally, used cars are shipped throughout the Micronesia Region. The short
5 transport time makes survival of hitchhiking vertebrate invasive species highly likely.

6 Natural dispersal was associated with a relatively low level of risk of moving invasive species because
7 there are few species likely to migrate from Guam to the nearest island. Although the Micronesia Region
8 is vulnerable to typhoons, it is unlikely typhoons will move species from one island to another because
9 of the distance between most of them. The risk associated with typhoons and man-made disturbance is
10 the increased potential for vertebrate invasive species to be moved into the transportation network.
11 This is because preventive measures, such as BTS traps, are inoperable during a typhoon. Increased
12 vigilance immediately following any type of disturbance should help mitigate any risks.

13 Aquaculture is known to transport anurans, and will likely increase with the increased population due to
14 the military relocation. The primary risk associated with this pathway is the difficulty in distinguishing
15 between fish fry and tadpoles primarily due to the way they are packed. Some of this risk can be
16 mitigated by changing packing and shipping practices. Individually handling and packing fish fry may
17 increase the resources needed, but will decrease the likelihood of packing undetected tadpoles. Where
18 possible, shipping in higher salinity water decreases the survival probability of anurans.

19 Finally, plants used as food were considered the least risky of the 12 pathways. This is because fruits and
20 vegetables are inspected very closely for small insects and larvae, making it unlikely a vertebrate
21 invasive species could go undetected during inspection. However, some risk still exists because time and
22 resources only allow for inspections of a representative sample of each shipment. If a shipper places the
23 cleanest material closest to the front or top, and samples are not representative of the entire shipment,
24 a vertebrate invasive species could be missed.

25 In general, the risk of transporting vertebrate invasive species throughout the Micronesia Region will
26 increase due to the military relocation. Preventing the movement of vertebrate invasive species will
27 require increasing awareness of the risks in both the public and private sectors. Inspectors at ports in
28 particular need to be given training to make them aware of and enable them to identify other species of
29 concern. Resources need to be identified and made available to allow for additional training, equipment,
30 and personnel to improve the inspection processes. Emphasis should be placed on preventing the
31 movement of vertebrate invasive species, rather than on eliminating them once they have become
32 established. Prevention is more effective and less costly than elimination. Finally, a high degree of
33 cooperation among agencies will be required to minimize the risk of transporting vertebrate invasive
34 species.

35 **A4.1.3.13** ***Recommendations***

36 This section will discuss some overall, general recommendations for mitigating the risk of transporting
37 vertebrate invasive species unintentionally. More specific recommendations are covered in other

1 sections. These general recommendations should not be considered as the only, or the most important,
2 recommendations. Rather, they should be viewed as a starting point for more formalized
3 recommendations. Five key issues are central to successful implementation of the recommendations
4 given here. These key issues are: funding, coordination and communication, education and training,
5 control methods development, and regulatory drivers and enforcement.

6 **A4.1.3.14** ***Funding***

7 Regardless of the biosecurity strategy developed, lack of sufficient and properly managed funds will be
8 the weak link in any effort implemented. Military presence in the region calls for long-term allocation
9 and ongoing management of biosecurity funds. Current funding for regional biosecurity is distinctly
10 inadequate relative to the magnitude of the existing problems posed by invasive species, the emerging
11 problems and associated risks to other islands, and the scope and magnitude of military activity in the
12 region.

13 Short-term funding cycles hamper necessary methods development and interdiction activities and
14 restrict the forward momentum needed for effective control programs. For example, because BTS
15 efforts are currently underfunded, much higher costs are expected in the future to resolve expanding
16 threats not addressed now, such as eradicating the incipient population on Saipan. Cost-sharing among
17 agencies and the transportation industry has advanced greatly, with still more room for more
18 improvement. The Office of Insular Affairs is carrying much of the funding responsibility at present,
19 along with an incorrectly perceived primary ownership of the problem. Greater and sustainable
20 investment by the DoD is warranted as part of their doing business in high-risk areas for invasive species
21 dispersal and their overall stewardship of natural resources on their lands (USDA-APHIS WS 2008a).

22 **A4.1.3.15** ***Coordination and Communication***

23 The multiple human health and safety, economic, and ecological impacts of invasive species create
24 complex challenges in policy formation and governmental coordination (Williams et al. 2007). The
25 National Invasive Species Council was established by Executive Order 13112 to provide coordination and
26 planning, and facilitate cooperation among the diverse federal agencies and to take a more
27 comprehensive approach to invasive species. The National Invasive Species Council is co-chaired by the
28 Secretaries of Agriculture, Commerce and the Interior; and includes a total of 13 federal agencies and
29 departments that have a role in invasive species management (Williams et al. 2007). Communication
30 and coordination needs improved at all levels and in all directions. Micronesia and Hawai'i cover an
31 extensive area with numerous levels of authority for multiple sovereign nations as well as numerous
32 local, regional and international NGOs, all of which have roles to play in enhancing biosecurity and IAS
33 control and management for the region.

34 Federal agencies that must work in coordination to maintain a biosecurity plan include APHIS, the
35 USFWS, CBP, and the Departments of the Interior, Defense, Commerce, Energy, Homeland Security, and
36 Transportation, among others. Interagency coordination is effective to the implementation of planning,
37 and is sustained and enhanced by frequent and comprehensive communication. This communication
38 network still needs to be improved and more importantly expanded to insure that all levels including

1 non-U.S. nations are appropriately networked in order to facilitate a truly regional effort at improving
2 biosecurity and reducing the risk of IAS transport and establishment. The communication network that
3 occurs between government agencies results in information that can be compiled, consolidated, and
4 reproduced in a manner suitable and clear to the general public and private industry (e.g.,
5 transportation, construction). Local capacity-building is needed to support research, operations and
6 program management, and to improve local recruitment pools. Efforts could include cooperative
7 university and government programs, such that funding is utilized in a most resourceful manner (Colvin
8 et al. 2005). For example, the public outreach program on Saipan is a model, particularly the partnership
9 with private industry. This public outreach effort, fielded by the Office of Economic Adjustment and the
10 Military Integration Management Committee, conducts Community Outreach Dialogue sessions on
11 Saipan to hear concerns of citizens. This and other demonstration projects illustrate attempts at
12 achieving biological, social, and economic objectives through managing invasive species on islands
13 (Saunders et al. 2007).

14 **A4.1.3.16 Education and Training**

15 Gaps in invasive species management can be bridged by increased education and training, with an
16 emphasis placed on public outreach including both military and civilian populations. Public perception
17 and lack of support have affected efforts to manage or eradicate vertebrate species in the United States,
18 as elsewhere in the world (NISC 2001). Knowledge levels regarding invasive species and the harm they
19 can cause are relatively low amongst the general public (NISC 2001). For example, reports on invasive
20 species management in Hawai'i (TNC and NRDC 1992, OTA 1993) concluded an overall gap in public
21 awareness of invasive species. This resulted in the formation of the Coordinating Group on Alien Pest
22 Species (CGAPS), a voluntary government/non-government partnership, formed in 1995 to increase
23 public awareness of invasive species. Following the formation of the partnership, CGAPS launched phase
24 two of the campaign in 2006, with television and print media and a new toll-free hotline number
25 regarding the dangers of BTS. Encouragingly, follow-up surveys confirmed a rising awareness about BTS
26 (Martin 2007).

27 Furthermore, staff involved in the enforcement aspect of invasive species (e.g., inspection agents) need
28 to be educated on biological risks on which they act daily. Knowledge of the impacts of introduction is
29 bound to increase staff motivation and efficiency in the workplace. Training should include the
30 taxonomic identification of species, continued education on species status updates, changes to
31 regulations, and new pest species listings (e.g., White-List). In complement, multimedia educational
32 material, such as the Distance Diagnostic and Identification System (University of Florida 2010), can
33 further facilitate proper identification of species, with written descriptions, physical attributes, and
34 animal behavior, as well as immediate human health and safety concerns.

35 Rapid response programs are designed to implement immediate action upon the detection of invasive
36 species. They are comprehensive programs that require the melding of coordination, communication,
37 education, and training. Rapid response actions and sightings are documented in incident reports and
38 response times are substantially reduced by emphasizing training and public awareness, as shown in
39 CNMI in 2003 (Colvin et al. 2005). The BTS review by Colvin et al. (2005) found rapid response to be

1 most successful when the following aspects are incorporated into the program: extensive training,
2 public awareness and outreach, use of technological advances, centralized documentation (e.g., SOPs),
3 and networking that allows the program to operate on a regional level. These aspects are central to the
4 recommendations for rapid response programs outlined in the review. Currently, the most developed
5 rapid response programs exist in Guam, Saipan, and Hawai'i but training and organizational efforts in
6 other archipelagoes in the Pacific Basin is underway. For example, the U.S. Geological Survey Rapid
7 Response program has conducted training throughout the Micronesia Region, including CNMI, Palau,
8 Chuuk, Pohnpei, Kosrae, Kwajalein, Ebeye, and Majuro (Stanford and Rodda 2007) with the goal of
9 expanadding the capacity regional rapid response program for alien snakes.

10 **A4.1.3.17 Control Methods Development**

11 Methods development is also needed to facilitate prevention measures occurring at the pre-border
12 stage, but its largest application in mitigation at the post-border stage of introduction of invasive
13 species. Methods development is most productive when closely coordinated and integrated to maximize
14 efficient use of funds and execution in the field (Colvin et al. 2005).

15 While extensive progress has been made on many aspects of BTS biology and control measures,
16 additional ecological research is needed to facilitate control and interdiction, including topics such as
17 population dynamics, reproductive biology, bait and attractants, application of control agents and
18 logistics of control measures (Colvin et al. 2005). Unlike BTS, there remains a lack of methods
19 development for particular invasive species, such as the Asian beauty snake, gecko species, and house
20 shrew. Certain species require integrative solutions for effective control methods; characteristics
21 inherent in their biology and behavior may make some species more difficult to control. For example,
22 effective baited trapping of BTS is feasible due to their large movements, while bait and attractants are
23 not as effective on the more sedentary Habu snake (Hattori 1999). Successful methods development
24 relies heavily on sufficient funding to fuel the education, training, human resources, and facilities
25 required to pursue a comprehensive, integrative approach to control and management of invasive
26 species.

27 **A4.1.3.18 Regulatory Drivers and Enforcement**

28 Regulatory drivers are in place to prevent the transport of vertebrate species, but these regulations are
29 only realized under well-funded, comprehensive enforcement. For example, pertinent regulatory drivers
30 include the Brown Treesnake Control and Eradication Act of 2004 and the National Defense
31 Authorization Act, Public Law 110-181, Section 314, requiring implementation of control, eradication,
32 and reporting efforts, as well as actions prohibiting the transport and spread of BTS from Guam. The BTS
33 Control and Eradication Act of 2004 required formation of the Brown Treesnake Technical Working
34 Group under authority of the Non-indigenous Aquatic Nuisance Prevention and Control Act of 1990. The
35 Brown Treesnake Technical Working Group specifies 100% BTS interdiction on Guam, which requires
36 inspections of aircraft, vessels, and cargo departing Guam, as described in the Brown Treesnake Control
37 Plan of 2009. Enforcement of these regulatory drivers for BTS depends upon coordination and
38 communication of several agencies such as APHIS-PPQ, Military Customs Inspection, CBP, the USFWS,
39 and the Transportation Security Administration across water and air related pathways. One caveat of

1 regulations in application to biosecurity lies in the fact that enforcement of the regulation may differ by
2 sector. For example, biosecurity inspections of aircraft differ for military and commercial aircraft, with
3 military aircraft themselves being exempt from inspection, and only contents such as passengers and
4 cargo being subject to inspection (U.S. Navy 2009k). Also, in the United States, regulatory drivers have
5 the tendency to differ in enforcement by State. This is seen in the implementation of biocontrol where
6 policies can differ vastly in stringency by State leading to disjointed implementation of the regulation
7 (Messing and Wright 2006). Therefore, monitoring and surveillance of enforcement such as detailed
8 reports, summaries of prosecution of regulation breaches, and corresponding trends of introduction
9 incidences are all necessary checks and balances to evaluate the efficacy of the upholding of regulations
10 regarding invasive species through enforcement.

11 **A4.1.3.19** *General Recommendations*

12 **Address funding issues necessary for regional biosecurity.** Regardless of the biosecurity strategy
13 developed, lack of sufficient, consistent, and properly managed funds will be the weak link in any effort
14 implemented, allowing for biological invasions of terrestrial vertebrates to occur in the region.

15 **Military funding for biosecurity efforts in the region must be continued.** Military presence in the region
16 calls for long-term allocation and ongoing management of biosecurity funds, as many risks to biosecurity
17 are associated with the relocation.

18 **A centralized group should be responsible for creating avenues for funding within the Micronesia**
19 **Region.** Regional funding is necessary because many of the risks are interrelated and require efforts that
20 cross political boundaries and sustained efforts are required to effectively minimize risk.

21 **Mandate and enforce regulations for handling cargo,** including packing, transport, cargo-staging,
22 palletizing, and loading. Funding is required to adequately develop and enforce regulations for
23 movement of cargo by military and civilian sources.

24 **Centralize biosecurity efforts.** The National Invasive Species Council was established by Executive Order
25 13112 to provide coordination and planning, and facilitate cooperation among the diverse federal
26 agencies and to take a more comprehensive approach to invasive species. However, the multiple
27 economic, ecological, and human health impacts of invasive species create complex challenges in policy
28 formation and governmental coordination (Williams et al. 2007), such that efforts must be centralized in
29 order to operate cohesively and effectively. A central group acting as a liaison can bridge gaps between
30 formal and informal, and military and civilian communications. A central group would outline the
31 current network of the biosecurity communications in the Micronesia Region, identify communication
32 gaps, provide information in the appropriate format for public, private, and military sectors, and be a
33 representative for media and news releases concerning biosecurity.

34 **Develop a biosecurity surveillance system** for improved data collection, reporting, and information
35 sharing network. There is a paucity of available information to fully assess risks associated with the
36 unintentional and accidental movement of terrestrial vertebrate species, posing significant risks and
37 undermining biosecurity efforts in the Micronesia Region. Sustained surveillance of biosecurity risks to

1 lead an adaptive response will decrease the risk due to changing threats and changes in the way cargo
2 and people are moved in the future.

3 **Encourage and participate in action to preserve biodiversity.** Include actions taken by joint agency
4 collaborations, such as the Micronesia Challenge (Micronesia Challenge 2009).

5 **Create community funding sources for local programs.** Promote “environmental citizenship” (Barry and
6 Knab 2005) for local training, education, eradication efforts, etc.

7 **Expand and manage university research efforts and programs.** The universities of the region can serve
8 as local facilities for methods development, education, and training to enhance biosecurity measures.

9 **Comprehensive and continued education is needed.** Educate everyone that can help or positively
10 influence the campaign against invasive species. Elements can include disseminating reports and
11 newsletters to educators, journalists, lawmakers, and business and community leaders; establishing
12 local reporting systems for rapid response teams; developing curricula for the schools; and conducting a
13 pre-campaign poll of island residents to gauge levels of awareness regarding species
14 introductions/invasions and subsequent impacts (Holt 1997). Include military and military-civilian
15 personnel.

16 **Implement biosecurity measures for detecting myriad terrestrial vertebrate species.** Biosecurity
17 activities need to account for several species of terrestrial vertebrates in the Micronesia Region, but
18 hazards and regulations currently driving biosecurity efforts on Guam are aimed primarily at preventing
19 the transport and spread of BTS. Detection methods for various terrestrial vertebrate species would
20 involve an increase in awareness, adequate training, and proper equipment for dealing with inceptions
21 and the capabilities to report all incidences, including incidental sightings. Such an integrative approach
22 also permits assessment of the cumulative effects of terrestrial vertebrate species movement in the
23 region.

24 **Increase the number of USDA-APHIS-WS canine inspection teams** at Apra Harbor, at the Commercial
25 Port, and at Naval Base Guam. To adequately protect movement of snakes on military and commercial
26 boats, the number and capacity of USDA canine inspection teams should be increased in response to
27 adequately cover outgoing boats.

28 **Create regionally based canine inspection stations for USDA-APHIS-WS canine teams on Guam.** Make
29 the existing canine housing facility a central inspection headquarters that houses the majority of canine
30 teams. Build smaller housing units regionally around the island for one to three canine teams that are
31 rotated regularly and randomly; these smaller units would reduce inspection team travel time, save fuel
32 costs, and allow for more inspections to occur on island. These sub-stations could also serve as
33 community collection points for vertebrate terrestrial species information, and awareness/training
34 programs, and also where the public can report observations and bring specimens.

1 **Establish a role for USDA-APHIS-WS BTS canine inspection teams in CNMI.** USDA-APHIS-WS does not
2 have a presence in CNMI for BTS inspections of materials and vessels departing Saipan, Tinian, and Rota.
3 Establishing USDA-APHIS-WS canine teams in CNMI can enhance screening abilities performed by CNMI
4 Division of Fish and Wildlife canine teams by increasing the number of personnel and canine teams
5 available, increasing ability to conduct random inspections, and increasing the number of inspections
6 and amount of materials that can be inspected.

7 **Develop a labeling and tracking system for all cargo.** Cargo that originates in areas with high BTS
8 densities is considered high risk. Implement a barcode-based data collection system and incorporate it
9 into a centralized biosecurity system. A barcode-based system will typically be comprised of any or all of
10 the following components: barcode scanners, barcode-based mobile computers (including wireless
11 scanners, pen/key-based terminals, and vehicle-mount computers), barcode printers, barcode labels
12 and ribbons, and barcode data collection software.

13 **Manage the grounds around ports to reduce populations of target invasive species.** Unintentional
14 transport of hitchhiking terrestrial vertebrate species may occur in a number of ways. Hitchhiking
15 species may be initially attracted to certain physical or chemical conditions, such as rats (*Rattus* spp.)
16 nesting in aircraft wheel wells (Vice 2010b), BTS sheltering inside shipping containers or packing material
17 (Fritts et al. 1999), and mice (*Mus* spp.) feeding on grain and garbage shipments transported overseas
18 (Baker 1994). Use vertebrate-proof staging areas, spot-lighting checks at night, etc.

19 **Expand capacity of control methods for BTS.** While progress has been made on many aspects of BTS
20 biology and control measures, additional or improvement of methods would facilitate control and
21 interdiction procedures, including bait and attractants, large area suppression, additional interdiction
22 techniques, and logistics of control measures (Colvin et al. 2005). Sustained funding to refine existing
23 strategies and develop new methods would decrease the long term costs of interdiction, improve
24 efficacy, and reduce risk.

25 **Improve detection methods for rodents on vessels and in cargo.** NAVMED P-5010-8 is the Naval
26 Manual of Preventative Medicine, Chapter 8, Navy Entomology and Pest Control Technology (U.S. Navy
27 BMS 2004) and outlines preventive measures for rodent control on ships. This includes proper
28 sanitation, pierside inspections, rat guards, illumination and movement restrictions, glue boards, snap
29 traps, and limitations on access points to the vessel. The information available on rodent prevention
30 measures is more extensive than that of aircraft. Currently, control methods for rodents in cargo consist
31 of anti-coagulant bait, snap traps and sticky traps. Most efforts regarding rodent presence on vessels
32 and in cargo remain in the control realm, while methods on rodent detection are underdeveloped.

33 **Assign trained, uniformed USFWS personnel to law enforcement at commercial and military ports.**
34 USFWS personnel can assist in preventing incidences of smuggling, help handle and process confiscated
35 animals, provide permits, provide education, assist in the handling and processing of terrestrial
36 vertebrates detected by USDA-APHIS-WS inspectors, enforce laws, and be part of Rapid Response Plans
37 at the border.

1 **A4.2 INTENTIONAL PATHWAYS**

2 **A4.2.1 Summary**

3 There are 10 pathways by which terrestrial vertebrates may be intentionally introduced into the
4 Micronesia Region. These pathways are evaluated for their risks to the region by analyzing for each the
5 component risks of importation, establishment, and hazard (or impact). The pathways of greatest risk to
6 the Micronesia Region are the pet trade, release for aesthetic purposes, and release for food use. The
7 first two of these also present the greatest range of species associated with release, making it difficult to
8 mitigate risk via those pathways using a species-based approach such as reliance on banning a few
9 species. The four pathways of zoo releases, game-hunting, biocontrol, and scientific research present
10 moderate risks of introducing new invasive vertebrates. With the exception of the zoo pathway, each
11 presents only a narrow range of species liable for introduction, but several of these pose high risks of
12 impacts should they become established. The final pathways of fur-ranching, religious release, and
13 bioterrorism present only low probabilities of leading to new vertebrate invasions in the Micronesia
14 Region under current circumstances, although the second of these could increase in importance should
15 the proportion of Buddhists in the region increase in coming years. Several of these species also pose
16 high hazard, but risk will be directly related to propagule pressure (numbers released), which is currently
17 small.

18 Mitigation of these risks is feasible for many pathways because of the intentional nature of the
19 introductions. The most reliable mitigation actions involve expanding regulations of importation and
20 ensuring enforcement and public outreach regarding the regulations. Future methods development may
21 make it feasible to develop more specific screening models to determine comparative risks on a species-
22 by-species basis for a broad array of taxa, but that goal is not yet scientifically available. Until that goal is
23 met, banning certain well-known, high-risk invasives from importation into the region is a reasonable
24 measure for the avoidance of the potential spread of these invasive species. Supplementation of explicit
25 efforts to remove or highly restrict certain pathways (zoological gardens, game hunting, scientific
26 research, fur farming) would go some way toward providing the Micronesia Region greater biosecurity
27 for the near future.

28 **A4.2.2 Introduction**

29 Vertebrates have been among the most spectacularly destructive groups of alien species transported by
30 humans, with many species creating threats to human health and safety, the economy, and ecology in
31 the regions where they have been introduced (Greenway 1967; Honegger 1981; Morgan and Woods
32 1986; Ebenhard 1988; Case and Bolger 1991; Henderson 1992; Pimentel et al. 2000; Pimentel 2002;
33 Blackburn et al. 2004; Pimentel et al. 2005; Jenkins et al. 2007; Kroeger 2007). Progress has been made
34 in recent years toward reversing some of these impacts by removing certain alien vertebrates from
35 some invaded regions (Bell 2002; Burbridge and Morris 2002; Merton et al. 2002; Tershy et al. 2002;
36 Nogales et al. 2004; Campbell and Donlan 2005; Clout and Russell 2006; Howald et al. 2007). In most
37 instances, however, perpetual control of widespread or abundant alien vertebrates is required to
38 minimize damage to especially important areas or resources. But such eradication and control
39 operations are achieved at high cost and can only be successful in limited circumstances, making them

1 an unreliable foundation upon which to base a nation's biosecurity future. A much more efficient and
2 cost-effective means of managing alien species is to prevent their introduction (Naylor 2000; Touza et al.
3 2007). Consequently, prevention of future invasions should form the centerpiece of any region's alien-
4 species management program.

5 To date this has been rarely attempted. Australia and New Zealand have taken measures to develop
6 proactive systems to prohibit the introduction of new vertebrate species onto their shores unless they
7 are first evaluated and shown likely to be safe for importation. Most jurisdictions, however, if they
8 prohibit the importation of a species at all, only ban species famous for being pests elsewhere. This
9 approach is of some use for avoiding additional damages from known invasives having high impact, but
10 it is inherently reactive and can only be applied to species already creating damage elsewhere. It cannot
11 identify pests from the large pool of species not yet introduced anywhere or of those introduced
12 elsewhere but not yet having erupted into pest status.

13 In developing a meaningful prevention system for terrestrial vertebrates, assessment of risk must take
14 into account the means of introduction. This is important because different taxa are introduced for
15 different reasons and via different pathways (Kraus 2003). For example, the most important
16 introduction pathways for all terrestrial vertebrates are intentional pathways, with mammals being
17 introduced mostly for game hunting, food use, and fur farming; birds primarily for the pet trade and for
18 game hunting; and reptiles and amphibians mostly for the pet trade, for related aesthetic reasons, and
19 for food use (Kraus 2003; 2009). As well, some taxa are moved via more than one pathway. For example,
20 the invasive North American bullfrog (*Lithobates catesbeianus*) has been introduced via the pet trade,
21 for food use, and for aesthetic reasons, and the Chinese soft-shelled turtle (*Pelodiscus sinensis*) has been
22 introduced via the pet trade, for food use, and for religious purposes, with different pathways applying
23 in different locations (Kraus 2009). Pathway importance also varies temporally, with some pathways
24 increasing in importance through time (e.g., the pet trade since the 1960s) and others generally
25 decreasing in importance (e.g., biocontrol since the 1930s). As a result of the taxonomic, temporal, and
26 geographic variation among pathways, the proper means of assessing biosecurity risk will vary by
27 pathway, location, and time, as will the appropriate means of managing that risk (Kraus 2009).

28 Pathway definitions differ depending on which class of pathways is under consideration; intentional are
29 pathways based on the motive for importation. As a result, intentional pathway categories are diverse in
30 their introduction methods. For example, use of animals as pets may involve purchase via commercial
31 pet shops, purchase from websites, or direct smuggling of desired animals; their release may be
32 deliberate with the intent to establish new populations, deliberate to remove the burden of unwanted
33 animals, or accidental due to poor caging conditions.

34 In mitigating risk of intentional introductions, public education can prevent deliberate importation or
35 release of new invasive vertebrates and should be included in the arsenal of tools used for invasive-
36 species management. However, it is an insufficient tool in itself, so it is also desirable to prohibit the
37 intentional import and keeping of high-risk species (Reed 2005), and seek to remove the economic or
38 social incentives for some of the intentional pathways. Prevention of dangerous introductions via the

1 assorted intentional pathways can be most effectively achieved by means of adopting scientific
2 screening systems to evaluate proposed importations for likelihood of invasiveness. This would enable
3 quarantine authorities to permit the import of low-risk species, while identifying and excluding high-risk
4 species (Kolar and Lodge 2002; Bomford 2003). Yet how these risks can be reliably assessed is still a
5 matter for debate, and it is likely that simple generalizations across all taxonomic groups are not feasible
6 (Williamson 1999b; Kolar and Lodge 2001; Heger and Trepl 2003; Cassey et al. 2004). But risk
7 assessment across a particular taxonomic group (e.g., birds) may be feasible. So, ecologists continue to
8 suggest and test a large number of attributes for these different vertebrate groups in search of a set that
9 is consistently predictive of establishment success for each group, and risk analysts continue to
10 recommend their use in risk-management schemes (Kolar and Lodge 2002; Stohlgren and Schnase 2006;
11 Hayes and Barry 2008).

12 To that end, a number of studies have sought to identify such attributes for birds (Moulton and Pimm
13 1986; Brooke et al. 1995; Duncan 1997; Sol and Lefebvre 2000; Blackburn and Duncan 2001; Cassey
14 2001; Duncan et al. 2001; Cassey 2002; Cassey et al. 2004; Allen 2007a; Blackburn and Cassey 2007;
15 Blackburn et al. 2009), mammals (Forsyth et al. 2004; Bomford et al. 2006), and reptiles and amphibians
16 (Bomford et al. 2009). Different attributes have been found to be important in these various studies,
17 depending in large part on the taxon and region investigated. Hayes and Barry (2008) examined 24 of
18 these studies, and they found that only three parameters (climate match between native and host
19 ranges, successful prior establishment elsewhere, and propagule pressure) consistently predicted
20 establishment success across all taxa, although other factors were sometimes important for a particular
21 taxon, such as birds. The results of these assorted studies have been used by Bomford (Bomford 2003;
22 Bomford et al. 2005; 2006; Bomford 2008; Bomford et al. 2009) to construct simple models for assessing
23 the likely invasiveness of vertebrates proposed for introduction to Australia and New Zealand. Some of
24 the relevant variables (e.g., prior history of invasion, propagule pressure) are uniform across regions
25 because they are taxon specific, but the climate-matching variables need to be adjusted for each
26 separate jurisdiction under consideration because climate varies so widely among regions.

27 Even with proper application of an effective screening system for intentional introductions, smuggling of
28 pest species by uninformed or malicious individuals will continue to be attempted. So, effective
29 enforcement of biosecurity laws prohibiting pest importations is also a requisite part of any meaningful
30 preventive system for intentionally introduced vertebrates. Developing a screening system without
31 some form of enforcement capability is a sterile exercise and will compromise biosecurity.

32 In considering the risk of introduction of alien vertebrates into the Micronesia Region via intentional
33 pathways, the most sensible approach at present is to identify all relevant motives, consider the most
34 hazardous types of animals that are likely to arrive by that motive, and assess the degree of threat
35 posed. For some pathways, only a few taxa are able to be transported; for other pathways, many taxa
36 may be moved (e.g., zoological garden stocking). This threat will be the product of likelihood of
37 introduction, likelihood of establishment, and the hazard posed by the taxa arriving by that pathway.
38 Likelihood of introduction will be a function of the volume of material arriving by the pathway, degree to
39 which the pathway is inspected or regulated, and degree to which compliance with regulations occurs.

1 Likelihood of establishment can be dependent on many things, but factors scientifically assessed and
2 proven useful for birds and mammals include degree of climate match, whether the species is already
3 established somewhere else outside its native range, overseas range size, taxonomic order, diet, ability
4 to inhabit disturbed habitats, and non-migratory behavior (Bomford 2008). Factors proven useful for
5 reptiles and amphibians include degree of climate match, whether the species is already established
6 somewhere else outside its native range, and taxonomic family (Bomford and Kraus 2008; Bomford et al.
7 2009). For all terrestrial vertebrate taxa, climate match is best ascertained by using a formal climate-
8 matching algorithm, such as CLIMATE (Bomford 2008; Bomford et al. 2009). However, such comparisons
9 rely on quantitative matching between meteorological stations within a species' total range and those in
10 the jurisdiction of concern. These comparisons are not easily made for oceanic islands because the
11 sampling of meteorological stations in such regions is often too sparse to sample the full range of
12 climatic variation, especially that variation due to ascending elevation. So, for this risk assessment,
13 climatic suitability of the Micronesia Region for a species was assessed by determining whether that
14 species occurred in similar climatic zones or ecoregions elsewhere in the world. A caveat to the
15 application of climatic suitability is that it does not account for other parameters or pressures that may
16 make the given region unsuitable for reasons other than climate.

17 Hazard (or pest status, or invasiveness) posed by a species has been moderately well assessed for birds
18 and mammals (Bomford 2008) but has been poorly evaluated for reptiles and amphibians. For both
19 birds and mammals, hazard is a function of taxonomic group as well as other factors. Factors that also
20 heighten risk of establishment for both taxa (overseas range size, whether it is a pest elsewhere, and
21 climate match) also predict invasiveness, as do whether a species is harmful to humans, their property,
22 or their domesticated animals, either by direct action or by transmitting disease or parasites. Mammal
23 orders that have a demonstrated history of detrimental effects on prey abundance or habitat quality
24 (Artiodactyla, Carnivora, Lagomorpha, Marsupialia, Perissodactyla, and Rodentia) and mammal families
25 that are prone to causing agricultural damage (Bovidae, Canidae, Cervidae, Leporidae, Muridae, and
26 Mustelidae) are of higher hazard, as are those that are strict carnivores, or strict browsers/grazers. Bird
27 taxa that cause high agricultural damage (Anatidae, Corvidae, Fringillidae, Ploceidae, Sturnidae, and
28 Psittaciformes) or which frequently hybridize with native species (e.g., Anatidae, Cacatuidae,
29 Phasianidae) are of higher hazard. Species in both Aves and Mammalia can also be social hazards
30 because they invade buildings, have communal nests that create large amounts of waste, or generate
31 large amounts of noise. Hazard for reptiles and amphibians is more tentatively assigned, but factors that
32 clearly impinge on hazard include risk to human health via envenomation or constriction, noise
33 production, whether the species has been a pest elsewhere, or whether it is congeneric with isolated
34 native species and thereby increases the risk of hybridization (Kraus 2009). The first of these hazard
35 categories for herpetofauna is unambiguously determined, but the last three have received little
36 attention, although some species clearly fall into each category.

37 Because risk assessment for alien vertebrates is still in the process of development, probabilities of
38 introduction, establishment, and hazard are often only qualitatively ranked by category at present. In
39 the United States, categories used by USDA and the Environmental Protection Agency are "high",
40 "medium", and "low" (Simberloff 2005). In this approach, the total risk is taken to be the lowest-ranked

1 probability across the three categories, an approach that is in accord with a juridical tradition of
2 presuming innocence until proven otherwise, but which seems inadequate to stopping additional
3 invasions (Simberloff 2005). Thus, e.g., a species having a low probability of introduction, a medium
4 probability of establishment, but a high probability of hazard would be assigned a total risk score of
5 “low”. The Australian government provides a slightly more expanded set of risk ranks, including “low”,
6 “moderate”, “high”, and “extreme”, and addresses contrasting risks across the categories of
7 introduction, establishment, and hazard in a more quantitative and directly comparable fashion. In this
8 system, values for each variable contributing to risk, whether for introduction, establishment, or hazard,
9 are given numerical values, with assigned values depending on how much the attribute contributes to
10 the particular risk. These numerical scores are then summed across all pertinent variables among the
11 three stages of invasiveness and the final risk is determined by the overall score, with high scores
12 meriting assessments of “extreme” risk, while low totals merit a “low” overall ranking (Bomford 2003;
13 Bomford et al. 2006; Bomford 2008). As noted above, as attributes predictive of risk become better
14 identified, these quantitative models may be expanded to provide a finer degree of risk assessment than
15 can currently be achieved.

16 **A4.2.3 Risk Assessment**

17 Ten pathways potentially contribute to the risk of intentional introduction of vertebrate pests into the
18 Micronesia Region, with the first nine being well-documented pathways from around the globe, and the
19 last being hypothetical. Different sets of taxa characterize each pathway. Most pathways have a
20 relatively small set of taxa of primary concern, but the pet trade and aesthetic pathways move a large
21 and open-ended set of species, making assessing specific risks from those pathways more challenging.
22 For consideration of risk to the Micronesia Region, a set of representative taxa of greatest likely risk is
23 here identified for each pathway, basing this on species known to be involved in these pathways and of
24 ecological, economic, or social hazard elsewhere. This allows for quick comparison of relative risk among
25 the pathways, points out the potential risks that invasive terrestrial vertebrates can pose to the
26 Micronesia Region, and highlights biological and transport issues relevant to developing appropriate
27 biosecurity mitigation measures.

28 As stated earlier, each pathway can typically involve several different routes of ingress. Specimens may
29 be either purchased or carried personally into the jurisdiction in question. Purchases may be through
30 commercial local businesses (such as pet shops) or via the Internet (Derraik and Phillips 2010), in which
31 case, transportation may be via commercial freight carrier or the mail. Personally carried items may be
32 legally brought into the jurisdiction of interest or may be smuggled. In the Pacific islands, smuggling is
33 generally very easy because of poor inspection of arriving passengers and baggage for contraband
34 animals (see for example Kraus and Cravalho 2001 for Hawai’i). Although there are no data to indicate
35 that it is happening, smuggling would be very easy for personnel arriving on military craft. When
36 developing biosecurity programs for intentional pathways of introduction it will be important to ensure
37 that the public and military are educated about prohibited items, that rigorous inspection of each
38 potential route of arrival is provided, and that enforcement of laws is politically and financially
39 supported. Otherwise, merely identifying source pathways and noting their hazards are of little benefit.

1 For this risk assessment for the Micronesia Region, insufficient information is available to meet the
2 detailed, quantitative standards followed by the Australian system (Bomford 2003; Bomford et al. 2006;
3 Bomford 2008). However, the USDA approach, which chooses an overall risk score by automatically
4 defaulting to the lowest of the three constituent risk scores, is of dubious justification or utility in
5 stopping invasions (Simberloff 2005). For the purposes of this risk assessment, the best that can be done
6 at present is to assign a risk of “low,” “moderate,” or “high” to each component of introduction risk
7 (importation, establishment, and hazard), similar to the approach adopted by USDA. But then a score is
8 assigned to each of these risk levels (low=1, moderate=2, high=3), and the scores summed across the
9 three components of risk to achieve a final score, with the overall risk of introduction being “low” if the
10 sum score is 3-5, “moderate” if 6-7, and “high” if 8-9. This provides a more balanced means of
11 adjudicating overall risk among the three constituent components of introduction risk.

12 Historically, the Pacific region, and especially the oceanic islands, have been heavily impacted by
13 introductions of alien terrestrial vertebrates. Virtually no island in the region has been immune to them.
14 More than 40% of bird introductions around the world have been to Pacific islands (Long 1981; Kraus
15 2003), as have large numbers of mammals (Lever 1985; Long 2003) and reptiles and amphibians (Kraus
16 2009). Many of these have been deliberate introductions. As a result of this heavy introduction history,
17 some of the most heavily impacted jurisdictions (especially New Zealand and Hawai’i) have served as
18 cautionary tales for much of the remainder of the Pacific islands and have been at the vanguard of
19 research into the impacts and invasion processes on these species. This research, as well as that from
20 lower-elevation islands (e.g., Guam, Ogasawara Islands, see Fritts and Rodda, 1998; Kawakami and
21 Okochi, 2010), has made clear how susceptible oceanic islands are to introduced alien species generally
22 (Fritts and Rodda 1998; Kawakami and Okochi 2010). Thus, even though many areas of the Micronesia
23 Region currently lack most of the invasive terrestrial vertebrates that plague other regions, without
24 thoughtful assessment of the risks of acquiring these species, protection of those islands from these
25 pests is compromised.

26 One important component of risk is whether eradication of a species is feasible should it become
27 established. It is politically easy to think that prevention of additional invasions can be neglected
28 because too many species are involved, and that instead management can be focused on removing the
29 worst invasive species that do become established. Invasive species are difficult to eradicate once
30 established, and the same holds equally for most vertebrate species. It is true that several species of
31 mammals were successfully eradicated from islands with new techniques developed in the past 20 years
32 (Nogales et al. 2004; Campbell and Donlan 2005; Howald et al. 2007). However, only a very few species,
33 primarily rats, cats, and ungulates, have widely benefited from this attention. There are very few
34 instances of successful eradication efforts for amphibians, and none for reptiles (Kraus 2009) or birds,
35 although ongoing efforts in Britain against ruddy ducks (*Oxyura jamaicensis*) seem successful (Genovesi
36 2005; Henderson 2010). One important reason for these failures is that detection of these species is
37 usually sufficiently difficult that not all members of the targeted population are liable to control, a
38 precondition for successful eradication operations (Bomford and O'Brien 1995). Another reason is that
39 control methods have not been developed for many species beyond those few mammals mentioned
40 above (Kraus 2009). Even for the few species that are sometimes feasibly eradicated, costs are almost

1 always high (Martins et al. 2006; Donlan and Wilcox 2007; Howald et al. 2007), restricting such actions
2 to only the most damaging invasions. The importance of this is that the impossibility or difficulty of
3 eradication increases the hazard of virtually all species considered below because damage usually
4 continues in perpetuity.

5 **A4.2.3.1** *Pet Trade*

6 This pathway includes all acquisitions of animals for use as pets, whether purchased from commercial
7 pet stores, purchased from Internet dealers, or directly captured and imported by interested individuals.
8 It also involves the deliberate release of animals to establish populations that will then be harvested to
9 sell to the pet trade. Globally, the pet trade is the largest source of introductions for reptiles and
10 amphibians and is one of the two largest pathways for birds, with introductions of those taxa increasing
11 exponentially (Kraus 2003, 2009). But the pathway is a relatively insignificant source for mammal
12 introductions, with a few notable exceptions. For reptiles, amphibians, and birds this pathway has
13 exploded in importance since the 1960s and shows no sign of abating in the near future (Kraus 2003,
14 2009). Furthermore, although the pathway has been of greatest importance in the wealthier countries,
15 there is virtually no part of the world untouched by it (Kraus 2009). The diversity of bird, reptile, and
16 amphibian species spread via this pathway numbers in the hundreds (Jenkins et al. 2007), and the
17 numbers of individuals moved is in the millions (e.g., Beissinger 2001; Franke and Telecky 2001). The
18 most commonly spread mammals via this pathway are cats, dogs, rabbits, and an assortment of rodents,
19 again moved worldwide by the millions.

20 Importation risk via this pathway is high and growing. A large and diverse array of species is available
21 through the pet trade, and there are few restrictions in the Micronesia Region on what is available for
22 importation. Pet stores occur in at least Guam, CNMI, and FSM, and even where pet stores are lacking,
23 travelling citizens will often bring animals of interest back with them from overseas trips (e.g., Buden et
24 al. 2001). Occasionally, visitors arriving on private boats or on foreign fishing vessels also bring in pets
25 that escape captivity. Even when import restrictions on some pets do apply, smuggling and release or
26 escape of banned species is sufficiently common that risk remains high. An example of this is from
27 Guam, where ball pythons have recently been confiscated or turned over to officials even though the
28 possession of snakes in the territory is banned (Vice 2010a). Smuggling is probably more frequent than
29 that single example suggests, judging from the experience in culturally similar Hawai'i (Kraus and
30 Cravalho 2001). The magnitude of the pet-trade problem will generally co-vary with population size,
31 meaning that smaller jurisdictions will have fewer problems, but these will not disappear entirely. This is
32 well illustrated by the appearance of turtles brought into Pohnpei for use as pets and maintained there,
33 in at least one instance, by government officials (Buden et al. 2001). The CNMI has three or four active
34 pet stores. IAS which are typical of the pet trade and which are known to have feral populations in the
35 CNMI include the red-eared sliders (*Trachemys scripta*), orange-cheeked waxbills (*Estrilda melpoda*),
36 rock doves (*Columba livia*), and quails (Williams 2010). Importation risk via this pathway will entail the
37 risk of species legally allowed for import for commercial sale or ownership as well as the risk of
38 smuggling, done either by direct personal transport of an animal or by Internet purchase and shipment
39 via postal service or private carrier service (Derraik and Phillips 2010). Experience in Hawai'i has shown

1 that smuggling of banned animals is generally easy because of lax inspection standards (Kraus and
2 Cravalho 2001). The same will be true for much of the Micronesia Region.

3 Establishment risk via the pet trade is high overall, although there is tremendous variation among
4 species. Quantification of establishment success for reptile and amphibian introductions indicates this
5 pathway to be one with the lowest probability of successful establishment per release. However,
6 because the total number of releases via this pathway is so vast, overall establishment risk is high, and
7 the pathway has contributed the greatest number of herpetofaunal introductions worldwide (Kraus
8 2009). A similar pattern holds for birds (Kraus 2003). Although not explicitly tested, the same pattern
9 may be expected for mammals, although mammals seem to establish more easily than do the other two
10 groups. Many species of birds, reptiles, and amphibians introduced through the pet trade have become
11 established in numerous countries around the globe, including tropical Pacific islands (Long 1981; Kraus
12 2009). Other taxa frequently kept in the pet trade are predicted to pose high establishment risks even
13 though populations have not yet established (Bomford et al. 2005; Reed 2005; Carrete and Tella 2008;
14 Bomford et al. 2009). At least among birds, wild-caught animals appear at greater risk of establishment
15 than do species that have been bred in captivity for many generations, which seem to have lost much of
16 their ability to live in the wild (Carrete and Tella 2008). It is doubtful whether the wild-caught vs.
17 captive-bred distinction in establishment success will hold for reptiles and amphibians because their
18 behavior is probably less environmentally dependent, so few species have been genetically modified in
19 captivity, and, even when they have, there is evidence that mutant forms can survive when released into
20 novel environments (e.g., Pether and Mateo 2007). However, at least one exception exists: wild-caught
21 pythons are at greater risk of release and present a greater risk of impact because behavioral irascibility
22 promotes release by owners and parasite loads present an added risk to native wildlife when released
23 (Reed 2005). The most widely kept mammals (cats, dogs, rabbits, mice, rats) have well-established
24 histories of successful establishment around the globe in a broad diversity of environments, including
25 tropical islands (Lever 1985; Long 2003), and there is no doubt that they can easily establish populations
26 if released in new islands in the Micronesia Region.

27 Hazard for species transported via this pathway is just as variable as is establishment risk, and for the
28 same reason: the large pool of species travelling via this pathway are diverse in biological attributes,
29 providing some species that are highly hazardous invaders and others that are of little concern.
30 Especially hazardous among mammals are predatory cats (Lever 1985; Pimentel et al. 2000; Nogales et
31 al. 2004; Vázquez-Domínguez et al. 2004; Pimentel et al. 2005; Denny and Dickman 2010; GISD 2010),
32 dogs (Lever 1985; van't Woudt 1990; Pimentel et al. 2000; Bergman et al. 2002; Pimentel et al. 2005),
33 and grazing rabbits (Lever 1994; Courchamp et al. 2003; Long 2003). Rats and mice are also highly
34 invasive across the globe (Atkinson 1978, 1985; Towns et al. 2006; Hilton and Cuthbert 2010), but it is
35 uncertain whether domesticated pet varieties survive well upon release. Among the most destructive
36 birds imported for pets are mynahs, bulbuls, pigeons, and a wide variety of parrots and finches, which
37 damage agriculture, disperse seeds of invasive plants, harass native birds, compete with native birds for
38 food and nest sites, and serve as reservoirs or vectors for diseases (Long 1981; van Riper and van Riper
39 III 1985; van Riper III et al. 1986; Lever 1987; Meyer and Florence 1996; Pell and Tidemann 1997;
40 Pimentel et al. 2000; Loope et al. 2001; Bergman et al. 2002; Bomford and Sinclair 2002; Thibault et al.

1 2002; Blanvillain et al. 2003; Eguchi and Amano 2004; Pimentel et al. 2005; Koopman and Pitt 2007;
2 Bomford 2008; Atkinson and LaPointe 2009; Linnebjerg et al. 2009; Feare 2010; Linnebjerg et al. 2010).
3 Some of these species are known to be actively sold as pets in the Micronesia Region. Hazard from
4 reptiles and amphibians moved via the pet trade is less clear, but is likely to be large in some cases,
5 especially on oceanic islands. In particular, snakes of many species are likely to be of high risk to native
6 wildlife via predation (Kraus and Cravalho 2001; Loope et al. 2001), and venomous snakes and large
7 constrictors, which pose obvious threats to human welfare and have become established on several
8 tropical islands (Martínez-Morales and Cuarón 1999; Ota 1999, 2000; Nishimura 2005; Quick et al. 2005)
9 as well as in the sub-tropical United States (Greene et al. 2007; Snow et al. 2007) are of considerable risk
10 (Fritts et al. 1990; Fritts et al. 1994; Rodda et al. 1997; Nishimura 2005; Reed 2005). But snakes are not
11 the only herpetofaunal threat. Predatory lizards are a potential problem, including monitor lizards
12 (Varanidae) and chameleons (Chameleontidae) (Loope et al. 2001; Campbell 2003; Enge et al. 2004;
13 Holland et al. 2009), due to predation on native wildlife, although large monitors can be a danger to
14 humans as well. North American bullfrogs (*Rana catesbeiana*) have been introduced into some countries
15 via the pet trade, and these frogs pose a large number of risks to native wildlife, including from
16 predation, competition, and disease vectoring (summarized in Kraus 2009). Perhaps the most frequent
17 impact from established populations of invasive reptiles and amphibians will be from changes in food-
18 web dynamics occasioned by the high densities formed by novel predators in tropical island ecosystems.
19 This can serve to either keep populations of other invasive pests unnaturally high by serving as a large
20 food resource, or such species may act as energy sinks, making nutrients unavailable to native species
21 (Fritts and Rodda 1998; Kraus et al. 1999; Moore et al. 2004; Greenlees et al. 2006; Kraus 2009). Many
22 species of small frogs (e.g., Hylidae, Ranidae) and lizards (e.g., Gekkonidae, Scincidae) kept in the pet
23 trade have the potential to induce such effects if released and established in the right environments. A
24 final risk of considerable importance for all taxa is the risk of transmitting disease to humans or native
25 species. Mammals, of course, pose a higher risk of transmitting diseases to humans because of their
26 closer phylogenetic affinity (e.g., Daszak et al. 2000; Karesh and Cook 2005), but birds and reptiles also
27 serve as vectors or reservoirs for human diseases (e.g., Haddock et al. 1990; Haddock and Nocon 1993;
28 Mermin et al. 1997; Reed et al. 2003; Mermin et al. 2004). Spread of diseases to native wildlife is of even
29 higher probability and threatens to reduce global biodiversity, with several spectacular examples
30 emerging in recent years (Daszak et al. 2000, 2001; Fisher and Garner 2007).

31 Total risk via the pet-trade pathway is high in the Micronesia Region. Importation risk for many species
32 is virtually assured by moderate to high public interest, lack of government regulation of the industry,
33 and poor inspection and enforcement capabilities. Also, establishment risk and hazard are high for many
34 of the most popular pet species. This is clearly the riskiest intentional pathway for terrestrial vertebrates
35 in the Micronesia Region and in many other parts of the world. Given the relatively modest scope of the
36 commercial pet trade in the Micronesia Region, the largest risk at present is probably the transport of
37 cats and dogs to islands on which they currently lack feral populations, but a wide diversity of species,
38 both mammalian and non-mammalian, pose a significant risk to the region.

- 39 • Risk of importation 3
- 40 • Risk of establishment 3

- 1 • Hazard 3
- 2 • Total risk 9 **HIGH**

3 **A4.2.3.2 Aesthetic Releases**

4 This pathway is very closely related to the pet-trade pathway and involves intentional release of animals
5 to establish populations because the species is considered in some sense desirable by the releaser (this
6 is the "intentional" pathway of Kraus 2009). Examples of this include birds (largely songbirds and some
7 parrots), frogs, or lizards released around a home because they remind the owner of a place they lived
8 previously or because they like the appearance of the species or the calls made by it (e.g., Long 1981;
9 Kraus and Campbell III 2002). Historically, this has been an important, but uncommon, introduction
10 pathway for birds, but a more important pathway for mammals, reptiles, and amphibians (Kraus 2003,
11 2009). Animals introduced via this pathway may be obtained directly from the pet trade for release, but
12 often those introducing the animals collect the species directly from the wild and release them in an
13 extralimital location. One variant of this pathway of particular concern is the desire by some resort
14 hotels to release colorful birds such as ducks and parrots on their grounds to amuse tourists and
15 increase the appearance of these resorts as "exotic." Among other problems created by this practice is
16 the release of mallard ducks (*Anas platyrhynchos*) in Hawai'i, which hybridize with and threaten the
17 native koloa ducks (*Anas wyvilliana*) (Browne et al. 1993; Engilis Jr. and Pratt 1993; Fowler et al. 2009).

18 Importation risk for this pathway will be largely the same as that for the pet trade, with animals
19 available in the pet trade or available for personal legal importation typically being those chosen for
20 release. However, this pathway also includes animals smuggled into a jurisdiction that bans their
21 ownership, as has repeatedly been demonstrated in Hawai'i (Kraus 2002). Given the overlap with the
22 pet trade for legal importations (see above) and the additional risk of importation posed by smugglers of
23 banned wildlife, importation risk via this pathway is just as high as for the pet-trade pathway.

24 Risk of establishment via this pathway is a function of three variables: the number of individuals within a
25 population desiring to establish a new species, the availability of animals for release, and the number of
26 animals released (propagule pressure). For smaller jurisdictions, the first number will generally be low
27 because relatively few people want new species in their environment that they will go through the
28 trouble (sometimes including smuggling) to attempt establishing new populations. Availability of
29 animals in the Micronesia Region varies depending on size of the local commercial pet trade and
30 frequency with which citizens travel overseas and, therefore, have the opportunity to return with
31 animals. Both of these are likely highest for Guam and CNMI because their large military presence leads
32 to high passenger volume and frequent turnover of personnel. Lastly, propagule pressure via this
33 pathway is usually high once a decision has been made to try to establish a species because everyone
34 knows that multiple animals will increase the probability of founding a population. For most countries in
35 the Micronesia Region, it is probably safe to assume that interest in establishing novel species is low.
36 Across the region, availability of animals varies, but may be summed as moderate in Guam and CNMI
37 and low in the other countries. But propagule pressure will generally be high. In sum, these three
38 variables make establishment risk via this pathway moderate.

1 For the same reasons described above for the pet-trade pathway, hazard of animals released via this
2 pathway will be of wide variability, but should generally be considered high because of the large number
3 of clearly hazardous species transported. Hence, as for the aesthetic release pathway, overall risk is
4 high. Opportunity for release is high, establishment risk is moderate, and impact risks are high. The only
5 uncertainty is the will to release animals for this purpose, and experience around the globe shows that a
6 significant (but small) percentage of most human populations are willing to engage in this behavior (see
7 data in Long 1981, 2003; Lever 1985, 1987; Kraus 2009). Once that decision is made, animals are
8 generally sufficiently available that a determined individual can acquire the needed material.

- 9 • Risk of importation 3
- 10 • Risk of establishment 2
- 11 • Hazard 3
- 12 • Total risk 8 **HIGH**

13 **A4.2.3.3** *Animals for Entertainment*

14 Releases by zoological gardens are also closely related to the previous two categories inasmuch as the
15 species displayed (and sometimes released) are chosen for their aesthetic interest. However, species
16 available via this pathway present an even wider array of taxa than those available in the pet-trade or
17 aesthetic pathways. Zoos range from large publicly funded, well-secured institutions to small, private,
18 poorly secured tourist facilities. Most records of release come from the latter end of the spectrum;
19 however, there have clearly been several instances of intentional releases of animals by personnel at
20 larger, public zoos too (Shaw 1946; Long 1981). Releases include those done deliberately as well as
21 escapees from poor caging conditions. Releases via this pathway have not been as well documented as
22 for other pathways, but those involving reptiles and amphibians have recently been summarized (Kraus
23 2009), and some records of bird and mammal releases have also been noted (Long 1981; Washitani
24 2004; Holzapfel et al. 2006; Jansson et al. 2008). But most mammals retained in zoos are larger and
25 dangerous enough to attract immediate recapture efforts, so few records exist of mammals becoming
26 established via this pathway (but see Washitani 2004).

27 There are relatively few zoos in the Micronesia Region, with one (previously two) on Guam, one on Rota,
28 and one on Saipan (Stanford 2010). A recently captured skunk on Guam likely arrived via this pathway,
29 suggesting that, although few zoos exist in the Micronesia Region, the pathway cannot be ignored. Low
30 volume of activity via this pathway makes risk of importation rather low, but the rather poor
31 maintenance standards evinced by many private zoos make risk of release into the wild rather high. So
32 overall, risk of importation and release/escape is moderate.

33 Risk of establishment is probably lower than for the pet-trade pathway because most species retained in
34 zoos are kept only in small numbers. However, when large colonies of a species are kept, risk of
35 establishment will increase. Information on what stocks are currently held in zoos in the Micronesia
36 Region is not easily available, so establishment risk is currently uncertain for most jurisdictions.
37 However, the zoo on Saipan has multiple individuals of some species (Calindas 2006), including some

1 that are invasive elsewhere, so establishment risk will be higher for those. Given this uncertainty,
2 establishment risk is here scored as “moderate.” Assuming that governments have the interest to
3 mandate that zoos retain only one or two individuals of each species, however, establishment risk can
4 be kept low.

5 Hazard via this pathway is high. Current regulations on Guam and possible elsewhere are likely not
6 adequate to deal with this pathway effectively (as was demonstrated when the animal facility on Guam
7 closed a few years ago where it appears that the ultimate repository of some of the captive animals
8 from that facility were never ascertained (Pers Comm. Bassler). This high hazard results from all the
9 same reasons given above under discussion of the pet-trade pathway as well as the fact that zoos
10 frequently exhibit a number of species dangerous to humans. As well, some of the species exhibited at
11 the Saipan Zoo (and obtained from a prior zoo on Guam) are known invasives elsewhere. These include
12 parrots, cockatoos, and green iguanas (Calindas 2006).

- 13 • Risk of importation 2
- 14 • Risk of establishment 2
- 15 • Hazard 3
- 16 • Total risk 7 **MODERATE**

17 **A4.2.3.4 Food Use**

18 Transport of animals for use as food sources has historically been one of the largest pathways for
19 mammal introductions but has been an important source of bird, reptile, and amphibian introductions
20 as well (Kraus 2003, 2009). Introductions of domesticated mammals and birds via this pathway were a
21 fundamental characteristic of European colonization efforts around the world (Crosby 1986), but most
22 of these introductions tapered off by the start of the 20th century because virtually worldwide spread of
23 their domesticated mammals had been completed. Prior to that, Polynesians and Micronesians had
24 spread pigs and red jungle fowl widely across the Pacific, and Polynesians also moved iguanas
25 (*Brachylophus* spp.) regionally (Gibbons 1981). However, there still remain many Pacific islands that lack
26 feral populations of these Eurasian domesticated animals. Introductions of reptiles and amphibians for
27 food use intensified during the 20th century and still continue around the world, with the most well-
28 known example being the continued farming and spread of the North American bullfrog (*Lithobates*
29 *catesbeianus*) for frog legs. Several of the most notoriously invasive mammals (pigs, goats, sheep, cattle,
30 rabbits), reptiles (Chinese soft-shelled turtles, *Pelodiscus sinensis*), and amphibians (North American
31 bullfrogs) have been spread via this pathway. Most of the alien vertebrates currently used for food in
32 Micronesia include the usual assortment of ungulates (pigs, cattle, goats, caribou, sheep) and birds
33 (chickens, quail, geese, ducks). Some members of the Asian communities in this region also eat dogs.

34 Risk of continued importation via this pathway is high. Most humans view their domesticated mammals
35 and chickens as a natural part of their environment and do not think of them as invasive. As a
36 consequence, transport and release of domesticated food species onto islands lacking them is typically
37 viewed as simply exercising one’s right to feed oneself, and the practice continues around the globe.

1 Many of these introductions will involve transport between islands within nations, although others
2 involve importation across national boundaries. Other food introductions are for more directly
3 commercial purposes. North American bullfrogs and other large frog species continue to be touted as an
4 easy way to raise protein in one's backyard either for direct consumption or, more often, for commercial
5 sale. This despite the fact that frog farming is logistically difficult and most farms fail, with leftover
6 animals released or escaping into nearby habitats. Despite decades of evidence that this is a difficult
7 way of making money, agricultural extension agents around the world still promote the practice. As a
8 result, regions naive to the experience of trying to farm frog legs are susceptible to the claims of easy
9 profits and, therefore, to future invasions by these animals. None of the Micronesian Region countries
10 has suffered commercial attempts to farm frogs before and, hence, each may be liable to persuasion
11 that it is worthwhile. This inexperience makes risk of introduction of these species high for the region. In
12 addition, new food species often attend the immigration of new ethnic groups into countries as they
13 bring in preferred food resources from their home regions. For example, birds and turtles were
14 introduced into Hawai'i by Chinese immigrants in the late 1800s/early 1900s for this purpose (Brock
15 1947; McKeown and Webb 1982). CNMI, Guam, and Palau all have significant populations from East
16 Asian countries (56.3%, 32.6%, and 22.6%, respectively) (CIA 2010) and would be most liable to these
17 sorts of introductions, although risk would increase should other countries also allow increased
18 immigration or tourism from these regions.

19 Risk of establishment via the food pathway is high. Bird, reptile, and amphibian establishment rates
20 have all been quantitatively shown to be very high for this pathway (Kraus 2003, 2009), and the same is
21 certainly true for mammals, judging from the widespread distributions of the most popular food species
22 (Lever 1985; Long 2003). High establishment rates reflect the persistent, deliberate attempts by humans
23 to establish such species, which has led to frequent and widespread releases of large numbers of
24 animals, and, consequently, provided the high propagule pressure needed for successful establishment
25 (Forsyth et al. 2004; Lockwood et al. 2005; Hayes and Barry 2008). Given this continued motivation,
26 there is no reason for establishment risk to decline through time.

27 Hazard of species released via this pathway is also very high. The assorted feral ungulates are among the
28 most widely distributed and most destructive invasive species globally (Coblentz 1978; Cuddihy 1984;
29 Ebenhard 1988; Atkinson 1989; Tunison et al. 1995; Pimentel et al. 2000; Donlan et al. 2002; Pimentel et
30 al. 2005; GISD 2010), as is the bullfrog (Kraus 2009). Many other species known to be introduced as food
31 sources (e.g., rabbits [*Oryctolagus cuniculus*], banteng [*Bos javanicus*], water buffalo [*Bubalus bubalis*],
32 Polynesian rat [*Rattus exulans*], spotted turtledove [*Streptopelia chinensis*], and water frogs [*Rana*
33 *ridibunda*]) are also highly invasive in one or more countries (Crook 1973; Atkinson 1978; Long 1981,
34 2003; Lever 1994; Arano et al. 1995; Pagano and Schmeller 1999; Athens et al. 2002; Courchamp et al.
35 2003; Pagano et al. 2003; Vorburger and Reyer 2003; Towns et al. 2006; Hunt 2007). Less frequently
36 released species have not been well studied, but, on average, this pathway has generated a tremendous
37 amount of ecological and economic damage worldwide. The fact that relatively few vertebrate species
38 are moved via this pathway, and that a large percentage of those have figured among the most
39 destructive invasive species in the world gives this pathway a very high risk of continued hazard.

1 Overall risk via this pathway is high for the Micronesia Region. Component risks of importation,
2 establishment, and hazard are all high; social constraints on moving food animals are minimal and,
3 hence, regulation and enforcement against such movements are likely to remain low in the Micronesia
4 Region, as elsewhere.

- 5 • Risk of importation 3
- 6 • Risk of establishment 3
- 7 • Hazard 3
- 8 • Total risk 9 **HIGH**

9 **A4.2.3.5 Game Hunting**

10 This pathway is not entirely separate from the previous one inasmuch as game hunting is engaged in
11 both to provide food as well as for recreation, and animals are not actively farmed. However, the
12 species pools in each category are largely non-overlapping because the domesticated animals
13 transported for food use are generally not transported for use as game animals, although feral
14 populations may be secondarily utilized as a game resource. Further, the motivations behind the
15 pathways are not entirely the same, so separate consideration of them is warranted. Game
16 introductions include only mammals and birds; reptiles and amphibians are not transported for this
17 purpose (Kraus 2003, 2009). Globally, this has been the most important pathway for mammals,
18 accounting for 25% of total introductions; it has been the second most important pathway for bird
19 introductions, accounting for 35% of the total (Kraus 2003). For both groups, introduction rates have
20 exploded since the mid-1900s and continue to be high (Kraus 2003).

21 Importation risk for mammals in the Micronesia Region would appear to be moderate via this pathway.
22 The only mammals currently hunted in the region were introduced centuries ago, although some of
23 them continue to be moved to new islands within countries (Long 2003; Vogt and Williams 2004). The
24 only birds introduced into the region for this purpose appear to be the black francolin (*Francolinus*
25 *francolinus*) and bluebreasted quail (*Coturnix chinensis*) (Long 1981; Fritts and Rodda 1998; Vogt and
26 Williams 2004), introduced in the 1960s. However, large numbers of game birds have been introduced
27 elsewhere in the Pacific (Long 1981; Wodzicki and Wright 1984; Moulton et al. 2001), and interest in
28 additional releases of game animals has recently been expressed in at least CNMI (Williams 2010), so the
29 Micronesia Region may not be immune to this pathway. In recent decades most introductions via this
30 pathway have occurred under government auspices, so proper education of authorities about the risks
31 of game animals may serve to keep future risk low via this pathway.

32 Establishment risk via the game pathway is moderate. Globally, this pathway has had a rather low
33 probability of success for birds (35%, Kraus 2003). Although information was insufficient for assessing
34 establishment probability for mammals via this pathway, it is probably somewhat higher because many
35 of the widely used game mammals are less susceptible to extinction via predation than are the game
36 birds. Against this rather low establishment rate must be counted the frequently persistent attempts at
37 establishment via this pathway, which have often resulted in ultimate success. This combination of

1 persistence with a low establishment probability per attempt results in an overall moderate risk of
2 establishment. As for probability of importation, risk of establishment largely depends on what local
3 governments will tolerate in this regard because so many of these efforts have involved either direct
4 government sponsorship or at least governmental acquiescence in importation and release of large
5 numbers of animals.

6 Hazard from this pathway is very high for mammals and moderate to high for birds. Many of the
7 ungulates introduced for game purposes (primarily involving a variety of deer [*Cervus*, *Odocoileus*], tahr
8 [*Hemitragus jemlahicus*], and mouflon [*Ovis ammon*]) have proven very destructive of native ecosystems
9 on Pacific islands and elsewhere (Stone 1985; Conry 1988b; Wardle et al. 2001; Wiles 2005; Hughey and
10 Hickling 2006; GISD 2010). This is both because of direct herbivory on native vegetation as well as
11 trampling of the substrate (e.g., Duncan and Holdaway 1989), both of which lead to loss of vegetation
12 and increased erosion. Galliform game birds may benefit local ecosystems by dispersing seeds of native
13 plants previously dispersed by extinct avifauna (Cole et al. 1995), but they may also threaten native
14 ecosystems by dispersing invasive plant seeds, preying on rare native invertebrates, or serving as
15 reservoirs for parasites or diseases that threaten native species (Lewin and Mahrt 1983; Lewin and
16 Lewin 1984; van Riper and van Riper III 1985; Cole et al. 1995). Mallard ducks are notorious for having
17 hybridized with many other native duck species in North America, Asia, and Australia (Rhymer and
18 Simberloff 1996), and introduced populations have threatened native ducks with introgressive
19 hybridization in Hawai'i (Browne et al. 1993; Engilis Jr. and Pratt 1993; Fowler et al. 2009) and New
20 Zealand (Gillespie 1985; Rhymer et al. 1994). Similar problems would be expected to attend
21 establishment of mallards in Palau or Chuuk, FSM, where the native Pacific Black Duck (*Anas*
22 *supercilliosa*) occurs.

23 Overall introduction risk to the Micronesia Region via this pathway is moderate. Recent importation risk
24 has been low, and governmental control over this pathway is rather easily established, so with proper
25 attention by government authorities, risk of importation can readily be kept low. Similarly,
26 establishment risk can be kept low by proper government regulation of the practice, but without this,
27 releases for game purposes have often involved large numbers of animals, so establishment risk must be
28 considered moderate without explicit governmental policy discouraging this practice. Absent
29 governmental attention, risk would increase because of the tendency for some people to move animals
30 regardless of broader societal risks. Hazard from many of the most frequently distributed species is high,
31 and some of these have already colonized parts of the Micronesia Region.

32 Proper education of authorities regarding the risk associated with game animals would undoubtedly
33 assist with keeping future risks low to moderate. The hunters should also be educated about the
34 impacts of the animals they hunt and how hunting can help the environment and sustainability of
35 natural resources.

- 36 • Risk of importation 2
- 37 • Risk of establishment 2
- 38 • Hazard 3

- 1 • Total risk 7 **MODERATE**

2 **A4.2.3.6 Fur Ranching**

3 The majority of alien mammals introduced for fur ranching have involved the three species mink
4 (*Mustela vison*), muskrat (*Ondatra zibethicus*), and nutria or coypu (*Myocastor coypus*), although a few
5 introductions have involved raccoon (*Procyon lotor*), raccoon dog (*Nyctereutes procyonoides*), and
6 brush-tailed possum (*Trichosurus vulpecula*) (Lever 1985; Long 2003). Virtually all of these introductions
7 have been to temperate areas; none has been to an oceanic island (Lever 1985; Long 2003).

8 Risk of importation of species for this purpose in the Micronesia Region is very low. There is no record of
9 historical interest in the fur trade in that region, and it is doubtful that the industry could establish in
10 that climate with any of the species historically released through the trade.

11 Risk of establishment is low for the same reason: it is unlikely that any of the species historically
12 released through the trade would survive the climate and habitat, although raccoons might be an
13 exception, given their wide habitat tolerance and adaptability.

14 Hazard from the species involved in the fur trade is high. Mink depredate native vertebrates in Europe
15 and may interfere with metapopulation dynamics, thereby increasing chances of population extinction;
16 they also cause some economic damage from their depredations (Telfer et al. 2001; Banks et al. 2004;
17 Bonesi and Palazon 2007). Coypu and muskrats depredate crops; undermine human structures; and
18 graze vegetation, thereby depressing native plants, altering community structures of plants and
19 invertebrates, and sometimes resulting in complete loss of marsh habitat (Danell 1996; Carter and
20 Leonard 2002; Nummi et al. 2006; DAISIE 2008; GISD 2010). Raccoons depredate and compete with
21 native animals, depredate crops, damage buildings, and potentially spread serious human diseases
22 (Ikeda et al. 2004; Hayama et al. 2006). Raccoon dogs depredate and compete with native animals and
23 serve as an important vector of rabies and other diseases in Europe (DAISIE 2008). Brush-tailed possums
24 browse on native plants, leading to forest dieback, shifts in community structure, and endangerment of
25 native flora; they also serve as disease reservoirs for humans and livestock (Veblen and Stewart 1982;
26 Norton 1991; Rose et al. 1992; Crump et al. 2001). All of these species are invasive and should not be
27 imported to the Micronesia Region.

28 Overall risk to Micronesia from the fur trade is low. Although hazard from the species involved is high,
29 probabilities of importation and survival of these species are low in that region.

- 30 • Risk of importation 1
- 31 • Risk of establishment 1
- 32 • Hazard 3
- 33 • Total risk 5 **LOW**

1 **A4.2.3.7 Biocontrol**

2 Biocontrol introductions are those made for the purpose of providing predatory control of another pest
3 species. Most of these releases have failed to control the pests they were intended to destroy; rather,
4 the biocontrol species have become pests themselves. The classic examples involving vertebrates
5 released for this purpose are cats (*Felis catus*) and weasels (*Mustela erminea*, *M. nivalis*, *M. putorius*, *M.*
6 *sibirica*), widely released around the world for controlling rodents and rabbits damaging to agriculture
7 (Lever 1985; Parkes and Murphy 2003; Denny and Dickman 2010); mongoose (*Herpestes edwardsi*, *H.*
8 *ichneumon*, and *H. javanicus*), widely released around the world for controlling rats and vipers (Lever
9 1985; Long 2003); and cane toads (*Rhinella marina*), widely released across the tropics for controlling
10 insect pests of sugarcane (Easteal 1981; Lever 2001). Although these are the classic species typically
11 associated with biocontrol releases, a wide array of bird, frog, lizard, snake, and turtle species has been
12 introduced for these purposes too. For example, at least 19 species of birds and 32 species of reptiles
13 and amphibians have been introduced for biocontrol (Long 1981; Kraus 2009). Early releases of
14 vertebrates for biocontrol often involved official government sponsorship (Thomson 1922; Easteal 1981;
15 Long 1981; 2003), although private action was also common. Nowadays, government release of
16 vertebrates is rare because the damage caused by prior releases is widely known, and, consequently,
17 these actions have lost official favor. However, education about this subject among the general public is
18 less advanced, and private individuals still frequently retain the simplistic notion, largely lacking in
19 factual merit, that animal pests can be controlled simply by introducing a predator. Even so, if a target
20 group with specific behavior changes is identified, this is where effort should begin. As a result, more
21 recent vertebrate introductions for “biocontrol” purposes have tended to be private actions, often done
22 for the purpose of providing local control (sometimes restricted to a single building) of pest insects such
23 as cockroaches.

24 Because of negative fallout from prior vertebrate introductions and government eschewal of those
25 releases, the global risk of introduction via this pathway has declined dramatically since the 1960s (Long
26 1981; Kraus 2009). Such private actions that still occur often involve either translocation of species easily
27 obtained from nearby source areas or from the pet trade. Hence, importation risk for the biocontrol
28 pathway will be correlated to these two factors. In the Micronesia Region, ready access to foreign
29 faunas for private importation is generally limited, although individuals may be able to translocate
30 invasives already established on nearby islands. The species of greatest concern for movement that way
31 would be cats and some lizards, which are present as pests on some islands in the Micronesia Region but
32 not on all. Control of the pet trade via proper regulation (see above) could limit access to hazardous
33 species via the biocontrol pathway as well. The long flight times to the Micronesia Region from most
34 parts of the world also make obtaining live animals via internet purchase of doubtful reliability. Hence,
35 risk of importation for biocontrol purposes is probably generally low at present (except for animals
36 available in the pet trade) and likely to stay that way for the foreseeable future. One exception to this
37 rule is the ease with which U.S. servicemen can import pet animals from overseas stations by hand-
38 carrying them on military aircraft. This route of importation is worsened by the fact that the USFWS and
39 national quarantine services do not typically have inspectors stationed at military bases in the region, so
40 the probability of interception of such imports is remote. This route has led to numerous illegal
41 importations of banned reptiles into Hawai’i (Hawai’i DoA 2010), and some of these species include

1 those released elsewhere for control of house pests. Similar activities likely occur on military bases in
2 the Micronesia Region and would likely increase with the relocation of military personnel to Guam and
3 in CNMI, making this the likeliest source of importations via the biocontrol pathway.

4 Vertebrate biocontrol releases have tended to have high probabilities of successful establishment (Kraus
5 2003; Long 2003; Kraus 2009). This is because these releases were often the result of well-funded
6 programs supported by scientific or agency personnel and often resulted in the coordinated release of
7 many individual animals (Kraus 2009), which is highly correlated with successful establishment across a
8 wide variety of taxa (Lockwood et al. 2005; Hayes and Barry 2008; Bomford et al. 2009). Even when
9 releases were not the result of scientific effort, the widespread release of a preferred species by
10 numerous interested parties often created sufficient numbers of propagules that successful
11 establishment was ensured (Long 2003). As well, even releases by single parties often involve multiple
12 animals because the intent of release is to establish viable populations of the vertebrates, and everyone
13 recognizes that multiple individuals are needed for this purpose. Thus, because propagule pressure is
14 typically high, this pathway presents a very high risk of successful establishment, whether done under
15 the auspices of an official governmental or scientific program or enacted solely by private parties. This
16 would hold true in the Micronesia Region as elsewhere.

17 Hazard of the species involved in this pathway can be high. Indeed, biocontrol using vertebrates was
18 largely discontinued for precisely this reason, with wide recognition of the ecological and economic
19 impacts from cats (Lever 1985; Pimentel et al. 2000; Nogales et al. 2004; Vázquez-Domínguez et al.
20 2004; Pimentel et al. 2005; Denny and Dickman 2010; GISD 2010), mongooses (Honegger 1981; Case
21 and Bolger 1991; Pimentel et al. 2000; Roy et al. 2002; Yamada and Sugimura 2004; Pimentel et al. 2005;
22 Hays and Conant 2007; GISD 2010), weasels (Thomson 1922; McLennan et al. 1996; Basse et al. 1999;
23 Dowding and Murphy 2001; GISD 2010), and cane toads (Freeland 1994; Williamson 1999a; Crossland
24 2000; Lever 2001; van Dam et al. 2002; Phillips et al. 2003; Boland 2004b, a; Doody et al. 2006a; Doody
25 et al. 2006b; Greenlees et al. 2006; Smith and Phillips 2006; Griffiths and McKay 2007). What are less
26 well studied are the impacts attending the dozens of other species introduced for purported biocontrol
27 purposes. Mynahs (*Acridotheres tristis*) are well-known pests on tropical islands (Long 1981; Pell and
28 Tidemann 1997; Bergman et al. 2002; Feare 2010), as are several other birds (Long 1981), but most
29 other released biocontrol species remain unstudied. Cats are still widely spread by humans, so islands in
30 the Micronesia Region that currently lack them are susceptible to receiving this pest. The other
31 notorious invaders via the biocontrol pathway are no longer moved intentionally, except perhaps rarely
32 by ignorant private parties. Biocontrol introductions made by private individuals now rely largely on
33 animals available in the pet trade, because most insectivorous vertebrates will easily be viewed as
34 meaningful biocontrol agents by the general public, and because availability within the pet trade
35 fluctuates based on fads and perceived novelty, the pool of vertebrates potentially available for
36 “biocontrol” use is potentially unlimited. This makes precise estimation of hazard for species other than
37 those discussed above impossible at this time. However, given the large pool of species potentially
38 available, it is reasonable to assume that they range in hazard risk from low to high. Hence, hazard for
39 future biocontrol introductions can perhaps be best viewed as an average across this gamut and
40 summarized as “moderate.”

1 As a safeguard measure any proposed biocontrol releases should follow a standard SOP including
2 conducting a risk assessment, environmental impact studies and host specificity testing prior to any
3 releases.

4 In sum, risk for the Micronesia Region from the biocontrol pathway is low for probability of importation,
5 high for probability of establishment, and moderate for probability of impact, providing an overall risk
6 via this pathway of “moderate.”

- 7 • Risk of importation 1
- 8 • Risk of establishment 3
- 9 • Hazard 2
- 10 • Total risk 6 **MODERATE**

11 **A4.2.3.8 Scientific Research**

12 Vertebrates have frequently been released in association with scientific research enterprises. Releases
13 have been of two main types: 1) intentional or unintentional releases from medical research facilities,
14 and 2) intentional releases to study the ecology or behavior of the released species. The most
15 destructive consequences have arisen from the first of these, which have involved the release primarily
16 of monkeys and frogs. A variety of monkey species has been introduced into tropical and subtropical
17 locations around the globe from medical and/or behavioral research labs (Long 2003). Release of these
18 animals has sometimes been deliberate and sometimes resulted from poor caging. Most releases date
19 from the 1930s through the 1960s (Long 2003), but some are still occurring (Kyes 1993). Monkeys are
20 notoriously difficult to control once wild populations are established, with even decades-long control
21 efforts failing (Evans 1989; Boulton et al. 1996; Breckon 2000). This is a consequence of their
22 intelligence, which makes them elusive, and their ability to utilize a wide variety of food resources,
23 which allows them to attain high population densities in a diversity of environments.

24 Frog releases stemming from medical research have largely involved formerly widespread use of
25 *Xenopus laevis* (African clawed frogs) in pregnancy tests, a practice that is now obsolete. However,
26 releases of this species from medical research facilities have continued through the 1990s, making it still
27 a relevant concern. This species too has proven invasive in many areas of release, spreading quickly and
28 widely and creating some ecological damage in at least Chile (Lobos et al. 1999; Lobos and Measey 2002;
29 Lobos and Jaksic 2005), France (Grosselet et al. 2005; Eggert and Fouquet 2006), and California (Lafferty
30 and Page 1997). Populations of this frog have not generally proven amenable to control although three
31 small populations in the eastern United States were eradicated with the assistance of cold weather
32 (Tinsley and McCoid 1996).

33 Several species of frogs, salamanders, and lizards have been released in the United States, Caribbean
34 islands, and Europe with a view of determining what ecological results attended their establishment in
35 novel circumstances (Kraus 2009). Most releases for ecological research occurred prior to the 1970s, and

1 the practice is largely condemned now. But a few rogue researchers have continued such releases into
2 more recent times (Kraus 2009).

3 Risk of importation to the Micronesia Region from this pathway appears relatively low. There is only one
4 medical school in the area (Pacific Basin University Medical School in FSM). Inasmuch as that institution
5 appears to provide only the basics of a medical education, it is unlikely to be involved in research
6 involving hazardous vertebrates. Ecological research in the region involving movement of hazardous
7 vertebrates also appears non-existent to the present time. Given the growing expansion of awareness of
8 the risks posed in the Pacific region by invasive alien species, this seems unlikely to change.
9 Furthermore, at least some countries in the region (e.g., Palau) explicitly prohibit the introduction of
10 monkeys, which are the species of greatest hazard moving via this pathway.

11 Risk of establishment from this pathway is high. Monkeys could easily establish in the Micronesia
12 Region, as they have elsewhere in the tropics (Lever 1985; Long 2003), but it is less certain whether the
13 African clawed frog could do so. Populations have established on tropical Ascension Island in the Atlantic
14 (Tinsley and McCoid 1996), and this frog inhabits tropical regions of Africa, so it is feasible that it is
15 capable of colonizing tropical Pacific islands too.

16 The hazard of these species ranges from moderate to high. Impacts from monkeys can be severe, with
17 them proving especially damaging to birds and plants in island ecosystems (Meier et al. 1989; Breckon
18 2000; Cheke and Hume 2008), but also depredating agriculture and serving as potentially serious vectors
19 of human diseases (Boulton et al. 1996; Jensen et al. 2004; Engeman et al. 2010). Damage from *Xenopus*
20 has also been observed, with the species resulting in displacement of native amphibians (Lobos et al.
21 1999; Lobos and Measey 2002; Grosselet et al. 2005; Lobos and Jaksic 2005; Eggert and Fouquet 2006).
22 The Micronesia Region, however, lacks native amphibians, so hazard from this species would be
23 correspondingly less; however, broader impacts on freshwater ecosystems from this species remain
24 uninvestigated.

25 In sum, risk from this pathway appears moderate for the Micronesia Region under current regulatory
26 regimes. Such risk could be lowered if importation of monkeys and *Xenopus laevis* were banned and
27 such bans enforced.

- 28 • Risk of importation 1
- 29 • Risk of establishment 3
- 30 • Hazard 3
- 31 • Total risk 7 **MODERATE**

32 **A4.2.3.9 Religious Ceremonies**

33 There have been two sources of vertebrate releases for religious purposes. The larger of the two is the
34 common Buddhist and Taoist practice of releasing captive animals as an expression of compassion to
35 improve one's karma (Shiu and Stokes 2008). Typically, these releases occur during religious services

1 once or twice per year, but some traditions involve monthly releases (Shiu and Stokes 2008), and a large
2 percentage of releases may be conducted individually, not in organized groups (Severinghaus and Chi
3 1999). Birds and turtles are the most common terrestrial vertebrates used for release (Severinghaus and
4 Chi 1999; Kraus 2009), but mammals, frogs, and snakes are targeted as well (Agoramoorthy and Hsu
5 2005; 2007; Corlett 2010). Many of these released animals are purchased from pet stores, with one
6 study finding one-quarter of all birds stocked in Taipei pet stores slated for this purpose (Severinghaus
7 and Chi 1999). Releases of terrestrial vertebrates via this pathway have been primarily documented
8 from countries or regions with practicing Buddhists comprising a significant portion of the population,
9 such as Cambodia, Hong Kong, Indonesia, Korea, Malaysia, Singapore, Taiwan, Thailand, and Vietnam
10 (Severinghaus and Chi 1999; Kraus 2009; Corlett 2010), but they have occurred in Western countries too
11 (Sherwood 2001; Shiu and Stokes 2008; Gochfeld 2010). Numbers released can be huge, with 0.5-1
12 million birds imported annually into Hong Kong for release (Shiu and Stokes 2008) and 200 million
13 animals being released annually in Taiwan alone (Agoramoorthy and Hsu 2005; 2007), although most of
14 these latter involve native species. In locations where ritual Buddhist release of animals occurs, risk of
15 establishment is high because of the large volume of animals released and the high frequency of release,
16 both of which lead to high propagule pressure. Hazard can also be high, first due to direct competition
17 or hybridization with native species (Severinghaus and Chi 1999), and second via vectoring of diseases to
18 native wildlife or to humans. The latter has been an especial concern with the avian flu virus (Shiu and
19 Stokes 2008).

20 The second documented source of religious release has been by members of Christian snake-handling
21 cults, who have released alien venomous snakes on occasion (Wilson and Porras 1983). This particular
22 form of religious practice is largely limited to small numbers of individuals in the southern United States,
23 and, to date, the release of only two alien cobras has been documented in the literature.

24 Risk of importation to the Micronesia Region for this purpose appears rather low at this time. The
25 Micronesia Region presently contains few Buddhists (NationMaster 2010), although at least one
26 Buddhist temple is present in Guam and at least one is present in the CNMI, suggesting the presence of
27 a large community there (Williams 2010) that is not captured in the NationMaster database. The
28 varieties of Christianity present in the region do not include snake-handling cults. Consequently,
29 introduction volume along the religious pathway is likely to remain low through much of this region
30 (CNMI may be an exception), and, correspondingly, risk will also remain low. However, risk will not be
31 non-existent given that even small numbers of Buddhists can release significant numbers of animals in
32 private ceremonies. Should immigration patterns change such that more Buddhists migrate to the
33 region, this could become a pathway of greater importance. In that event, alien birds, frogs, and turtles
34 of east or southeast Asian origin would be the taxa most liable to introduction and establishment
35 because that would be the likely source of immigrating Buddhists and, hence, the easiest source from
36 which to obtain animals. Many of those species have already proven successful in colonizing Pacific
37 islands (Long 1981; Christy et al. 2007a; Christy et al. 2007c; Kraus 2009).

38 Risk of establishment is probably low for most species so long as propagule pressure is low. This will be a
39 reflection of release effort, which will, in turn, reflect the size of the Buddhist population in the region,

1 which currently is low. However, should release effort focus on one or a few species readily available in
2 the pet trade, establishment risk would increase because of the greater propagule pressure per species.

3 Hazard for released species probably ranges from low to moderate. Most species bought for release are
4 probably relatively inexpensive, which rules out rampant release of some species (like many parrots)
5 that create much damage but are of greater monetary value. Some released birds (e.g., finches, bulbuls)
6 may have higher hazard because of their depredations on agriculture, ability to spread weed seeds, and
7 ability to transmit disease (Long 1981; van Riper and van Riper III 1985; van Riper III et al. 1986; Lever
8 1987; Pell and Tidemann 1997; Pimentel et al. 2000; Loope et al. 2001; Bergman et al. 2002; Bomford
9 and Sinclair 2002; Thibault et al. 2002; Blanvillain et al. 2003; Eguchi and Amano 2004; Pimentel et al.
10 2005; Koopman and Pitt 2007; Bomford 2008; Atkinson and LaPointe 2009; Linnebjerg et al. 2009;
11 Linnebjerg et al. 2010). Most reptiles and amphibians associated so far with this pathway have relatively
12 limited impacts, or their impacts have not been investigated (Kraus 2009).

13 In summary, risk from this pathway is low for the Micronesia Region at present, although this could
14 change if larger numbers of Buddhists were to immigrate to the region.

- 15 • Risk of importation 1
- 16 • Risk of establishment 1
- 17 • Hazard 2
- 18 • Total risk 4 **LOW**

19 **A4.2.3.10 Bioterrorism**

20 Most vertebrates that are directly dangerous to humans are generally large and often rare. The use of
21 vertebrate species for bioterrorism would be unlikely because of the number of animals required to
22 produce the desired response. One possible exception would be that a large number of a common
23 venomous snake could potentially be introduced for such a purpose, but the numbers required for
24 importation for the task (hundreds to thousands would have to be released for the public to notice them
25 in anything approximating real time) could likely not easily be overlooked by even a modestly
26 functioning border-security system. Hence, volume of animals introduced for such purposes appears
27 low, and degree of inspection and corresponding regulations are likely sufficient to deter massive
28 importation of such animals. Establishment risk could be moderate to high for some venomous snake
29 species, and risk to humans would be high by definition. In sum, because of low probability of
30 importation and low probability of establishment, the risk of vertebrates being introduced for this
31 purpose seems low.

- 32 • Risk of importation 1
- 33 • Risk of establishment 1
- 34 • Hazard 3
- 35 • Total risk 5 **LOW**

1 **A4.2.3.11** *Discussion and Conclusions*

2 A large diversity of terrestrial vertebrates potentially threatens the human health and safety, economy,
3 and ecology of the five Micronesian Region jurisdictions under consideration in this risk assessment.
4 Risks come from 10 potential intentional pathways, with 3 (pet-trade, aesthetic, and food pathways)
5 posing a high overall risk of introduction, 4 (zoos, game-hunting, biocontrol, and scientific research
6 pathways) posing a moderate overall risk, and 3 (fur-ranching, religious, and bioterrorism pathways)
7 posing a low overall risk. In each case, overall risk is a compound of risk of importation and release, risk
8 of establishment, and risk of impact or hazard.

9 Risk at this time is rather broadly painted by pathway in order to allow government leaders in the region
10 to decide how best to direct resources in protecting their islands from further invasions of terrestrial
11 vertebrates. Except for species that have proven damaging elsewhere in tropical regions, it is difficult at
12 this time to predict exact risk for each species on a case-by-case basis without a far more detailed
13 examination of each species of concern. This is feasible for some taxa (Bomford 2003; Bomford et al.
14 2005; 2006; Bomford 2008; Bomford et al. 2009), with many mammal species and some bird species
15 most amenable to this more detailed approach (Bomford 2008). But there are few comparable variables
16 yet available for determining risk of reptiles and amphibians (Bomford and Kraus 2008; Bomford et al.
17 2009), and for many species in all taxa there are limitations in available biological knowledge that will
18 hinder or prevent detailed species-by-species assessments. Lastly, not all of the world's tens of
19 thousands of species amenable to human movement can feasibly be evaluated in politically meaningful
20 time-frames. Hence, at this time, analysis of the important pathways of ingress provides the best guide
21 for determining risk of additional introductions of terrestrial vertebrates to Micronesia.

22 Risks of introducing additional invasive vertebrates will expand with increasing population and
23 increasing transport activities in the region, most notably with the relocation of additional military
24 forces on Guam and in the CNMI. This is for the simple fact that numbers of alien introductions track
25 both increase in population density and growth in trade (Levine and D'Antonio 2003; Costello et al.
26 2007; Westphal et al. 2008; Pyšek et al. 2010). So, with more people living in the Micronesia Region and
27 transiting in and out of the area, intentional movement of desirable animals can be expected to
28 increase. This increased risk may well be significant, at least for the pathways involving pets, aesthetic
29 release, and the zoo trade, which will serve to better entertain the larger population.

30 Species invasions are not an ineluctable force of nature but simply reflect values and actions of humans.
31 Hence, there is much that can be done to mitigate a predicted rise in risk of future introductions. For
32 intentional pathways of introduction, such as those considered here, governmental efforts to restrict
33 the availability of the most serious invaders can considerably mitigate such risk. That already occurs to
34 some extent in the Micronesia Region. For example, Palau, CNMI, and Guam prohibit the importation
35 and ownership of several highly invasive vertebrates, such as snakes, parrots, mink, mongoose, and
36 bulbuls. Such limited lists are a good beginning to preventing some future invasions, but they are
37 inherently reactive (to known invasives) and, hence, limited in preventing further disasters. For
38 pathways moving only a few hazardous species (e.g., fur ranching, medical research), banning trade in
39 those species could provide an effective degree of protection from the risk attendant upon those

1 pathways. For pathways that move a greater diversity of species (e.g., pet trade and the other pathways
2 largely dependent on it), simply banning a few species will provide insufficient protection, and broader
3 regulation of the pathways themselves will be required. A more useful approach would be to allow for
4 importation of only species known to be non-hazardous in the region, a so-called White List approach
5 that has been adopted elsewhere in the Pacific Region. But application of this approach to a wide variety
6 of vertebrates is currently hindered by insufficient biological information for most species that make
7 prediction of invasiveness reliable. Hence, the former (so-called Black List) approach is a feasible
8 beginning while better predictive models of vertebrate invasiveness are developed (Pyšek et al. 2010).
9 But additional measures may be taken to better protect the Micronesia Region from these invasions as
10 well. These are enumerated in the following section.

1 **A5 WILDLIFE DISEASES⁷**

2 **SUMMARY**

3 The importation of animals and/or animal products involves an element of disease risk to the country
4 that is importing the animal or their parts (OIE 2009d). For obvious reasons, this is the case whether
5 animals are intentionally or unintentionally imported into the country in question. For example,
6 monkeypox virus was unintentionally brought into the United States in 2003 from wild African mammals
7 through the legal pet trade (Guarner et al. 2004). In addition, a shipment including 101 Silver-eared
8 Mesia (*Leiothrix argenteauris*) from Taiwan arrived at London's Heathrow Airport; subsequent laboratory
9 analyses found Asian-strain H5N1 AIV in 13.5% of specimens tested. From these few examples, it is
10 obvious that a wildlife disease introduction could occur almost anywhere in the world. Therefore, the
11 objective of this document is to assess, given the data available, the risk of introduction of select
12 wildlife-associated pathogens (where the pathogen has been found in wildlife in some region of the
13 world), their hosts, and vectors during the DoD build-up in the Micronesia Region.

14 This document outlines potential disease threats in the Micronesia Region from wildlife-associated
15 pathogens (Table A5-1). Ten primary pathogens associated with expected trade partners in the Pacific
16 Rim were assessed using a qualitative risk assessment tool developed by Morgan et al. (2009) for
17 emerging public health diseases in the United Kingdom. The tool was adapted to consider disease
18 threats to humans, livestock, and endemic wildlife in the Micronesia Region. The 10 pathogens
19 considered were hantaviruses, rabies virus, WNV, JEV, highly pathogenic AIVs, Plasmodium species
20 (avian malaria), henipaviruses (Hendra virus and Nipah virus), NDV, Yersinia pestis (plague), and TBEV.
21 The risk tool was divided into two parts such that we separately assigned a risk category (minimal, low,
22 moderate, high) to the probability that a pathogen would be introduced into the Micronesia Region
23 (Probability of Infection) and a risk category (minimal, low, moderate, high, very high) to the likely
24 impact of a pathogen if it were introduced (Impact of Infection). Risk assignments ranged from minimal
25 to very high for the various pathogens, depending whether probability or impact of infection was
26 examined.

27 This document is not intended to provide data on all potential pathogens that could be imported into
28 the Micronesia Region. Rather, it is intended to be a tool that focuses on select potentially important
29 pathogens as assessed by the authors at the time of writing. Many aspects of the pathogen(s) in
30 question, as well as the ecology of the wildlife associated with these pathogens, were evaluated for
31 inclusion in this list. However, this document should be revised as more data become available, when
32 new pathogens emerge in strategic locations, and when major changes in the Micronesia Region might

⁷ This section was prepared by APHIS-WS, National Wildlife Research Center, Ecology of Emerging Viral & Bacterial Diseases in Wildlife Project, 4101 Laporte Avenue, Fort Collins, Colorado 80521-2154. In Terrestrial plant and animal health risks associated with the U.S. military relocation in the Micronesia Region. United States Department of Agriculture, Animal and Plant Health Inspection Service. Washington, D.C.

1 affect the underlying assumptions of this risk assessment. As such, adaptive management is key to
2 reduce this risk associated with the introduction of wildlife-associated pathogens to this region.

3 **A5.1 INTRODUCTION**

4 **A5.1.1 Threat of Wildlife-Associated Diseases**

5 Of the 1,415 infectious organisms (pathogens) known to cause disease in humans, the majority (61%)
6 are zoonotic, i.e., transmissible between humans and animals (Taylor et al. 2001; Jones et al. 2008), and
7 zoonotic pathogens are twice as likely to be associated with diseases that have recently emerged in

8
9
10 *Box A5-1 – Near introduction of avian
11 influenza Asian-strain H5N1 virus into
12 England.*

13 Although Asian-strain H5N1 already
14 occurred in England at the time of this
15 story, it serves as an example of how a
16 disease of consequence can be
17 introduced through the legitimate
18 wildlife trade, much less the illegal
19 trade.

20 On 27 September 2005, a shipment
21 including 101 Silver-eared Mesia
22 (*Leiothrix argenteauris*; pictured below)
23 from Taiwan arrived at London's
24 Heathrow Airport and were
25 subsequently transferred about 80
26 miles to the quarantine facilities in
27 Essex, England where they were held
28 (NEEG 2005). Four of the birds were
29 dead on arrival and 10 more died
30 shortly thereafter but none were tested
31 for pathogens. Between 7 and 14
32 October 38 more died and were placed
33 in cold storage. Subsequent laboratory
34 analyses of 37 of these specimens
35 found highly pathogenic Asian-strain
36 H5N1 avian influenza virus in five
37 (13.5%) of them. This strain of A/H5N1
38 was most closely genetically related to
one found in wild ducks in China.

8 humans (Taylor et al. 2001). In addition, the incidence of
9 emerging infectious diseases has increased dramatically since
10 1940, and most of this increase has occurred in tropical regions
11 (Jones et al. 2008). These recent incidents of emerging
12 infectious diseases have been caused by 1) newly evolved
13 strains of pathogens, such as drug-resistant strains of bacteria
14 and the Asian-strain H5N1 AIV, 2) pathogens that have recently
15 entered populations for the first time, such as a coronavirus
16 causing SARS in humans and Nipah virus in domestic swine,
17 and 3) pathogens that have been present historically but have
18 recently increased in incidence, such as *Borrelia burgdorferi*
19 causing Lyme disease in humans (Wolfe et al. 2007; Jones et al.
20 2008).

21 Wildlife plays a critical role in both the emergence of new
22 pathogens in livestock and humans and the increased
23 incidence of emerging diseases. Here, we define wildlife as
24 non-domestic vertebrate species that can be either invasive
25 (e.g., Norway rat, house mouse, etc.) or native and we focus on
26 key pathogens that are associated with wildlife and have the
27 potential to cause disease in humans, domestic animals, or
28 native wildlife. Of the recent increases in incidence of
29 emerging infectious diseases in humans, 71.8% were caused by
30 pathogens originating in wildlife (Jones et al. 2008). In addition,
31 there is an inextricable linkage among pathogens affecting
32 wildlife, domestic animals, and humans, with these pathogens
33 often originating in wildlife and subsequently moving to
34 domestic animal hosts and then to humans (Wolfe et al. 2007).
35 For example, Nipah virus recently moved from its wildlife host
36 (fruit bats) to domestic swine where it caused disease and
37 mortality in both swine and local agricultural workers (Epstein
38 et al. 2006).

1 In this assessment, we examined the risk of wildlife-associated diseases relative to three primary
2 categories of concern for pathogens transmitted from wildlife either directly or indirectly (i.e., through
3 intermediate hosts):

- 4 • Human health—a public health threat because they cause morbidity and mortality in humans.
- 5 • Agricultural health—causing morbidity and mortality in livestock (including poultry)
- 6 • Wildlife conservation—threaten population viability of native wildlife species, especially those
7 that are currently considered threatened and endangered.

8 In developing this assessment, we considered human disease only from a wildlife perspective (i.e., only
9 those zoonotic diseases affecting humans that were associated with wildlife). There are a number of
10 transmission routes by which wildlife-associated pathogens can be introduced into the Micronesia
11 Region, including infected stowaway hosts (e.g., rodents, bats, etc.) on ships and aircraft, intentional and
12 unintentional introductions of infected host and reservoir species, natural invasions by infected wildlife,
13 and infected human travelers. These mechanisms and their pathways are described in more detail
14 elsewhere in this document. In general, the role of wildlife and domestic animal movement in pathogen
15 transmission has been well understood, with controls and legislation implemented to prevent such
16 spread (Fèvre et al. 2006). Despite preventive and mitigation measures, disease outbreaks regularly
17 occur because of legal and illegal movement of infected animals (Fèvre et al. 2006). International trade
18 in both wildlife and livestock contribute to this problem; trade in livestock is discussed in more detail in
19 Section A6, *Livestock and Poultry Diseases*. The global trade in wildlife involves billions of dollars and
20 hundreds of millions of animals (Rosen and Smith 2010), with much of this trade being illegal. One
21 example of how wildlife-associated pathogens can enter a country or region is described in Box A5-1.
22 However, there are a number of requisite conditions before a novel or re-emerging pathogen can
23 become established in an area and affect one or more of the categories of concern (human health,
24 agricultural health, and wildlife conservation) (Wobeser 2006):

- 25 • Pathogen longevity and survival—how long the pathogen can remain infectious in the host and
26 outside of the host under different environmental conditions.
- 27 • Environmental conditions—the optimal conditions outside of hosts under which the pathogen
28 can persist and remain infectious.
- 29 • Pathogen infectivity—how infectious the pathogen is and at what doses.
- 30 • Host presence—whether the natural host species is present.
- 31 • Vector presence—for vector-borne diseases, whether a competent vector is present.
- 32 • Host density—whether the host is of sufficient density to spread and maintain long-term
33 pathogen persistence.
- 34 • Contact rates—how often hosts and/or vectors contact each other to spread and maintain the
35 pathogen and whether pathogens are transmitted between hosts by direct, air-borne and/or
36 vector-borne transmission.

1 Because of these requisite conditions, it is often very difficult for most pathogens to become established
2 in a new environment. In most cases, there needs to be a “perfect storm” of events where all the
3 requisite conditions fall into place. For example, for WNV to become established on Guam from an
4 infected human arriving there, the human needs to be viremic at a minimum threshold, the requisite
5 mosquito vectors need to be present, the human individual needs to be bitten by an appropriate
6 mosquito vector, and the mosquito needs to feed upon and pass on the virus to a suitable host, which in
7 turn needs to be fed upon by a mosquito while the host is infectious and the virus passed on to another
8 suitable host. While seemingly implausible, this is one hypothesis as to how WNV was first introduced
9 into North America in 1999.

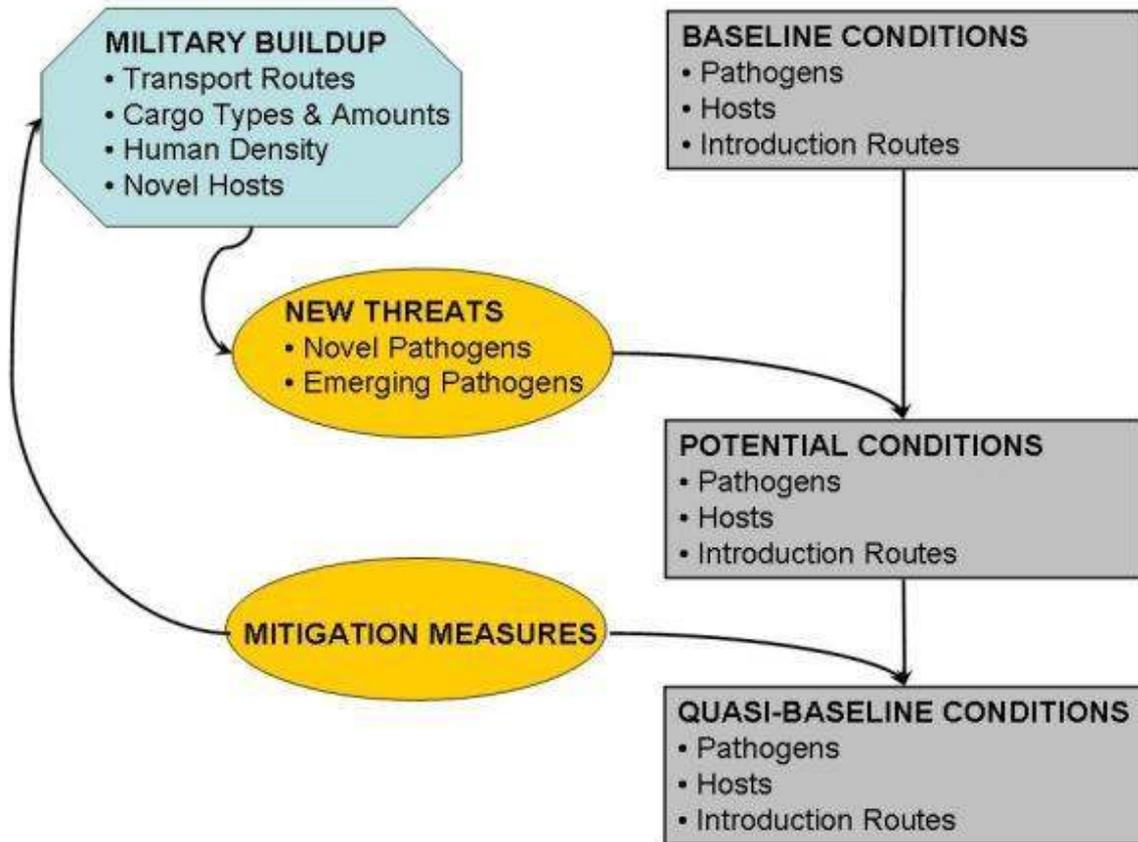

10 Not only are currently recognized diseases moving into new environments and regions around the
11 globe, but novel diseases have emerged in the past two decades that include interactions among
12 wildlife, domestic animals, and humans (Daszak et al. 2000; Cleaveland et al. 2001; Dobson and
13 Foutopoulos 2001; Jones et al. 2008). In particular, the number of emerging infectious disease events for
14 humans has increased significantly since the 1940s. These events have increasingly been zoonotic with
15 wildlife as the primary origin, and the increases in emerging infectious disease events stemming from
16 wildlife have been significantly associated with human population density and wildlife host richness
17 (Jones et al. 2008), although in recent years more surveillance efforts and improved technology may
18 have also contributed to increased detection of emerging infectious diseases.

19 Here, our primary objective was to identify and qualitatively evaluate risk of introduction or re-
20 introduction of wildlife-related pathogens causing disease in humans, livestock, and native terrestrial
21 vertebrate fauna to the Micronesia Region as a result of the proposed U.S. military relocation in that
22 region. Specifically, given the available data, we attempted to:

- 23 • Identify the risk of introduction of wildlife-associated pathogens causing disease in humans,
24 agriculture, and native wildlife from wild and feral animals to the Micronesia Region as a result
25 of the military relocation.
- 26 • Assess occurrence of pathogen and host introduction (given the probability of species
27 introduction) through field sampling in the Micronesia Region.
- 28 • Assess pathogen introduction from a variety of potential pathways using risk assessment.
- 29 • Recommend mitigation measures based on risk assessment modeling.
- 30 • In order to accomplish these objectives, we used the following general strategy (Figure A5-1):
 - 31 • Identified the baseline conditions in the Micronesia Region with respect to existing pathogens,
32 hosts, and routes of introduction using existing information,
 - 33 • Identified how the military build-up may add and/or modify those baseline conditions,
 - 34 • Identified how the changes from the military build-up could provide opportunities for new
35 threats from historically occurring pathogens that have not yet been introduced into the Region,
36 recently emerged pathogens that are not yet found in the Region, or re-emerging pathogens

- 1 (pathogens that have been found in the Region, but have been eradicated, yet have the
 2 potential to be re-introduced) and how this will affect baseline conditions, and
- 3 • Developed mitigation measures targeted at eliminating and/or minimizing threats, such that
 4 baseline conditions are closely maintained.

5 **Figure A5-1: General Strategy Used For Identifying and Mitigating Threats of Introduction of**
 6 **Wildlife-Associated Pathogens to the Micronesia Region**

7

8

9 We collected data pertaining to relevant disease agents and pathways associated with wildlife. A focus
 10 was made on wildlife-associated diseases not currently found in the Micronesia Region that either are of
 11 high consequence or have a reasonable probability of introduction. Literature reviews were conducted
 12 for relevant pathogens using multiple databases. Data sources included published literature,
 13 government reports, and, in some instances, articles in the popular media (e.g., if they were the only
 14 source available). In addition, multiple interviews and/or site visits were conducted in Guam, Saipan,
 15 Tinian, and Palau to obtain additional information pertaining to wildlife and wildlife diseases. The
 16 interviews were conducted with government officials, nongovernmental organizations, and/or citizens
 17 of the islands.

1 The purpose of this risk analysis was to assess the increased risk of introduction of wildlife-associated
2 diseases that the proposed military relocation could introduce into Guam and the rest of the Micronesia
3 Region. The objective was to identify likely pathways of introduction of relevant wildlife-associated
4 diseases directly and indirectly associated with the military relocation on Guam, assess the potential
5 impacts of these pathogens if they are introduced, and recommend procedures for risk reduction. In
6 developing this risk assessment, we focused on wildlife-associated diseases in the Pacific Rim (Asia,
7 Australia, and North America), and wildlife-associated diseases and their potential hosts that could have
8 significant morbidity and mortality in humans, livestock, and native wildlife. We did not consider
9 wildlife-associated diseases already widespread throughout the Micronesia Region.

10 In addition, the scope of this risk assessment is limited to relevant pathogens of terrestrial vertebrate
11 wildlife species (primarily birds and mammals) that could be associated with the military relocation in
12 Guam (e.g., increased building materials and other commodities, temporary construction workers,
13 military activity, etc.). Because the bulk of the DoD relocation is associated with Guam, it is our primary
14 focus. However, several other islands in the Micronesia Region were considered in the risk assessment,
15 with an additional emphasis on CNMI and Palau.

16 It is beyond the scope of this risk assessment to determine an overall risk on Guam for the introduction
17 of all wildlife-associated disease agents. As such, a focus was made on potentially high-consequence
18 pathogens not known from the Micronesia Region that could be introduced during multiple phases of
19 the military relocation. In addition, wildlife-associated diseases from regions from which trade is likely to
20 the Micronesia Region (e.g., Asia and the United States) are a focus of this risk assessment. Overall, we
21 focused on wildlife-associated pathogens which could affect the health of humans, livestock, or native
22 wildlife.

23 **A5.1.2 Current Situation**

24 **A5.1.2.1 Pathways of Introduction and Spread**

25 **A5.1.2.1.1 People**

26 Humans can become infected with zoonotic pathogens and act as direct introduction pathways by
27 moving disease agents to novel locations. People also contribute to the spread of zoonotic pathogens by
28 1) acting as amplifying hosts for some pathogens, 2) interacting with livestock (increasing the probability
29 of transmission to livestock from infected humans or transmission to humans from infected livestock),
30 or 3) interacting with wildlife (increasing the probability of transmission to wildlife from infected
31 humans or transmission to humans from infected wildlife).

32 **A5.1.2.1.2 Shipping**

33 **Military**

34 Maritime vessels can harbor rodent populations that are host competent for a variety of wildlife
35 pathogens. The DoD has many established procedures to conduct rodent control on ships (U.S. Army et
36 al. 1992).

1 Recently, a DoD memorandum directed Navy medical personnel with authority to inspect and issue ship
2 sanitation certificates (ship sanitation control exemption certificate and ship sanitation control
3 certificate) for Navy, Army, Military Sealift Command, Coast Guard, and National Oceanic and
4 Atmospheric Administration vessels (U.S. Navy 2010b). The certificate, issued in accordance with Article
5 39 of the International Health Regulations 2005, has a section for observed rodent infestations and is
6 valid for 6 months (U.S. Navy 2010c). Data pertaining to military seaports is included in Section A2.2.3.

7 **Commercial**

8 Commercial maritime vessels can harbor rodent populations that may be infected with zoonotic disease
9 agents and can therefore cause the introduction of wildlife pathogens to novel areas or spread
10 pathogens between mooring locations. Data pertaining to commercial shipping is summarized in Section
11 A2.2.

12 Maritime vessel route durations are discussed in Section A2.2.1. Route times are important factors
13 determining the likelihood of pathogen movement via ships because short-lived pathogens can “burn
14 out” prior to a ship arriving at its next destination. Thus, pathogens associated with long-term
15 persistence are more likely to move via ships. On the other hand, if a large host or vector population is
16 on a vessel, shorter-lived pathogen infections can be maintained until a ship arrives at its next
17 destination.

18 Maritime vessels are important contributors to the introduction and spread of wildlife pathogens and
19 their vectors. Historic outbreaks of plague, cholera, and yellow fever have resulted from unintentional
20 movement of pathogens via hosts or their vectors on ships (Tatem et al. 2006a; Tatem et al. 2006b).
21 More than 100 disease outbreaks since 1970 have been associated with ships (WHO 2002) and rats on
22 ships are considered to be responsible for the current global distribution of plague (Gubler 1998).

23 Rodent importation through international transport can cause serious problems. For example, an
24 inspection in China found 266 rats arriving in a single ship, while a survey of ships arriving from 1990 to
25 1998 indicated that 270 of 1,093 ships arrived with rodents aboard (Song et al. 2003). In addition,
26 aircraft, trains, and cargo containers arriving in China have been found to have rodent problems (Song et
27 al. 2003). Very low percentages of international vessels inspected entering New Zealand and Australia
28 had rats or rat sign during the 2006-2007 financial year (Russell et al. 2007). During 1981 to 1986, a
29 study was conducted to assess the prevalence of antibodies reactive with Hantaan virus among *Rattus*
30 *norvegicus* and *Rattus rattus* sera collected in the harbor area and anchored vessels of Port Shimizu,
31 Japan (Suzuki et al. 1988). Seropositive rates were 12.8% (49/384) and 4.7% (3/64) of sera collected in
32 the harbor area and 20% (1/5) and 4.8% (2/42) of sera collected from anchored ships from *R. norvegicus*
33 and *R. rattus*, respectively (Suzuki et al. 1988).

34 **Methods**

35 Maritime cargo shipping containers may harbor rodent species or bat species infected with wildlife
36 pathogens either inside the container or on the outside of the container. Infected vectors such as

1 mosquitoes and ticks may also be present in shipping containers. In general, standard 20- and 40 foot
2 metal containers are used in association with maritime vessels.

3 **A5.1.2.1.3 Air**

4 **Military**

5 Aircraft can harbor infected rodent species, bat species, or arthropod vectors such as ticks and
6 mosquitoes infected with wildlife pathogens. Host species may be found in cargo areas or on the outside
7 of aircraft such as in wheel wells. Air Force joint instruction 48–104, the Quarantine Regulations of the
8 Armed Forces (DoD 1992), incorporate regulations to mitigate the risk for introduction and
9 dissemination of arthropod vectors by movement of vessels, aircraft, and other transport of the Armed
10 Forces arriving at or leaving installations in the United States and foreign countries, ports, or other
11 facilities where arthropod vector-borne diseases are known to exist. The information on the materials
12 and procedures for disinsection can be found in the Military Entomology Operational Handbook
13 (NAVFAC M0-310; Army TM 5-632; Air Force AFM 91-16) (U.S. Navy 1972; USAPHC 2010). The DoD
14 outlines recommendations in their DoD customs and border clearance policies and procedures (DoD
15 2001).

16 **Commercial**

17 Commercial aircraft can harbor infected avian, mammalian, or arthropod species in cargo areas or on
18 the outside of the aircraft. In particular, mosquitoes and their larvae are commonly transported via
19 aircraft. In 1961, the U.S. Public Health Service published a comprehensive survey of insects found in
20 aircraft over a thirteen year period. Among the more than 20,000 insects were 92 species of mosquito,
21 51 of which were not known to be present in the continental United States, Hawai'i, or Puerto Rico.
22 Since then several similar reports have corroborated these findings (Gratz et al. 2000). Mosquito species
23 commonly intercepted from flights of Asiatic origin include *Culex pipiens*, *Culex quinquefasciatus*, *Culex*
24 *tritaeniorhynchus*, *Ochleratus japonicus*, *Aedes albopictus*, *Aedes aegypti*, and *Anopheles subpictus*
25 *indefinitus* (Joyce 1961; Takahashi 1984; Goh et al. 1985).

26 Mosquitoes can survive air traffic under a variety of conditions (Laird 1947). The longest survival period
27 recorded aboard aircraft was 6.5 days. Furthermore, adult and newly hatched mosquitoes can survive
28 and go on to breed and lay eggs in other locations. Mosquitoes tend to remain aboard an airliner despite
29 multiple stopovers. Flights from major Asian countries to Guam are on average less than 5 hours away
30 such that high survival is likely.

31 **Methods**

32 Air cargo shipping containers may harbor rodent species or bat species infected with wildlife-associated
33 pathogens. Infected arthropod vectors may also be present inside or outside of shipping containers. Air
34 cargo shipping containers are generally smaller than maritime containers, but larger aircraft can
35 transport standard 20- and 40 foot containers. Commercial air cargo may harbor rodent (Baker 1994) or
36 bat species (Wiles and Hill 1986; Constantine 2003) that may be infected with zoonotic disease agents

1 and can therefore cause the introduction of wildlife pathogens to novel areas or spread pathogens
2 between landing locations.

3 **A5.1.2.1.4 Natural**

4 ***Wind and Natural Movements***

5 Bird migration and dispersal can lead to the introduction and spread of wildlife pathogens. All islands in
6 the Micronesia Region provide winter grounds for a large number of migrating birds which come from a
7 myriad of locations within the Pacific Rim where a number of wildlife pathogens are endemic, but are
8 not distributed in the Micronesia Region.

9 There is some evidence that Mariana fruit bats travel between Guam and Rota (Wiles and Jonhson
10 2004). In addition, the black drongo (*Dicrurus macrocercus*), introduced to Rota during the 1930s, is
11 thought to have naturally moved to Guam and established a population during the late 1950s and is now
12 found throughout the island (Guam DAWR 2010).

13 ***Rafting***

14 Various animal species have the potential to raft (e.g., float on a piece of vegetation or other object)
15 from island to island. If rafting species are infected with a wildlife disease agent or an infected vector is
16 parasitizing them there is the opportunity for pathogen introduction or spread.

17 It has been suggested that reptiles may be more capable of rafting than mammals (Murphy and Wilcox
18 1986). In addition, various species may have different abilities. For example, at an island study site in
19 Washington it was suggested that *Microtus* (voles) can easily swim distances up to 1 km (0.6 mile) while
20 *Peromyscus* (mice) apparently must rely on rafting across water bodies at this site (note: neither of
21 these rodent species occur in the Micronesia Region) (Aubry and West 1987).

22 ***Smuggling***

23 Smuggling of wildlife species or products harboring wildlife species and/or disease vectors provides
24 introduction pathways for the movement of wildlife-associated disease agents into novel regions as well
25 as opportunities for the spread of pathogens. Large quantities of smuggled goods (e.g., agriculture and
26 wildlife) are most likely to be moved by international shipping routes (Ferrier 2009). For wildlife and
27 wildlife products, the average shipment refusal rate was approximately 2.5% annually during 2000
28 through 2004, although personal shipments were refused more frequently than commercial shipments
29 (Ferrier 2009).

30 **A5.1.2.1.5 Foreign Trade Partners**

31 Commodities from multiple countries currently are imported into Guam. In addition, several countries in
32 the Micronesia Region host tourists from several regions of the world. These data are discussed in
33 Section A2. Multiple shipping lanes currently serve Guam. Waterways to the east/northeast connect
34 with Hawai'i and the continental United States, while the waterways running north and west connect to
35 CNMI and ports in Asia. In 2002, Guam imported agricultural commodities primarily from Australia, Asia
36 (China, Korea, Hong Kong, Japan, Malaysia, the Philippines, Singapore, Taiwan, and Thailand), the rest of

1 the Micronesia Region (Chuuk, CNMI, Palau, Pohnpei, and Yap), New Zealand, and the United States.
2 Tourism is also a large industry in the Micronesia Region. In 2008 in Guam, most visitors (excluding
3 transit arrivals and crew) arriving by air were from Japan or Korea (see Table A5-2). The bulk of arrivals
4 to CNMI yielded a similar trend during 2002 (data from Table A5-5) and for Palau during 2007 (data from
5 Table A5-8). The bulk of visitors arriving by air to FSM were from the United States, followed by Japan,
6 and Europe (see Table A5-6). The bulk of visitors to Majuro were from the Americas, Japan, and other
7 Pacific islands (see Table A5-10). In terms of the risk of introducing diseases associated with wildlife,
8 movement of people and products from Asia poses the greatest risk, especially with respect to emerging
9 zoonotic diseases (Mackenzie et al. 2001). Of particular concern is introduction of wildlife-associated
10 diseases from China, Korea, Hong Kong, and Thailand (e.g., highly pathogenic AIVs), and Malaysia and
11 the Philippines (e.g., henipaviruses).

12 **A5.1.2.1.6 Wildlife-associated Diseases in the Micronesia Region**

13 Several wildlife-associated diseases are known to occur in the Micronesia Region. Important wildlife-
14 associated diseases presently found in the Micronesia Region are summarized in Table A5-1. Some of
15 these include Aujeszky's disease, avian chlamydiosis, avian infectious laryngotracheitis, avian leukosis,
16 avian mycoplasmosis, avian tuberculosis, botulism, brucellosis, canine distemper, clostridial infections,
17 fowl pox, infectious bursal disease, leptospirosis, Old World screwworm, Q fever, salmonellosis, scrub
18 typhus, and toxoplasmosis (see citations in Table A5-1). Other disease-causing pathogens likely exist in
19 the Micronesia Region, but have not yet been detected. Overall, much of the Micronesia Region appears
20 to be presently free of many of the high-consequence pathogens that affect many other regions of the
21 world, including many high-consequence pathogens from Asia.

Table A5-1: Wildlife-Associated Diseases and Their Pathogens That Have Been Found on one or More Islands in the Micronesia Region on at Least One Occasion

Disease ^a	Type ^b	Pathogen	Wildlife host(s)	Impact			Transmission	Distribution ^c	References ^d
				Humans	Agriculture	Wildlife			
Aujeszky's disease*	V	Pseudorabies virus	Feral swine		X	X	Contact, body fluids	Palau, FSM	1, 29

^a For example, pet rabbits released.
^b For example, feral swine.

There is little information pertaining to the status of wildlife diseases in the Micronesia Region. The few and dated animal disease surveys that have been conducted were typically conducted on livestock. With the exception of wild bird surveillance for AIV, few systematic surveys have been conducted for wildlife diseases in the Micronesia Region. Because of this, several assumptions were made in this risk assessment. If, e.g., a pathogen is known to have occurred in the Micronesia Region in livestock and the pathogen in question has been detected in wildlife in some other region at some point in time, the pathogen is considered to be a wildlife pathogen in the Micronesia Region. In addition, due to the limited data on this subject in this region, published data were supplemented with personal communications, interviews, and other resources.

In March 2010, we conducted a brief survey of rodents, bats, feral swine, and wild birds on Guam and Saipan. We sampled 230 birds (30 on Guam, 119 on Saipan, and 81 on Palau; Table A5-3) and 297 mammals (21 on Guam, 48 on Saipan, 80 on Palau, and 148 interdicted), which were from *Rattus* spp., *Suncus murinus*, *Mus* sp., feral swine (*Sus scrofa*), and fruit bats (*Pteropus* spp.) (Table A5-4). Select results of this survey are included for some pathogens of concern elsewhere in this document.

Table A5-3: Avian Species and Numbers Sampled for Pathogens in 2010 on Guam, Saipan, and Palau

Common name	Scientific name	Individuals
	Guam	
Blue-breasted Quail	<i>Coturnix chinensis</i>	11
Eurasian Tree Sparrow	<i>Passer montanus</i>	12
Pacific Golden-Plover	<i>Pluvialis fulva</i>	2
Philippine Turtle Dove	<i>Streptopelia bitorquata</i>	3

Feral swine	Guam DAWR	Pseudorabies virus	United States (Campbell et al. 2008, Corn et al. 2009)
		<i>Brucella suis</i>	United States (Campbell et al. 2008, Corn et al. 2009)
		Porcine circovirus	United States (Campbell et al. 2008, Corn et al. 2009)
		Influenza A virus	United States (Hall et al. 2008)
		<i>Giardia</i> <i>Cryptosporidium</i> <i>Balantidium</i> <i>Entamoeba</i>	Australia (Hampton et al. 2006)
		Multiple pathogens (viral and bacterial)	Spain (Vicente et al. 2002)
		At least 30 viral and bacterial pathogens	Multiple (Witmer et al. 2003)
		Foot and mouth disease virus	(Pinto 2004)
Asiatic water buffalo	Guam DAWR		

10 Potentially important pathogens of these species are listed, but their listing does not suggest that these pathogens
 11 are necessarily located on Guam.
 12 ^a GDOA, Division of Aquatic and Wildlife Resources.
 13

14 **A5.1.2.1.8 Small Mammals**

15 The terrestrial small mammal fauna of Guam and CNMI typically comprises approximately five species
 16 (Wiewel et al. 2009) (see Table A5-5). The major species typically include *Rattus exulans*, *Rattus*
 17 *norvegicus*, *Mus musculus*, *Suncus murinus*, and a third *Rattus* species of uncertain taxonomic identity
 18 (i.e., *R. rattus*, *R. tanezumi*, or *R. diardii*) (Wiewel et al. 2009). Some species have been thought to occur

1 in this region for great periods of time (e.g., *Rattus exulans*) (Steadman 1999), while other introductions
2 are thought to have been more recent (e.g., *Suncus murinus*) (Peterson Jr. 1956). Rats of the genus
3 *Rattus* are common on many islands of the Micronesia Region and can be found in most regions of the
4 world. In a wildlife trade risk assessment for the United States, rats of this genus were listed as one of
5 the top mammalian species for having the capacity to harbor a large number of zoonotic pathogens for
6 risk of importation into the United States (Pavlin et al. 2009). Indeed, a large variety of pathogens can be
7 harbored by a great diversity of rodent species. Because of this, many islands within the Micronesia
8 Region, often with very abundant rat (i.e., host) populations, appear to have the elements needed to
9 sustain select pathogens if they were to be introduced by related species. In addition, *Suncus murinus*, a
10 shrew species known to occur on some islands within the Micronesia Region, is known to host
11 Thottapalayam virus (a hantavirus not known to be a human pathogen) (Calisher et al. 2003). Overall, it
12 is obvious that certain small mammal species are well established on many islands within this region. As
13 such, their potential to perpetuate an introduction of many pathogens is of great concern. A good
14 example of this scenario can be found in Seoul virus (an Old World hantavirus hosted by the genus
15 *Rattus*). This virus, which has its origins in the Old World, can now be found in many port cities (e.g.,
16 Baltimore, Maryland, United States), likely originating from rats transported on cargo ships. In addition,
17 the initial introduction of *Suncus murinus* onto Guam has been hypothesized to have occurred through
18 cargo materials from ports in the Philippines (Peterson Jr. 1956).

19 **A5.1.2.1.9 Birds**

20 Most native land birds have been extirpated on Guam due to the invasive BTS. Currently native birds are
21 restricted to the critically endangered Mariana crows (*Corvus kubaryi*), Mariana swiftlets (*Aerodramus*
22 *vanikovens*), and the endangered Micronesian starling (*Alphonis opaca guami*). Guam rails (*Rallus*
23 *owstoni*), and Guam Micronesian kingfisher (*Halcyon cinnamomina cinnamomina*) are extinct in the wild,
24 although some individuals are presently held in captivity. Each of these species is threatened by the
25 potential introduction of avian disease agents. In particular, crows have been shown to be very
26 susceptible to WNV such that its introduction to Guam has the potential to drive the Mariana Crow to
27 extinction if an outbreak occurs. Some HPAIVs have been shown to be lethal to a number of wild bird
28 species and therefore endangered poses a serious threat to native bird species. Five species of introduced
29 land birds are currently common on Guam—black drongo (*Dicurus macrocercus*), black francolin
30 (*Francolinus francolinus*), Philippine turtle dove (*Streptopelia bitroquata*), rock dove (*Columba livia*), and
31 Eurasian tree sparrow (*Passer montanus*). The presence of these species provides a pool of avian species
32 that have the potential to maintain and spread introduced avian diseases to native birds. The yellow
33 bittern (*Ixobrychus sinensis*) is the only common native aquatic bird on Guam although more than 150
34 migratory species have been known to visit Guam. The most common migratory species is the Pacific
35 Golden-Plover (*Pluvialis fulva*). Migratory species on Guam visit many countries along the Pacific Rim
36 and have the potential to carry a number of avian disease agents such as AIV and WNV.

37 The landbird fauna of the Northern Mariana Islands is more intact than that of Guam, but a number of
38 species are endangered or critically endangered, including the Mariana crow, Mariana swiftlet,
39 nightingale reed warbler (*Acrocephalus luscinia*), and the Micronesian megapode (*Megapodius*
40 *laperouse laperouse*).

1 A serological survey of poultry on Guam indicated serological evidence of infectious bronchitis (multiple
 2 types), infectious laryngotracheitis, infectious bursal disease, Marek’s disease, *Mycoplasma*
 3 *gallisepticum*, *Mycoplasma synoviae*, eggdrop syndrome, avian encephalomyelitis, and *Mycobacterium*
 4 sp. (Duguies et al. 2000). However, no evidence of antibodies to the etiologic agents associated with
 5 avian influenza and Newcastle disease were found during this survey (Duguies et al. 2000).

6 Savidge et al. (1992) tested 762 avian biological samples from Guam and conducted 112 necropsies on
 7 wild birds but did not find any significant pathogens. The authors tested for evidence of hematozoans
 8 (blood parasites of the Haemosporidia family), AIV, and NDV, but did not detect any evidence of the
 9 pathogens causing these diseases. More recently, U.S. surveillance efforts by the U.S. Department of
 10 Interior and USDA for HPAIV in wild birds from 2006 to 2010 have not detected the presence of highly
 11 pathogenic H5N1 AIV out of 5,827 samples tested that were collected in Guam, CNMI, Palau, and RMI
 12 and have detected only three cases of low pathogenic AIV (NBII 2010) (Table A5-7).

13 **Table A5-7: AIV Surveillance Results for U.S. Department of Interior and USDA Testing for**
 14 **the Detection of HPAIV, 2006-Present**

Location	Samples tested	H5N1 positives	LPAIV positives	Percent LPAIV positives
Guam	4,201	0	1	0.02
CNMI	611	0	1	0.16
Palau	824	0	1	0.12
RMI	191	0	0	0.00
TOTAL	5,827	0	3	0.05

15

16 **A5.1.2.1.10 Feral Swine**

17 Feral swine (*Sus scrofa*) are an invasive and destructive species found in many regions of the world.
 18 Foraging activities by feral swine can result in damage to crops and natural ecosystems (USDA-APHIS-WS
 19 2008b). Although destructive, feral swine are often valued as a natural resource for hunting. Aside from
 20 their destructive tendencies, this species can also harbor a significant number of pathogens of
 21 agricultural and public health significance (Witmer et al. 2003) (see Table A5-6). Feral swine are known
 22 to occur on some islands within the Micronesia Region. It appears unlikely that feral swine will be
 23 smuggled or accidentally introduced onto islands in the present day. Therefore, there is a low likelihood
 24 of new feral swine associated pathogens being introduced into the Micronesia Region via this route.
 25 However, feral swine have been well documented to interact with domestic swine. This interface could
 26 be of key concern if a virulent swine pathogen were to be accidentally imported into Guam. Notably, the
 27 swine industry, although relatively small, is the largest livestock industry on Guam (Duguies et al. 2000).
 28 A serological survey of Guam swine during 1999 indicated evidence of only one pathogen, a parvovirus,
 29 among the swine tested (Duguies et al. 2000).

30 **A5.1.2.1.11 Philippine Deer**

31 As of 1999, Philippine deer (*Cervus mariannus*) were known to occur on four islands in the Micronesia
 32 Region: Guam, Rota, Saipan, and Pohnpei, with populations thought to be expanding on Guam and
 33 stable or declining on the other islands at that time (Wiles et al. 1999). The size of these animals makes

1 them and similar sized animals unlikely to be accidentally introduced into most islands in the Micronesia
2 Region. In addition, no significant diseases were found during literature reviews of this species.
3 However, there are several wildlife diseases known to negatively affect various deer species, such as
4 chronic wasting disease and others (see Table A5-6).

5 **A5.1.2.1.12 Asiatic Water Buffalo**

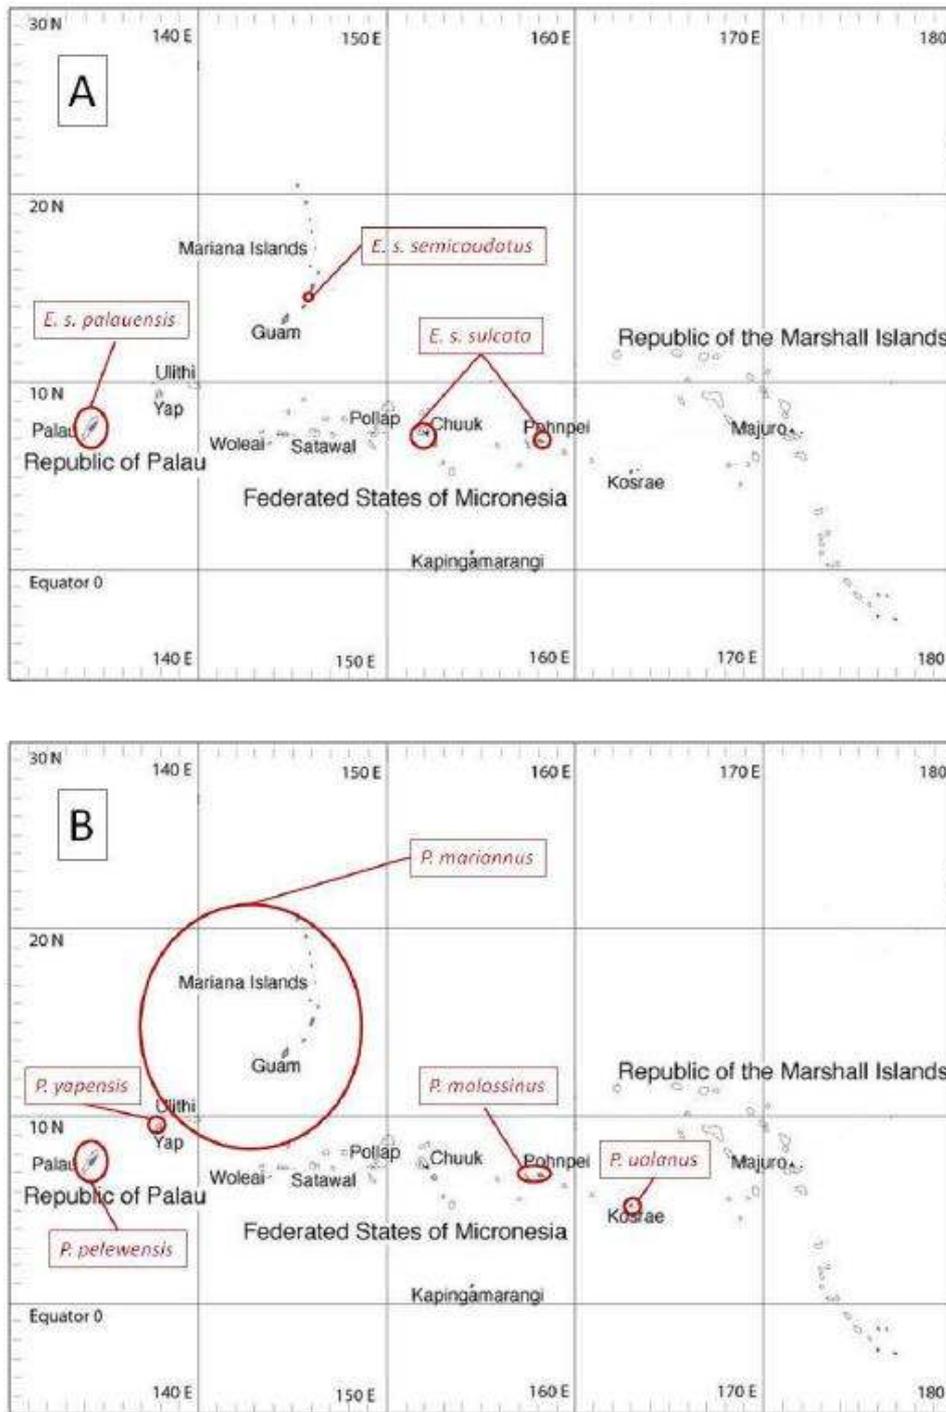

6 Likely originally introduced for farm use from the Philippines, a large feral herd of Asiatic water buffalo
7 existed on Guam as of 1988 (Conry 1988b). Efforts to control this species on naval lands have been
8 conducted since 1996 and the population is thought to have been reduced (personal communication
9 cited in USFWS 2009b). It is highly unlikely that an animal of this size could be accidentally introduced
10 into Guam or elsewhere in the Micronesia Region. No accounts of serious disease associated with this
11 species on Guam were discovered. In a serosurvey of a small number of animals, only one animal tested
12 positive for a single disease agent (*Anaplasma* sp.) of nine tested (Duguies et al. 2000). However, this
13 species could be afflicted by bovine diseases of cattle. For example, workers have indicated that Indian
14 water buffalo (*Bubalus bubalis*) are susceptible to infection with foot and mouse disease virus (Pinto
15 2004).

16 **A5.1.2.1.13 Bats**

17 There are one species of insectivorous bat and five extant species of frugivorous bats (flying foxes or
18 fruit bats) in the Micronesia Region (Simmons 2005); two other species of frugivorous bats once
19 occurred in the Micronesia Region but are now extinct. In the Micronesia Region, the single species of
20 insectivorous bat (Pacific sheath-tailed bat, *Emballonura semicaudata*) is currently found as *E. s.*
21 *palauensis* on Palau (Koror, Peleliu, Babeldaob, and Anguar), *E. s. sulcata* on Chuuk and Pohnpei, and *E.*
22 *semicaudata rotensis* only on Aguiguan (Goat) Island in the Mariana archipelago, although this
23 subspecies was historically found on Guam, Rota, Tinian, and Saipan (Lemke 1986; Simmons 2005;
24 Bonaccorso and Allison 2008) (Figure A5-2). Outside of the Micronesia Region, this species is also found
25 in Tonga and Fiji (Bonaccorso and Allison 2008). Historically, it was also found on American Samoa
26 (Bonaccorso and Allison 2008), but it has not been detected there in recent surveys (Fraser et al. 2009).
27 Pacific sheath-tailed bats are insectivorous and nocturnal and roost colonially in caves. They forage
28 primarily in mature forest on Aguiguan (Esselstyn et al. 2004; Gorresen et al. 2009), although they have
29 been observed in urban areas on Palau and Chuuk (Bruner and Pratt 1979; Wiles et al. 1997). Thus, in
30 some areas in the Micronesia Region, such as Palau, Chuuk, and Pohnpei, this species may come into
31 contact with humans. We found no evidence of pathogen surveys for Pacific sheath-tailed bats.

Source: Lemke 1986; Allison et al. 2008; Bonaccorso and Allison 2008; Bonaccorso et al. 2008a; Bonaccorso et al. 2008b; Buden et al. 2008; Wiles 2008; Wiles et al. 2008b, a

1 Historically, there were seven species of flying foxes (or fruit bats) in the Micronesia Region, all in the
2 genus *Pteropus* (Simmons 2005). Two of these species are now extinct: the Guam flying fox (*P. tokudae*),
3 which was endemic to Guam (Bonaccorso et al. 2008b) and the Large Pelew flying fox (*P. pilosus*), which
4 was endemic to Palau (Bonaccorso et al. 2008a). The remaining extant five species (Simmons 2005) are
5 the Mariana flying fox (*P. mariannus*) on Guam, the northern Mariana Islands, and Ulithi (Allison et al.
6 2008); the Caroline flying fox (*P. molossinus*) on Pohnpei and nearby atolls (Buden et al. 2008); the
7 Pelew flying fox (*P. pelewensis*) on Palau (Wiles 2008); the Kosrae flying fox (*P. ualanus*) on Kosrae (Wiles
8 et al. 2008a); and the Yap flying fox (*P. yapensis*) on the four main islands of Yap (Wiles et al. 2008b).
9 Flying foxes (herein referred to generically as fruit bats) are phytophagous, feeding on plant flowers,
10 leaves, and fruits (Marshall 1985).

11 In the Micronesia Region, fruit bats are a culturally significant food resource (Sheeline 1991). Fruit bats
12 are considered a delicacy for many of the native population of the Micronesia Region and are still legally
13 hunted and served in restaurants in Palau (Figure A5-3). Historically, there was considerable trade in
14 fruit bats among the islands of the Micronesia Region. Prior to federal listing as endangered in 1984 and
15 subsequent reclassification as threatened in Guam and CNMI (USFWS 2005), the Mariana flying fox was
16 commonly hunted for food. Overharvesting of these fruit bats severely depleted numbers on Guam and
17 fruit bats from other islands and countries were imported to supply demand (Wiles and Payne 1986;
18 Wiles 1992).

19 **Figure A5-3: Fruit Bat Offered on Restaurant Menus and Fruit Bat Soup in Restaurant In**
20 **Palau, Where Fruit Bats are Served Whole, Including Entrails and Fur**

21
22 Photos by Alan B. Franklin 2010
23

24 As of 1989, the trade in fruit bats had expanded from the Marianas to other islands in the Micronesia
25 Region, the South Pacific, and Asia (Wiles and Payne 1986; Wiles 1992). While the trade from within the
26 Marianas declined because of increased legal restrictions on hunting and declining fruit bat populations
27 (USFWS 2005), commercial imports from outside the Micronesia Region increased (Wiles and Payne
28 1986). From 1975 through 1989, at least 220,437 fruit bats were imported into Guam (an average of
29 11,550 bats per year) with 21.5% of these imports coming from outside the Micronesia Region (Table
30 A5-8). These were all legal imports and imported fruit bats were often sold commercially in stores,

1 fetching prices from \$17 to \$30 per bat (Wiles and Payne 1986). After 1990, legal imports of bats to
 2 Guam were curtailed considerably with the implementation of regulations under CITES and the addition
 3 of USFWS inspectors on Guam (Wiles 1990; Mickleburgh et al. 2002).

6

7 As of 1993, demand for fruit bats continued and they were still sold commercially (Wiles and Payne
 8 1986) for up to \$40 to \$50 per bat at markets and in roadside stands (Hamm 1994). Culturally, 53% of
 9 Chamorro residents of Guam surveyed indicated that they enjoyed eating fruit bats and significantly
 10 more older Chamorros ate fruit bat than younger Chamorros, suggesting an eventual decrease in
 11 demand (Sheeline 1991). However, many Chamorros further interviewed during this survey indicated
 12 that their children and grandchildren ate fruit bat, which suggested that some level of demand would
 13 continue into the future. At this time, imports of fruit bats from Palau were still legal because Palau was
 14 still part of the United States and, therefore, not regulated by CITES. However, implementation of the
 15 U.S. Lacey Act finally curtailed these exports (Wiles 1990).

1 Because of current legal restrictions across the Micronesia Region, fruit bats can now only be legally
2 hunted and sold within the Republic of Palau (USFWS 2005), where they are still hunted and sold in
3 markets and restaurants (see Table A5-8). Legal exports from Palau to other parts of the Micronesia
4 Region were discontinued under CITES when Palau became the Republic of Palau and no longer under
5 U.S. jurisdiction (Wiles 1990). However, illegal shipments continued through smuggling, based on
6 information on interdictions. For example, more than 200 fruit bats from 9 interdicted shipments were
7 collected at the GDOA that had been confiscated by Guam and Saipan Customs during 1990 through
8 1994; these shipments were coming from Palau, Yap, Rota, Chuuk, and Pohnpei. It is unknown to what
9 degree the demand for fruit bat continues today in the Micronesia Region, but the trade in fruit bats has
10 likely shifted from the legal commercial trade in the past to illegal smuggling today. How this demand
11 will shift in response to the military relocation on Guam depends largely on the nationality of the
12 workers employed to assist in the relocation and whether their customs include the consumption of
13 fruit bats. For example, fruit bats are widely used as a food resource in Indonesia, Malaysia, and the
14 Philippines, and some species of fruit bats (e.g., *Pteropus vampyrus*) have been smuggled into Guam
15 from the Philippines (Kunz and Jones 2000). In Malaysia and Indonesia, most of the trade in fruit bat
16 meat is with Chinese and Manadonese customers, who believe bat meat can be used to treat asthma,
17 kidney disease and malaise (Fujita 1988; Fujita and Tuttle 1991; Struebig et al. 2007). Bat hunting is legal
18 in Malaysia, and as of 2001, bat hunters could obtain licenses to take up to 50 individuals (Mohd-Azlan
19 et al. 2001). The estimated reported legal harvest from 1990 to 1996 on the Malaysian peninsula was
20 56,273 individuals; however, this was likely an underestimate of the total kill because of lack of
21 enforcement of quotas (Mohd-Azlan et al. 2001). In Indonesia, up to 4,500 fruit bats per month have
22 been harvested from a single location (Struebig et al. 2007). Hunted areas have become more remote as
23 fruit bat populations dwindle but the epicenters of trade, even from remote areas, are still large cities
24 and urban areas (Riley 2002). In the Philippines, fruit bats are also hunted heavily for food (Heaney and
25 Heideman 1987), especially by people with lower incomes (Shively 1997). In addition, market vendors in
26 Malaysia and Indonesia prefer live bats, which are then killed and prepared in front of the customer
27 when sold (Fujita and Tuttle 1991; Struebig et al. 2007). The illegal smuggling of live bats from these
28 countries (rather than dead, bats are now frozen) into the Micronesia Region could be disastrous in
29 terms of pathogen introduction.

30 As far as we know, there are no known pathogens carried by either the insectivorous or fruit bats in the
31 Micronesia Region that seriously affect human or agricultural health. The Chamorro people do suffer
32 from a neurodegenerative disease similar to Alzheimer's and Parkinson's disease (Amyotrophic Lateral
33 Sclerosis-Parkinsonism Dementia Complex), but this has been linked to consumption of fruit bats that
34 have fed on and bioaccumulated neurotoxins from cycad seeds (Cox and Sacks 2002; Monson et al.
35 2003), rather than a pathogen. Globally, both insectivorous and frugivorous bats are of considerable
36 concern because of the wide variety of pathogens they can carry, many of which can seriously affect
37 both human and agricultural health. For example, fruit bats have been implicated as reservoirs for Zaire
38 Ebola and Lake Victoria Marburg viruses (Leroy et al. 2005; Leroy et al. 2009; Kuzmin et al. 2010), SARS
39 (Calisher et al. 2008), and Henipaviruses, such as Hendra and Nipah viruses (Mackenzie et al. 2003;
40 Epstein et al. 2006). In addition, all species of bats in the Micronesia Region, including fruit bats, may
41 have the ability to carry rabies and/or other lyssavirus (Constantine 2009). While insectivorous bats are

1 often associated with rabies, fruit bats also serve as reservoirs for rabies-related lyssaviruses
2 (Constantine 2009), which has been transmitted to humans with fatal consequences (Samaratunga et al.
3 1998). These pathogens are discussed in more detail elsewhere in this document.

4 **A5.1.2.1.14 Interdiction Procedures**

5 GDOA provides technical assistance to USDA-APHIS-PPQ, has assisted in identifying confiscated wildlife
6 and wildlife products, placing wildlife in quarantine, and has assisted in multi-faceted efforts to prevent
7 illegal wildlife imports from entering Guam (Beck 2000). In general, anyone engaging in the business as
8 an importer or exporter of wildlife (living, dead, parts, or products) in the United States or its territories
9 must obtain a license from the USFWS (USFWS OLE 2006). Information on pet importation into Guam is
10 presented elsewhere in this document.

11 **A5.1.2.1.15 Wildlife Products**

12 During 2006 to 2008, USFWS inspected wildlife-derived products arriving in Guam from the following
13 countries or undefined regions: Argentina, Australia, Bolivia, Cameroon, Canada, Chad, China, Columbia,
14 Denmark, Fiji, Finland, French Polynesia, French Southern and Antarctic land, Germany, Greece, Hong
15 Kong, India, Indonesia, Japan, South Korea, Macau, Madagascar, Malawi, Malaysia, Mali, FSM,
16 Mozambique, Namibia, New Zealand, Norway, Palau, Papua New Guinea, Philippines, Russia, South
17 Africa, Switzerland, Taiwan, Thailand, United States, Unspecified, Venezuela, Vietnam, Zimbabwe.
18 During 1998 to 2003, there were 4,053 imported shipments and 696 exported shipments associated
19 with wildlife trade in Agana, Guam (USFWS OLE 2004). During 2003, 5,752,168 amphibians, 1,594,515
20 reptiles, 449, 294 birds, and 63,716 mammals were imported into the United States from foreign
21 countries (USFWS OLE 2004). From 1997 to 2003, the top 10 suppliers of wildlife shipments to the
22 United States included Canada (102,227), Hong Kong (48,936) Philippines (40,294), Italy (38,404),
23 Thailand (22,629), Indonesia (19,267), South Africa (18,844), Switzerland (14, 643), Mexico (13,701), and
24 China (12,896) (USFWS OLE 2004). Although much of the trade in wildlife is legal, it is difficult to assess
25 the risk from currently tabulated data if it is associated with illegally traded wildlife (Ferrier 2009). In
26 terms of the risk of introducing diseases associated with wildlife into the Micronesia Region, movement
27 of wildlife products from Asia, Africa, and South America pose the greatest risk, especially with respect
28 to emerging zoonotic diseases (Mackenzie et al. 2001; Karesh and Cook 2005; Karesh et al. 2005; Karesh
29 et al. 2007). Of particular concern to the Micronesia Region are the introduction of wildlife-associated
30 diseases from China, Korea, Hong Kong, Indonesia, Malaysia, Philippines, Thailand, and Vietnam.

31 **A5.1.3 Areas of Concern**

32 **A5.1.3.1 Wildlife-associated Diseases Outside the Micronesia Region**

33 There are a large number of wildlife pathogens of potential concern for introduction into the Micronesia
34 Region (Table A5-9). The World Organization for Animal Health (OIE) lists many animal diseases of
35 importance to international trade, many of which are applicable to this section, such as those that can
36 be found in wild or feral animals (see Table A5-2). For the sake of brevity, this section focuses on some
37 pathogens of major concern (as determined by the authors) primarily associated with Asia and the
38 United States, which will likely be two major regions for increased trade following the DoD relocation on

1 Guam. The biological and economic consequences of the introduction of a wildlife-associated disease
2 could vary widely. For example, if a pathogen is introduced but no competent host is available the
3 pathogen will likely go undetected and pose no biological or economic consequence to the region. This
4 may occur regularly in many regions of the world. However, an alternative scenario in which a pathogen
5 becomes established with significant host species could have enormous biological and economic
6 consequences.

1 **Table A5-9: Important Wildlife-Associated Diseases, Listed with their Pathogens, Hosts, and Distribution, that Could Be**
 2 **Introduced into the Micronesia Region**

Disease ^a	Type ^b	Pathogen	Potential wildlife host(s) in the Micronesia Region	Impact			Transmission	Distribution in the Pacific Rim	References ^c
				Humans	Agriculture	Wildlife			
Anthrax*	B	<i>Bacillus anthracis</i>	Most warm-blooded species (primarily grazing animals)	X	X	X	Ingestion, skin contact, or inhalation of spores, insect bites	Asia, Australia, N. America	1, 4
H5N1 A/HPAI*	V	Influenza virus A/H5N1	Birds (particularly waterfowl)	X	X	X	Close contact with secretions from infected animals, aerosol	Asia	2, 24
Low pathogenic avian influenza *	V	Influenza virus A	Feral swine, birds (particularly waterfowl and shore birds)	X	X	X	Close contact with secretions from infected animal, aerosol, environmental	Worldwide	2
Avian malaria	P	<i>Plasmodium spp.</i>	Birds		X	X	Mosquitoes	Worldwide	3
Bovine tuberculosis*	B	<i>Mycobacterium bovis</i>	Most mammals (particularly introduced water buffalo and deer)	X	X	X	Contact, aerosol, ingestion	N. America, Asia	5, 7
Chikungunya fever	V	Chikungunya virus	Rodents, birds	X		X	Mosquitoes	Asia	6, 30
Classical swine fever*	V	Classical swine fever virus	Feral swine		X	X	Contact between swine, ingestion of contaminated garbage, aerosol	Asia	7
Crimean Congo hemorrhagic fever	V	Crimean Congo hemorrhagic fever virus	Rodents, feral swine, bats	X			Ixodid ticks	Asia	26
Duck viral enteritis	V	Duck herpesvirus 1	Waterfowl			X	Contact between infected birds,	N. America, Asia	8

1 **A5.1.3.1.1 *Hantaviruses***

2 Hantaviruses are members of the genus *Hantavirus* and the viral family Bunyaviridae. They are etiologic
3 agents of human diseases called hantavirus pulmonary syndrome in the New World and hemorrhagic
4 fever with renal syndrome (HFRS) in the Old World and these diseases range from mild to severe. Even
5 in mild cases, these diseases should not be taken lightly. HFRS, e.g., has been thought to cause a large
6 number of human illnesses in Asia and Europe (e.g., as many as 50,000 to 100,000 per year) (Johnson
7 1999) (Figure A5-4). In addition, in China alone, 1,557,622 cases of HFRS were reported between 1950
8 and 2007, resulting in 46,427 deaths (Zhang et al. 2010). Even following the recent implementation of
9 preventive measures, the numbers of HFRS cases and deaths caused by this disease in China remain
10 amongst the highest reported in the world (Zhang et al. 2010). The viruses causing these diseases are
11 thought to be frequently transmitted to humans through the inhalation of rodent excreta (e.g., via
12 aerosolized virus (Padula et al. 2004). These viruses are hosted primarily by rodent hosts, but some
13 insectivore (e.g., shrew) associations with these viruses have been documented as well. Hantaviruses
14 are thought to cause persistent (i.e., the virus is not rapidly cleared from the host) infections in rodents,
15 which is often initiated by a short acute phase (high infectious virus levels) followed by a chronic stage
16 (typically lower virus levels) (Padula et al. 2004). Hantaviruses are generally thought to be transmitted
17 among rodents through interspecific interactions among animals. Although some of these viruses could
18 pose a great threat to human health, they appear to pose little threat to wildlife and livestock health.
19 The primary means of introduction of these viruses into the Micronesia Region are through rodent hosts
20 in cargo on ships and airplanes. Because one *Rattus* spp. could potentially transmit a hantavirus to naïve
21 individuals within this genus, and many islands within the Micronesia Region have large rat populations,
22 select viruses (e.g., Seoul virus) within this genus could become established following their introduction.
23 Because hantaviruses can be found in many different environmental conditions, the climate in much of
24 the Micronesia Region is likely suitable for their introduction. Hantaviruses are examples of wildlife-
25 associated diseases that could have both biological and economic consequences. Although these viruses
26 are unlikely to negatively affect native wildlife or livestock, they could cause human disease such as
27 hemorrhagic fever with renal syndrome. Thus, the economic consequences of this group of viruses could
28 entail increased hospitalizations, decreased work and productivity, increased need for laboratory
29 networks, and increased surveillance.

A5.1.3.1.2 Rabies Virus

6 Rabies virus is a member of the viral family Rhabdoviridae and the genus *Lyssavirus*. It can cause severe
7 human disease (typically resulting death) and is known to cause thousands of deaths each year,
8 especially in developing countries (Figure A5-5). The natural hosts of rabies virus are mammals, primarily
9 carnivores and bats. Rabies is primarily transmitted among susceptible individuals through bite wounds.
10 Guam is known to be free of rabies, as is Hawai'i. Wildlife poses a potential threat to the introduction of
11 rabies to Guam through the importation of wildlife (deliberate or not), especially through bats and
12 carnivores. Further, this virus poses a serious threat to human, agricultural, and wildlife health. Of
13 interest, in a recent risk assessment of wildlife importation into the United States, rabies viruses,
14 including zoonotic lyssaviruses, were listed as being able to potentially affect 155 of 190 genera
15 analyzed (Pavlin et al. 2009). Due to the lack of carnivores in much of the Micronesia Region, the
16 primary wildlife threat of rabies virus spread would appear to be associated with bat and feral
17 carnivores on these islands. However, the small Indian mongoose, *Herpestes javanicus*, is well-
18 established in parts of Hawai'i (Baldwin et al. 1952); although Hawai'i is rabies free, this species is known
19 to be a major reservoir and vector of rabies on other islands such as Puerto Rico (Everard and Everard
20 1988).

WNV is an arthropod-borne virus (i.e., an arbovirus) of the viral family Flaviviridae that is now common in many regions of the world (Figures A5-6 and A5-7). The normal transmission of WNV is thought to be associated with transmission of the virus from mosquito vectors to certain bird species (McLean et al. 2002). The virus is known to be able to cause severe disease in humans, some bird species, and some mammals. The mosquito *Aedes albopictus*, which is known to have occurred on Guam since 1944 (Rozeboom and Bridges 1972), is thought to be an efficient vector of WNV in a laboratory setting (Turell et al. 2005) (see Table A5-10). Although Guam does not have a rich avian fauna, some islands in the Micronesia Region still possess many avian species. Thus, this virus could pose a threat for some of these species if it were to be introduced into an area with competent vectors through the introduction of mosquitoes or viremic birds. For example, workers have estimated that a small number of WNV infected mosquitoes could reach Hawai'i by airplane each year following the expansion of this virus to the western United States and that U.S. exemptions of quarantine regulations (at the time of publication or earlier) could lead to the inadvertent importation of a small number of viremic birds each year (Kilpatrick et al. 2004). If introduced, WNV could have a severe biological impact on some bird populations in the Micronesia Region, such as the limited native bird populations on Guam which have already had severe population declines and extinctions due to the introduction of invasive species. In addition, a severe biological consequence exists in terms of human health and safety from this virus if the appropriate mosquito vectors are present on the island in question. Testing of 108 avian serum

1 samples and 2 pig serum samples collected in early 2010 by our group on Guam and Saipan were all
2 negative for generic flaviviruses (Franklin et al. unpublished data), which suggested that WNV was not
3 present in the samples we tested.

Species	Distribution	Potential disease through pathogen transmission	Global distribution	References ^b
ENDEMIC				
<i>Aedes oakleyi</i>	Anatahan Island Saipan and Guam	None found	Belongs to a group found throughout Australian, Papuan, Oriental, Indomalayan, South and West Pacific regions	1,3,4
<i>Aedes pandani</i>	Guam, CNMI	None found	Micronesia Region	1,4
<i>Aedes rotanus</i>	Guam, CNMI	None found	Micronesia Region	1,4
<i>Aedes saipanensis</i>	Guam, CNMI	None found	Micronesia Region	1,3,4
<i>Aedes guamensis</i>	Guam, Rota, Saipan, and Tinian	None found	Guam, Rota, Saipan, Tinian	1,4
<i>Culex litoralis</i>	Guam, CNMI	None found	Guam, CNMI	1,4
<i>Culex annulirostris marianae</i>	Guam, CNMI	Japanese encephalitis	<i>C. annulirostris</i> has a broad distribution in Pacific	1,3,4
COSMOTROPICAL INTRODUCTIONS				
<i>Aedes vexans</i>	Guam, Saipan	Japanese encephalitis, Dirofilariasis	Cosmotropical	1,2,3,4
<i>Culex quinquefasciatus</i>	Guam, Saipan	St. Louis encephalitis, Japanese encephalitis, Chikungunya fever, Avian malaria	Cosmotropical	1,2,3,4
ORIENTAL INTRODUCTIONS				
<i>Anopheles indefinitus</i>	Guam, Saipan	Malaria	Species extends from Malaya and Java to Taiwan and Philippines	1,3,4
<i>Culex fuscocephalus</i>	Guam	Japanese encephalitis	Widespread in Asia and found to be naturally infected with two strains of JEV in Thailand	1,2,4
<i>Anopheles barbirostris</i>	Guam	Japanese encephalitis	Widespread in Asia	1,2,4
<i>Anopheles litoralis</i>	Guam	Malaria vector in Philippines	Philippines	1,4
MICRONESIA INTRODUCTIONS				
<i>Aedes neopandani</i>	Guam, Rota, Saipan and Tinian	None found	Endemic to Saipan and Tinian. Introduced onto Guam and Rota	1,3,4
GLOBAL INTRODUCTIONS				

Species	Distribution	Potential disease through pathogen transmission	Global distribution	References ^b
<i>Aedes albopictus</i> ^a	Guam, Saipan	Dengue fever, Chikungunya fever, select hemorrhagic fevers, Japanese encephalitis, yellow fever, West Nile fever, western equine encephalitis	Abundant on many Pacific islands and responsible for Dengue epidemics on Guam	1,2,3,4
<i>Culex sitiens</i>	Guam, Saipan	Japanese encephalitis	Wide distribution through S. Pacific islands, Oriental, Papuan, Australian, Afrotropical and Palearctic areas	1,2,3,4
<i>Aedeomyia catastica</i>	Guam	None found	Distributed from India and Philippines to Fiji and North Australia	1,4
<i>Culex tritaeniorhynchus</i>	Guam, Saipan	Japanese encephalitis, Chikungunya fever, Sindbis fever	Widely distributed in Oriental, Afrotropical and Asian areas. Most important vector of Japanese encephalitis in Oriental region. Potentially involved in Japanese encephalitis outbreak in Saipan in 1990	1,2,3,4
<i>Mansonia uniformis</i>	Guam	Chikungunya fever	Old World tropics	1,2,4
<i>Armigeres subalbatus</i>	Guam	None found	Widely distributed through Oriental region	1,4
<i>Culex fuscans</i>	Guam, Saipan	Japanese encephalitis	Records of occurrence on Saipan/Rota. Widely distributed through Oriental region, Asian Palearctic, and Pacific islands	1,3,4
<i>Anopheles vagus</i>	Guam	Malaria	India, China, Indonesia, Borneo, and Philippines	1,2,4
<i>Anopheles subpictus</i>	Guam	Malaria	Middle East to India, Indonesia, New Guinea, Philippines	1,2,4

1 ^a Since the eradication of *Aedes aegypti* in 1945, *A. albopictus* has filled the *A. aegypti* niche and could be responsible for future Dengue outbreaks on
2 Guam.

1 **A5.1.3.1.4 *Highly Pathogenic Avian Influenza***

2 Avian influenza is a highly contagious disease of birds caused by influenza viruses from the family
3 Orthomyxoviridae, genus *Influenzavirus A*. AIVs are found worldwide and are closely related to human
4 and swine influenza viruses. While there are three influenza types—influenza A, influenza B, and
5 influenza C—all avian influenzas are type A. AIVs are a threat to humans, poultry, and wild birds. Humans
6 can be directly infected with AIVs and these viruses have the potential to recombine with mammalian
7 influenza virus strains to form novel strains that readily transmit between humans and have pandemic
8 potential. Poultry may experience reduced productivity or mass die-offs in response to different AIV
9 strains. Moreover, wild birds can suffer severe disease from some AIV strains.

10 The primary reservoirs for AIVs are wild birds, especially waterfowl, seabirds, and shorebird species.
11 AIVs have been isolated from more than 90 species and 13 orders of birds (CIDRAP 2010). Wild birds
12 have been associated with all known subtypes of Influenza A viruses. While wild birds are the natural
13 hosts for Influenza A viruses, many mammals such as humans, cats, dogs, pigs, horses, marine mammals,
14 mice, and rats are spillover species that can become infected with the low pathogenic strains of the
15 virus.

16 AIVs generally cause little or no disease in wild birds, but may cause significant disease in poultry. The
17 pathogenicity of an AIV is based on its ability to cause severe morbidity or mortality to poultry. Low
18 pathogenic AIVs (LPAIV) cause mild disease in poultry whereas AIVs (HPAIV) cause significant disease
19 and/or death in poultry. HPAIV that cause significant disease in poultry species may cause little or no
20 disease in wild birds which can be asymptomatic spreaders of the virus. Alternatively, HPAIV may cause
21 severe illness and death in wild species.

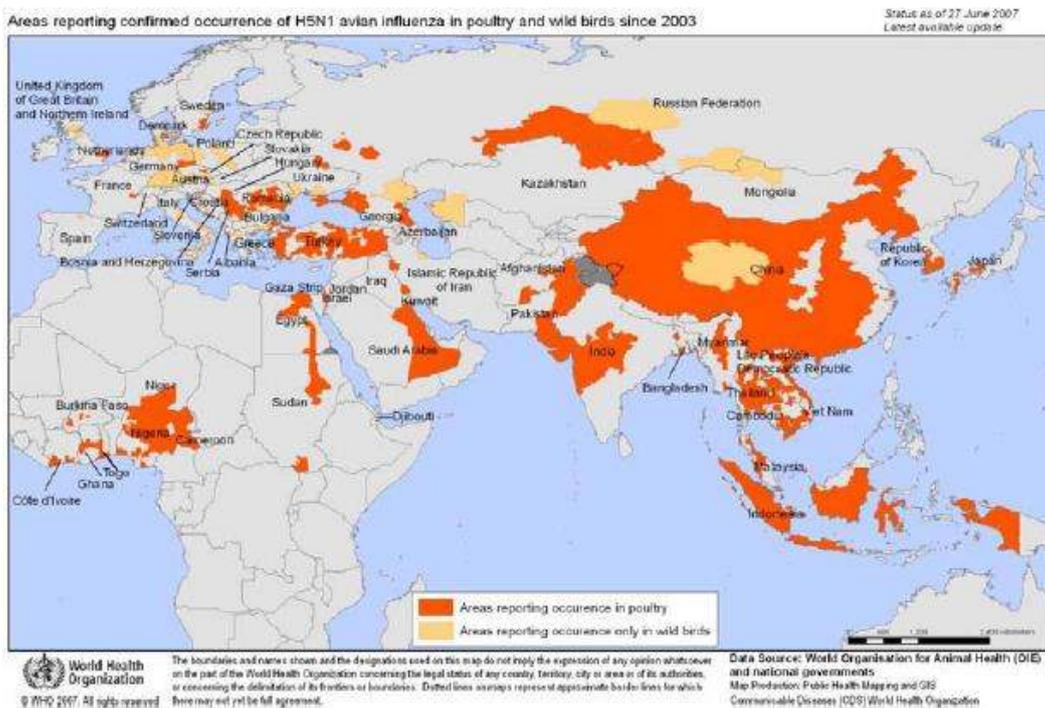

22 Influenza viruses are very dynamic and have a high capacity to evolve. Viral evolution generally occurs
23 via small genetic changes over time or via abrupt changes in response to novel environments. HPAIV are
24 thought to develop when poultry species are exposed to LPAIV from wild birds and the virus undergoes
25 a major change in response to a different host species. Alternatively, novel influenza viruses can also
26 evolve via genetic reassortment which occurs when a host species is infected with more than one strain
27 of influenza virus and the two viruses recombine into a new strain. Although wild birds may become
28 infected and transmit HPAIV, they are not associated with the development of HPAIV strains. To date, all
29 HPAIV have been subtypes including an H5 or H7 hemagglutinin surface protein.

30 While AIVs are closely related to human influenza A viruses, human and avian virus strains exhibit
31 significant genetic differences. Currently only subtypes H1N1, H1N2, and H3N2 are readily transmitted
32 between humans. Nonetheless, some AIVs, including H5N1, H7N2, H7N3, H7N7, H9N2, and H10N7, have
33 been known to cause human infections. Serological testing has shown human exposures to H3, H4, and
34 H6 subtypes. HPAIV do not readily transmit to humans, but humans can become infected with these
35 viruses. HPAIV infections in humans can cause disease symptoms that range from mild to severe.
36 Similarly, LPAIV do not generally infect humans and the infections that do occur are usually limited to
37 people that have extended and direct contact with birds. Most humans infected with LPAIV are
38 asymptomatic or develop conjunctivitis. However, in some cases, LPAIV infections have been known to

1 cause influenza-like symptoms. An influenza pandemic occurs when a novel subtype is introduced into
2 the human population, the novel virus causes serious illness, and the virus spreads easily from person to
3 person.

4 While a novel influenza virus can evolve at any time, currently the major avian influenza threat is from
5 highly pathogenic Asian-strain H5N1. This virus was originally detected in Hong Kong in 1997 and re-
6 emerged as an outbreak that began in poultry in Southeast Asia in 2003. The virus has spread to
7 domesticated and wild birds in Asia, Europe, the Pacific, the Middle East, and Africa and is now
8 considered endemic in Southeast Asia (Figure A5-8 and A5-9). To date, highly pathogenic Asian-strain
9 H5N1 has been associated with the death or depopulation of tens of millions of poultry, severe disease
10 in some wild birds, and more than 500 human cases (including nearly 300 deaths). As of July 2010,
11 human cases have occurred in Indonesia (166), Vietnam (119), Egypt (109), China (39), Thailand (25),
12 Turkey (12), Cambodia (10), Azerbaijan (8), Iraq (3), Pakistan (3), Bangladesh (1), Djibouti (1), Myanmar
13 (1), and Nigeria (1) (WHO 2010a). For obvious reasons, the introduction of this virus into the Micronesia
14 Region could have devastating economic effects due to loss of tourism revenue.

 5

6 The primary shedding pathway in wild birds is fecal excretion of the virus accompanied by some
 7 respiratory shedding. Shedding in feces versus respiratory tissues can vary by strain. For example, the
 8 highly pathogenic Asian-strain H5N1 virus has been found to exhibit higher shedding rates in
 9 oropharyngeal swabs compared to cloacal swabs. Feces deposited in water (ponds, lakes, reservoirs, and
 10 streams) by wild birds are most hazardous when the virus does not become diluted due to large water
 11 volume and/or movement. The virus can be transmitted to suitable hosts by ingestion of contaminated
 12 water, eye contact with contaminated water, or possibly by inhalation of aerosols.

13 Avian influenza infection occurs by direct contact with infected individuals via their feces or respiratory
 14 secretions or contact with contaminated materials (vehicles, clothing, shoes, food, water, crates, and
 15 cages). Transmission can also occur from contact with tissues from an infected animal. Virus can be
 16 moved by wild bird movement or transportation of infected birds, or it can be transported on humans
 17 and their machines. Aerosol transmission is unlikely, but may occur in enclosed, high density poultry
 18 operations. Vertical transmission is unlikely because virus causes egg death such that exposed eggs do
 19 not hatch. However, transmission can occur if chicks are exposed to broken infected eggs. Currently it is
 20 unknown whether HPAIV can become endemic in wild birds or if infections are a result of spillover from
 21 infected poultry.

1 Cool temperatures and the presence of organic material favor long term AIV survival in the
 2 environment. Different subtypes and conditions lead to differential virus survival. Virus can persist for
 3 long periods in water. Webster et al. (1978) were able to detect virus for up to 32 days at 4° C and for 4
 4 days at 22° C. More recently, Stallknecht et al. (1990) found that AIV could persist for 207 days in
 5 distilled water at 17°C and 102 days at 28°C. Brown et al. (2009) found that pH, temperature, and
 6 salinity affect the survival of AIVs. Virus is viable in liquid feces for 30 to 35 days at 4° C and for 7 days at
 7 20° C (Webster et al. 1978). LPAIV H7N2 persists for up to 2 weeks in feces and on cages, and
 8 composting kills most strains of AIV within 10 days (OIE 2009m).

9 Capua and Alexander (2004) summarized global avian influenza outbreaks and showed that the number
 10 of outbreaks has been increasing over the last decade (Table A5-11).

11 **Table A5-11: Major HPAI Outbreaks in Poultry**

Year	Subtype	Location	Impact	Comments
1983	H5	United States	17 million birds depopulated	Similar LPAIV had been detected in the previous 6 months (Swayne 2008)
1994-2003	H5N2	Mexico	Nearly 1 billion birds sick or culled	
1995-2003	H7N3	Pakistan	3.2 million birds died in 1995	Outbreak controlled via vaccination
1997	H5N1	Hong Kong	1.5 million birds depopulated/died in 3 days	18 human cases with 6 deaths; first human case of H5N1 infection
2002	H7N3	Chile	618,00 birds depopulated on one farm	First report of HPAIV in South America
2003	H7N7	Netherlands	30 million birds depopulated/died; 255 infected flocks	Spread to Belgium; outbreak rapidly controlled
2003-2010	H5N1	Asia, Europe, Africa	Panzootic; Nearly 300 million birds depopulated/died	Now considered endemic in Southeast Asia, more than 500 human cases and nearly 300 deaths
2004	H5N2	United States		
2004	H7N3	British Columbia	More than 19 million birds depopulated/died	Two human cases (conjunctivitis)
2005	H7	North Korea	Approximately 200,000 birds depopulated/died

 13

14 **A5.1.3.1.5 Japanese Encephalitis**

15 Japanese encephalitis is a disease caused by the arthropod-borne Japanese encephalitis virus (JEV)
 16 which is a member of the genus *Flavivirus* in the family Flaviviridae. Japanese encephalitis is a significant
 17 public health concern in Asia. While the majority of infections cause subclinical disease, acute
 18 encephalitis may occur and can result in permanent neurologic damage and mortality rates up to 60%
 19 (CDC 2010a). JEV is widespread in eastern, southeastern and southern Asia with 30,000 to 50,000 cases

1 reported annually (Umenai et al. 1985). Major epidemics have occurred in China, Korea, Japan, Taiwan,
2 and Thailand and minor epidemics have occurred in Vietnam, Cambodia, Myanmar, India, Nepal, and
3 Malaysia (see Figure A5-9). Epidemics are typically controlled by vaccination which can result in
4 significant economic impacts due to the high cost of the vaccine. JEV has been spreading both eastward
5 and westward (Mackenzie 2007). Currently Japanese encephalitis has spread to Indonesia, New Guinea,
6 and Northern Australia. While not currently established in the Micronesia Region, an outbreak occurred
7 in Guam in 1947/1948 (Hammon et al. 1958) and in Saipan in 1990 (Mitchell et al. 1993; Paul et al.
8 1993).

9 Wild birds, especially members of the family Ardeidae (herons and egrets) are the primary enzootic host
10 species for JEV and mosquitoes are the primary vector. Wild birds do not generally exhibit clinical
11 disease associated with JEV infection, but infected birds develop high viremias. Pigs are considered to be
12 a primary amplifying host for the virus and an important host species associated with Japanese
13 encephalitis outbreaks in humans.

14 In endemic areas in the tropics JEV is continuously transmitted between birds, pigs, and mosquitoes.
15 Humans become infected as a result of being bitten by an infected mosquito. One of the main mosquito
16 vectors is *Culex tritaeniorhynchus*, which is currently established in Guam and Saipan (Nowell 1977;
17 Ward 1984; Knechtges 1989; Mitchell et al. 1993). The virus is maintained by mosquitoes becoming
18 infected by taking a blood meal from wild birds and pigs infected with JEV. Infected mosquitoes can then
19 transmit the virus to susceptible wild birds and pigs where the virus replicates.

20 Definitive introduction pathways for the previous Japanese encephalitis outbreaks in Guam and Saipan
21 were not determined. Possible routes (Paul et al. 1993) are viremic mammals or birds, introduction of
22 infected mosquitoes or their eggs, or the movement of a viremic human. Some workers (Paul et al.
23 1993) also note that CNMI hosts several migratory bird species that migrate from Japanese encephalitis-
24 endemic countries to CNMI, such as the black-crowned night heron, the plumed egret, and the cattle
25 egret—all of which have the potential to develop adequate viremias for infecting mosquitoes (Buescher
26 et al. 1959). Likely routes of JEV introduction or re-introduction include migratory birds (Van Den Hurk et
27 al. 2009), migratory bats (Nga et al. 2004), especially fruit bats (Sulkin and Allen 1974), windblown
28 mosquitoes (Ming 1993; Ritchie and Rochester 2001), and incidental transport of infected mosquitoes
29 on aircraft (Haseyama et al. 2007).

30 **A5.1.3.1.6 Avian Malaria**

31 Avian malaria is a parasitic disease caused by protozoans in the genus *Plasmodium* that can infect birds.
32 *Plasmodium* parasites belong to the Haemosporidia family. The parasites reproduce in avian red blood
33 cells and if parasite loads becomes high enough red blood cells are lost and anemia may occur. The
34 parasites are not transmitted directly between birds, but are moved between hosts by mosquito vectors
35 (see Table A5-10), such as *Culex quiquefasciatus*. More than 40 *Plasmodium* species have been
36 described, but the primary species of concern in the Micronesia Region is *P. relictum*, which was
37 introduced into the Hawai'ian Islands and has been associated with significant population declines in
38 endemic Hawai'ian birds. While *Plasmodium* species are common in many continental areas, the

1 mosquitoes that transmit the parasite were traditionally absent in most island archipelagos such that
2 many endemic island bird species evolved in the absence of the parasites and are currently assumed to
3 be highly susceptible to morbidity and mortality associated with avian malaria infection.

4 The distribution of *P. relictum* on the Pacific islands has not been well characterized. Jarvi et al. (2003)
5 found a high prevalence of *P. relictum* in American Samoa along with stable bird populations. Due to the
6 presence of endemic mosquito vectors, the authors suggest *Plasmodium* is endemic in American Samoa.
7 Steadman et al. (1990) did not detect *Plasmodium* species in the Cook Islands and Savidge (1984) did not
8 find *Plasmodium* on Guam. Tompkins and Gleeson (2006) recently showed that *P. relictum* is common in
9 New Zealand, but additional study is needed to determine whether it is endemic or introduced.

10 The pathogen (*Plasmodium relictum*) causing avian malaria is considered one of the 100 worst invasive
11 species on the globe (Lowe et al. 2000). While many birds are susceptible to *Plasmodium* infection,
12 perching birds (Passeriformes) are primarily affected. *Plasmodium* may be a serious threat to endemic
13 Micronesian birds if those species have not evolved in the presence of this parasite.

14 Haemoproteus is another protozoan avian blood parasite genus in the Haemosporidia family. These
15 parasites are represented by more than 140 species, many of which are host specific. Haemoproteus
16 species are transmitted primarily by mosquitoes, but also by some midges and louses. Haemoproteus
17 infections are generally associated with subclinical infections and are considered less of a threat than
18 *Plasmodium* species. Nonetheless, Haemoproteus infections may cause significant disease in some
19 species and have been known to cause significant declines in poultry productivity and in some cases
20 mortality rates can be as high as 20%. Infections with Haemoproteus are sometimes referred to as
21 pseudomalaria.

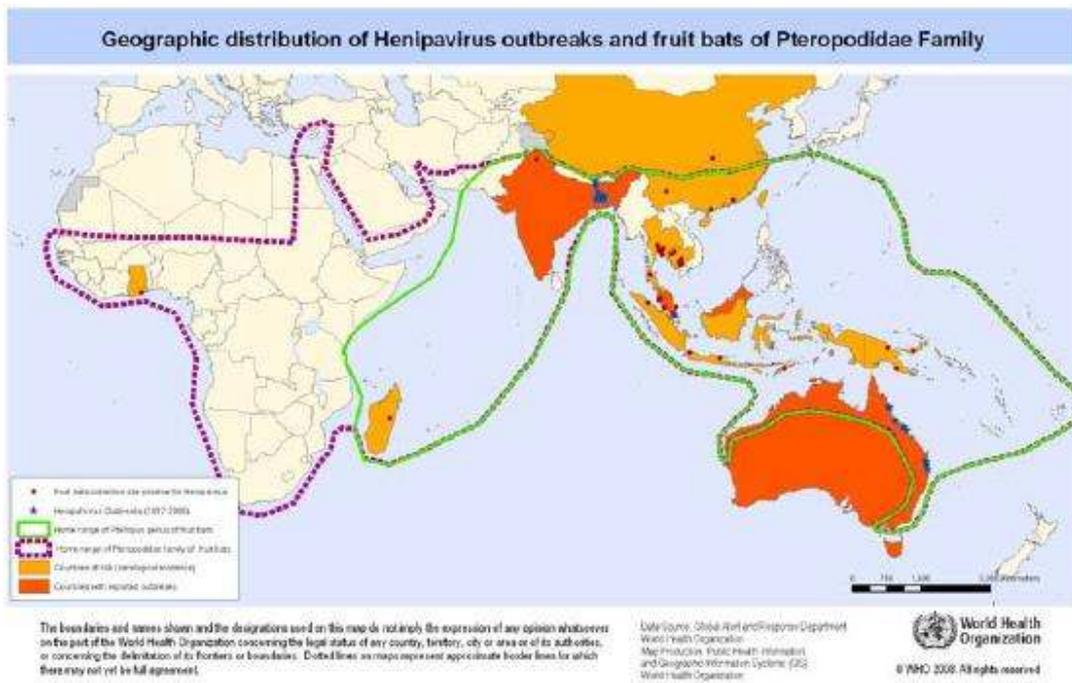

22 Preliminary screening of more than 100 avian serum samples collected by our group in early 2010 on
23 Guam and Saipan is currently ongoing for avian blood parasites (Franklin et al. unpublished data). The
24 blood samples (n=138) were screened for infection based on the presence of blood parasite DNA. The
25 proportion of samples provisionally positive in this initial screen was between 46.4% and 85.5%.
26 Suspected positives from Guam include several introduced species including the Philippine turtle-dove,
27 Eurasian tree sparrow, and bobwhite quail. Two yellow bittern, a common species on Guam, were also
28 suspected blood parasite positives. Subsequent testing on 30 samples from Saipan confirmed 53.3% to
29 be infected with *Plasmodium* species. These confirmed samples include several bridled white-eyes
30 which are endemic and currently listed as endangered. Confirmatory results for all samples are still
31 pending.

32 **A5.1.3.1.7 Henipaviruses**

33 Henipaviruses are zoonotic paramyxoviruses (family Paramyxoviridae) of the genus *Henipavirus* (Halpin
34 et al. 2000; Harcourt et al. 2000). The genus *Henipavirus* was first described based on the emergence of
35 two new viruses, Hendra virus, which first emerged in Australia in 1994, and Nipah virus, which first
36 emerged in Malaysia in 1998/1999. Although Hendra virus has remained confined to northeast
37 Australia, Nipah virus was subsequently detected in other Asian countries, including India and

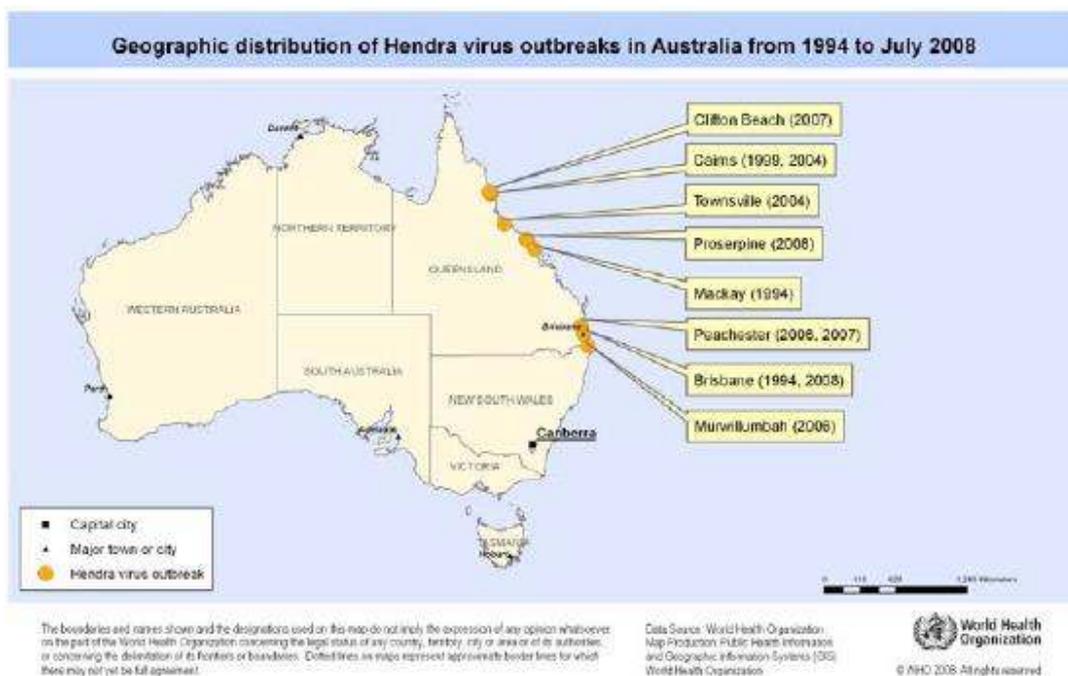

1 Bangladesh (Figures A5-10 and A5-11). The two viruses are similar in that they first emerged in domestic
2 animals (which served as amplifier hosts), were subsequently transmitted to humans, and have fruit
3 bats of the genus *Pteropus* as natural reservoirs (Epstein et al. 2006).

4 **Figure A5-10: Known Distribution of Henipavirus Outbreaks, Mostly Nipah Virus and Hendra**

8

1 **Figure A5-11: Geographic Distribution of Hendravirus Outbreaks Currently Confined to**
 2 **Northeast Australia**

3
 4 Source: WHO 2010d

5
 6 Both Hendra and Nipah viruses appear to be relatively stable in the environment. These viruses can
 7 survive for days in fruit bat urine and contaminated fruit juice, have a wide pH tolerance (4.0 to 10.0),
 8 and are inactivated only at high temperatures for relatively long periods (60°C for 60 minutes) (OIE
 9 2010f). Fruit bats are the natural reservoirs for both Hendra and Nipah viruses and generally show no
 10 signs of infection (i.e., are asymptomatic) from either virus.

11 Hendra virus was first discovered in 1994 when it caused an outbreak of severe, acute respiratory
 12 disease in domestic horses on two farms in Queensland, Australia (Murray et al. 1995, Mackenzie et al.
 13 2003). During these initial outbreaks, three humans in contact with the horses contracted the disease
 14 and two died from it (Field et al. 2007). Since then, eight more outbreaks have occurred in horses, all in
 15 northeast Australia (see Figure A5-11; Field et al. (2007)). Three of these outbreaks involved six human
 16 cases, with a case fatality rate of 50% (WHO 2009c). Thus far, horses have been the only domestic
 17 animals that have been naturally infected, with a case fatality rate of about 75% (WHO 2009c). The
 18 incubation period is 8 to 16 days for horses and 5 to 14 days for humans; there are no drugs or vaccines
 19 available to treat Hendra virus infection in either horses or humans (WHO 2009c).

20 Nipah virus was first discovered in pigs in Ipoh, Malaysia in 1998/1999 and was subsequently
 21 transmitted to humans. It was first identified as a swine respiratory and neurological disease, which
 22 spread throughout the Malaysian peninsula (Epstein et al. 2006). In the initial outbreak, 1.1 million pigs
 23 were destroyed and 105 (39.6%) of the 265 humans infected with this virus died (mostly adult male

1 Chinese farmers in contact with pigs) (Mackenzie et al. 2001; Field et al. 2007). Another outbreak
2 occurred during 1999 among slaughterhouse workers in Singapore, where 80% of the pigs slaughtered
3 came from Malaysia (Ling 1999; Chan et al. 2002). Nipah virus has since been detected in five outbreaks
4 in Bangladesh and one outbreak in India between 2001 and 2005 (Wang et al. 2008b). These outbreaks
5 involved 168 human cases with a case fatality rate of 67 to 92% (Wang et al. 2008b). Infections during
6 these outbreaks were also reported in domestic dogs, cats, horses, and goats (OIE 2010f). Average
7 incubation period in humans is 4 to 20 days (WHO 2009e).

8 Fruit bats of the genus *Pteropus* have been implicated as the likely reservoir in the outbreaks of Nipah
9 virus in both pigs and humans. The virus has been detected in urine collected under fruit bat roosts and
10 in fruits partially eaten by free-ranging fruit bats, suggesting two modes of transmission to pigs and
11 humans (Tee et al. 2009). Nipah virus and antibodies have been detected in fruit bats from Thailand,
12 Cambodia, Indonesia, Malaysia, Bangladesh, and India, suggesting widespread dissemination of the virus
13 in fruit bat populations (especially *Pteropus*) in Southeast and South Asia (Reynes et al. 2005; Field et al.
14 2007; Tee et al. 2009). Nipah virus has been classified as a potential agent of bioterrorism because it is
15 an extremely pathogenic organism, with no vaccines or drugs to treat infections (Lam 2003).

16 Hendra and Nipah virus infections can result in extremely high mortality rates in both domestic livestock
17 and humans but generally do not cause clinical signs in fruit bats of the genus *Pteropus*, which appear to
18 be the natural reservoirs for these viruses. The linkage of these viruses with fruit bats is cause for
19 concern when viewed in terms of the Micronesian fruit bat trade.

20 **A5.1.3.1.8 Newcastle Disease Virus**

21 Newcastle disease is caused by viruses in the genus *Avulavirus* in the family Paramyxoviridae. This is a
22 complex of viruses with nine serotypes and five pathotypes (Alexander 2009). Generically, the virus
23 causing Newcastle disease is referred to as NDV (used here) or avian paramyxovirus. Natural or
24 experimental infection of NDV has been demonstrated in 241 avian species from 27 (54%) of the 50
25 taxonomic orders of birds.

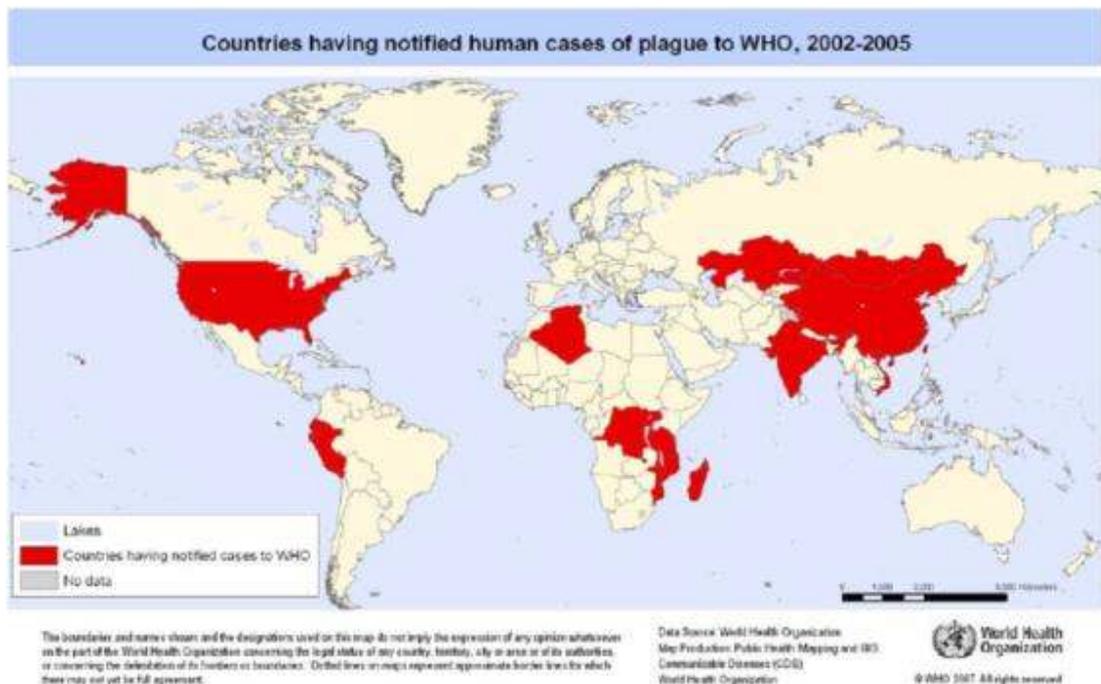

26 Domestic poultry and wild birds are infected by NDV, with the effects of infection dependent on the
27 serotype and pathotype. Although a wide variety of wild birds can remain asymptomatic when infected
28 (Alexander 2009; Coffee et al. 2010), poultry and some wild birds, such as certain passerine species,
29 Galliformes, crows and ravens, pigeons, and parrots, may exhibit severe mortality, depending on the
30 NDV strain (OIE 2010f). Humans are rarely infected and, when infected, show mild symptoms. Thus, NDV
31 is primarily of concern in the Micronesia Region because of effects on poultry and native wild birds,
32 especially pigeons (order Columbiformes).

33 Transmission occurs via direct contact with the secretions of infected birds which can be ingested (most
34 likely) or inhaled; transmission may also occur by way of fomites from feed, water, or equipment. Virus
35 survival is enhanced by the presence of feces (Alexander 2009).

1 **A5.1.3.1.9 *Plague***

2 The effect of plague on humanity has had a long history. It has been estimated that this disease may
3 have caused more than 200 million deaths (WHO 2005a). Significant plague foci are currently recognized
4 in Africa, Asia, North America, and South America (WHO 2005a; Meerburg et al. 2009) (Figure A5-12).
5 Notably, the observation of human cases of plague following decades of inactivity does not always mean
6 that plague foci are re-emerging, as *Yersinia pestis* bacteria have been thought to be naturally
7 maintained and circulated at low levels with no obvious indication of disease in the rodent populations
8 (Duplantier et al. 2005).

9 **Figure A5-12: Global Distribution of Human Cases of Plague, 2002–2005**

10
11
12 Source: WHO 2006
13

14 Plague is a rodent-associated, flea-borne infectious disease caused by the bacterium *Yersinia pestis* (CDC
15 2010f). Overall, this organism is found in rodents and their fleas in many regions of the world (WHO
16 2005a). Human plague infections are typically associated with being bitten by a rodent flea infected with
17 *Yersinia pestis* or by handling an infected rodent or other animal (WHO 2005a; CDC 2010f). Over 200
18 species of mammals (typically rodents and lagomorphs) are known to have been naturally infected with
19 *Yersinia pestis* (Gage and Kosoy 2005; WHO 2005a), although only a small number of these species that
20 have been exposed to the bacterium are considered significant hosts (Gage and Kosoy 2005). Untreated
21 plague has high case fatality rates (WHO 2005a). Globally, there are typically 1,000 to 3,000 human
22 cases of plague reported annually (CDC 2010f).

1 **A5.1.3.1.10 *Tick-borne Encephalitis***

2 Tick-borne encephalitis is a zoonotic disease caused by the tick-borne encephalitis virus (TBEV). TBEV is a
3 member of the genus *Flavivirus*, family Flaviviridae and is endemic throughout much of Europe and far-
4 eastern Asia. Three main subtypes of TBEV have been identified: European, Siberian, and far-eastern
5 (reviewed by Gritsun et al. 2003). While a majority of infections are asymptomatic, the reported case
6 mortality rates for tick-borne encephalitis are approximately 1 to 2% for European subtype infections, 2
7 to 3% following Siberian subtype infections, and as high as 20 to 40% in far-eastern subtype infections
8 (Gritsun et al. 2003; Mandl 2005). In terms of morbidity, TBEV is second only to JEV among neurotropic
9 flavivirus infections (reviewed by Lindquist and Vapalahti 2008). Safe and effective TBEV vaccines are
10 available but, with the exception of Austria, vaccination campaigns have had limited success due to cost
11 and necessary booster vaccinations (Gritsun et al. 2003).

12 TBEV is transmitted primarily through the bite of an ixodid tick. *Ixodes ricinus* is responsible for most
13 TBEV transmission in western Europe, while *I. persulcatus* is the primary vector in Siberia and the far-
14 east (Lindquist and Vapalahti 2008). The maintenance cycle for TBEV primarily involves ixodid ticks
15 feeding on small rodents. Rodents appear to act as both an amplifying host and a reservoir host for the
16 virus because they can maintain chronic infections throughout the year (Süss 2003; Bakhvalova et al.
17 2006). Humans, large mammals, and birds are also hosts for these same ticks, but are not primary
18 contributors to the TBEV maintenance cycle.

19 Tick-borne encephalitis may be considered an emerging disease as the geographic distribution of TBEV
20 and list of competent *Ixodes* vectors seem to be expanding (Kim et al. 2008; Lu et al. 2008). Generally
21 TBEV is isolated from areas with temperature ranges from 6°C to 25°C, humidity >85%, and a high
22 density of rodent hosts. However, even within areas where *Ixodes* vectors and rodent hosts are
23 abundant, TBEV is found only in small foci indicating that other environmental factors may be key in
24 predicting the risk of TBEV in an area (Lindquist and Vapalahti 2008). It is hypothesized that climate
25 change, social, political, ecological, economic, and demographic factors including changes in land use are
26 also factors that may contribute to increased incidence and risk of TBEV infection (reviewed by
27 Mansfield et al. 2009). Thus far *Ixodes* species have not been isolated from Guam, but *I. mindanensis* has
28 been reported on the island of Palau (Kohls 1957) suggesting that these vectors could thrive in the
29 Micronesia Region if introduced. The presence of rodent hosts, tick vectors, and suitable climate could
30 present a risk of TBEV introduction into Guam.

31 **A5.1.3.2 *Novel Hosts***

32 Some of the vertebrate species in the Micronesia Region are found only on certain islands at this point
33 in time. The musk shrew, *Suncus murinus*, provides a good example. The initial introduction of *Suncus*
34 *murinus* into Guam has been hypothesized to have occurred through cargo materials from ports in the
35 Philippines (Peterson Jr. 1956). Considering its relatively recent introduction into Guam, this species may
36 be of considerable risk for introduction into additional islands in the Micronesia Region, although it does
37 occur on more islands than Guam at present. Further, this species is known to play a role in plague
38 cycles in select locations (Duplantier et al. 2005) and is known to host a hantavirus (Calisher et al. 2003).

1 As of 1999, Philippine deer (*Cervus mariannus*) were known to occur on four islands in the Micronesia
2 Region: Guam, Rota, Saipan, and Pohnpei, with populations thought to be increasing on Guam and
3 stable or declining on the other islands at that time (Wiles et al. 1999). The introduction of pathogens
4 affecting this species is unlikely through wildlife-related means. However, this species could potentially
5 be a host of various pathogens affecting deer and related species in other regions of the world,
6 dependent on the introduction of the pathogen and, in some cases, the appropriate vector. Some
7 examples include chronic wasting disease, epizootic hemorrhagic disease, and bovine tuberculosis.

8 There are many avian species on some islands in the Micronesia Region. Some of these are endemic to
9 certain islands. As such, many of the avian species on some these islands have never been exposed to
10 some of the pathogens that have affected birds in other regions of the world (i.e., highly pathogenic
11 H5N1 AIV and WNV).

12 **A5.1.3.3 Potential Trade Partners**

13 During the past decade, Guam imported commodities from several countries, many of which were from
14 Asia. Tourism is a large industry in the Micronesia Region, with the majority of tourists originating from
15 Asian countries for several islands. In terms of the risk of introducing diseases associated with wildlife
16 into the Micronesia Region, movements between Asia and the Micronesia Region are of particular
17 concern because of the number and rate of emerging zoonotic diseases originating from wildlife species
18 in that region (Mackenzie et al. 2001; Jones et al. 2008). It is anticipated that trade and tourism will
19 continue with many of the countries that Guam currently trades with during and after the DoD
20 relocation. In addition, the relatively close proximity of many Asian countries to several islands in the
21 Micronesia Region may facilitate future trade among these countries.

22 The anticipated military relocation on Guam will likely increase construction on this island via increased
23 residences and support facilities. It is anticipated that this may result in a large influx of temporary
24 workers, possibly from Asian countries. Along with these foreign workers, wildlife products may be
25 imported (legally and illegally), which are culturally significant to some of these temporary workers.

26 **A5.2 RISK ASSESSMENT**

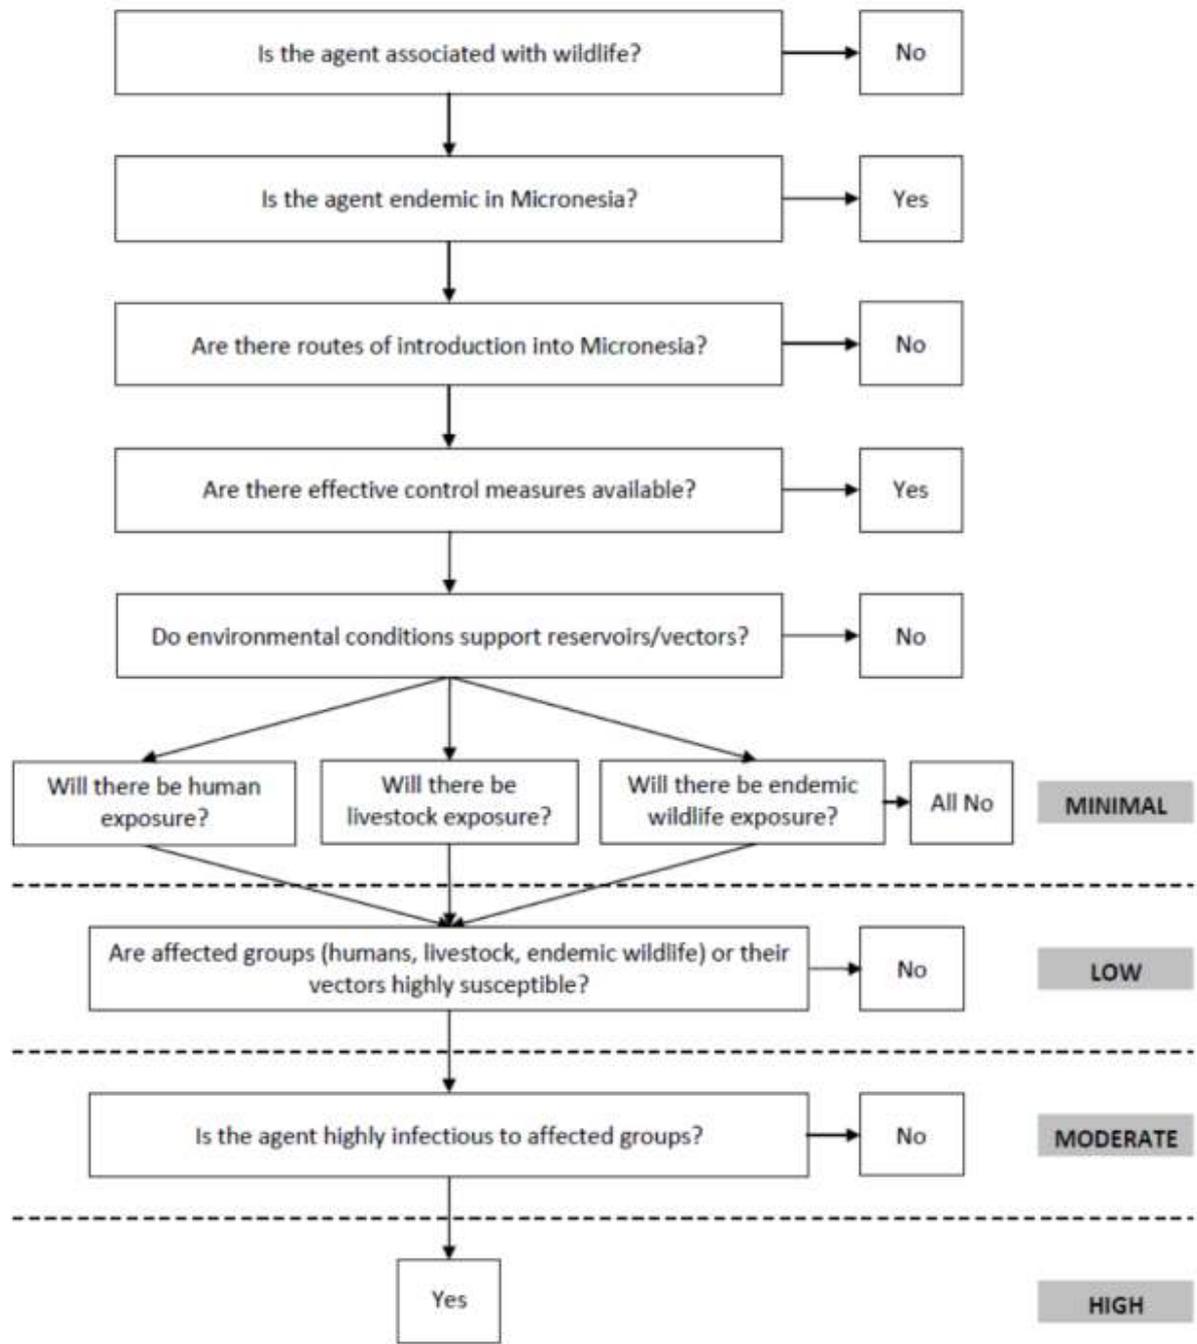

27 **A5.2.1 General Approach**

28 The risk associated with the 10 wildlife-associated pathogens outlined in Section A5.1.3 was assessed
29 following the general procedures outlined by Morgan et al. (2009) for estimating risk for emerging
30 infectious diseases. We focused on these 10 pathogens as they are all associated with Pacific Rim
31 countries that are the most likely trade partners with the Micronesia Region. These pathogens do not
32 represent a comprehensive list of possible pathogens that may enter the Micronesia Region as a result
33 of the military relocation. Rather, they represent the pathogens that we identified as representing
34 potential threats based on the properties of the pathogen in question and the ecology of its host(s).
35 Other potential pathogens are described in Table A5-9. Moreover, emerging pathogens that may
36 become important in the future are not addressed in the following analyses.

1 We adapted the Morgan et al. (2009) approach from a focus on human disease potential to disease
2 potential in humans, livestock, and endemic wildlife species from wildlife-associated diseases. In
3 general, Morgan et al. define risk as the product of the probability that a new infection occurs in the
4 area of interest and the potential impact of the infection. The method uses a series of decision questions
5 in a flow chart format to determine a qualitative estimate of risk for 1) the probability that an agent will
6 cause an infection in the area of interest and 2) the potential impact of the agent.

7 The risk assessment tool comprises two flow charts (Figure A5-13 and Figure A5-14) that characterize
8 the pathogen of interest and assign a level of risk (minimal, low, moderate, high, or very high) based on
9 the answers to the series of questions associated with each chart. The first flow chart addresses the
10 Probability of Infection as a function of a series of eight questions aimed at assessing the likelihood that
11 a pathogen will be introduced and the probability that the agent could be maintained based on
12 environmental conditions, host availability, and host infectiousness. In this risk assessment, the
13 probability of infection refers to the probability of an infectious agent causing infection in the
14 Micronesia Region in human populations, livestock populations, or endemic wildlife populations. The
15 specific questions in the Probability of Infection flow chart aimed at assessing risk are as follows (Figure
16 A5-13):

1 **Figure A5-13: General Procedure Used for Assessing the Probability of Infection from an**
 2 **Infectious Pathogen Associated with Wildlife into the Micronesia Region**

3
 4 Note: See text for explanation.
 5

6 The second flow chart assesses the potential Impact of Infection, or the level of potential harm that
 7 could be caused by the wildlife-associated pathogen in terms of morbidity and mortality. Impact is a
 8 function of the mode of transmission, infectiousness, severity of illness, and whether or not effective

1 interventions are available. The specific questions in the Impact of Infection flow chart are as follows
2 (Figure A5-14):

3 1. Is there spread to affected populations (humans, livestock, or endemic wildlife) or their vectors?
4 Spread should be considered as the potential for both spatial and temporal movement of the
5 pathogen. Factors that affect spread are the infective dose, the virulence of the pathogen,
6 whether or not routes of spread are available, and the susceptibility of affected populations.

7 2. Are wildlife hosts and/or vector populations present in the Micronesia Region?

8 3. Are affected populations susceptible?

9 4. Does the agent cause severe disease in affected populations? Severity refers to the level of
10 harm that can be inflicted on affected populations with respect to morbidity and mortality.

11 5. Is the agent highly infectious to affected populations?

12 6. Are effective interventions available? Factors to consider for assessing interventions are
13 whether or not it is feasible to change the potential impact of the introduction and spread of the
14 pathogen by containing or eliminating the pathogen via treatment or prophylaxis.

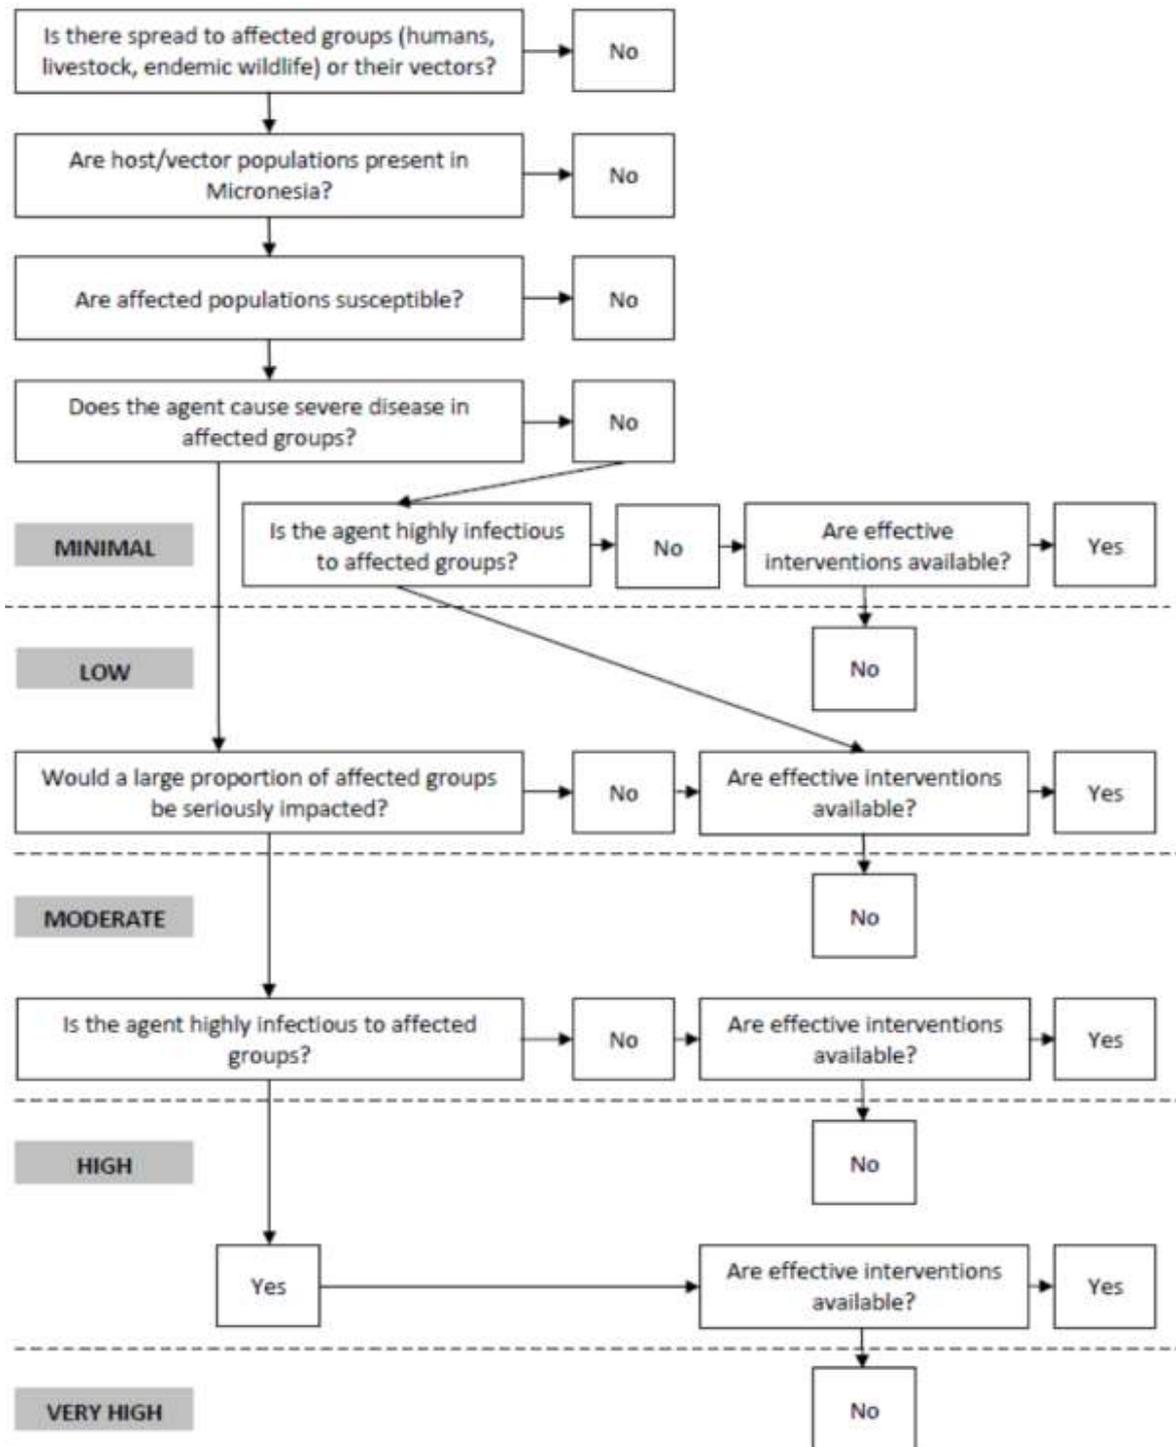

15 7. Would a large proportion of affected populations be seriously impacted?

16 8. Is the agent highly infectious to affected populations?

17 The risk assessment for each agent is based on current knowledge and should be updated and revised as
18 additional information becomes available.

1
2

Figure A5-14: General Procedure Used for Assessing the Impact of Infection from an Infectious Pathogen Associated with Wildlife into the Micronesia Region

3
4

1 **A5.2.2 Assumptions**

2 This risk assessment assumes that:

- 3 1. Current knowledge of pathogen, host, and vector distributions and characteristics is
4 relatively accurate. Knowledge gaps create uncertainty in the analyses and are generally
5 represented by alternative risk assignments to account for unknown information.
6
- 7 2. Major trade partners for the Micronesia Region are Pacific Rim countries: the United States
8 (especially Hawai'i), Russia, China, Singapore, Hong Kong, Taiwan, Japan, Indonesia, the
9 Philippines, Korea, Vietnam, Australia, and New Zealand.

10 **A5.2.3 Pathways of Introduction and Spread Associated With the Military Relocation**

11 **A5.2.3.1 People**

12 **A5.2.3.1.1 Military**

13 It is anticipated that the proposed DoD relocation on Guam will bring more than 30,000 people to Guam
14 through permanent military personnel, dependents, transient military personnel, and the DoD civilian
15 workforce (U.S. Navy 2009h) by 2014.⁸ Individual military members and their family members are
16 required to follow rules and laws of the host country in question and the laws and regulations
17 associated with imports to the United States (DoD 2001).

18 **A5.2.3.1.2 Civilian**

19 In addition to the increase in population associated directly with the proposed military relocation, the
20 DoD currently estimates that thousands (up to 18,373) of off-island temporary workers will be needed
21 for construction projects during certain years (U.S. Navy 2009h). There is an insufficient labor force for
22 the construction work associated with this upcoming relocation (U.S. Navy 2009h). During past
23 construction projects, much of the labor force came from China and the Philippines, but some skilled
24 labor came from other locations of the United States (U.S. Navy 2009h). It is anticipated that most off-
25 island construction workers will originate from the Philippines (U.S. Navy 2009h).

26 **A5.2.3.1.3 Methods**

27 Increases in human populations, both military and civilian, are expected to significantly increase the
28 likelihood of wildlife pathogen introductions and spread via humans.

29 **A5.2.3.2 Shipping**

30 **A5.2.3.2.1 Military**

31 The military relocation is expected to significantly increase maritime vessel traffic to accommodate
32 increased commodities to support military personnel and their dependents. Increased maritime traffic
33 will increase the likelihood of pathogen introduction.

⁸ Ibid.

1 It is anticipated that the relocation of the 3rd Marine Expeditionary Unit from Okinawa to Guam will
2 increase the amount of containerized cargo shipped into Guam to support the relocation and the
3 provisioning of increased military personnel stationed there.

4 Naval ships can carry up to 5,000 crewmen, of which up to 43% have been shown to be infected with
5 bacterial and viral pathogens (WHO 2002). Military transportation was the second highest reason for
6 insect invasion behind importation of plant material in Japan (Kiritani and Yamamura 2003).

7 **A5.2.3.2.2 Commercial**

8 Maritime vessel traffic to Guam is expected to increase through more container and break-bulk vessels
9 per year (U.S. Navy 2009f; PAG 2010b). These estimated increases in maritime traffic are expected to
10 significantly increase the likelihood of pathogen introduction.

11 **A5.2.3.3 Air**

12 **A5.2.3.3.1 Military**

13 The military relocation is expected to significantly increase military aircraft traffic to accommodate
14 increased commodities to support military personnel and their dependents. Increased military air traffic
15 will increase the likelihood of pathogen introduction.

16 **A5.2.3.3.2 Commercial**

17 The military relocation is expected to significantly increase commercial aircraft traffic due to expected
18 increases in commodities to support the population increase on the island and increased movement of
19 humans. Increased commercial air traffic will increase the likelihood of pathogen introduction.

20 **A5.2.3.4 Natural Movements**

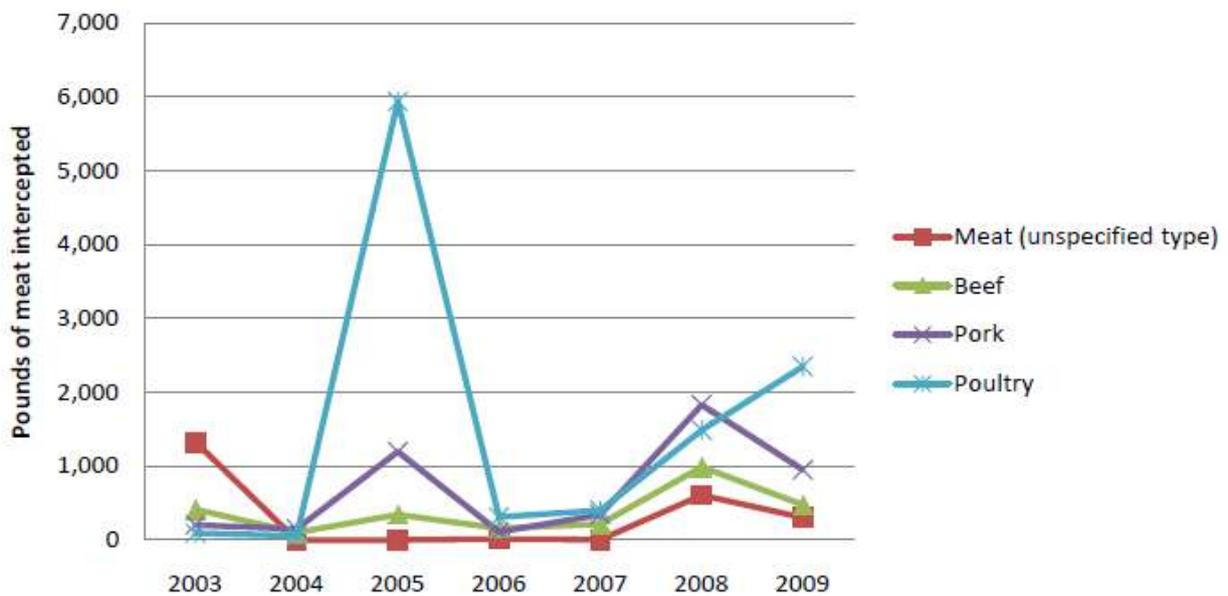

21 The military relocation is not expected to have a significant impact on the introduction of wildlife
22 pathogens via wind, rafting, and natural movements. However, the military relocation may be
23 associated with increased probabilities of establishment and spread of pathogens that are introduced
24 naturally. For example, a zoonotic disease agent is more likely to become established if increased human
25 population densities enhance the likelihood that the pathogen will move into a human host. Similarly,
26 increased human population densities may enhance the likelihood of zoonotic pathogen spread due to
27 higher numbers of susceptible individuals to act as hosts, so long as humans are not dead-end hosts for
28 the pathogen in question.

29 **A5.2.3.5 Smuggling and Legal Wildlife Trade**

30 The military relocation is expected to significantly increase the probability of introduction and spread of
31 wildlife pathogens due to increased demand for illegal and legal wildlife goods associated with the
32 anticipated increase in human population density. Up to 2,722 kg (6,000 pounds) of meat are
33 intercepted annually from travelers and shipments into Guam and Saipan (Figure A5-15 and A5-16), as
34 much as 15% which is from undetermined species. With an increase of foreign workers, there is concern
35 that illegal importation of bushmeat (the meat of wild animals) will increase, depending on the origin of

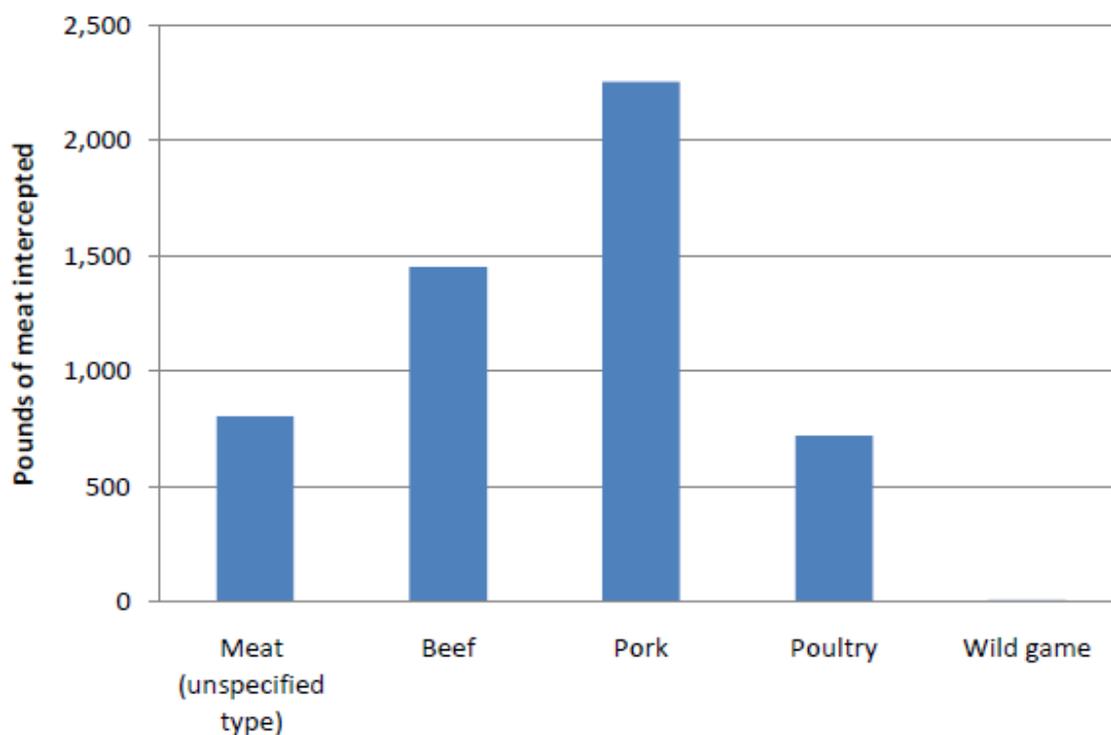

1 workers. Bushmeat is an important component of diet and culture in many parts of the world, especially
 2 Asia and Africa (Milner-Gulland et al. 2003; Chaber et al. 2010). The illegal importation of bushmeat has
 3 become a global problem related to immigration of different cultures. For example, more than 4,990
 4 metric tons (11 million pounds) of bushmeat and wildlife parts were smuggled into the United States
 5 between 2000 and 2004 from 14 species of monkeys, rodents, bats, and apes seized in mail and luggage
 6 (Viegas 2010). Projections indicate that 247,661 kg (273 tons) of bushmeat enter Paris annually via
 7 airline flights from Africa (Chaber et al. 2010) and 4,536 kg (5 tons) annually through Heathrow Airport
 8 in London (Milmo and Garman 2006).

9 **Figure A5-15: Meat Intercepted during Customs Inspections on Saipan from 2003 to 2009**

10

1 **Figure A5-16: Meat Intercepted during Customs Inspections on Guam in 2009**

2
3
4 Of particular concern in the Micronesia Region is the potential importation of fruit bats, which are
5 culturally important in the Micronesia Region and are regularly eaten in Asia (Cambodia, China, India,
6 Indonesia, Lao, Malaysia, Myanmar, the Philippines, Thailand, and Vietnam) and other Pacific islands
7 (American Samoa, Fiji, and New Caledonia) (Mickleburgh et al. 2002). Fruit bats illegally smuggled into
8 the Micronesia Region have the potential of introducing a wide variety of diseases, some of which cause
9 considerable morbidity and mortality in livestock and humans.

10 **A5.2.4 Risk Assessment Steps**

11 **A5.2.4.1 Release**

12 The biological pathways needed for an importation event to release (i.e., introduce) a pathogen are
13 complex with regard to many factors (OIE 2009d). We suggest that small mammals may be key species
14 of risk. In Guam, e.g., unlike domestic carnivores (e.g., cats and dogs, which are required to remain in
15 quarantine and arrive pre-vaccinated against some pathogenic agents; small mammals could arrive
16 undetected via various modes of transportation. Further, these small mammals could arrive from
17 various ports around the world. Although previous deratting procedures and modern recommended
18 ship sanitation procedures have likely led to a less frequent incidence of small mammal stowaways, it
19 likely still happens on occasion.

20 In addition to small mammals, bird species represent a risk pathway for the importation of wildlife-
21 associated disease agents. Infected birds could arrive via natural migration, excessive wind events,

1 smuggling, or intentional importation. Bats are another taxon of concern as they can host a number of
2 important pathogens such as rabies virus, other lyssaviruses, and henipaviruses. While importation of
3 bats is currently illegal outside of Palau, smuggling of bats is considered to occur such that the
4 introduction of a bat-hosted infectious agent into Palau is likely to be disseminated throughout the
5 Micronesia Region via smuggling.

6 **A5.2.4.2 Exposure**

7 **A5.2.4.2.1 Pathogen Properties**

8 The properties of a pathogen certainly influence the probability of it being introduced into a new
9 environment. An important characteristic that can affect the probability that a pathogen is introduced
10 into a novel region is the length of the typical infectious period. Many viruses infect a host but are
11 subsequently cleared by the host through immunological processes. On the other hand, some
12 pathogens cause persistent infections within hosts. In many instances, pathogens causing persistent
13 infections will have a higher probability of introduction when compared to pathogens which are cleared
14 from the host in a short amount of time.

15 Infectivity is another important pathogen attribute in terms of probability of introduction. For example,
16 some viruses are only efficiently transmitted through vector-competent arthropods, while others are
17 easily transmitted from host to host. The latter scenario suggests that multiple hosts may be needed on
18 a long-term movement (e.g., shipping containers) to maintain pathogen viability for pathogens that are
19 quickly cleared by susceptible hosts. Infectivity is also affected by the infectious dose required for an
20 active infection to develop for a particular pathogen. Exposure to agents with a low infectious dose is
21 more likely to result in an infection.

22 **A5.2.4.2.2 Vector and Host Presence**

23 A large number of mosquito species are known to occur on Guam (see Table A5-10). Some are endemic
24 and others have been introduced. Some of these species are known vectors of pathogens in many
25 regions of the world. For example, *Culex quinquefasciatus* is associated with a number of potential
26 diseases (e.g., St. Louis encephalitis, Japanese encephalitis, Chikungunya fever, and avian malaria) and
27 filarial infections (e.g., Bancroftian filariasis and Dirofilariasis). In addition, *Aedes albopictus*, which was
28 first recognized in Guam in 1944 (see Table A5-10) and is abundant on many Pacific islands, is associated
29 with many vector-borne diseases (e.g., Dengue fever, Chikungunya fever, Japanese encephalitis,
30 Dirofilariasis, yellow fever, and West Nile fever) some of which could pose a threat through the
31 introduction of their pathogens into the Micronesia Region. The large-scale global expansion of this
32 mosquito species during the last three decades has increased public health concerns because it is a
33 potential vector of a number of medically important arthropod-borne viruses (Lambrechts et al. 2010).

34 **A5.2.4.2.3 Human and Host Populations**

35 As of 2009, the population of the Micronesia Region was relatively small, estimated to be less than
36 500,000 individuals. The proportions of visitors to Guam are expected to change, with visitors from
37 Japan declining from 80 to 68% of total visitors, visitors from Korea increasing from 10 to 19% of total

1 visitors, visitors from the continental United States and Hawai'i increasing from 4to 5% of total visitors,
2 and visitors from East Asia increasing from 4to 6% of total visitors (PB International 2008).

3 Wildlife host populations are limited in much of the Micronesia Region. In some instances, this may be
4 primarily due to past introductions of invasive species (i.e., BTS). Guam, e.g., has low population levels
5 of most bird species and many of the mammal species (e.g., small mammals) that are found there.
6 When compared to the three major islands of CNMI, the densities of several small mammal species
7 were often notably lower on Guam (Wiewel et al. 2009). Overall, several small mammal species
8 (especially *Rattus* spp.) can be found on many islands in the Micronesia Region. Very few mammals are
9 endemic to these islands. However, many mammalian introductions have occurred in this region, often
10 leading to viable populations. For example, feral swine and Philippine deer are known to occur on
11 multiple islands in the Micronesia Region. In many instances, densities of potential wildlife host
12 populations are limited or non-existent.

13 **A5.2.4.2.4 Human Culture**

14 Human culture in the Micronesia Region directly affects the probability of exposure to wildlife-
15 associated pathogens. Historically many wildlife species, including fruit bats and most avian species,
16 were eaten and hunted by native humans. This legacy increases the probability of close interaction
17 between humans and wildlife and increases the likelihood of human exposure in the event of pathogen
18 importation. In addition, relatively high population densities on Guam increase the likelihood of human-
19 wildlife interactions and consequently the likelihood of pathogen exposure. Increased population
20 densities associated with the military relocation will only exacerbate human-wildlife interactions in the
21 region.

22 **A5.2.4.2.5 Environment**

23 Micronesian countries have tropical climates that offer excellent environmental conditions for a wide
24 variety of wildlife-associated pathogens, wildlife hosts, and vectors. Human environmental exposure to
25 wildlife-associated pathogens is likely to result from contact with vectors (e.g., mosquitoes) while
26 outdoors (for recreation, work, cooling off) as well as disease agents that are able to survive in the
27 environment (e.g., AIVs).

28 **A5.2.4.2.6 Trade**

29 Legal and illegal wildlife trade provides a pathway for exposure/introduction of wildlife pathogens.
30 While few animal hosts are imported legally, disease exposure/introduction may occur from animals
31 with subclinical disease. In addition, illegal importation of wildlife is more likely to cause wildlife-
32 associated pathogen exposure as animals are not checked for signs of disease.

33 **A5.2.4.2.7 Consequences**

34 The consequences of exotic pathogen introductions can be enormous. WNV provides a good example.
35 There is little doubt that the introduction of this virus caused tens of millions of dollars in costs
36 associated with animal infections, disease, and/or human health. For example, an outbreak of WNV in
37 Louisiana during 2002 was estimated to cost more than \$20 million to treat illnesses and for public

1 health responses (e.g., mosquito control) (The Associated Press 2004). During 2002, this virus was
2 thought to cost the equine industry hundreds of thousands of dollars in Colorado and Nebraska (USDA-
3 APHIS-VS 2003b). During 2005, a WNV outbreak in Sacramento County, California was estimated to have
4 cost nearly \$3 dollars (Barber et al. 2010).

5 Emerging infectious diseases of wildlife pose a substantial threat not only to human health but also to
6 wildlife conservation (Daszak et al. 2000). For example, the introduction of WNV has affected wildlife
7 conservation issues, as has been the case with sage grouse (Naugle et al. 2004). Further, several
8 extinctions and near extinctions of local animal populations that have been thought to have been
9 directly caused by disease have been noted (Woodroffe 1999).

10 **A5.2.4.2.8 Estimation**

11 Because information is often lacking for specific pathogens, alternative answers to the risk assessment
12 questions listed elsewhere in this document were considered in cases where a definitive answer could
13 not be confidently drawn. In such cases the most likely qualitative risk level is assigned, but the
14 alternative outcome is also reported. In order to visualize the assignments of risk and potential
15 alternatives, for each wildlife-associated pathogen considered, the flow charts for Probability of
16 Infection and Impact of Infection are filled in to represent the answers to the series of questions. The
17 more likely path is filled in as gray and if an alternative path and risk assignment is considered, it is
18 represented with cross-hatching in the flow chart (Figure A5-17 through Figure A5-36). As noted
19 previously, in addition to considering multiple risk categories for pathogens lacking complete
20 information, risk assessments should be updated in response to new information or developments. The
21 following section describes our estimates of risk of introduction for specific wildlife-associated
22 pathogens. The categorization of risk for each of these pathogens is summarized in Table A5-12.

23 **HANTAVIRUSES** (described in Section A5.1.3.1)

24 **PROBABILITY OF INFECTION** (Figure A5-17)

25 **Is the agent associated with wildlife?** Yes, the reservoir hosts are small mammals (rodents, most often
26 mice and rats, also insectivores, such as shrews).

27 **Is the agent endemic in the Micronesia Region?** No, but host species are known to occur. No detections
28 have been reported, but Seoul virus (an old world hantavirus) is known to have been imported into
29 ports in the New World.

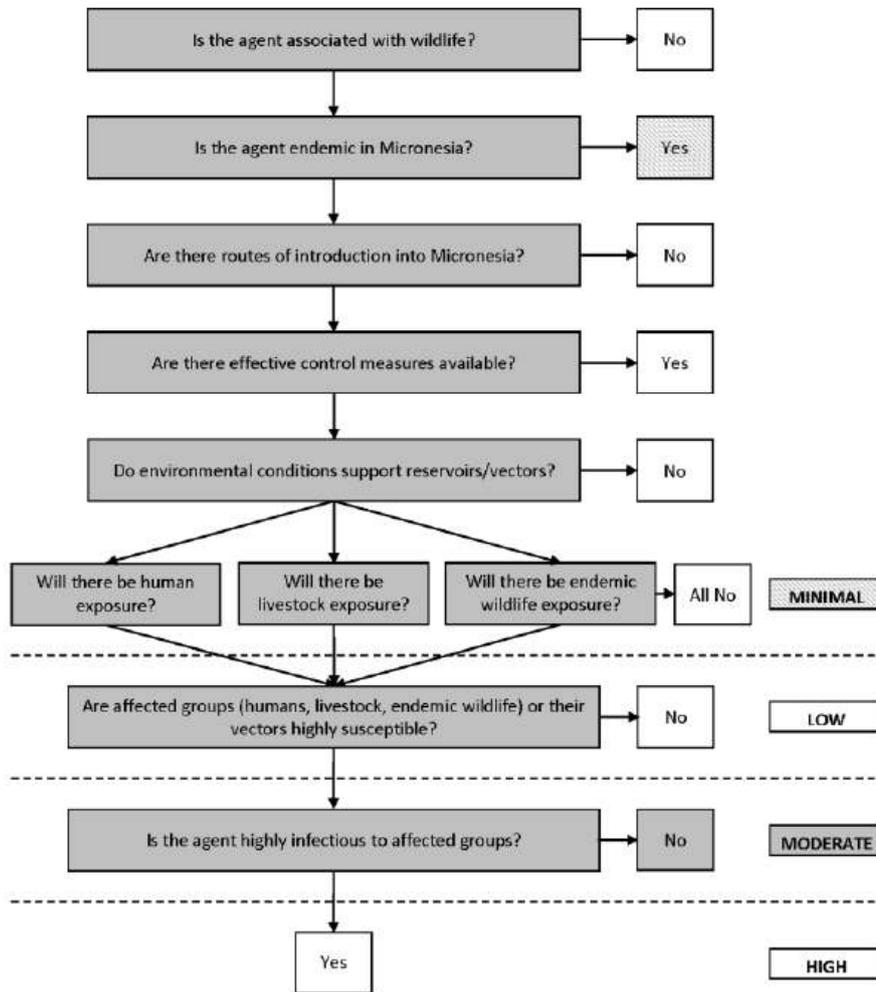

30 **Alternative answer:** Yes. No screening has been conducted in the Micronesia Region so it is possible that
31 the agent is present, but has not been detected.

32 **Are there routes of introduction into the Micronesia Region?** Yes, infected mammals may be
33 introduced via shipping and cargo planes. The agent often causes persistent infections in rodents.
34 Therefore, rodents introduced via shipping cargo can easily be infectious upon arrival in the Micronesia
35 Region.

- 1 **Are there effective control measures available?** No.
- 2 **Do environmental conditions support reservoirs/vectors?** Yes.
- 3 **Will there be human, livestock, or endemic wildlife exposure?** Yes, human exposure is possible for high
4 risk populations living in close association with commensal rodents.
- 5 **Are affected populations highly susceptible?** Yes, for humans that have a high rate of exposure to
6 commensal rodents or their excreta, especially in enclosed environments.
- 7 **Is the agent highly infectious to affected populations via hosts or vectors?** No, humans are considered
8 dead-end hosts for most hantaviruses. However, hantaviruses are readily transmissible between select
9 non-endemic wildlife species (introduced small mammals).
- 10 **Risk category:** Moderate
- 11 **Alternative risk category:** Minimal
- 12 **IMPACT OF INFECTION** (Figure A5- 18)
- 13 **Is there spread to affected populations?** Yes.
- 14 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, rodent densities
15 are very high on some islands, especially in CNMI.
- 16 **Are affected populations susceptible?** Yes.
- 17 **Does the agent cause severe disease in affected populations?** Yes, humans can develop severe disease
18 with high rates of mortality. On the other hand, rodent populations infected with the virus do not
19 exhibit severe disease.
- 20 **Is the agent highly infectious to affected populations?** No; the agent is primarily infectious to humans
21 that come in frequent contact with commensal rodents in enclosed spaces where urine and feces may
22 become aerosolized due to disturbance.
- 23 **Are effective interventions available?** No.
- 24 **Risk category:** Low

1

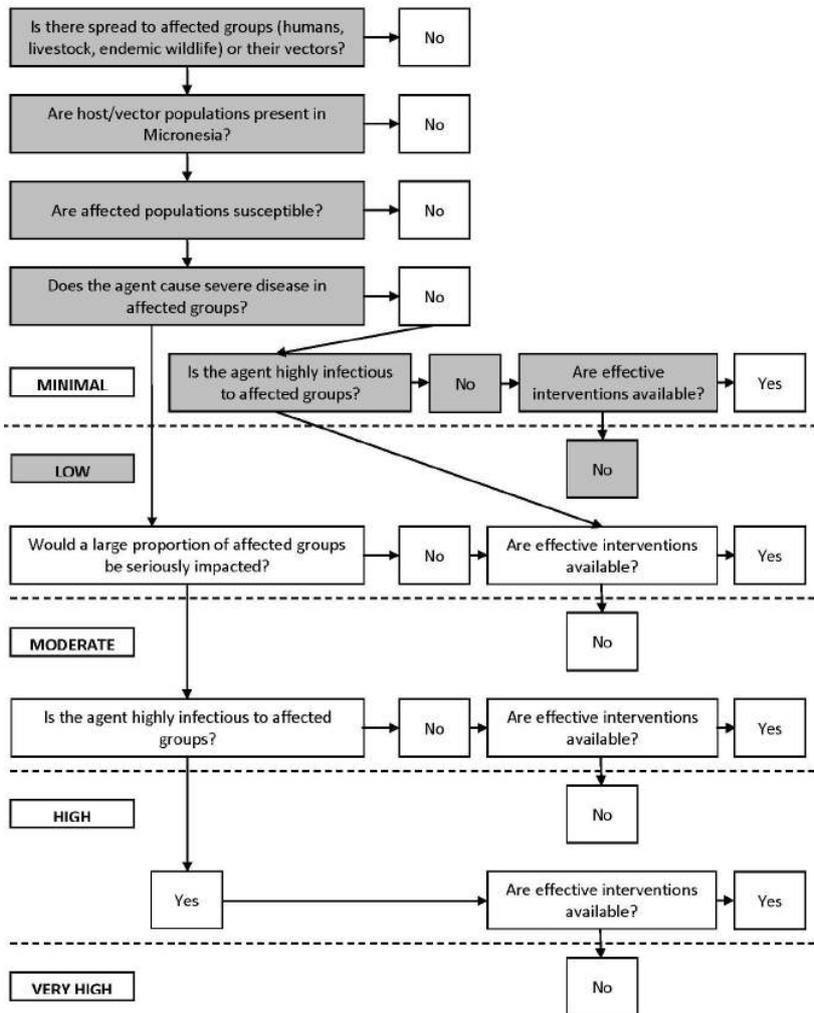

Figure A5-17: Probability of Infection with Hantaviruses

2

3

1 **Figure A5-18: Impact of Infection with Hantaviruses in the Micronesia Region**

2
 3 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
 4 assignment is considered, it is represented as light gray in the flow chart.

5 **RABIES VIRUS** (described in Section A5.2.3.1)

6 **PROBABILITY OF INFECTION** (Figure A5-19)

7 **Is the agent associated with wildlife?** Yes, the reservoir hosts are typically carnivores and bats.

8 **Is the agent endemic in the Micronesia Region?** No, Guam is considered to be free of rabies. Little
 9 testing has been conducted outside of Guam. However, despite limited testing it is unlikely that the
 10 agent is present elsewhere, but has not been identified since the symptoms of the disease are well
 11 known.

- 1 **Are there routes of introduction into the Micronesia Region?** No, Guam has strict quarantine
- 2 procedures to prevent the introduction of rabies from cats, dogs, and other carnivores. However,
- 3 illegally smuggled live bats may be a potential route of introduction.

- 4 **Are there effective control measures available?** Yes, vaccination programs would likely limit the spread
- 5 of rabies among feral carnivores.

- 6 **Risk category:** Minimal

- 7 **IMPACT OF INFECTION** (Figure A5-20)

- 8 **Is there spread to affected populations?** Yes, if the agent was introduced via wildlife, it would likely
- 9 spread to pets and then to humans.

- 10 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes.

- 11 **Are affected populations susceptible?** Yes.

- 12 **Does the agent cause severe disease in affected populations?** Yes.

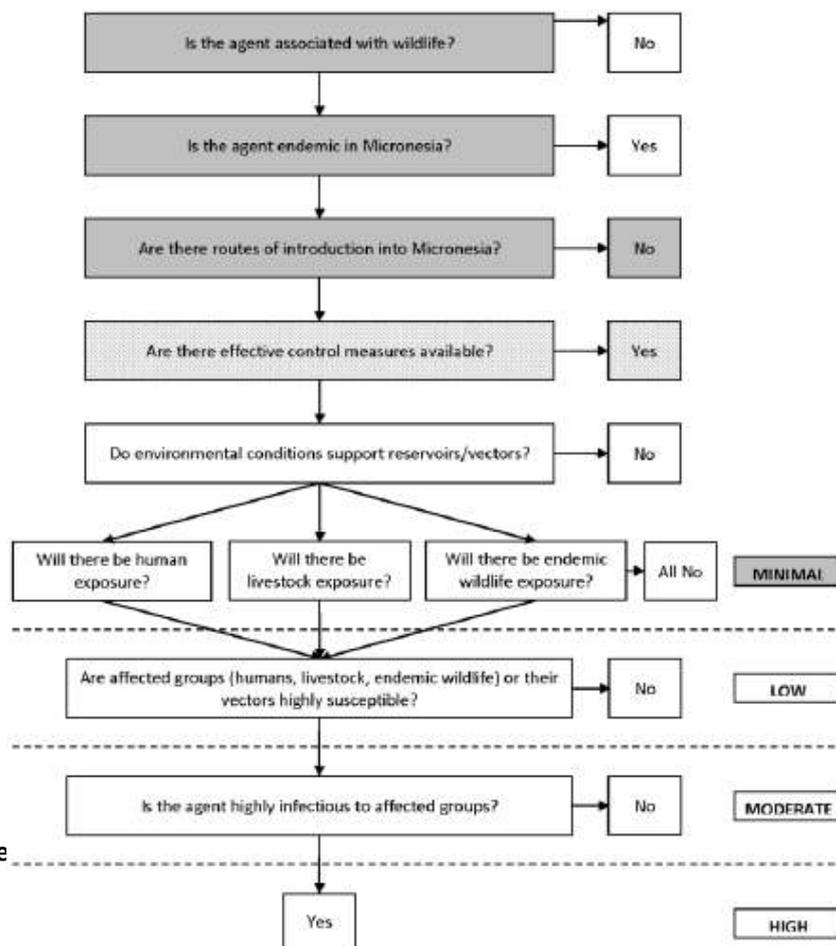

- 13 **Is the agent highly infectious to affected populations?** Yes.

- 14 **Would a large proportion of affected groups be seriously impacted?** No.

- 15 **Are effective interventions available?** Yes.

- 16 **Risk category:** Low

6 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
7 assignment is considered, it is represented as light gray in the flow chart.

8 **WNV** (described in Section A5.2.3.1)

9 **PROBABILITY OF INFECTION** (Figure A5-21)

10

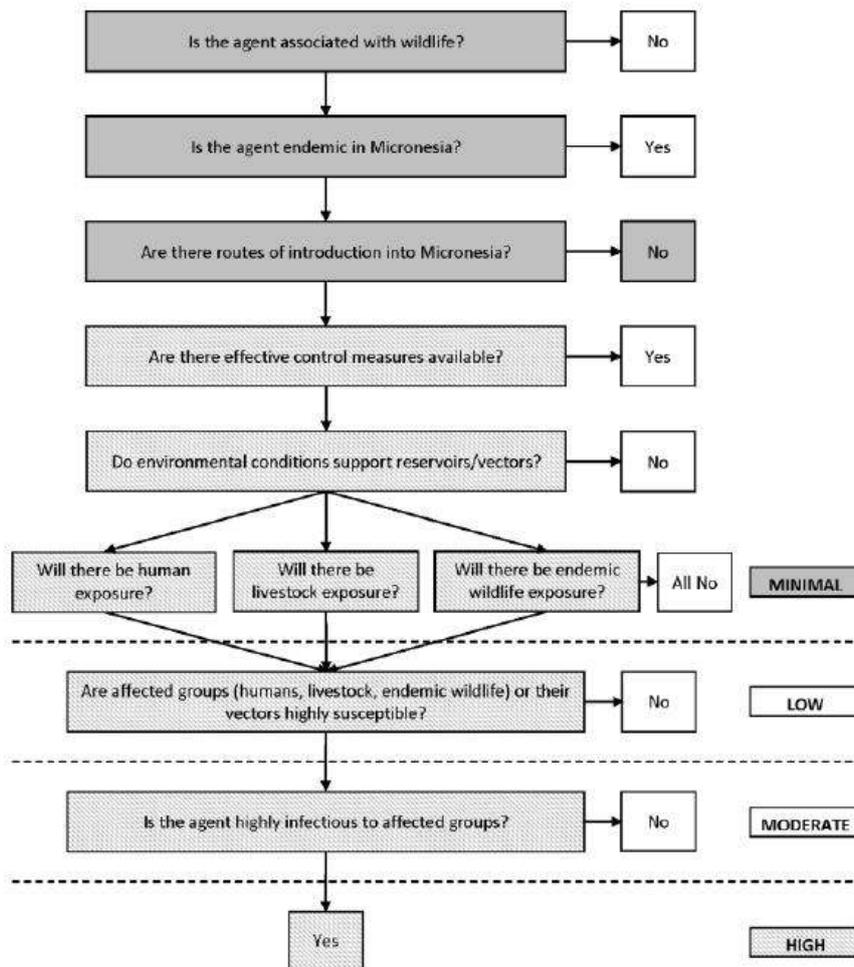

11

- 1 **Is the agent associated with wildlife?** Yes, wild birds are reservoir competent. Most mammals are not
2 involved in natural WNV cycles; however, some mammal species have recently been shown to develop
3 viremias sufficient for infecting some mosquito species.
- 4 **Is the agent endemic in the Micronesia Region?** No.
- 5 **Are there routes of introduction into the Micronesia Region?** No, the likelihood of introduction is low.
- 6 **Alternative answer:** Yes, if WNV becomes established in Hawai'i or Alaska in which case WNV would
7 have the potential to enter Micronesian countries via infected mosquitoes or migratory birds arriving
8 from Alaska or Hawai'i. Introduction via the import of poultry and fighting cocks is negligible. A lesser
9 probability of introduction via an infected mammal (including humans) is possible.
- 10 **Are there effective control measures available?** No.
- 11 **Do environmental conditions support reservoirs/vectors?** Yes.
- 12 **Will there be human, livestock, or endemic wildlife exposure?** Yes, human, livestock, and endemic
13 wildlife exposures are possible.
- 14 **Are affected populations highly susceptible?** Yes.
- 15 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes.
- 16 **Risk category:** Minimal
- 17 **Alternative risk category:** High (if WNV becomes established in Hawai'i or Alaska)
- 18 **IMPACT OF INFECTION** (Figure A5-22)
- 19 **Is there spread to affected populations?** Yes.
- 20 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, both host and
21 vector species are present in the Micronesia Region.
- 22 **Are affected populations susceptible?** Yes.
- 23 **Does the agent cause severe disease in affected populations?** Yes, WNV can cause serious disease in
24 wild bird populations, especially corvids. In addition, a small proportion of humans can suffer severe
25 morbidity and mortality.
- 26 **Is the agent highly infectious to affected populations?** Yes, WNV is highly infectious to wild birds.
- 27 **Would a large proportion of affected populations be seriously impacted?** Yes.
- 28 **Is the agent highly infectious to affected populations?** Yes.

1 **Are effective interventions available?** Yes, mosquito control and education can reduce vector
2 populations.

3 **Risk category:** High

4 **Figure A5-21: Probability of Infection with WNV**

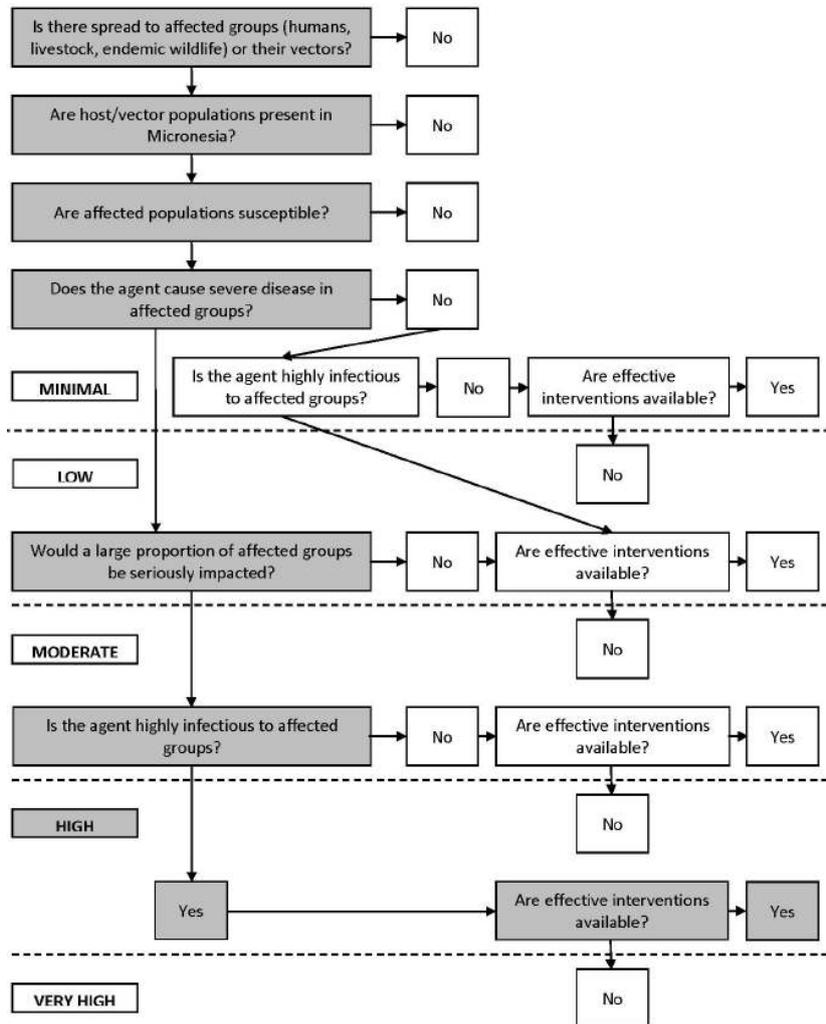

5

6

1

Figure A5-22: Impact of Infection with WNV

2

3 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
4 assignment is considered, it is represented as light gray in the flow chart.

5 **HIGHLY PATHOGENIC AVIAN INFLUENZA VIRUS** (described in Section A5.2.3.1)

6 **PROBABILITY OF INFECTION** (Figure A5-23)

7 **Is the agent associated with wildlife?** Yes, the reservoir host is wild birds, particularly waterfowl,
8 shorebirds, and seabirds. In addition, select wild mammals have been infected.

9 **Is the agent endemic in the Micronesia Region?** No, but low pathogenic AIVs have been detected in 3
10 wild birds (out of more than 5,000 sampled).

11 **Are there routes of introduction into the Micronesia Region?** Yes, AIVs have the potential to enter
12 Micronesian countries via infected migratory birds. Introduction via the import of poultry and fighting

1 cocks is negligible. AIVs may also enter Micronesian countries via spillover into mammals. However,
2 because the course of infection is approximately a week, this type of release is likely to be limited to air
3 cargo because infections would be expected to resolve prior to shipping for sea cargo.

4 **Are there effective control measures available?** No, control measures (depopulation and quarantine)
5 are generally effective if implemented quickly, but the high densities of feral chickens on Guam and
6 Saipan render effective control unlikely.

7 **Do environmental conditions support reservoirs/vectors?** Yes.

8 **Will there be human, livestock, or endemic wildlife exposure?** Yes.

9 **Are affected populations highly susceptible?** Yes (for livestock and endemic wildlife).

10 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes.

11 **Risk category:** High

12 **IMPACT OF INFECTION** (Figure A5-24)

13 **Is there spread to affected populations?** Yes.

14 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes.

15 **Are affected populations susceptible?** Yes.

16 **Does the agent cause severe disease in affected populations?** No, highly pathogenic subtypes do not
17 generally cause severe morbidity and mortality in wild birds.

18 **Alternative answer:** Yes, while uncommon, some strains of HPAIV have been associated with severe
19 disease and mortality in wild birds.

20 **Is the agent highly infectious to affected populations?** Yes, especially in wild birds; moreover, humans
21 in close contact with infected birds can also become infected.

22 **Are effective interventions available?** No, vaccines are available for domestic birds, but control of the
23 virus in wild populations is not feasible.

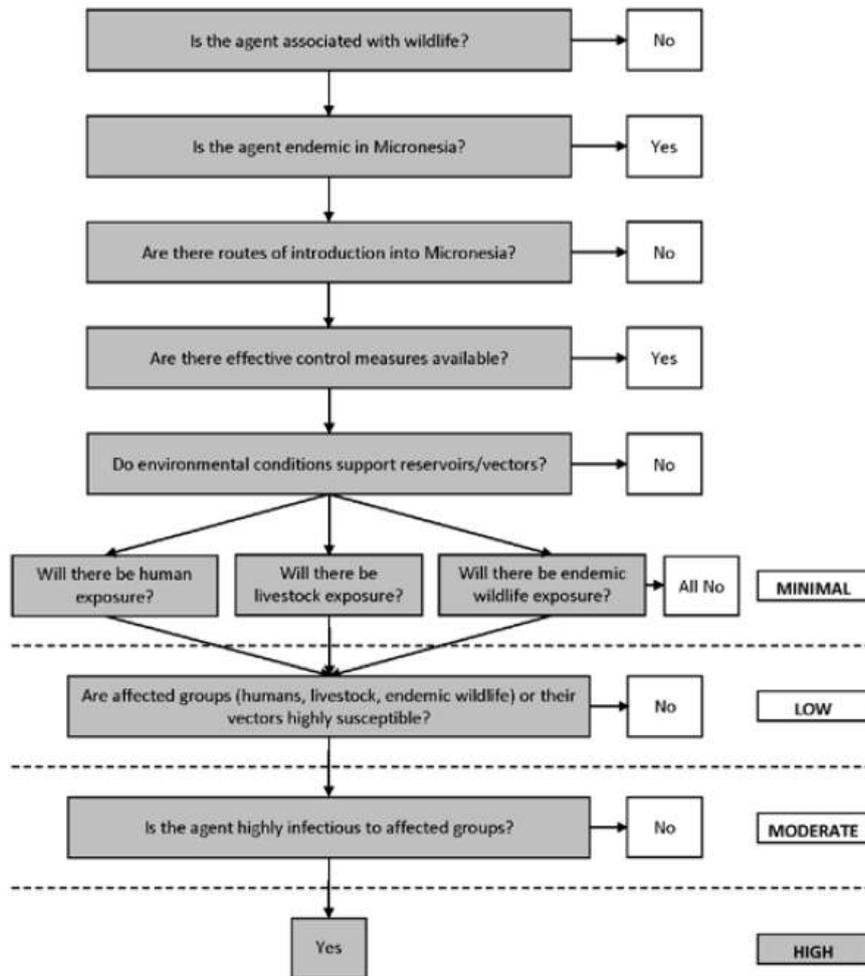

24 **Would a large proportion of affected groups be seriously impacted?** No, most wild bird populations do
25 not exhibit severe morbidity or mortality.

26 **Risk category:** Moderate

27 **Alternative risk category:** Moderate

4 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
5 assignment is considered, it is represented as light gray in the flow chart.

6 **JAPANESE ENCEPHALITIS VIRUS** (described in Section A5.2.3.1)

7 **PROBABILITY OF INFECTION** (Figure A5-25)

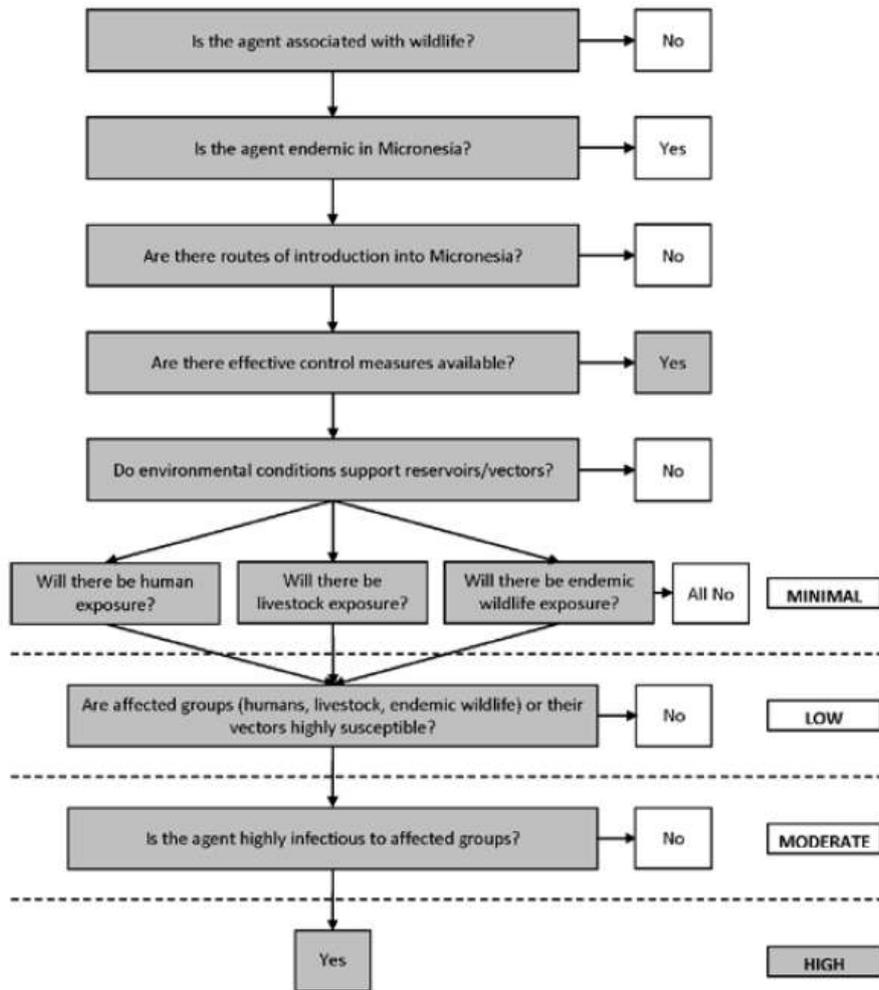

8 **Is the agent associated with wildlife?** Yes, wild birds are reservoir competent and pigs can act as
9 amplifying hosts.

10 **Is the agent endemic in the Micronesia Region?** No, but an outbreak occurred in Guam in 1947 and in
11 Saipan in 1990.

- 1 **Are there routes of introduction into the Micronesia Region?** Yes, infected mosquitoes, migratory
2 birds, or humans could move the virus into the Micronesia Region
- 3 **Are there effective control measures available?** Yes for mitigation of human and swine infections, but if
4 the virus becomes established in wild birds, control is unlikely. However, JEV does not cause clinical
5 illness in wild birds.
- 6 **Do environmental conditions support reservoirs/vectors?** Yes.
- 7 **Will there be human, livestock, or endemic wildlife exposure?** Yes, human, livestock, and endemic
8 wildlife exposures are possible.
- 9 **Are affected populations highly susceptible?** Yes.
- 10 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes, wild birds as well as
11 humans and livestock are readily infected.
- 12 **Risk category:** High
- 13 **IMPACT OF INFECTION** (Figure A5-26)
- 14 **Is there spread to affected populations?** Yes, JEV is easily spread among wild birds which represent the
15 primary natural reservoir. Humans and livestock can act as spillover hosts.
- 16 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, both host (birds
17 and mammals) and vector populations are currently present.
- 18 **Are affected populations susceptible?** Yes, wild birds, livestock, and humans are susceptible.
- 19 **Does the agent cause severe disease in affected populations?** No, JEV does not cause severe disease in
20 wild bird populations.
- 21 **Alternative answer:** Yes, JEV may cause severe disease in a small proportion of humans that may
22 become infected.
- 23 **Is the agent highly infectious to affected populations?** No; while JEV is highly infectious to wild birds, it
24 is less infectious to humans which are most likely to be impacted.
- 25 **Are effective interventions available?** Yes, vaccinations are available for humans.
- 26 **Would a large proportion of affected populations be seriously impacted?** No.
- 27 **Risk category:** Minimal
- 28 **Alternative risk category:** Low

4 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
5 assignment is considered, it is represented as light gray in the flow chart.

6 **AVIAN MALARIA PARASITES** (*Plasmodium* spp.) (described in Section A5.2.3.1)

7 **PROBABILITY OF INFECTION** (Figure A5-27)

8 **Is the agent associated with wildlife?** Yes, wild birds are reservoir competent.

9 **Is the agent endemic in the Micronesia Region?** No (not likely), screening for blood parasites in Guam
10 has not yet identified any *Plasmodium* spp.

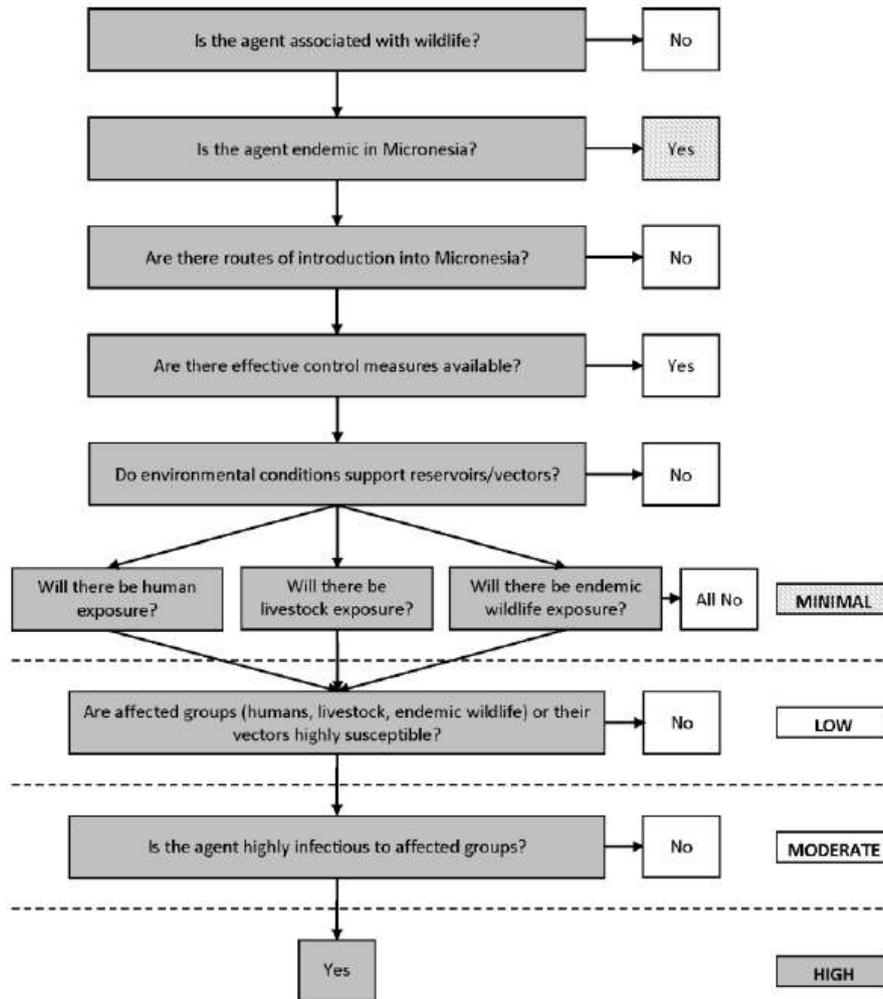

11 **Alternative answer:** Yes, testing in Saipan more than 50 years ago revealed the possible presence of
12 *Plasmodium* sp. in birds; however, modern detection methods were not available.

- 1 **Are there routes of introduction into the Micronesia Region?** Yes, infected mosquitoes or migratory
2 birds could move the virus into the Micronesia Region. Movement of infected mosquitoes or their larvae
3 from Hawai'i is possible via air cargo.
- 4 **Are there effective control measures available?** No.
- 5 **Do environmental conditions support reservoirs/vectors?** Yes.
- 6 **Will there be human, livestock, or endemic wildlife exposure?** Yes, endemic wild bird exposures are
7 possible.
- 8 **Are affected populations highly susceptible?** Yes, wild birds are highly susceptible.
- 9 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes, *Plasmodium* spp. are
10 highly infectious to wild birds.
- 11 **Risk category:** High
- 12 **Alternative risk category:** Minimal
- 13 **IMPACT OF INFECTION** (Figure A5-28)
- 14 **Is there spread to affected populations?** Yes, *Plasmodium* spp. would spread easily between wild bird
15 hosts via mosquito vectors.
- 16 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, both wild bird
17 hosts and mosquito vectors are present.
- 18 **Are affected populations susceptible?** Yes, wild bird populations are highly susceptible to *Plasmodium*
19 spp.
- 20 **Does the agent cause severe disease in affected populations?** No, *Plasmodium* spp. do not cause
21 severe disease in most bird species.
- 22 **Alternative answer:** Yes, *Plasmodium* spp. are associated with severe disease in some Hawai'ian bird
23 species that did not evolve with the agent. If bird species in the Micronesia Region did not evolve in the
24 presence of *Plasmodium* spp. it is possible that severe population impacts may be felt in some wild bird
25 species as has happened in Hawai'i.
- 26 **Is the agent highly infectious to affected populations?** Yes.
- 27 **Are effective interventions available?** No.
- 28 **Would a large proportion of affected populations be seriously impacted?** No, not all wild bird species
29 would be likely to suffer serious impacts.

1 Risk category: Moderate

2 Alternative risk category: Moderate

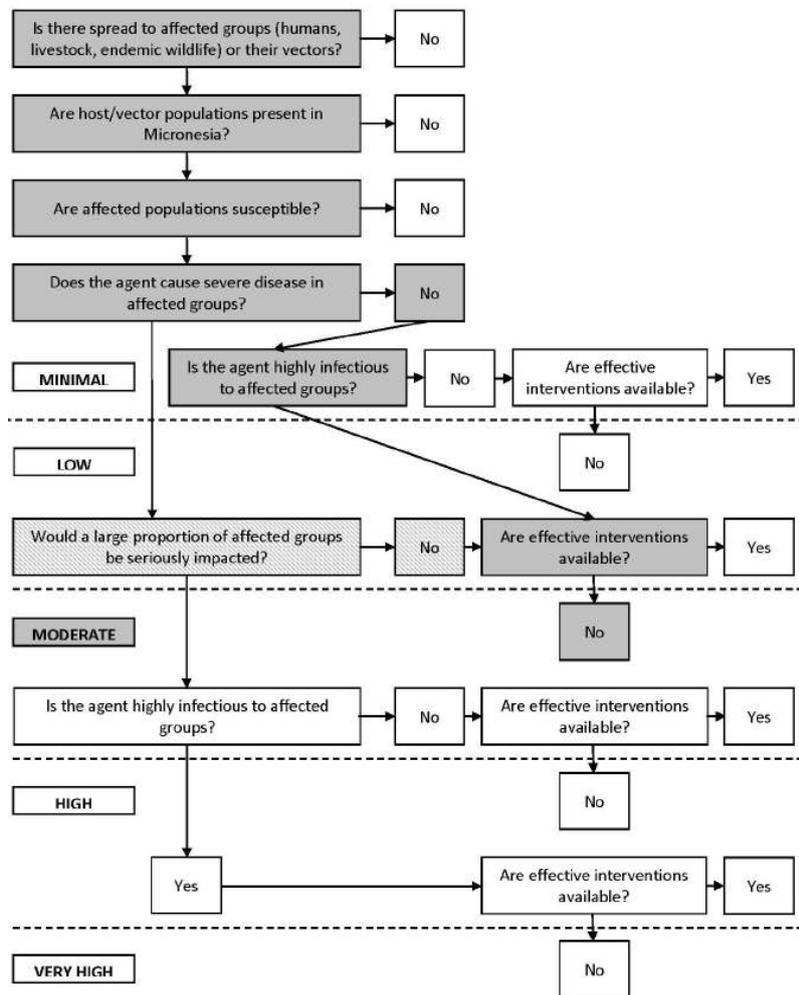

3 Figure A5-27: Probability of Infection with Avian malaria Parasites in the Micronesia Region

4 assignment is considered, it is represented as light gray in the flow chart.

5 **HENIPAVIRUSES** (described in Section A5.2.3.1)

6 **PROBABILITY OF INFECTION** (Figure A5-29)

7 **Is the agent associated with wildlife?** Yes, bats are considered the reservoir species and livestock can

8 act as amplifying hosts.

9 **Is the agent endemic in the Micronesia Region?** No.

10 **Are there routes of introduction into the Micronesia Region?** No, the likelihood of introduction is low.

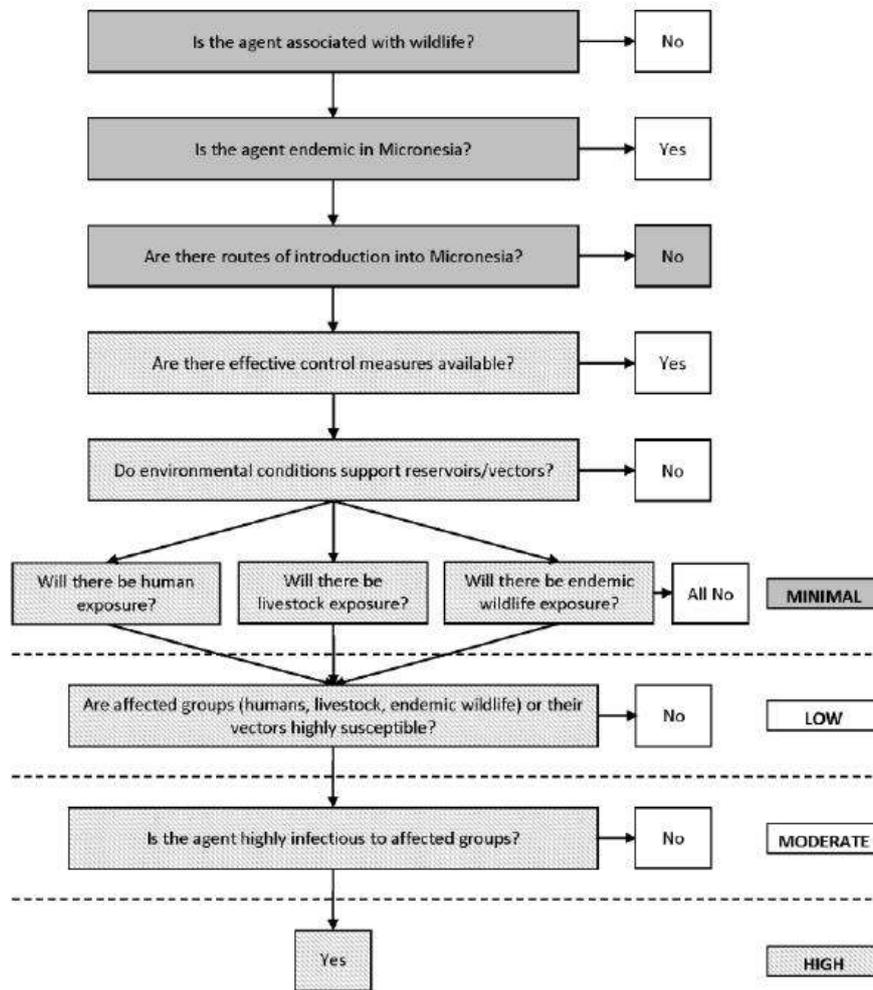

11 **Alternative answer:** Yes, henipaviruses could move into the Micronesia Region via smuggling of infected

12 bats or introduction via shipping or air cargo.

- 1 **Are there effective control measures available?** No.
- 2 **Do environmental conditions support reservoirs/vectors?** Yes.
- 3 **Will there be human, livestock, or endemic wildlife exposure?** Yes, if introduced, human, livestock, and
4 endemic wildlife exposures are possible.
- 5 **Are affected populations highly susceptible?** Yes.
- 6 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes.
- 7 **Risk category:** Minimal
- 8 **Alternative risk category:** High
- 9 **IMPACT OF INFECTION** (Figure A5-30)
- 10 **Is there spread to affected populations?** Yes, the virus spreads easily between bats and spillover hosts
11 such as pigs and humans.
- 12 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, in parts of the
13 Micronesia Region (e.g., Palau), bat populations are still relatively large.
- 14 **Are affected populations susceptible?** Yes, bats, humans, and pigs are susceptible.
- 15 **Does the agent cause severe disease in affected populations?** No, henipaviruses do not cause severe
16 illness in reservoir bat populations.
- 17 **Alternative answer:** Yes, henipaviruses can cause severe disease in pigs and humans.
- 18 **Is the agent highly infectious to affected populations?** Yes.
- 19 **Are effective interventions available?** No.
- 20 **Would a large proportion of affected populations be seriously impacted?** No; while the agent can
21 cause severe morbidity and mortality in humans and pigs, only individuals in close contact with bats are
22 likely to be impacted.
- 23 **Risk category:** Moderate
- 24 **Alternative risk category:** Moderate

1

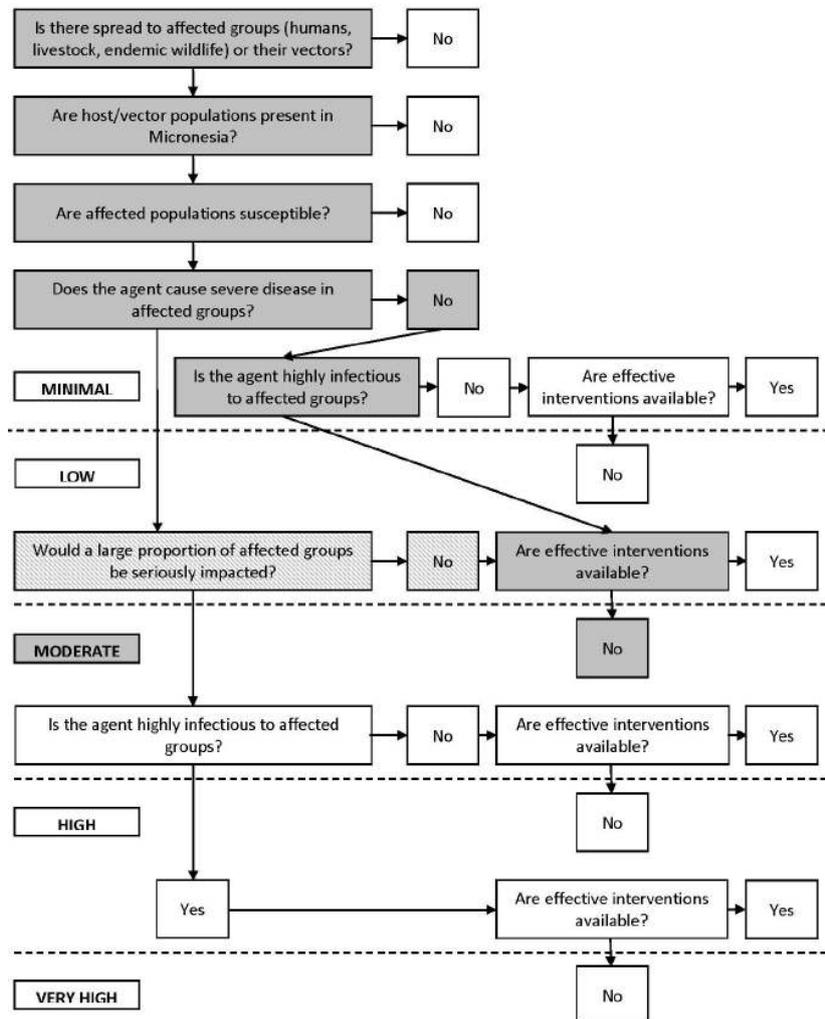

Figure A5-29: Probability of Infection with Henipaviruses in the Micronesia Region

5 assignment is considered, it is represented as light gray in the flow chart.

6 **NEWCASTLE DISEASE VIRUS** (described in Section A5.2.3.1)

7 **PROBABILITY OF INFECTION** (Figure A5-31)

8 **Is the agent associated with wildlife?** Yes, more than 240 wild bird and poultry species are known to

9 become infected.

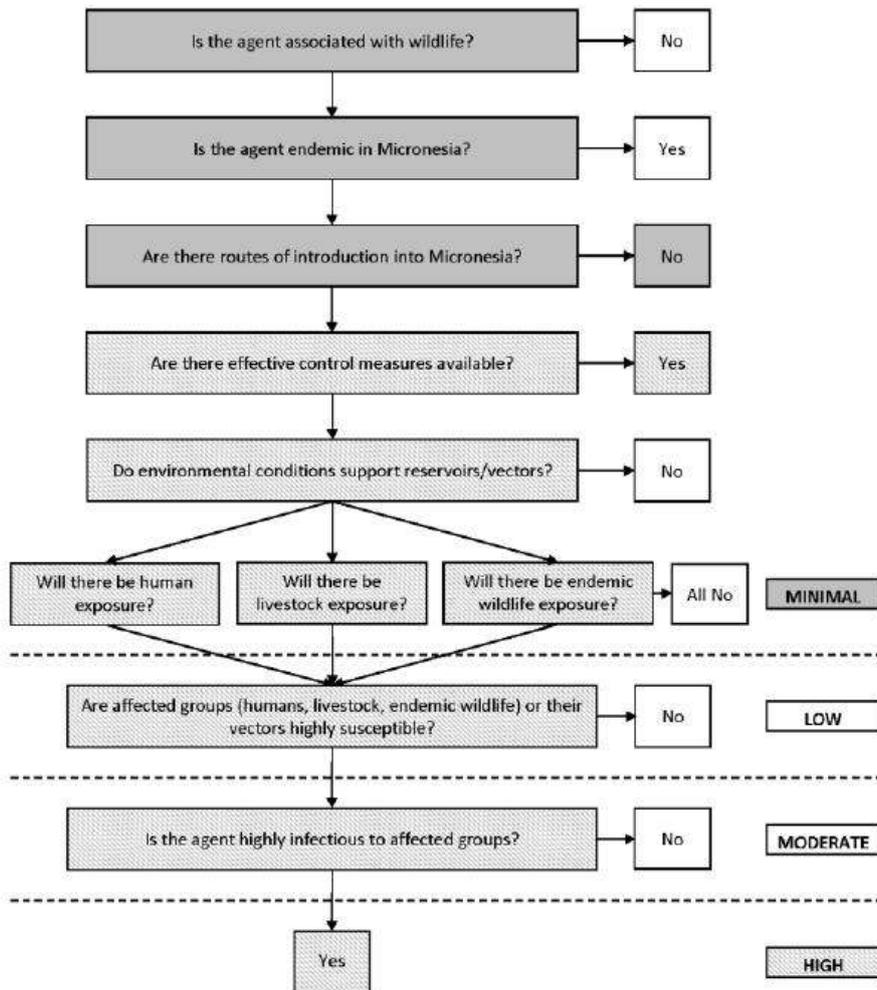

10 **Is the agent endemic in the Micronesia Region?** No.

- 1 **Are there routes of introduction into the Micronesia Region?** No, NDV has been endemic throughout
2 Southeast Asia for a long period of time without any known introductions into the Micronesia Region.
- 3 **Alternative answer:** Yes, infected migratory birds from Southeast Asia are a potential route of
4 introduction. Introduction via the import of poultry or fighting cocks is negligible.
- 5 **Are there effective control measures available?** Yes, vaccination and quarantine are effective for
6 poultry species, but are not a viable option for wild birds.
- 7 **Do environmental conditions support reservoirs/vectors?** Yes.
- 8 **Will there be human, livestock, or endemic wildlife exposure?** Yes, livestock and endemic wildlife
9 exposures are possible. NDV can be particularly harmful to columbid species and therefore pose a risk to
10 the endangered fruit doves.
- 11 **Are affected populations highly susceptible?** Yes.
- 12 **Is the agent highly infectious to affected populations via hosts or vectors?** Yes, wild bird populations
13 are highly susceptible to NDV.
- 14 **Risk category:** Minimal
- 15 **Alternative risk category:** High
- 16 **IMPACT OF INFECTION** (Figure A5-32)
- 17 **Is there spread to affected populations?** Yes, NDV spreads readily among wild birds.
- 18 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, wild bird species
19 expected to be susceptible to the agent are present.
- 20 **Are affected populations susceptible?** Yes.
- 21 **Does the agent cause severe disease in affected populations?** No, many bird species remain
22 asymptomatic.
- 23 **Alternative answer:** Yes, certain pathotypes of the agent are capable of causing severe morbidity and
24 high mortality certain of wild bird species (e.g., columbids).
- 25 **Is the agent highly infectious to affected populations?** Yes.
- 26 **Are effective interventions available?** No, there are no feasible interventions for wild bird populations.
- 27 **Would a large proportion of affected populations be seriously impacted?** No, only select species are
28 expected to be seriously impacted.

1 Risk category: Moderate

2 Alternative risk category: Moderate

3 Figure A5-31: Probability of Infection with Newcastle Disease Virus in the Micronesia Region

4 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
5 assignment is considered, it is represented as light gray in the flow chart.

6 **YERSINIA PESTIS (PLAGUE)** (described in Section A5.2.3.1)

7 **PROBABILITY OF INFECTION** (Figure A5-33)

8 **Is the agent associated with wildlife?** Yes, rodents and their associated fleas.

9 **Is the agent endemic in the Micronesia Region?** No.

10 **Are there routes of introduction into the Micronesia Region?** Yes, introduction of infected rodents and
11 their fleas is possible via shipping and air cargo originating from Southeast Asia or the West Coast of
12 North America.

- 1 **Are there effective control measures available?** Yes, environmental management (e.g. use of
- 2 appropriate insecticides in response to plague outbreaks), public health education, and preventive drug
- 3 therapy are effective control measures for reducing the impact of plague on humans.

- 4 **Risk category:** Minimal

- 5 **IMPACT OF INFECTION** (Figure A5-34)

- 6 **Is there spread to affected populations?** Yes, if introduced, *Yersinia pestis* would likely spread to
- 7 reservoir rodent species and could subsequently spread to humans as a spillover species.

- 8 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes.

- 9 **Are affected populations susceptible?** Yes.

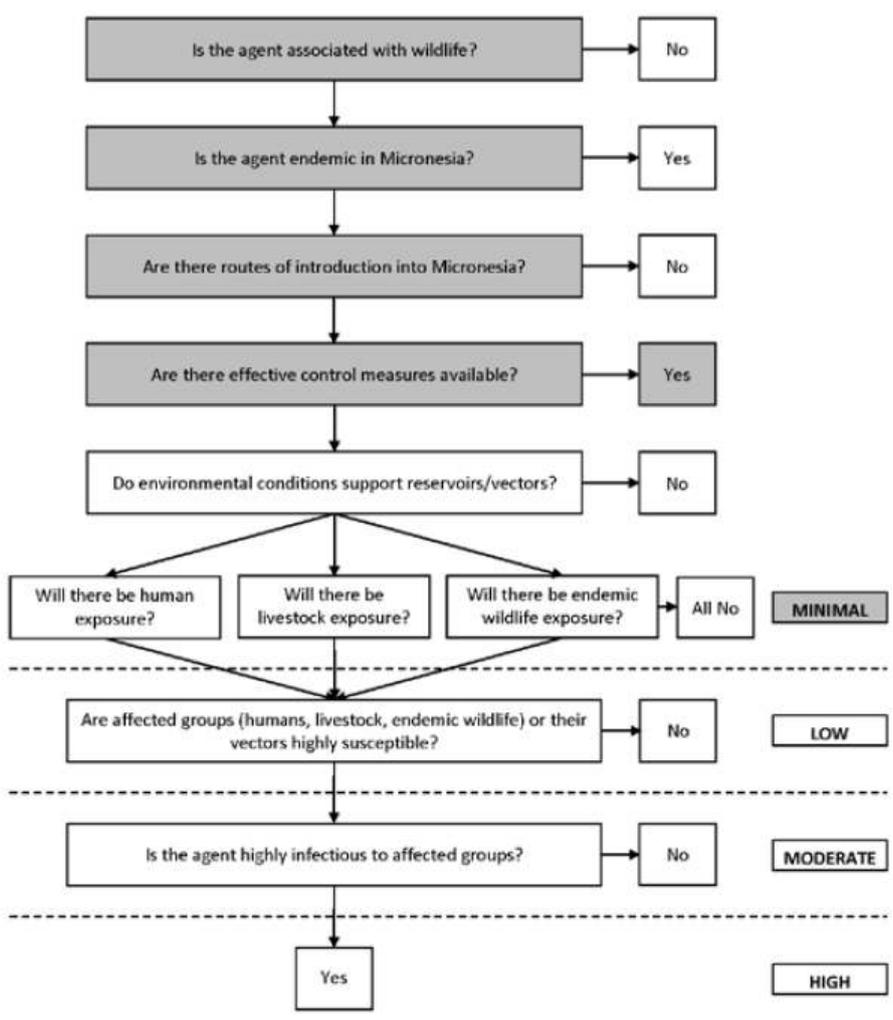

- 10 **Does the agent cause severe disease in affected populations?** Yes, plague has the potential to cause
- 11 severe disease in humans.

- 12 **Would a large proportion of affected populations be seriously impacted?** No, only humans in close
- 13 contact with infected rodents would be impacted.

- 14 **Are effective interventions available?** Yes.

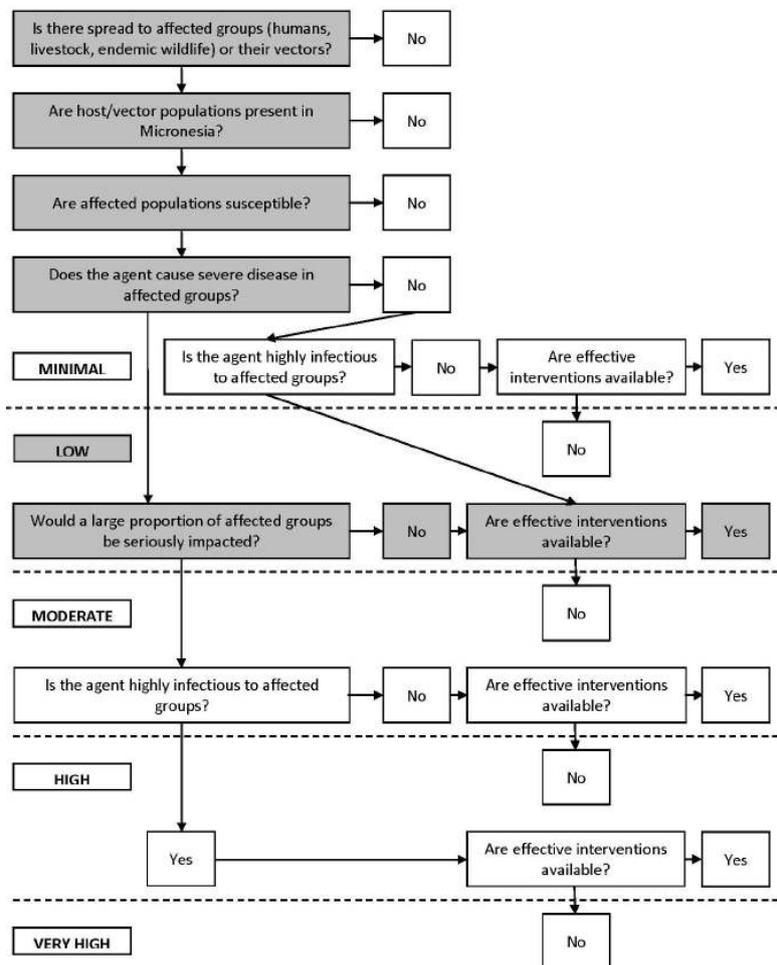

- 15 **Risk category:** Low

1 **Figure A5-33: Probability of Infection of *Yersinia pestis* (Plague) in the Micronesia Region**

2
3

1 **Figure A5-34: Impact of infection with *Yersinia pestis* (Plague) in the Micronesia Region**

2

3

4 The more likely path and risk level assignment is filled as dark gray and, if an alternative path and risk
 5 assignment is considered, it is represented as light gray in the flow chart.

6 **TICK-BORNE ENCEPHALITIS** (described in Section A5.2.3.1)

7 **PROBABILITY OF INFECTION** (Figure A5-35)

8 **Is the agent associated with wildlife?** Yes, small rodents are important in the transmission cycle with
 9 incidental infection of larger mammals and birds.

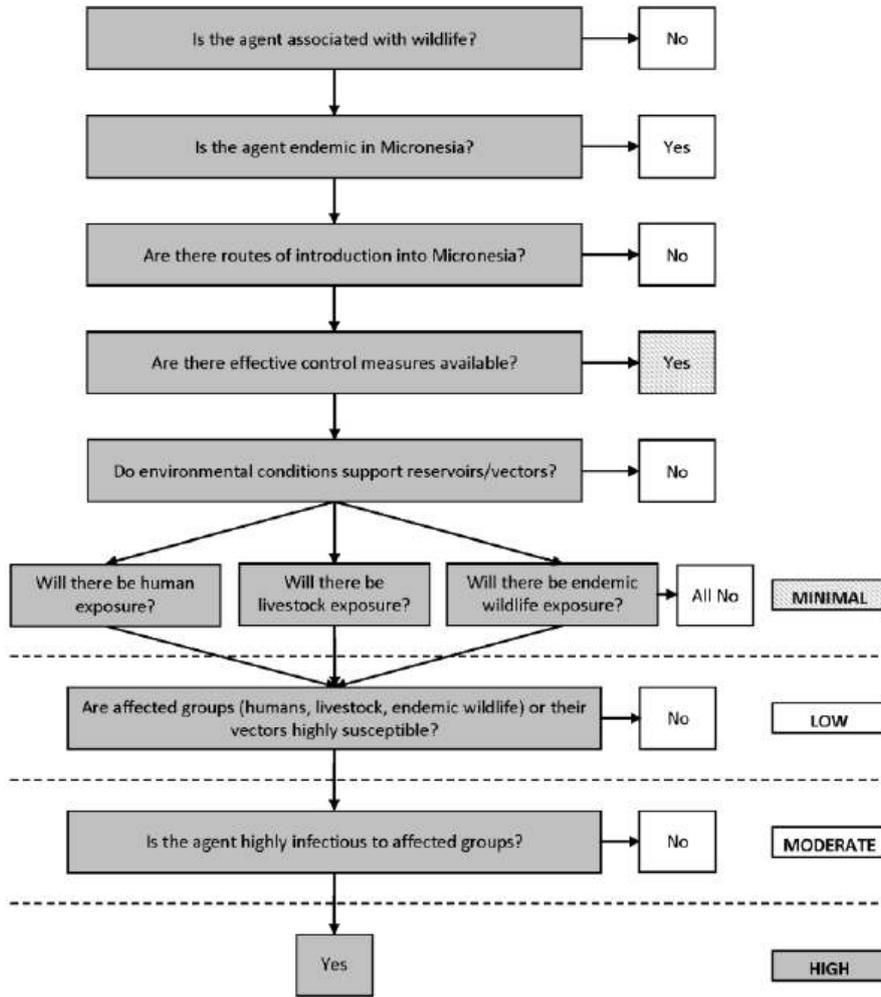

10 **Is the agent endemic in the Micronesia Region?** No, the virus has never been isolated in the Micronesia
 11 Region.

12 **Are there routes of introduction into the Micronesia Region?** Yes, infected ticks or stowaway rodents
 13 may be introduced via shipping or cargo planes.

- 1 **Are there effective control measures available?** Yes, a vaccine is available for mitigation of human
2 infections, but if the virus becomes established in rodent and tick populations, establishment is possible.
- 3 **Do environmental conditions support reservoirs/vectors?** Yes, the climate is appropriate and a genus
4 of competent ticks has been identified in Palau.
- 5 **Will there be human, livestock, or endemic wildlife exposure?** Yes, human, livestock, and endemic
6 wildlife exposure are possible.
- 7 **Is the agent highly infectious to affected populations?** Yes, humans and other mammals are highly
8 susceptible, but most infections are asymptomatic.
- 9 **Is the agent readily transmitted to affected populations via hosts or vectors?** Yes, the agent is readily
10 transmissible between rodents and ticks and between ticks and ticks.
- 11 **Risk category:** High
- 12 **IMPACT OF INFECTION** (Figure A5-36)
- 13 **Is there spread to affected populations?** Yes, the agent would be expected to spread readily via rodents
14 where appropriate tick species have been identified (e.g., Palau).
- 15 **Are wildlife hosts and/or vector populations present in the Micronesia Region?** Yes, rodents and
16 livestock are present and the vector is present in Palau.
- 17 **Are affected populations susceptible?** Yes, humans are very susceptible.
- 18 **Does the agent cause severe disease in affected populations?** No, TBEV does not cause severe disease
19 in a majority of humans.
- 20 **Alternative answer:** Yes, while many humans experience asymptomatic or mild disease symptoms,
21 others experience severe disease.
- 22 **Is the agent highly infectious to affected populations?** Yes.
- 23 **Are effective interventions available?** Yes, a vaccine is available for humans.
- 24 **Would a large proportion of affected populations be seriously impacted?** No, most cases are
25 asymptomatic.
- 26 **Risk category:** Low
- 27 **Alternative risk category:** Moderate

1

Figure A5-35: Probability of Infection with TBEV in the Micronesia Region

 5 assignment is considered, it is represented as light gray in the flow chart.

6 **Table A5-12: Summary of Risks for Introduction of Wildlife-Associated Pathogens into the**
 7 **Micronesia Region**

Pathogen	Probability of infection risk category	Alternative risk category	Impact of infection risk category	Alternative risk category	Comments
Hantaviruses	Moderate	Minimal	Low		
Rabies virus	Minimal		Low		

Pathogen	Probability of infection risk category	Alternative risk category	Impact of infection risk category	Alternative risk category	Comments
WNV	Minimal	High	High		Alternative risk associated with potential introduction of WNV into Hawai'i or Alaska
AIV	High		Moderate	Moderate	Risk category partially based on proximity to Asia. Introduction more likely from natural bird movement than from DoD-associated introductions.
JEV	High		Minimal	Low	
Avian malaria parasites (<i>Plasmodium</i> spp.)	High	Minimal	Moderate	Moderate	
Henipaviruses	Minimal	High	Moderate	Moderate	While the risk of introduction is low an alternative risk was considered for possible pathogen introduction via smuggling of bats or movement of infected bats in air or shipping cargo.
NDV	Minimal	High	Moderate	Moderate	The risk of NDV introduction is low, but possible.
<i>Yersinia pestis</i> (plague)	Minimal		Low		
Tick-borne encephalitis	High		Low	Moderate	

1

2 **A5.3 DISCUSSION AND CONCLUSIONS**

3 Within this report, we have focused on wildlife-associated pathogens. Arthropod vectors, however,
4 should not be discounted in the overall risk assessment in this region. For example, *Aedes albopictus* is
5 an invasive mosquito species of Guam (GISIN 2010). Unfortunately, this species is thought to be a
6 competent vector for several distinct arboviruses (Gratz 2004). Table A5-10 outlines many other
7 mosquito species that occur on Guam and in CNMI.

1 **A5.3.1 General Threat of Wildlife-Associated Diseases**

2 Of the 1,415 infectious organisms (pathogens) known to cause disease in humans, the majority (61%)
3 are zoonotic, i.e., transmissible between humans and animals (Taylor et al. 2001; Jones et al. 2008), and
4 zoonotic pathogens are twice as likely to be associated with diseases that have recently emerged in
5 humans (Taylor et al. 2001). Considering these figures, along with the large number of exotic species
6 already established in many locations in the Micronesia Region, a general threat of wildlife-associated
7 diseases in this region is apparent. Many introduced species have, at a minimum, a potential to
8 introduce a novel pathogen to a new area. Furthermore, on islands with established host populations
9 (e.g., rats), the introduction of a single animal that has acquired a pathogen could (dependent on a
10 myriad of factors) potentially introduce this pathogen into a novel population.

11 **A5.4 RECOMMENDATIONS**

12 **A5.4.1 Adaptive Management**

13 Information on wildlife-associated pathogens is often incomplete so risk assessments and their
14 associated recommendations must be updated as new information becomes available. Moreover,
15 distributions of pathogens, hosts, and vectors can change in response to changing environmental
16 conditions, movements, or introductions. As conditions change, risk assessments need to be re-
17 evaluated to determine if risks and associated recommendations need to be updated.

18 Adaptive management has been widely used in natural resource management (Nichols and Williams
19 2006) but has direct application to biosecurity. It is framed within structured decision making and
20 emphasizes uncertainty about responses to management actions with the general objective being to
21 reduce that uncertainty in order to improve management (Williams et al. 2007). Thus, adaptive
22 management is an iterative learning process producing improved understanding and improved
23 management over time. In terms of biosecurity, initial measures to prevent introduction of wildlife-
24 associated diseases should be implemented with a surveillance and monitoring strategy to “test”
25 whether measures are performing adequately, with these measures subsequently adjusted to improve
26 biosecurity.

27 **A5.4.2 General Recommendations**

28 The importation of wildlife diseases into the Micronesia Region is a potential threat to human,
29 agriculture, and wildlife health in this region. Although it is clear that the risk of the establishment of
30 some pathogens is far greater than risks of others, a diversity of pathogens could have negative
31 consequences to the Micronesia Region if they are introduced onto islands that are free of the
32 pathogens in question. The importation of live animals (intentional or unintentional) is one of the
33 biggest risk factors associated with the introduction of wildlife-associated pathogens in the Micronesia
34 Region. Once established in this region, the movement of these pathogens to other islands in the
35 Micronesia Region may increase due to the close proximity of some of the islands and frequent
36 transportation events among islands. In general, prevention is more effective and more cost efficient
37 than eradication (Kingsford et al. 2009). Consequently, investment in prevention measures is a high
38 priority for reducing the risk of introduction of wildlife-associated diseases into this region.

1 **A5.4.3 Specific Recommendations**

2 Recently, it was suggested that the potential for importation of etiological agents causing zoonoses that
3 could pose a major public health threat warrants that enhanced surveillance be conducted on imported
4 wildlife in the United States (Pavlin et al. 2009). There is little doubt that this suggestion is warranted in
5 other regions, such as the Micronesia Region. Some specific recommendations to prevent the
6 importation of wildlife-associated diseases into the Micronesia Region include these:

- 7 • Strengthen USFWS inspections and interdiction capabilities.
- 8 • Extend training of customs personnel to be enhanced for wildlife surveillance and to recognize
9 taxonomic groups that are a large threat to pathogen introduction.
- 10 • Use employee-trained dogs to detect wildlife and wildlife products.
- 11 • Ideally, all trade in live wildlife and wildlife products should be illegal or, at a minimum, heavily
12 regulated and highly discouraged.
- 13 • Develop outreach programs to inform the public and military about the negative (and in some
14 cases, lethal) consequences of wildlife disease introductions.
- 15 • Stop existing wildlife populations from interacting with introduced wildlife at ports of entry.
- 16 • Conduct background surveys at ports of entry to ensure customs and quarantine personnel are
17 familiar with the local animals in the area.
- 18 • Develop a reference collection of plausible wildlife (i.e., taxidermy mounts) to aid in the
19 identification of incoming species. In addition, adequate resources (taxonomic keys,
20 microscopes) should be available for the assistance in taxonomic identifications.
- 21 • Set up an agreement with a genetics laboratory to identify species that cannot be identified
22 through general morphology. In some instances, a genetics laboratory might also be useful in
23 determining the origins of wildlife if an appropriate marker library has been developed for the
24 species in question.
- 25 • Develop action plans for inadvertent wildlife introductions.
- 26 • Randomly sample imports (e.g., cargo containers, ships, planes) for wildlife. This may include
27 actively trapping in the aforementioned vessels and containers to detect small, nocturnal, and
28 secretive species. Be aware that some wildlife species are nocturnal while others are diurnal. As
29 such, sampling programs may need to be modified to account for this behavioral ecology.
- 30 • Conduct periodic inspections of markets and pet shops for prohibited species.
- 31 • Utilize active rodent control methods in areas harboring incoming cargo.
- 32 • Establish surveillance/early detection programs for pathogens emerging in Pacific Rim countries.
- 33 • Establish isolated and/or captive populations of endemic wildlife to prevent extinction in
34 response to outbreaks.

1 **A6 LIVESTOCK AND POULTRY DISEASES⁹**

2 **A6.1 SUMMARY**

3 The following risk assessment was prepared to identify the increased risks of poultry and livestock
4 disease agents entering the Micronesia Region as a result of the planned military relocation on Guam.
5 We used primary data sources whenever possible, supplemented by substantial literature review when
6 they were not, and used standard methods defined by the OIE.

7 We limited our consideration of the impacts to humans and pet dogs, cats, and birds to those that arise
8 from their association with livestock or poultry disease hazards. In interpreting our findings, it is also
9 important to note that we did not assess or define a baseline risk, but focused only on that incremental
10 change in risk attributable to the influx of people and the associated changes that will come during the
11 course of the relocation. The inevitable outcome of this approach is the paradox that we may conclude a
12 risk to be present or even significant, yet discount it from further consideration if there is not an
13 increase in risk that we can attribute to the military relocation. This is an unfavorable shortcoming of
14 the approach used and should not be overlooked.

15 Our key findings are summarized in Table A6-1 below and at the end of this document. An estimate
16 appears for each of the possible means (pathways) by which a given hazard might be introduced into
17 Guam or the Micronesia Region. We considered the various preventive measures that might be in place,
18 including regulations, prohibitions and inspection procedures, and which when effective, should
19 mitigate against a hazard (although in reality these measure are likely not currently fully functional and
20 without significant capacity building efforts will remain as such even for current import levels).
21 Conversely we provide an estimate for the possible illegal pathways that might bypass these measures,
22 including smuggling activities. If we assume that a hazard could be released, we estimated the likelihood
23 that animals will become exposed, thereby allowing for spread and establishment of the hazard. Finally,
24 we provide a combined estimate of risk that incorporates likelihood of hazard release and exposure,
25 with an estimate of consequences to Guam, the Micronesia Region, and the rest of the United States.

26 We found that in most cases regulations are in place to mitigate the likelihood of the hazard being
27 introduced. Further, we found that any incremental increase in risk for most hazards, specifically related
28 to the relocation, was relatively small. However, there are pathways where the increased traffic related
29 to the relocation may overwhelm the mitigations currently in place. Current mitigation measures are
30 already overwhelmed in most locations and in need of additional capacity support. In addition, these
31 same mitigation measures could be bypassed by illegal means in certain pathways, or if the measures
32 were inconsistently or ineffectively applied. Smuggling of poultry or the illegal importation of food and

⁹ This section was prepared by: 1)APHIS-Veterinary Services, Centers for Epidemiology and Animal Health, 2150 Centre Avenue, Building B, Fort Collins, Colorado 80526; 2) Veterinary Services, Western Region Office, Fort Collins, Colorado; and 3) Veterinary Services, National Center for Import and Export, Regionalization Evaluation Services, Raleigh, North Carolina. Suggested citation: Veterinary Services, Centers for Epidemiology and Animal Health. 2010. Livestock and poultry diseases. In Terrestrial plant and animal health risks associated with the U.S. military build-up in the Micronesian Region. United States Department of Agriculture, Animal and Plant Health Inspection Service. Washington, D.C.

1 other animal products would bypass the normal regulations and inspection procedures, as might the
 2 improper disposal of domestic and international garbage. Each of these hazards could result in the
 3 introduction and spread of foreign animal disease agents to susceptible domesticated and feral animals.
 4 In addition, their impact could extend beyond Guam and the Micronesia Region, posing a risk for spread
 5 to the rest of the United States that could impact trade with other countries. While the risks for any
 6 given hazard associated with the relocation are relatively low, it is these types of hazards that should
 7 receive attention as plans proceed.

8 **Table A6-1: Summary of Risk Analysis Results**

Pathway	Release Assessment			Consequence Assessment			Risk estimation
	Legal introduction	Illegal introduction	Exposure assessment	Guam	Micronesia Region	United States ^c

14

15 **A6.2 INTRODUCTION**

16 This analysis was prepared by USDA-APHIS, at the request of the DoD. The purpose of this analysis is to
 17 assess the likelihood that the military relocation will be associated with an increase in the risk of
 18 livestock or poultry infection in the Micronesia Region with a disease agent that is exotic to the region.
 19 For the purpose of this risk assessment, we define a disease agent as an etiologic agent of an OIE-
 20 notifiable disease of livestock or poultry (OIE 2010e).

21 While the scope of this risk analysis includes the entire Micronesia Region, many of the perspectives
 22 presented herein focus on Guam. The majority of DoD activities will occur directly on Guam, making this
 23 the area where consequences will be felt most immediately. In addition, Guam is the largest point of
 24 entry for the Micronesia Region, serving as both the gateway and bellwether for the rest of the Region;
 25 one assumption of our analysis is that exotic species issues significant in Guam are relevant throughout
 26 the Micronesia Region. Because Guam serves as a hub to the rest of the Micronesia Region, the risk to
 27 Guam serves as a proxy for the entire Micronesia Region. It may be convenient for importers to use

1 CNMI for transshipment of goods needed for the relocation on Guam. However, they would still need to
2 comply with CNMI regulations, which, for animal disease concerns, are similar to those in the rest of the
3 Micronesia Region. We consider impacts to individual islands in the Region if there is a specific concern
4 associated with the pathway.

5 We include impacts to human and companion animal health only as related to the livestock and poultry
6 disease agents that we consider. We consider wildlife and feral animals only as potential vehicles for
7 exposure or spread of disease agents or their vectors. It is important to note that livestock are culturally
8 important in the Micronesia Region, and cultural and societal impacts might be more significant than
9 economic consequences; however, this assessment does not take into consideration these intrinsic
10 values.

11 **A6.3 RISK ASSESSMENT**

12 **A6.3.1 Methods**

13 The methods we use in this risk analysis follow the guidelines outlined in the OIE Terrestrial Animal
14 Health Code for import risk analysis (OIE 2010c). An import risk analysis, as defined by the OIE, includes
15 a hazard identification step, followed by a risk assessment. The risk assessment components are release,
16 exposure, and consequence assessments, followed by risk estimation. Below, we briefly summarize the
17 methods we used for each step of this analysis. We used a qualitative approach in our analysis because
18 insufficient information is available for meaningful quantitative assessment.

19 **A6.3.1.1 Hazard Identification Methods**

20 For the purpose of this analysis, we define a hazard as a disease agent that causes clinical illness in
21 livestock or poultry, or an arthropod vector of such a disease agent. We limit disease agents to the
22 etiologic agents of OIE-notifiable diseases of livestock and poultry (OIE 2010e). Animal diseases are
23 listed as OIE-notifiable based on potential for rapid or international spread, zoonotic transmission, or
24 significant mortality or morbidity, by agreement of the World Assembly of OIE Delegates (OIE 2010b, a).
25 We define livestock and poultry as follows.

- 26 • Livestock: Domesticated ruminants (cattle, carabaos, sheep, and goats), domesticated swine
27 including feral swine, and domesticated equids (horses, mules, and asses).
- 28 • Poultry: Chickens, doves, ducks, geese, grouse, guinea fowl, partridges, peafowl, pheasants,
29 pigeons, quail, swans, and turkeys, including eggs for hatching (9 CFR § 93.100).

30 We excluded from our analysis hazards that are known or suspected to be present in the Micronesia
31 Region.

32 **A6.3.1.2 Pathways Risk Analysis Methods**

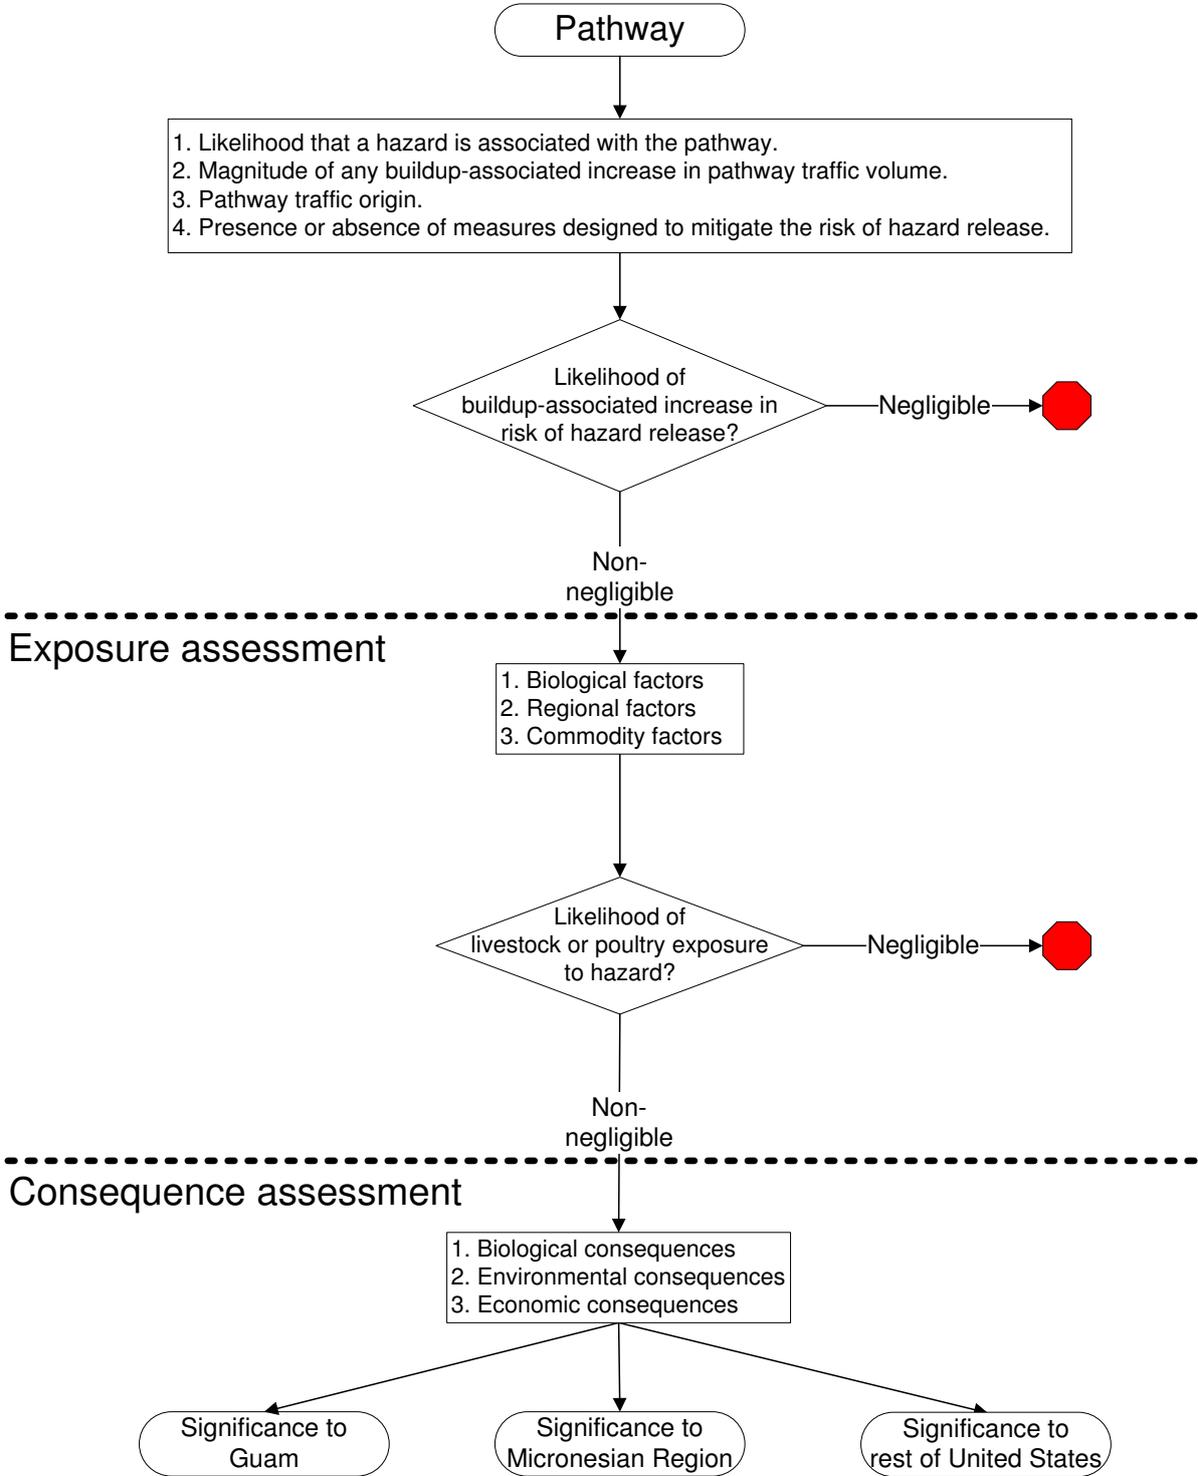

33 First, we identified and characterized pathways by which hazards could be released into the Micronesia
34 Region. Second, we determined which pathways are likely to increase in traffic volume as a direct or
35 indirect result of the military relocation. For each pathway likely to increase in traffic volume as a result

1 of the relocation, we performed a risk assessment, consisting of release, exposure, and consequence
2 assessments, as outlined in Figure A6-1.

3

1 **Figure A6-1: Risk Assessment: Release, Exposure, and Consequence Assessments**

Release assessment

2
3

1 For each pathway likely to increase in traffic volume as a result of the relocation, we qualitatively
 2 assessed the likelihood that the military relocation will be associated with an increase in the risk of
 3 hazard release into the Micronesia Region through that pathway. Hazard release into the Micronesia
 4 Region by any of the pathways requires the presence of the hazard in the country of origin; the presence
 5 of the hazard in the pathway; and passage of the hazard through any mitigation procedures, such as
 6 inspection or quarantine. Therefore, for each release pathway, we based our likelihood estimation on:
 7 1) the likelihood that a hazard is associated with the pathway, 2) the magnitude of any relocation-
 8 associated anticipated increase in pathway traffic volume, 3) pathway traffic origin, and 4) the presence
 9 or absence of measures in place that are designed to mitigate the risk of hazard release.

10 Then, for each pathway for which the release assessment result was non-negligible, we qualitatively
 11 assessed the likelihood of exposure of livestock or poultry in the Micronesia Region to hazards released
 12 through that pathway. We based our likelihood estimation on: 1) biological factors, such as disease
 13 agent survival characteristics; 2) regional factors, such as cultural practices and livestock demographics;
 14 and 3) commodity factors, such as the intended use of imported animals.

15 We expressed our likelihood estimates for release and exposure qualitatively, as negligible, very low,
 16 low, medium, high, or very high. These categories are intended to indicate relative likelihoods among
 17 the pathways. The levels are described in Table A6-2.

18 **Table A6-2: Risk Assessment Estimation Terms and Definitions**

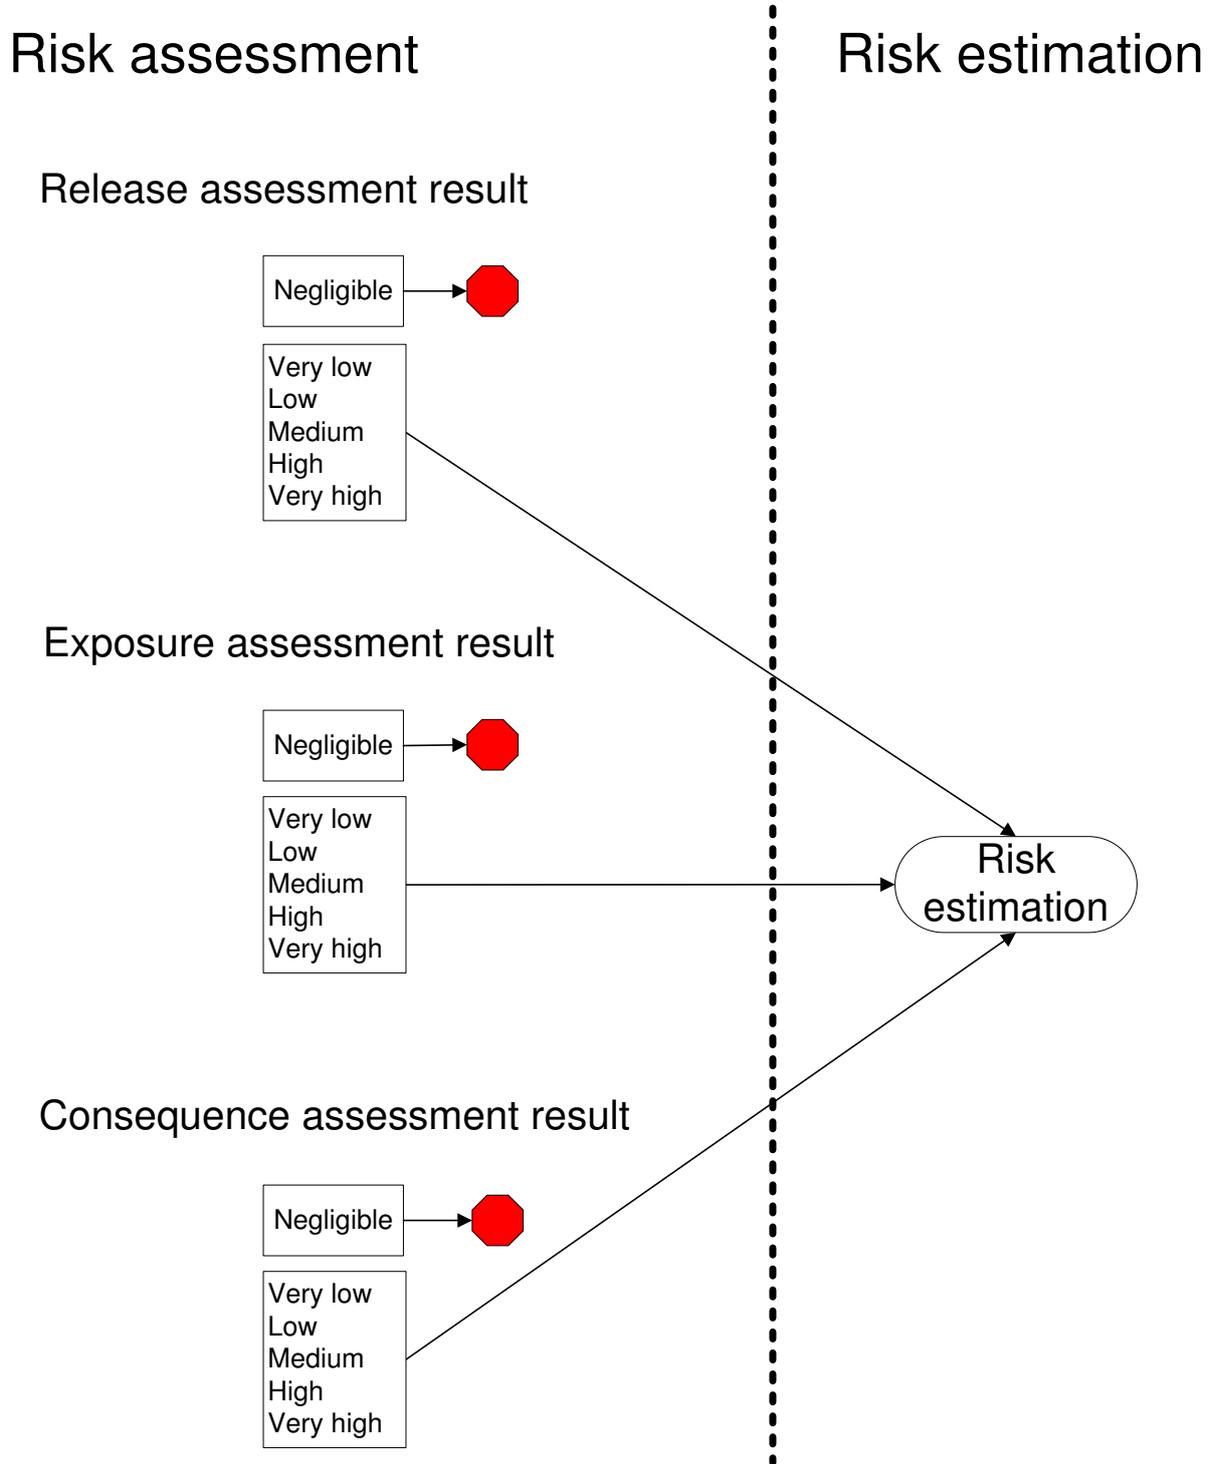

Term	Definition
Negligible	So rare that it does not merit consideration
Very Low	Very rare but cannot be excluded
Low	Rare but does occur
Medium	Occurs regularly
High	Occurs very often
Very High	Occurs extremely often

19
 20 For each pathway for which the exposure assessment result was non-negligible, we qualitatively
 21 evaluated the consequences of livestock or poultry exposure to hazards. The scope of the consequence
 22 assessment is limited to biologic, environmental, and economic consequences, in keeping with the OIE
 23 guidelines for import risk analysis (OIE 2010c). The biological consequences we considered include
 24 hazard characteristics, such as disease agent transmissibility; the number of susceptible host species;
 25 and the magnitude of impact of host species infection, in terms of morbidity and mortality. We
 26 considered biodiversity and impacts on environmental resources as environmental consequences of
 27 hazard exposure. The economic consequences we considered include the magnitude of production and
 28 trade losses and costs associated with surveillance and disease control as a result of host species
 29 exposure or infection.

30 We evaluated consequences in terms of significance to Guam, the Micronesia Region, and the rest of
 31 the United States, and expressed our results qualitatively as negligible, very low, low, medium, high, or
 32 very high. These categories are intended to indicate relative significance among the pathways.

1

Figure A6-2: Risk Estimation

2

3 For each pathway for which the consequence assessment result was non-negligible, we integrated the
4 results of the release, exposure, and consequence assessments to produce an overall measure of risk
5 posed by the pathway (Figure A6-2). We expressed risk levels qualitatively, as negligible, very low, low,

1 medium, high, or very high. These categories are intended to indicate relative risk levels among the
2 pathways.

3 **A6.3.1.3** *Animal Health Data Sources and Limitations*

4 The information evaluated for this assessment includes data gathered from relevant scientific literature
5 and other public sources, information provided to APHIS by the DoD, and information gathered by APHIS
6 during two site visits to the Micronesia Region in November 2009 and January 2010. For information
7 regarding livestock numbers and industry trends, we relied primarily on the most current USDA Census
8 of Agriculture (2007) (USDA-NASS 2009b, a).

9 During the site visits to the Micronesia Region, APHIS staff interviewed staff of the University of Guam as
10 well as federal and local government staff and agricultural industry representatives in Guam, CNMI,
11 Palau, and FSM. Agencies represented include GCQA, GDOA, PPQ, the Joint Guam Program Office, the
12 U.S. Army Veterinary Command, and NAVFAC Pacific. In addition, APHIS staff visited animal production
13 facilities, animal research facilities, maritime and air ports of entry, postal facilities, and garbage
14 handling facilities.

15 Veterinary and laboratory infrastructure is not well developed in the Micronesia Region, where no
16 formal, systematic surveillance of animal health occurs (Poole 2009; SPC 2010). Therefore, little
17 information is available regarding the status of animal health in the Micronesia Region. Our sources for
18 animal health information include the OIE databases Handistatus II and the World Animal Health
19 Information Database, which include sporadic reports for some island groups in the Micronesia Region
20 from 1997 to 2010 (OIE 2004, 2010h). We also sourced reports of convenience sampling-based surveys
21 of livestock health conducted in the 1990s in Guam, Palau, and FSM (Saville 1999; Duguies et al.
22 2000; Simms 2000).

23 Because data about tick interceptions from live animals, live plants, and inanimate articles arriving in
24 Guam and elsewhere in the Micronesia Region are sparse, we used data on ticks intercepted from
25 imports entering the United States to characterize the potential risks of tick-transporting pathways.
26 Databases we used include the USDA national tick survey database which includes records from 1969
27 through 2006, and the USDA-APHIS-PPQ pest interception database which includes records from 1989
28 through 2009, as well as published reports of tick surveys (USDA-APHIS-VS CEAH 2006; USDA-APHIS-PPQ
29 2010a). Data on mosquitoes in tropical climates were more widely available.

30 In general, the data supporting this analysis are sparse and incomplete. Thus, our conclusions should be
31 interpreted with caution, in the context of high levels of uncertainty.

32 **A6.3.1.4** *Assumptions*

33 We assume that current regulations and inspection and quarantine procedures designed to mitigate
34 hazard release are effectively enforced; and that the origins of pathway movement to the Micronesia
35 Region will not substantially change as a result of the military relocation. We realize that our first

1 assumption is not likely true, as is pointed out elsewhere within the MBP and this section. This is a
 2 unfortunate element of our risk assessment and may lead to less than ideal conclusions.

3 **A6.3.2 Hazard Identification**

4 We categorized our hazards as disease agents or vectors. Below, we list these hazards, further
 5 categorized based on whether they are known or suspected to be present in the Micronesia Region, or
 6 not known or suspected to be present in the Micronesia Region.

7 **A6.3.2.1 Disease Agents**

8 A list of disease agents that are known or suspected to be present in the Micronesia Region is presented
 9 in Table A6-3. Other disease agents might exist in the Micronesia Region, but where available data
 10 sources are not sufficient to allow us to conclude with confidence that they are present, we assume that
 11 they are not.

12 Because available data are inadequate to determine baseline and overall risk for the introduction of
 13 disease agents, our assessment is limited to the additional risk posed by the relocation on potential
 14 disease agents and their pathways. Similarly, we did not consider the risk for increased introduction of
 15 pathogens already known or believed to be present on Guam or in the Micronesia Region, nor new
 16 strains of these same pathogens. Thus, we did not consider these indigenous disease agents further in
 17 our analysis.

18 A list of disease agents that are not known or suspected to be present in the Micronesia Region is
 19 presented in Table A6-4. These disease agents are the focus of our analysis.

A6.3.2.2 Vectors

Several of the disease agents that we consider in our analysis can be transmitted by arthropod vectors, such as ticks, mosquitoes, or midges. Introduction and establishment of exotic vectors can increase the likelihood of disease agent transmission to a susceptible vertebrate host (Korch Jr. 1994), and can be associated with disease outbreaks. For example, *Dermacentor (Anocenter) nitens*, a tick species that had not been seen in Florida prior to 1958, was the primary vector for an equine piroplasmosis outbreak in Florida during the 1960s (Strickland and Gerrish 1964; Knowles et al. 1966; Becklund 1968; Holbrook 1969).

1 Based on our list of disease agents (see Table A6-4), we developed a list of vectors of those disease
 2 agents. As we did for disease agents, we categorized the vectors based on whether they are known or
 3 suspected to be present in the Micronesia Region, or not known or suspected to be present in the
 4 Micronesian Region.

5 A list of vectors that are known or suspected to be present in the Micronesia Region is presented in
 6 Table A6-5. We did not consider these vectors further in our analysis. Although other vectors might be
 7 present in the Micronesia Region, where available data sources are not sufficient to allow us to conclude
 8 with confidence that they are present, we assume that they are not.

2 ^b Not all species of all families or genera transmit each of the etiologic agents of the diseases listed.

3 **A6.3.3 Pathways Risk Analysis**

4 Hazards can move into, through, or out of the Micronesia Region through any of numerous pathways,
5 including movement of infected live animals or contaminated cargo. Types of movement can be
6 categorized in terms of whether the movement is initiated by people (intentional movement),
7 proceeding through either legal or illegal means, or not initiated by people (accidental movement), such
8 as through natural spread or stowing away on conveyances. For the purpose of this analysis, stowaways
9 are animals, including arthropods, which are carried by, but are not biologically associated with, a
10 conveyance.

11 We defined pathways based on categories of traffic movement to which animal health import risk
12 mitigations are typically applied (CFR; 9 GARR 1, Division 1, Chapter 1; OIE 2010g; USDA-APHIS 2010b).
13 Table A6-7 lists the pathways that we considered feasible for transporting hazards along with the
14 expected direct and indirect effects of the military relocation on pathway traffic volume, based upon the
15 data and discussion elsewhere in this document. We excluded from further analysis pathways for which
16 traffic volume is not expected to increase as a result of the relocation.

1 **Table A6-7: Pathways and the Effect of the Military Relocation on Pathway Traffic Volume**

Pathway	Description	Effect of military Relocation on Pathway Traffic Volume
<i>Livestock</i>		
Domesticated ruminants	Cattle, carabaos, goats, and sheep	No effect
Swine	Domesticated swine, including feral swine	No effect
Domesticated equids	Horses, mules, and asses	Increase
Livestock germplasm	Semen, ova, and embryos of livestock	No effect
<i>Birds</i>		
Poultry	Chickens, doves, ducks, geese, grouse, guinea fowl, partridges, peafowl, pheasants, pigeons, quail, swans, and turkeys, including eggs for hatching	Increase
Non-poultry birds	All birds, except poultry	Increase
<i>Cats and dogs</i>		
	Domesticated cats, and domesticated dogs, including working dogs	Increase
<i>Other animals</i>		
Large mammals	Ungulates and carnivores, other than livestock and domesticated cats and dogs	No effect
Small mammals	Small mammals species common in the pet trade, including rodents, lagomorphs, and hedgehogs	Increase
Reptiles and amphibians	Lizards, snakes, turtles, tortoises, frogs, toads	Increase
<i>Humans</i>		
	People and their accompanying baggage	Increase
<i>Animal products</i>		
	Products of animal origin, including meat and meat products, milk and milk products, blood and blood products, skins, feathers, wool and hair, animal feed containing products of animal origin	Increase
<i>Garbage</i>		
	All waste material that is derived in whole or in part from fruits, vegetables, meats, or other plant or animal (including poultry) material, and other refuse that has been associated with any such material	Increase
<i>Other cargo</i>		
	Live plants and inanimate objects, excluding animal products and garbage	Increase
<i>Conveyances</i>		
	Aircraft, maritime vessels, and shipping containers	Increase

2

3 Detailed data on the trends in live animal imports are available elsewhere in this document. We do not
 4 expect demand for imports of domesticated ruminants or swine into the Micronesia Region to increase
 5 as a result of the relocation. The USDA Census of Agriculture documents the decline of livestock farming
 6 in Guam; both the number of farms and the numbers of cattle, carabaos, goats, and swine have
 7 decreased in Guam over the past decade, and the relocation will place additional negative pressure on
 8 animal agriculture through increased urbanization and competition for land resources (USDA-NASS
 9 2009a; U.S. Navy 2010a). Horseback riding is a popular adventure travel activity, and the adventure

1 travel industry is growing worldwide (Heyniger 2006). Therefore, increases in population and tourism in
2 the Micronesia Region may increase demand for animals associated with recreational activities,
3 particularly horseback riding. Livestock industries in the Micronesia Region have not adopted assisted
4 reproduction practices, such as artificial insemination or embryo transfer, to any degree and this is not
5 expected to change (Duguies et al. 2000; Poole 2009). We expect the demand for game fowl used in
6 cock fighting to increase during the military relocation, and therefore, imports of live poultry and
7 hatching eggs may increase as a result. The increase in the human population in the Micronesia Region
8 will likely be accompanied by an increase in demand for exotic pets, including birds, small mammals, and
9 reptiles.

10 The relocation will be associated with a substantial increase in maritime and air conveyance traffic to
11 the Micronesia Region. This traffic will support substantial increases in the volume of movement of
12 people, animal products, garbage, and other cargo.

13 **A6.3.3.1 Livestock**

14 Livestock can be moved legally or they can be smuggled onto Guam; due to geographic barriers,
15 accidental movement (straying) is not feasible.

16 Overall, livestock populations in the Region are declining (USDA-NASS 2009a, b). However, compared to
17 other islands in the Region, beef cattle production on Tinian is large scale, with over 1,000 animals
18 distributed among approximately 60 farms (USDA-NASS 2009b). The military is planning to increase
19 training activities on Tinian, related to the relocation.

20 Cattle producers on Tinian are interested in improving production and range management practices, as
21 well as increasing the size of their industry (Jimenez et al. 2009). Additionally, they are interested in
22 developing a certified slaughter industry so they can sell their beef throughout the Region. However,
23 current business opportunities for the beef cattle industry in Tinian are hampered by the lack of
24 veterinary infrastructure, meat inspection services, and, possibly, by expansion of military operations.

25 At present, Tinian cattle are raised on the lease-back area controlled by the military. Expansion of
26 training activities may result in reduced access to that land for grazing. This is a concern for Tinian
27 ranchers. In addition, there is a concern that training activities may include weapons training, which
28 could have a negative impact on cattle production (Jimenez et al. 2009).

29 While cattle production on Tinian may be impacted by military training activities, we do not expect that
30 the military relocation will directly or indirectly increase legal or illegal traffic volume to the Region in
31 most types of livestock, namely domesticated ruminants, swine, or their germplasm. Traffic volume in
32 domesticated equids (horses, mules, and asses) to Guam might increase as a result of the military
33 relocation. Therefore, we consider only those hazards associated with domesticated equids in the
34 release and exposure assessments of the livestock pathway. We consider only intentional movement of
35 domesticated equids to the Micronesia Region through legal means; smuggling of domesticated equids
36 to the Micronesia Region is infeasible due to geographic barriers.

A6.3.3.1.1 Hazards Associated with the Livestock Pathway

Domesticated equids can play three roles in the transport of hazards: they can be infected hosts, they can be contaminated with disease agents and serve as fomites, or they can serve as hosts to tick vectors of disease agents. Table A6-8 lists hazards that are associated with domesticated equids through these three roles, including hazards for which domesticated equids may serve as dead-end hosts or play a minor or theoretical role in transmission.

^b Not all species of all genera feed on domesticated equids.

A6.3.3.1.2 Release Assessment: Livestock Pathway

Likelihood of Hazard Association

Infected domesticated equids are the primary source for the etiologic agents of African horse sickness, contagious equine metritis, dourine, equine infectious anemia, equine piroplasmosis, and glanders (CFSPH 2006a, 2007f, 2008b, 2009f, g, i). Domesticated equids can be infected with and serve as reservoirs for Nipah, rabies, Venezuelan equine encephalitis, and vesicular stomatitis viruses, but they are not the only, or the most important, hosts (CFSPH 2007j, 2008g, 2009m; OIE 2009u). Other hosts are epidemiologically more important than domesticated equids for harboring screwworms, *Echinococcus* spp., and *Leishmania* spp. parasites (Eckert and Deplazes 1999; CFSPH 2009k; OIE 2009q; Pavlin et al. 2009). Domesticated equids can be infected with, but do not serve as reservoirs for transmission of, *M. bovis*, and eastern equine encephalitis, Japanese encephalitis, western equine encephalitis, and WNV (Calisher 1994; CFSPH 2007h; 2009c, q).

African swine fever, classical swine fever, and foot and mouth disease viruses can be mechanically spread by domesticated animals, such as equids, which have been in contact with affected premises (CFSPH 2007e, 2009d, 2010a).

Domesticated equids are frequently reported hosts for tick species that are competent vectors for equine piroplasmosis, and less frequently host tick species that are competent vectors for heartwater (Estrada-Peña et al. 2004).

Traffic Volume

Detailed data on livestock imports are available elsewhere in this document. According to the Territorial Veterinarian of Guam, no livestock, including domesticated equids, have been imported to Guam over the last five years (Poole 2009). The equine industry on Guam is small; the USDA Census of Agriculture (2007) identified only two farms with horses on the island (USDA-NASS 2009a). The high cost of feed, most of which is imported, and the lack of services, such as farriers and equine practitioners, are cited as challenges to keeping horses on Guam (Earth.org 2009). If the volume of domesticated equid imports to Guam increases as a result of increased demand by the tourism industry, we expect the numbers to be very small. We do not expect the military relocation to be associated with an increase in traffic volume of domesticated equids to the rest of the Micronesia Region.

1 ***Traffic Origin***

2 Any domesticated equids imported onto Guam will likely originate in the mainland United States, due to
3 Federal regulations pertaining to importation of livestock, discussed below in mitigations. The United
4 States is free of African horse sickness, African animal trypanosomiasis, dourine, foot and mouth
5 disease, glanders, heartwater, Japanese encephalitis, Nipah virus encephalitis, screwworms, surra, and
6 Venezuelan equine encephalomyelitis (USDA-APHIS 2008b). Outbreaks of contagious equine metritis,
7 equine piroplasmiasis, and vesicular stomatitis have recently occurred in parts of the United States
8 (Webb et al. 1987; OIE 2008c; CFSPPH 2009f; OIE 2009c, v).

9 ***Mitigations***

10 APHIS regulations governing the importation of domesticated equids are set forth in 9 CFR Part 93.
11 These regulations pertain to the movement of horses, mules, asses, and zebras from foreign countries
12 into any of the 50 States, the Commonwealth of Puerto Rico, CNMI, the District of Columbia, and any
13 territories and possessions of the United States. Domesticated equids intended for importation into the
14 United States from any part of the world must be shipped directly to an approved port and be
15 quarantined at the port until negative results to specified tests, depending upon the country of origin,
16 are obtained and the equids are certified by the port veterinarian to be free from clinical evidence of
17 disease. In special cases, unapproved ports may be designated as quarantine stations by the APHIS
18 Administrator. No ports on Guam are approved for importation of livestock, and therefore, at this time,
19 horses intended for import to Guam must first enter through ports in the continental United States.

20 Prior to importation, each domesticated equid must be inspected by a veterinarian at the premises of
21 origin and found free of evidence of or exposure to communicable disease. Domesticated equids
22 intended for import to the United States from regions affected by screwworm, contagious equine
23 metritis, and Venezuelan equine encephalomyelitis are subject to inspection or treatment procedures
24 specified in 9 CFR § 93.308. Imported domesticated equids, with limited exceptions for those originating
25 in certain countries, cannot enter the United States until they have been tested for equine infectious
26 anemia, equine piroplasmiasis, dourine, and glanders by an official test with negative results. Before a
27 horse imported from any part of the world is released from the port of entry into the United States, an
28 inspector may require the horse and its accompanying equipment to be disinfected as a precautionary
29 measure against the introduction of foot and mouth disease or any other disease dangerous to the
30 livestock of the United States (9 CFR § 93.314).

31 APHIS regulations pertaining to interstate movement of domesticated equids are set forth in 9 CFR §§ 71
32 and 75. Animals, including domesticated equids, affected with any communicable disease are generally
33 prohibited from interstate movement. Domesticated equids affected with equine piroplasmiasis,
34 dourine, glanders, contagious equine metritis, or screwworms may not be moved interstate.
35 Domesticated equids that have tested positive on an official test for equine infectious anemia are
36 prohibited from moving interstate, except under limited circumstances.

37 Specific regulations regarding the importation of live animals onto Guam can be found in the Guam
38 Administrative Rules and Regulations (9 GARR 1, Division 1, Chapter 1). No animals that are affected

1 with or have been exposed to an infectious, contagious, or communicable disease or ectoparasites or
2 which originated in an area under state or federal quarantine shall be permitted to be introduced into
3 Guam. Horses are subject to specific mitigations to prevent the entry of equine infectious anemia, and
4 Eastern, Western, and Venezuelan equine encephalomyelitis viruses.

5 ***Summary***

6 Traffic volume in domesticated equids to Guam might increase as an indirect result of the military
7 relocation (increased demand for recreational activities). However, we expect that the increase in traffic
8 volume will be very small. Due to federal regulations governing the importation of livestock,
9 domesticated equids intended for importation to Guam are highly likely to originate in the continental
10 United States, which is free of most of the hazards for which domesticated equids are the primary
11 source. The risk of importation or interstate movement of hazards for which domesticated equids might
12 play a significant role in transporting to Guam is mitigated by APHIS and Guam territorial regulations.

13 ***Livestock Pathway Release Assessment***

14 The increased risk of release of hazards into the Micronesia Region due to the military relocation
15 through the livestock pathway is negligible.

16 ***Livestock Pathway Risk Estimation***

17 Because the increased risk of release of hazards into the Micronesia Region due to the military
18 relocation through the livestock pathway is negligible, we conclude that the military relocation-
19 associated overall risk for the livestock pathway is negligible.

20 **A6.3.3.2 Poultry**

21 For the purpose of this risk assessment, poultry are chickens, doves, ducks, geese, grouse, guinea fowl,
22 partridges, peafowl, pheasants, pigeons, quail, swans, and turkeys, including eggs for hatching. In this
23 pathway, poultry can be moved legally or illegally; due to geographic barriers and characteristics of
24 these species, we do not consider accidental movement (straying, migration, or stowing away) feasible.

25 We expect the popularity of cock fighting to temporarily increase during the military relocation because
26 most temporary workers are expected to come from the Philippines (U.S. Navy 2010a). Cock fighting is
27 very popular in the Philippines and is a major source of entertainment for Filipino immigrants in the
28 continental United States (Bautista 1998). Additionally, previous waves of temporary construction-
29 associated immigration from the Philippines have resulted in increased fight attendance (Sgambelluri et
30 al. 2009).

31 Federal regulations and APHIS policy restrict importation of live poultry, poultry products, and hatching
32 eggs from regions affected by exotic Newcastle disease (END) or HPAI subtype H5N1; several of these
33 regions include Asia-Pacific countries (9 CFR §§ 93.201 and 94.6). Live poultry permitted to enter the
34 United States (except those from Canada) must be inspected, quarantined for 30 days, and tested at a
35 quarantine facility on the mainland United States (9 CFR § 93.209). Importers bear the cost of these
36 import requirements. The importation of hatching eggs is restricted from countries affected by END,

1 which includes the Philippines and several other Asia-Pacific countries (9 CFR § 93.209). These
 2 regulations reduce the practicality of importing foreign poultry (including hatching eggs and game cocks)
 3 to Guam from Asia-Pacific countries.

4 Experts believe the worldwide movement of people and their demand for familiar, culturally important
 5 foods and traditional items leads to the smuggling of poultry, particularly hatchlings and hatching eggs
 6 (Rosenthal 2006). Temporary foreign workers related to the relocation are expected to come primarily
 7 from Asia-Pacific countries where cock fighting is popular (Jimenez et al. 2009; Poole 2009). These
 8 workers may be tempted to smuggle fighting fowl onto Guam in order to circumvent import
 9 requirements. We expect that the military relocation will increase the volume of illegal traffic in live
 10 poultry, particularly chickens and chicken eggs for hatching.

11 Because of increased urbanization and competition for land resources on Guam, the relocation will place
 12 additional negative pressure on animal agriculture; therefore, we do not expect shipments of live
 13 poultry for commercial purposes to increase. Nor do we expect that the increased number of military
 14 personnel or their dependents will result in increased importation of pet poultry species. The high cost
 15 of shipping and health certification relative to the perceived value of these birds is likely a deterrent to
 16 bringing pet poultry to Guam. For example, the cost of shipping a bird from Hawai'i to Guam, including
 17 fees for health certification, shipping box, and air freight, exceeds \$75.00 (Poole 2009). In addition,
 18 military regulations prohibit poultry in private housing (U.S. Army 2008).

19 **A6.3.3.2.1 Hazards Associated with the Poultry Pathway**

20 Poultry can transport hazards in three roles: they can be infected hosts, they can be contaminated with
 21 disease agents and serve as fomites, or they can serve as hosts to tick vectors of disease agents. Table
 22 A6-9 lists hazards that are associated with the poultry pathway, including hazards for which poultry may
 23 serve as dead-end hosts or play a minor or theoretical role in transmission.

3

4 **A6.3.3.2.2 Release Assessment: Poultry Pathway**

5 **Likelihood of Hazard Association**

6 Infected poultry are the primary source for the etiologic agents of avian metapneumovirus, duck virus
7 hepatitis, fowl typhoid, and pullorum (OIE 2008d, k; CFSPH 2009j; OIE 2009w). Poultry can be infected
8 with and serve as reservoirs for END, HPAI, equine encephalomyelitis, and WNV, but they are not the
9 only reservoir hosts (Calisher 1994; Falcon 2004; CFSPH 2009q; OIE 2009u; CFSPH 2010b). Infestation of
10 poultry with screwworms occurs, but is rarely reported (OIE 2009q; USDA-APHIS 2009c).

11 African swine fever, classical swine fever, and foot and mouth disease viruses can be mechanically
12 spread by domesticated animals, such as poultry, which have been in contact with affected premises
13 (CFSPH 2007e, 2009d, 2010a).

14 Commercial poultry raised in confinement are unlikely to be infested by ixodid ticks; however,
15 gamefowl, pet, and exhibition poultry may have opportunities to encounter ticks. Hyalomma ticks were
16 removed from partridge (*Perdix perdix*) offered for importation into the United States in the 1960s
17 (USDA-APHIS-PPQ 2010a).

18 **Traffic Volume and Origin**

19 Data on poultry imports are presented elsewhere in this document. We do not expect the military
20 relocation to be associated with an increase of legally imported poultry to Guam or the rest of the
21 Micronesia Region. Due to import regulations, most poultry breeding stock will likely continue to be
22 imported from the continental United States and Hawai'i. The United States is free of African swine
23 fever, classical swine fever, END, foot and mouth disease, HPAI, screwworms, and Venezuelan equine
24 encephalomyelitis (USDA-APHIS 2008b).

25 Illegal importation of live poultry, including hatching eggs, is known to occur (Poole 2009). The increased
26 interest in cock fighting, related to the number of temporary workers from the Philippines and other

1 areas where cock fighting is legal, may result in an increase in smuggling of poultry and hatching eggs.
2 END is widespread in Asia, and HPAI is present in some areas as well.

3 ***Mitigations***

4 Federal regulations and APHIS policy restrict importation of live poultry, poultry products, and hatching
5 eggs from regions affected by END or HPAI H5N1, including the Philippines and several other Asian
6 countries, and from free regions that may import and commingle live poultry originating in an END-
7 affected region (9 CFR § 92, 9 CFR § 93, 9 CFR §94). Legal poultry imports must be accompanied by an
8 import permit issued by APHIS and be received and inspected at an approved port of entry with
9 quarantine facilities. Approved bird quarantine facilities are located in New York, Miami, and Los
10 Angeles. Birds are quarantined for 30 days, during which they are tested for certain communicable
11 diseases. Since the implementation of quarantine requirements in 1972, introductions of END through
12 legal importation of live birds declined substantially and were essentially eliminated after the
13 requirements for approval of private quarantine facilities were strengthened in 1979 (USDA-APHIS-VS
14 2005).

15 A 2002 modification to the Animal Welfare Act made interstate trade of a bird or birds for the purpose
16 of fighting illegal, regardless of the law in the destination state, including Guam (USDA-APHIS-VS 2003a).
17 However, this amendment does not restrict the possession of fighting fowl for breeding or as show
18 birds. In response to the changes to the Animal Welfare Act, United Airlines stopped accepting
19 shipments of live adult poultry in 2007, although the airline continues to carry day-old poultry and
20 hatching eggs (Huemer 2007). United Airlines provides air freight service to the Micronesia Region.

21 Guam territorial regulations require all imported birds and hatching eggs to be accompanied by an entry
22 permit and a health certificate approved by the chief livestock sanitary officer, or a state or federal
23 veterinarian (9 GARR 1 § 1110). The health certificate must be issued within 10 days prior to shipment
24 attesting that the bird has been found free of ectoparasites and symptoms of transmissible disease. No
25 poultry affected by or exposed to an infectious, contagious, or communicable disease or ectoparasites
26 during state or federal quarantine shall be permitted on Guam and will be returned to the point of origin
27 or destroyed.

28 Guam requires imported poultry to 1) originate from flocks and hatcheries free of pullorum disease or
29 with a pullorum controlled status; in the latter case birds must be serologically negative for pullorum
30 disease within 30 days of entry; 2) be vaccinated for NDV between 30 and 60 days prior to shipment; 3)
31 be free of symptoms of Newcastle disease or other communicable diseases at the time of shipping; and
32 4) have a health certificate issued by an accredited veterinarian (9 GARR 1 § 1110). Requirements 2, 3,
33 and 4 above do not apply to hatching eggs and day-old poultry accompanied by an affidavit from the
34 shipper stating that the flock of origin has not been exposed to and is free of Newcastle disease within
35 60 days period prior to shipment. All poultry and hatching eggs shall be shipped in new (unused)
36 containers and inspected by the territorial veterinarian or deputy prior to entry into Guam.

1 Guam has additional quarantine requirements for birds from the continental United States to prevent
2 the introduction of WNV. These birds are required to be quarantined for a minimum of seven days in an
3 approved quarantine facility or veterinary clinic followed by 30 days of isolation in a mosquito-proof
4 cage on Guam (Poole 2009).

5 USPS regulations prohibit the mailing of hatchling (day-old) poultry vaccinated for Newcastle disease.
6 Day-old chickens, ducks, emus, geese, guinea fowl, partridges, quail, and turkeys must be delivered to
7 the addressee within 72 hours of hatching (USPS 2009).

8 ***Summary***

9 The number of live poultry legally imported to Guam is unlikely to change as a result of the military
10 relocation, but the number of illegally imported live poultry is likely to increase by an unknown quantity
11 in response to demand for fighting cocks. The number of illegally imported hatching eggs may increase
12 as well. The risk of hazard release through legal entry of live poultry to Guam is reduced by inspection
13 and quarantine measures required by federal and territorial regulations. Illegally imported poultry
14 bypass mitigations intended to reduce the likelihood of release of hazards.

15 ***Poultry Pathway Release Assessment***

16 The increased risk of release of hazards into the Micronesia Region due to the military relocation
17 through legal movement of poultry is negligible.

18 The increased risk of release of hazards into the Micronesia Region due to the military relocation
19 through illegal movement of poultry is very low.

20 **A6.3.3.2.3 *Exposure Assessment: Poultry Pathway***

21 ***Biological Factors***

22 Most poultry disease agent hazards are present in the feces or secretions of infected birds and are
23 spread primarily through direct contact between birds. People, other animals, vehicles, and equipment
24 can become contaminated with poultry feces or secretions and can carry disease agents from one
25 location to another; END, e.g., is readily transmitted on fomites (CFSPH 2008d).

26 ***Regional Factors***

27 Chickens are the primary poultry species raised on Guam (USDA-NASS 2009a). Since the disappearance
28 of commercial layer operations on Guam, imports of day-old chicks have declined and most chicken
29 imports supply birds to small, backyard flocks for domestic consumption or to cock fighting operations
30 (Poole 2009). Like on other islands in the Micronesia Region, a sizeable population of feral chickens
31 roams freely on Guam (Poole 2009; GTIS 2010). Epidemiologic investigations of outbreaks around the
32 world have shown the close proximity of backyard flocks, feral chickens, and cockfighting operations to
33 be related to spread of an introduced poultry disease (Awan et al. 1994; Swayne and King 2003; Falcon
34 2004). Outdoor housing and contact with feral and wild birds makes biosecurity for backyard flocks
35 problematic. Similarly, cock fighting operations facilitate the spread of poultry diseases through the
36 frequent movement and commingling of birds. END and HPAI can be spread through direct contact

1 between live birds or contact between live birds and contaminated objects such as dead birds or
2 contaminated hatching eggs.

3 If live poultry infected with an arbovirus, such as JEV or WNV, are imported to Guam or elsewhere in the
4 Micronesia Region, the disease agent could be transmitted to an existing competent mosquito vector,
5 such as *Aedes albopictus* or *Culex quinquefasciatus*, potentially resulting in establishment of the disease
6 agent (Reeves and Rudnick 1951; Mitchell et al. 1993; Lounibos 2002).

7 Guam's existing livestock population and number of imported live poultry are both small, making
8 contact between livestock and imported live poultry unlikely. Therefore, imported live poultry are
9 unlikely to have contact with and serve as fomites for exposure of livestock to African swine fever,
10 classical swine fever, and foot and mouth disease viruses.

11 **Summary**

12 Poultry imported to Guam are most likely destined for premises on which poultry already exist and have
13 exposure to feral chickens and their disease agents. Contact between livestock and imported poultry is
14 much less likely. Competent mosquito vectors for arboviruses are present in the Micronesia Region, and
15 imported live poultry infected with an arbovirus could serve as a source to infect mosquitoes.

16 **Poultry Pathway Exposure Assessment**

17 The risk of exposure of livestock or poultry to hazards released into the Micronesia Region through the
18 poultry pathway is medium.

19 **A6.3.3.2.4 Consequence Assessment: Poultry Pathway**

20 END and HPAI are hazards of high consequence associated with imported live poultry; therefore, these
21 agents are the focus of the consequence assessment for the poultry pathway. Introduction of
22 arboviruses from the importation of infected live birds, especially JEV and WNV, would have minimal
23 effects on poultry populations, though the consequence to native wild bird populations and humans
24 could be significant.

25 **Biological Consequences**

26 END and HPAI are two of the most severe poultry diseases in the world and their animal health
27 consequences are significant. For both diseases, morbidity and mortality rates vary according to the
28 strain of virus, but morbidity may approach 100% and mortality may approach 90% in susceptible
29 chickens (CFSPH 2008d, 2010b).

30 Human health consequences of END are minor and generally limited to conjunctivitis, though rare
31 serious opportunistic infections may occur in those with compromised immune systems (CFSPH 2008d).
32 Humans are not normally susceptible to infection with avian strains of influenza and the risk from HPAI
33 is therefore generally low to most people (CFSPH 2010b). However, on rare occasions, influenza viruses
34 of avian origin have become more efficient at infecting humans, causing three pandemics within the
35 past century (Rappole and Hubálek 2006). The spectrum and severity of AI symptoms in humans

1 depends on the specific viral subtype (Capua and Alexander 2004; Hirst et al. 2004) and range from
2 typical human influenza-like symptoms (e.g., fever, cough, sore throat, and muscle aches) or
3 uncomplicated eye infections, to pneumonia, acute respiratory distress and life-threatening
4 complications. In 1997, a virulent avian subtype, H5N1, was first identified as the cause of severe, yet
5 sporadic influenza illness in humans. Human cases of H5N1 have since been reported in Asia, Africa, the
6 Pacific, Europe, and the Near East according to the WHO (WHO 2010a). Indonesia and Vietnam have
7 reported the highest number of human H5N1 cases to date with mortalities of up to 60%, especially in
8 individuals hospitalized late in the course of their illness. Nearly all confirmed human cases have
9 resulted from direct contact to poultry or their excreta (WHO, CDC 2010b), with little evidence for
10 human-to-human transmission. To date, human cases of H5N1 remain rare.

11 The introduction of WNV and JEV would have minimal effects on poultry (Ghosh and Basu 2009; OIE
12 2010d). Experimental studies have shown that poultry rapidly develop an antibody response capable of
13 neutralizing the virus. Infection in chickens is typically asymptomatic or with minimal clinical signs and
14 pathology, and no mortality (Senne et al. 2000).

15 Some deaths have been reported in horses from WNV and JEV infection, though the number of clinical
16 cases is very low compared to the total number of exposed animals (CFSPH 2007h; OIE 2010d). Because
17 of the small number of horses in Guam and relatively low importance of this industry, and the
18 availability of effective vaccines to protect horses against JEV and WNV, we conclude that the biological
19 consequences of introduction of WNV or JEV to the livestock and poultry industries are negligible.

20 Guam's native birds have been driven nearly to extinction (Savidge et al. 1992). Exposure to END, HPAI,
21 or WNV could have severe negative consequences to the remaining population.

22 As in the continental United States, the major impact of WNV establishment would be to humans. Once
23 established in a tropical environment and in the absence of preventive measures, spread would be
24 expected to be rapid among human populations with no prior exposure or immunity, as would be the
25 case in Guam and throughout the Micronesia Region (Hayes et al. 2005). In humans the ratio of
26 asymptomatic to clinical infection is high and the majority of clinical illness would be limited to mild
27 febrile disease; however about one of every hundred infected may develop severe neurological disease
28 with mortality rates as high as 14% (Madden 2003).

29 Establishment of Japanese encephalitis on Guam would also be of consequence to humans, especially to
30 children. While asymptomatic infection can occur, approximately 30% of Japanese encephalitis cases are
31 fatal and nearly half result in permanent neurological sequelae (Ghosh and Basu 2009). However, any
32 such introduction might well be short lived. In 1990, a rare introduction of Japanese encephalitis on
33 Saipan ended as the population of susceptible pigs which serve as amplifying hosts became infected and
34 developed immunity, and Japanese encephalitis has not recurred (Paul et al. 1993).

35 ***Environmental Consequences***

36 Environmental consequences of END or HPAI in poultry primarily result from the disposal of large
37 numbers of carcasses due to death from disease or depopulation of flocks. Disposal of large amounts of

1 litter and manure can also be problematic. Because Guam and the rest of the Micronesia Region lack
2 large commercial poultry farms, disposal activities are unlikely to create a significant environmental
3 impact.

4 On Guam, conservation programs maintain captive breeding populations of the endangered Guam rail,
5 Micronesian kingfisher, and Marianas crow (Beauprez and Brock 1999). Guam and other islands of the
6 Micronesia Region provide the only habitat for several critically endangered bird species (Sherley and
7 Lowe 2000). Introduction of END, HPAI, or other high mortality avian diseases could have a catastrophic
8 effect on the very small populations of the Micronesia Region's endangered bird species, potentially
9 resulting in extinction.

10 The spread of WNV in the continental United States has caused a marked decline in the number of
11 particular bird species in entire regions, such as the American crow and eastern bluebirds (Rappole et al.
12 2000). Native bird populations on Guam have been severely diminished as a result of invasive species
13 and feral cats (Poole 2009); thus WNV, as with END and HPAI, could decimate remaining populations.

14 ***Economic Consequences***

15 The assessment of economic consequences is largely based on historical experience of END or HPAI
16 outbreaks in the United States, which can be characterized as having either relatively limited disease
17 spread or relatively extensive disease spread.

18 The outbreaks in 2002-2003 in Arizona, Nevada, and Texas could each be considered representative of a
19 relatively limited outbreak. Arizona and Texas each had only one premise on which infection was
20 detected; 10 infected premises were identified in Nevada. Approximately \$3.5 million were spent on
21 eradication efforts in Arizona; \$6.2 million in Nevada; and \$4.2 million in Texas (USDA-APHIS-VS 2005).

22 Eradication efforts for the extensive 2002-2003 END outbreak in California were labor intensive and
23 expensive (USDA-APHIS-VS 2005). Ultimately, birds from 920 premises in California tested positive for
24 the disease, and nearly 4 million birds were depopulated. More than \$160 million was spent on
25 eradication efforts. More than 1,500 personnel were recruited from various federal, state, county, and
26 metropolitan agencies to participate in disease control activities.

27 Information from the 2002-2003 outbreaks can be used to characterize the effects of an extensive END
28 outbreak on U.S. trade. Immediately following the confirmation of END in the United States in 2002,
29 trading partners imposed trade restrictions on live birds; fresh, frozen, or chilled poultry meat; and
30 hatching eggs from the United States (USDA-APHIS-VS 2005). At the peak of the incident, 46 countries
31 had imposed restrictions. The direct trade impacts were calculated from October 2002 to September
32 2003 for five categories of product: live poultry (other than ducks and geese), ducks and geese, poultry
33 meat and offal, hatching eggs, and table eggs. The total estimated cost of the poultry restrictions for the
34 roughly 12 month period of the END eradication effort was \$121 million, approximately 7% of the trade
35 recorded during that period. The trade losses were relatively low due to the regionalization approach
36 taken by most countries, in which imports of live birds and products were banned from only areas
37 adjacent to affected areas and/or affected areas alone.

1 Therefore, in the event of a poultry disease outbreak on U.S. islands in the Micronesia Region, involving
2 a significant hazard like END or HPAI, countries would likely use a regionalization approach, in order to
3 reduce the wider trade impacts to the United States as a whole. The local effect of trade restrictions is
4 not likely to be significant to Guam or the rest of the Micronesia Region, where no commercial poultry
5 export trade occurs.

6 Release and establishment of WNV or JEV would be expected to result in little or no economic loss to
7 the poultry industry or to the few remaining equine operations on Guam; however, significant cost
8 would be incurred for human public health and mosquito vector surveillance, and for vector control to
9 prevent spread throughout the region. A 2005 outbreak of WNV in Sacramento County, California
10 (population 1.3 million) resulted in 163 reported human cases and a response that included emergency
11 aerial spray to control vectors. Costs for aerial spray totaled just over \$700,000 and when added to
12 estimated medical costs and patients' loss in productivity, the total economic impact was estimated at
13 \$2.98 million (Barber et al. 2010).

14 ***Summary***

15 Guam's native birds have been driven nearly to extinction by predation, but conservation programs are
16 operating in the Region and exposure to END, HPAI, or WNV could have severe negative consequences
17 on their attempts to preserve avifauna biodiversity in the Micronesia Region. The islands of the
18 Micronesia Region are connected to each other, Hawai'i, and the continental United States by air and
19 sea transportation, so the appearance of END or HPAI in the Region poses a threat of introduction into
20 North America. The economic impact of trade bans due to a poultry disease outbreak in the Micronesia
21 Region is likely to be insignificant to Guam and rest of the region, which lacks commercial poultry
22 industries, but potentially significant to the rest of the United States. Regionalization policies would
23 likely reduce the trade consequences at the national level. Human health on Guam and other islands of
24 the Micronesia Region could likewise be impacted by exposure to WNV, JEV, or other arboviruses
25 released as a result of the importation of infected birds, though those risks appear limited and
26 manageable.

27 ***Poultry Pathway Consequence Assessment***

28 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
29 the Micronesia Region through the poultry pathway is low.

30 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
31 exposure to hazards released into the Micronesia Region through the poultry pathway is low.

32 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
33 hazards released into the Micronesia Region through the poultry pathway is medium.

34 ***Poultry Pathway Risk Estimation***

35 Because the increased risk of release of hazards into the Micronesia Region due to the military
36 relocation through the poultry pathway is very low, the risk of exposure of livestock and poultry is

1 medium, and the significance of consequences of livestock and poultry exposure is low, we conclude
 2 that the military relocation-associated overall risk for the poultry pathway is low.

3 **A6.3.3.3 Non-poultry Birds**

4 In this pathway, we consider the movement of birds other than poultry as previously defined in this
 5 document. Non-poultry birds moved in this pathway may be intended for zoological collections or
 6 research, or to be used as pets, performing birds, or commercial birds, which are defined as birds
 7 imported for resale, breeding, public display, or any other purpose except those already mentioned (9
 8 CFR § 93.100). Birds in this pathway may be moved through legal or illegal means. We do not consider
 9 accidental movement of non-poultry birds in our analysis because it is not expected to increase with the
 10 relocation. The risk posed by free-living birds is considered elsewhere in this document.

11 Birds are the fourth most common type of pet owned by U.S. households behind dogs, cats, and
 12 freshwater fish (APPMA 2008). Rates of pet bird ownership in the United States have remained steady
 13 for the past two decades at approximately 6% of households. Although few data are available regarding
 14 rates of pet bird ownership by military families, one survey of 184 military families found at least 7%
 15 reported keeping a pet bird (Anderson 1985). The sample for the survey was drawn from the population
 16 of military families recently transferred to duty stations in Hawai'i; roughly 16% of pet-owning military
 17 families brought their pets with them in the transfer and 41% had acquired their pet after transferring.
 18 Residents of military base housing on Guam are permitted to keep non-poultry pet birds (VETCOM
 19 2009). Therefore, we expect the military relocation to result in an increase in the number of non-poultry
 20 pet birds legally imported to the island as pets or to be sold as pets.

21 Worldwide, the illegal trade in live birds is substantial and profitable (Wyler and Sheikh 2009). The
 22 United States is considered one of the largest markets for illegal wildlife from around the world and wild
 23 birds are major commodities (Wyler and Sheikh 2009). According to the USFWS, U.S. demand for
 24 illegally imported live wild animals is driven primarily by demand for exotic pets and tourist souvenirs
 25 (Wyler and Sheikh 2009). Because the military relocation will expand the human population of Guam,
 26 demand for live birds for personal use might increase and result in increased illegal traffic of live birds.

27 **A6.3.3.3.1 Hazards Associated with the Non-poultry Birds Pathway**

28 Non-poultry birds can transport hazards in three roles: they can be infected hosts, they can be
 29 contaminated with disease agents and serve as fomites, or they can serve as hosts to tick vectors of
 30 disease agents. Table A6-10 lists hazards that are associated with the non-poultry birds pathway,
 31 including hazards for which non-poultry birds may serve as dead-end hosts or play a minor or theoretical
 32 role in transmission.

33 **Table A6-10: Hazards Associated With the Non-Poultry Birds Pathway**

Hazard	Disease	Transport role ^a	References

3

4 **A6.3.3.3.2 Release Assessment: Non-poultry Birds Pathway**

5 **Likelihood of Hazard Association**

6 Like poultry, other birds can be infected with and serve as reservoirs for equine encephalomyelitis, END,
7 HPAI, and WNV, but they are not the only reservoir hosts (Calisher 1994; Falcon 2004; CFSPH 2009q; OIE
8 2009u; CFSPH 2010b). Infected birds can serve as sources for the etiologic agents of fowl typhoid and
9 pullorum. Infestation of birds with screwworms occurs, but is rarely reported (OIE 2009q, USDA-APHIS
10 2009c).

11 African swine fever, classical swine fever, and foot and mouth disease viruses can be mechanically
12 spread by birds which have been in contact with affected premises, though it is difficult to definitively
13 link birds as a primary source for spread in outbreaks and their role remains theoretical.

14 Psittacines (parrots, cockatiels, parakeets, budgerigars, and other parrot-like pet birds), the most
15 popular pet birds in the United States, are uncommon hosts for vector hazards (Estrada-Peña et al.
16 2004, Estrada-Peña 2008). A variety of songbirds are captured and moved around the world in the caged
17 bird trade, and some of these birds, particularly the buntings, sparrows, finches, and weavers of the
18 families Emberizidae, Passeridae, and Ploceidae, are frequent hosts for European, Asian, or African ticks
19 (Estrada-Peña et al. 2004). However, only two records of tick interceptions from imported pet birds
20 were found in the USDA national tick survey database (USDA-APHIS-PPQ 2010a).

1 ***Traffic Volume***

2 According to the Territorial Veterinarian, the number of pet birds brought to Guam in recent years
3 averages less than twelve birds annually (Poole 2009). If, as we expect, the number of pet birds and
4 commercial birds imported to the island will increase relative to the increase in the human population,
5 the number of birds brought to Guam through legal means will remain small.

6 While no reliable estimates of illegal live pet bird import volumes are publicly available, analysts agree
7 that demand for illegal wildlife in the United States is likely to parallel U.S. demand for legal wildlife
8 (Wyler and Sheikh 2009). We assume this trend to be similarly true for Guam; thus demand for illegal
9 live pet bird imports would also be expected to remain small.

10 ***Traffic Origin***

11 Due to strict federal regulations, live birds imported legally to Guam as a result of the relocation are
12 likely to originate from the mainland United States. The United States is free of African swine fever,
13 classical swine fever, END, foot and mouth disease, heartwater, HPAI, Japanese encephalitis,
14 screwworms, and Venezuelan equine encephalomyelitis (USDA-APHIS 2008b).

15 Most smuggled live birds seized by U.S. officials between 2004 and 2008 originated from Mexico,
16 Central America, and South America, but smuggled birds have also been intercepted from Japan, Hong
17 Kong, and Indonesia (USDA-APHIS 2006; USFWS 2009a).

18 ***Mitigations***

19 USDA defines pet birds as those that are imported for the personal pleasure of their owners and are not
20 intended for resale (USDA-APHIS 2009a). Commercial birds are those imported for resale, breeding,
21 public display, or other similar purpose.

22 Birds not of U.S. origin must be accompanied by an import permit and be received and inspected by
23 USDA personnel at an approved port of entry with quarantine facilities. Approved bird quarantine
24 facilities are located in New York, Miami, and Los Angeles. Birds are quarantined for 30 days, during
25 which they are tested for certain communicable diseases. USDA maintains trade restrictions on the
26 importation of live birds from countries affected by HPAI H5N1 including certain countries in Africa,
27 Europe, and Asia (USDA-APHIS 2009a).

28 Importation of exotic birds into the United States must comply with APHIS and USFWS requirements.
29 Certain exotic birds are protected by CITES and the Wild Bird Conservation Act (Beissinger 2001). CBP
30 and the USFWS enforce the international trade regulations related to exotic birds. The USFWS requires
31 an importation permit and the Wild Bird Conservation Act limits imports to two birds per year, per
32 person, and that person must have been continuously residing outside the continental United States for
33 at least one year.

34 All birds entering the territory of Guam must be accompanied by an import permit and an official health
35 certificate approved by the chief livestock sanitary officer, or a state or federal veterinarian. The health

1 certificate must be issued within 10 days prior to shipment attesting that the bird(s) have been found
2 free of ectoparasites and symptoms of transmissible diseases. Animals should have a leg band number
3 identifying the scientific name of the animal. Any animal found to be clinically affected or recently
4 exposed to any infectious, contagious, or communicable disease or infested with ectoparasites shall be
5 returned to their point of origin or destroyed (9 GARR 1, Division 1, Chapter 1).

6 Regulations for the importation of pet birds (all birds except poultry) are found under Title 9 of the
7 Guam Administrative Rules and Regulations, in chapter 2, §2101 and §2102 and require pet shops and
8 importers to keep a record of each sale made for at least 90 days and make the record available to
9 GDOA, if a quarantine is placed on the premises by the territorial veterinarian.

10 Guam has introduced additional quarantine requirements for the importation of birds from the
11 continental United States to prevent the introduction of WNV. These regulations are similar to the ones
12 in place in Hawai'i. All birds are required to be quarantined a minimum of seven days in an approved
13 quarantine facility or veterinary clinic followed by 30 days of isolation in a mosquito-proof cage on
14 Guam (Poole 2009).

15 According to USPS regulations, non-poultry birds cannot be transported via the mail (USPS 2009).

16 Illegal imports, by their very nature, are difficult to describe and quantify. Illegally imported birds and
17 hatching eggs would need to enter Guam via boat or airplane. Both birds and hatching eggs may be
18 carried on private vessels or fishing boats and are relatively easy to conceal. Hatching eggs may be
19 carried in a suitcase, and can therefore be brought into Guam via commercial flights. GCQA attempts to
20 enforce the regulations, mitigating the risks by these pathways.

21 Military personnel and families are unlikely to smuggle birds to Guam. However, it is possible that the
22 increased population will lead to an increase in customers for pet shops on Guam. It is then possible that
23 unscrupulous pet shop owners may attempt to acquire birds from illicit sources. Private boats or fishing
24 vessels may be involved in supplying such trade.

25 It is assumed that foreign workers will be traveling to Guam by air, given the time involved in sea travel
26 from many of the countries that will be providing workers. United Airlines is reportedly planning to
27 increase flight frequencies to the Philippines to accommodate the workers (Arnaldo 2010).

28 Opportunities for smuggling live birds on a commercial airline are present, though limited. Therefore, it
29 is assumed that immigrant workers will also be unlikely to smuggle non-poultry birds into Guam.

30 However, hatching eggs may be smuggled on board flights, as they are small and easily concealed in
31 luggage. It is possible that private or fishing vessels may be involved in smuggling non-poultry birds for
32 commercial sale. However, it is unlikely that the foreign workers would be supporting such efforts,
33 because under the requirements of their contracts, involvement in an illegal activity such as smuggling
34 will have serious consequences if they are caught.

1 **Summary**

2 The number of live non-poultry birds imported to Guam is currently small, and may increase slightly as a
3 result of the military relocation, due to demand in the pet trade. The risk of hazard release through legal
4 entry of live non-poultry birds to Guam is reduced by inspection and quarantine measures required by
5 federal and territorial regulations. Illegally imported live non-poultry birds bypass mitigations intended
6 to reduce the likelihood of release of hazards.

7 **Non-poultry Birds Pathway Release Assessment**

8 The increased risk of release of hazards into the Micronesia Region due to the military relocation
9 through legal movement of non-poultry birds is negligible. Currently, pet birds arriving to Guam are to
10 be quarantined by the owner at the owner’s home. The Guam territorial veterinarian insures that a
11 double mosquito netted quarantine cage is provided pet owner for this purpose, but regulating the
12 quarantine period is not feasible at this time. The situation could be improved by developing a bird
13 quarantine facility at GDOA and insure compliancy with current import regulations.

14 The increased risk of release of hazards into the Micronesia Region due to the military relocation
15 through illegal movement of non-poultry birds is very low.

16 **A6.3.3.3 Exposure Assessment: Non-poultry Birds Pathway**

17 **Biological Factors**

18 Deliberate or accidental release of imported non-poultry birds provides another potential route of
19 exposure of livestock or poultry to hazards or opportunities for dissemination of vector hazards in
20 suitable habitats for establishment. Sightings of non-native songbirds by U.S. birders have been
21 attributed to accidental escape or deliberate release by importers, breeders, and disinterested pet
22 owners (Craves 2008).

23 **Regional Factors**

24 Birds smuggled to Guam or CNMI could readily be dispersed throughout the Micronesia Region.

25 **Summary**

26 We expect the smuggling of non-poultry birds to be an infrequent event; however, once released, the
27 opportunities for exposure of livestock and poultry are present, though the overall risk is considered to
28 be very low.

29 **Non-poultry Birds Pathway Exposure Assessment**

30 The risk of exposure of livestock or poultry to hazards released into the Micronesia Region through the
31 non-poultry birds pathway is very low.

1 **A6.3.3.4 Consequence Assessment: Non-poultry Birds Pathway**

2 **Biological Consequences**

3 Non-poultry pet birds may carry and serve as reservoir hosts for many of the same diseases as poultry,
4 including equine encephalomyelitis, END, HPAI, and WNV viruses (Calisher 1994, Falcon 2004, CFSPH
5 2009q, OIE 2009u, CFSPH 2010b). Infected birds can serve as sources for the etiologic agents of fowl
6 typhoid and pullorum. Infestation of birds with screwworms occurs, but is rarely reported (OIE 2009q,
7 USDA-APHIS 2009c); these birds can also serve as fomites for the spread of African swine fever, classical
8 swine fever, and foot and mouth disease viruses (CFSPH 2007e, 2009d, 2010a). The consequences would
9 be most significant from the resultant release and exposure of END and HPAI, which may cause
10 mortality approaching 100% for poultry on Guam.

11 **Environmental and Economic Consequences**

12 Release of infected non-poultry birds may result in similar environmental and economic consequences
13 as for infected poultry.

14 **Non-poultry Birds Pathway Consequence Assessment**

15 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
16 the Micronesia Region through the non-poultry birds pathway is low.

17 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
18 exposure to hazards released into the Micronesia Region through the non-poultry birds pathway is low.

19 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
20 hazards released into the Micronesian Regio through the non-poultry birds pathway is medium.

21 **Non-poultry Birds Pathway Risk Estimation**

22 Because the increased risk of release of hazards into the Micronesia Region due to the military
23 relocation through the non-poultry birds pathway is very low, the risk of exposure of livestock and
24 poultry is very low, and the significance of consequences of livestock and poultry exposure is low, we
25 conclude that the military relocation-associated overall risk for the livestock pathway is very low.

26 **A6.3.3.4 Cats and Dogs**

27 The domesticated cats and dogs moved in this pathway may be pets or serve as working animals
28 performing tasks to assist or entertain people. Specifically, we consider the effect of the military
29 relocation on risk to livestock and poultry health through movement of military working dogs and pet
30 cats and dogs kept by military or civilian personnel to Guam. Discussion of impacts to human and
31 companion animal health is limited to the livestock and poultry hazards associated with dogs and cats.

32 Cats and dogs are the most common types of pets owned by U.S. households (APPMA 2008). According
33 to the 2007 American Pet Products Manufacturers Association survey, 39% of U.S. households keep at
34 least one dog, and 34% keep at least one cat. Rates of cat and dog ownership among U.S. households
35 have increased slightly over the past two decades. Although few data are available regarding rates of

1 pet cat and dog ownership by military personnel, one survey of 184 military families found 34% reported
 2 keeping at least one dog and 18% reported keeping at least one cat (Anderson 1985). The sample for the
 3 survey was drawn from the population of military families who had recently transferred to duty stations
 4 in Hawai'i, where, similar to Guam, quarantine is required for dogs and cats imported from regions
 5 affected by rabies. Roughly 16% of the pet-owning military families in this survey brought their pets with
 6 them in the transfer, undeterred by quarantine requirements. Residents of military base housing on
 7 Guam are permitted to keep two pet dogs or cats (VETCOM 2009).

8 Currently, there are seven military working dogs on the Navy base and 16 on Andersen AFB (U.S. Navy
 9 2009f). The number of military working dogs present on Guam will probably increase along with the
 10 military relocation (VETCOM 2009).

11 Dog fighting is an illegal activity occurring on Guam (Taijeron 2009) despite recently implemented
 12 regulations making dog fighting a felony. Additionally, the U.S. Army recently issued a memo banning
 13 "aggressive or potentially aggressive" dogs from military housing (US Army 2008, CDC 2010c). Therefore,
 14 we do not anticipate an increase in imports of dogs for fighting associated with the military relocation.

15 We expect the military relocation will result in increased numbers of domesticated cats and dogs being
 16 moved through legal means to Guam. Illegal introduction of dogs or cats to Guam might occur via
 17 private vessels, such as cruising or fishing vessels, which occasionally carry companion animals aboard
 18 (Sgambelluri et al. 2009), but we do not expect this traffic to increase as a result of the military
 19 relocation.

20 **A6.3.3.4.1 Hazards Associated with the Cats and Dogs Pathway**

21 Domesticated cats and dogs can transport hazards in three roles: they can be infected hosts, they can be
 22 contaminated with disease agents and serve as fomites, or they can serve as hosts to tick vectors of
 23 disease agents. Table A6-11 lists hazards that are associated with domesticated cats and dogs through
 24 these three roles, including hazards for which these animals may serve as dead-end hosts or play a
 25 minor or theoretical role in transmission.

26 **Table A6-11: Hazards Associated With the Cats and Dogs Pathway**

3

4 **A6.3.3.4.2 Release Assessment: Cats and Dogs Pathway**

5 **Likelihood of Hazard Association**

6 Domesticated dogs and cats can be infected with and serve as reservoirs for rabies (CFSPH 2009m; CDC
7 2010g). Domesticated dogs and cats, among many other mammalian hosts, can harbor screwworms,
8 *Echinococcus* spp., *Leishmania* spp., and *Trypanosoma* spp. parasites (Barr et al. 1991; Bradley et al.
9 2000; Jenkins et al. 2000; USDA-APHIS 2000; Beard et al. 2003a; Dantas-Torres 2007; CFSPH 2009k; OIE
10 2009q, t). Cats and dogs are susceptible to infection with HPAI virus, although the significance of their
11 roles in transmission of the virus has not been elucidated (CFSPH 2010b). Dogs can be infected with
12 African horse sickness and Venezuelan equine encephalomyelitis viruses, and both cats and dogs can be
13 infected with *Salmonella* Pullorum, but most sources suggest that dogs and cats do not play a significant
14 role in the maintenance or spread of these hazards (CFSPH 2006a, 2008a, 2009j).

15 African swine fever, classical swine fever, and foot and mouth disease viruses can be mechanically
16 spread by domesticated animals which have been in contact with affected premises (CFSPH 2007e,
17 2009d, 2010a). Theoretically, this would include dogs and cats, though it is difficult to definitively link
18 dogs or cats as a primary source for spread in prior outbreaks.

19 Dogs are common hosts for several tick species that are competent vectors of equine piroplasmosis and
20 heartwater (Estrada-Peña et al. 2004). In a few instances, hazard ticks, specifically *Amblyomma* spp.,
21 have been found on dogs imported to the United States (James and Freier 2004; USDA-APHIS-VS CEAH
22 2006). Hazard ticks are infrequently collected from domesticated cat hosts, perhaps because the
23 grooming behavior of cats limits tick attachment (Hart 1990).

1 **Traffic Volume**

2 We were unable to find data on the importation to Guam of civilian pets, except for FY 2002 (Table A6-
3 12) (GovGuam 2002; Campbell 2010c). The number of cats and dogs imported to Guam annually is low,
4 with estimates ranging from 10 to 100 animals a year (Poole 2009). As described elsewhere in this
5 document, the military and civilian population on Guam will grow during the military relocation, and
6 some people will bring pet cats and dogs with them. A 1985 survey suggests that many pet owners
7 choose not to bring their pets with them when transferring to an overseas assignment, after considering
8 the time, expense, and animal’s physiologic stress associated with shipping and quarantine procedures
9 (Anderson 1985). Based upon the anticipated increase in the number of military and civilian families,
10 U.S. household pet ownership rates, and the estimate of the rate of pets accompanying transferring
11 military personnel, we estimate that at least 500 additional pet cats and dogs will be imported over the
12 course of the relocation.

13 Due to the increased military presence on Guam, it is likely that the number of military working dogs will
14 increase (VETCOM 2009). Estimates are not available, because decisions on redeployment have not yet
15 been made, but the number of additional dogs is expected to be small.

16 **Traffic Origin**

17 The majority of past imports originated from the continental United States and Australia, with a few
18 animals imported from Japan and CNMI (USDA-APHIS-PPQ 1997).

19 **Table A6-12: Country of Origin and Total Numbers of Cats and Dogs**
20 **Imported to Guam, 2002**

Country of origin	Cats	Dogs
United States	0	53
Australia	20	54
Japan	4	4
CNMI	0	2
Total	24	113

21 Source: GovGuam 2002; Campbell 2010c
22

23 It is unusual for military personnel to have two consecutive assignments outside of the continental
24 United States (VETCOM 2009). Therefore, most of the cats and dogs imported due to the relocation will
25 come from the continental United States or Hawai’i. Civilian personnel employed by the military are also
26 likely to come mostly from the continental United States or Hawai’i (VETCOM 2009). Guam territorial
27 import regulations for cats and dogs, which are discussed below, are likely to dissuade or prevent many
28 foreign temporary workers from bringing pets with them to Guam, except workers from regions
29 unaffected by rabies, including Japan, Australia, and New Zealand.

30 Of the more than one million tourists that visit Guam yearly, 80% come from Japan. Japanese tourists
31 average a three night stay on the island, making it unlikely that they will bring any pets with them (Mok

1 and Iverson 2000). The time and expense of pet quarantine is likely to deter tourists from most other
2 areas from traveling with their pets to Guam.

3 The United States is free of most of the livestock and poultry disease agents that can be associated with
4 cats and dogs (see Table A6-11), with the exception of *Echinococcus* spp., *Leishmania* spp., and rabies
5 (USDA-APHIS 2008b).

6 **Mitigations**

7 Under 42 CFR § 71.51, cats and dogs imported to the United States are subject to inspection at ports of
8 entry and may be denied entry if they have evidence of an infectious disease that can be transmitted to
9 humans. Dogs imported to the United States, with limited exceptions, must be accompanied by a
10 certificate for rabies vaccination; imported cats are not required to be vaccinated for rabies. The entry
11 of pets from areas affected by screwworms is subject to APHIS regulations (9 CFR § 93.600), requiring a
12 health certificate stating that the dog was examined and found to be free of screwworm infestation
13 within 5 days of export (USDA 2000; USDA-APHIS 2009c; 9 CFR § 93.600).

14 Guam's restrictions on the importation of cats and dogs are even more stringent than federal
15 requirements and include additional specific quarantine requirements to protect its rabies-free status.
16 Cats and dogs must enter Guam through A.B. Won Pat International Airport or the maritime port of Apra
17 Harbor. All cats and dogs must be accompanied by documentation including an entry permit, a health
18 certificate signed by a veterinarian no more than 14 days prior to shipment, and a confirmed quarantine
19 kennel reservation. They must also have identification, comply with all quarantine procedures, and
20 undergo rabies vaccination and testing prior to arrival (9 GARR 1, Division 1, Chapter 1). Dogs must have
21 a rabies vaccination certificate dated no less than 30 days and no more than one year prior shipment;
22 and a certificate of immunization against distemper, hepatitis, leptospirosis, parainfluenza, parvovirus,
23 coronavirus, and bordetella. Cats must have a certificate of immunization for feline distemper, feline
24 viral rhinotracheitis, calicivirus, panleukopenia, and chlamydia (9 GARR 1, Division 1, Chapter 1).

25 The importation of pets to Guam is regulated by GDOA (5 GCA § 60108). Title 10 Guam Code Annotated
26 Chapter 34 Article 3 states that animals imported are to complete a maximum of 120-day confinement
27 in a commercial quarantine facility. Animals may undergo 30 days of quarantine if they meet pre- and
28 post-arrival requirements, including the administration of two doses of rabies vaccine; the presence of
29 an adequate protective antibody titer against rabies based on a fluorescent antibody virus neutralization
30 (FAVN) rabies test as tested by the GDOA quarantine program; and a properly implanted identification
31 microchip (GCA 2010b). A five-day quarantine program is available for pets if the FAVN test is conducted
32 by an eligible laboratory no less than 120 days or more than 12 months prior to arrival on Guam (GDOA
33 2007b). Under certain conditions, pets may qualify for the option of home quarantine (GDOA 2009).

34 Animals originating from Japan, Hong Kong, Oceania, and the continental United States (except for
35 counties on the Mexican border) can be quarantined on Guam. Animals originating from elsewhere
36 must be quarantined in Hawai'i prior to arrival on Guam. Cats and dogs originating from rabies-free

1 areas, such as Hawai'i, New Zealand, Australia, and the United Kingdom, will be exempted from
2 quarantine if they comply with all other requirements.

3 Other import regulations for cats and dogs are included in the Guam Administrative Rules and
4 Regulations, Title 9, Division 1, Chapter 1, § 1109. All cats and dogs originating from Africa, Asia, or
5 islands of the Pacific Ocean (except Australia, Hawai'i, and New Zealand) must have a certificate from
6 the national chief livestock sanitary officer stating that the animals originated in a state, country, or
7 other political subdivision officially declared free of surra, African animal trypanosomiasis, and
8 leishmaniasis.

9 Cats and dogs that do not comply with regulations may be declared ineligible to enter and remain in the
10 custody of the carrier at a designated inspection area at the port of entry until the animal is sent back
11 (maximum 72 hours) or humanely disposed of. In addition, the carrier is fined between \$500 and \$1,000
12 for transporting the animal without an entry permit (GDOA, GCA 2010b).

13 The U.S. military has published rules and regulations for the importation of cats and dogs. These
14 regulations include the federal and state requirements, and are published in the Quarantine Regulations
15 of the Armed Forces (DoD 1992). General requirements for the admission of cats and dogs include
16 these: 1) all animals arriving in the United States are subject to inspection by a public health or military
17 quarantine officer; 2) animals will require testing and confinement when they do not appear in good
18 health or in the event that they have been exposed during shipment to a sick or dead animal suspected
19 to have a communicable disease; 3) unsanitary containers of cats and dogs arriving in the United States
20 must be cleaned and disinfected before the animal can be admitted; and 4) a valid rabies certificate is
21 required for dogs. The military requires dogs to be vaccinated for rabies and inspected at the port in
22 accordance with Quarantine Regulations (DoD 1992). In addition, all pets belonging to military personnel
23 must meet the requirements for importation to Guam.

24 GDOA does not operate a quarantine facility for imported cats and dogs. One private veterinary clinic on
25 Guam maintains a quarantine facility. The military has one veterinary clinic and a boarding and
26 quarantine facility at Andersen AFB and another veterinary treatment facility at the Navy base (USMA
27 2008). The Andersen AFB facility maintains 14 canine and 6 feline quarantine kennels. A new Navy
28 facility will be constructed to include space for 10 military working dogs, a veterinary examination area,
29 an outdoor dog wash, and 4 quarantine runs (U.S. Navy 2009f). The kennel will be fenced and the
30 building and gate will have an intrusion detection system to avoid escape or intrusion of other animals
31 into the kennel. The facilities are designed to prevent disease transmission between dogs. Solid waste
32 will go to the Navy landfill.

33 Since the Vietnam War era, when many military working dogs could not return to the United States after
34 deployment due to the threat of introduction of exotic diseases, veterinary care and treatment for
35 military working dogs has significantly improved (English 2000). Following the 1990-1991 Persian Gulf
36 conflict, the health records of 118 military working dogs were reviewed and none indicated evidence of
37 zoonotic disease (Burkman et al. 2001). More recent studies have shown that few military working dogs

1 are exposed to infectious diseases and that the major cause of mortality is natural death or euthanasia
2 associated with advanced age (Moore et al. 2001; Evans et al. 2007).

3 ***Summary***

4 The number of domesticated cats and dogs imported to Guam is likely to increase as result of the
5 military relocation. Most of these animals are likely to originate from the continental United States,
6 which is free of most of the poultry and livestock disease hazards for which domesticated cats and dogs
7 are epidemiologically significant sources. The one important exception is rabies, which is present in the
8 continental United States. However, the risk of importation or interstate movement of hazards for which
9 domesticated cats and dogs might play a significant role in transporting to Guam is mitigated by U.S.
10 military and Guam territorial regulations.

11 ***Cats and Dogs Pathway Release Assessment***

12 The increased risk of release of hazards into the Micronesia Region due to the military relocation
13 through the cats and dogs pathway is negligible.

14 ***Cats and Dogs Pathway Risk Estimation***

15 Because the increased risk of release of hazards into the Micronesia Region due to the military
16 relocation through the cats and dogs pathway is negligible, we conclude that the military relocation-
17 associated overall risk for the cats and dogs pathway is negligible.

18 **A6.3.3.5 *Other Animals***

19 In this pathway, we consider the effect of the military relocation on the risk to livestock and poultry
20 health through the movement of terrestrial vertebrates, other than livestock, birds, cats, dogs, and
21 humans, into the Micronesia Region. These animals include non-domesticated mammals, reptiles, and
22 amphibians that might be intended for pets, food, zoological collections, research, or commercial trade.
23 Animals intended for any of these purposes may be moved through legal or illegal means. We do not
24 consider accidental movement of these animals in this analysis, because the risk posed by free-living
25 non-domesticated animals is considered elsewhere in this document. In this section, discussion of risk to
26 human and companion animal health is limited to the livestock and poultry hazards associated with
27 these animals; information on other hazards is addressed elsewhere in this document.

28 With certain exceptions, live non-domesticated animals may legally enter the United States through
29 Guam (Jenkins 2007; Jenkins et al. 2007). However, in the USFWS Law Enforcement Management
30 Information System (LEMIS) database we found no records of importation of large exotic mammals to
31 Guam between 2006 and 2008 (USFWS 2009a). On Guam, animal agriculture is in decline, due in part to
32 competition for land use and the relatively high cost of feed, most of which must be imported (Poole
33 2009); these conditions probably also limit the potential for game ranching and the establishment or
34 expansion of zoological collections. Therefore, we do not expect that the military relocation will alter
35 this trend and increase traffic volume in large non-domesticated mammals, such as carnivores or hooved
36 animals.

1 On the other hand, the U.S. live animal trade in small mammals, reptiles, and amphibians has grown
 2 significantly since the 1990s, driven in part by the increasing popularity of exotic pets and demand for
 3 traditional foods and medicines (Jenkins 2007; TRAFFIC 2008). The United States is the leading import
 4 market in this global trade, receiving millions of animals each year (Bergman 2009; Pavlin et al. 2009).
 5 Worldwide, illegal trade in these animals is also substantial and profitable, though challenging to
 6 quantify (Wyler and Sheikh 2009). The larger human population resulting from the military relocation
 7 will likely increase demand for exotic pets and for traditional foods and medicines, and therefore,
 8 increase pathway traffic volume in small mammals and reptiles through either legal or illegal means.

9 **A6.3.3.5.1 Hazards Associated with the Other Animals Pathway**

10 The groups of terrestrial vertebrates considered in this pathway are limited to species common in the
 11 pet or wildlife trade, which have been associated with pathogen or vector hazards. These are small
 12 mammals (rodents, lagomorphs, and hedgehogs), and reptiles and amphibians (lizards, snakes, turtles,
 13 tortoises, frogs, and toads).

14 Small mammals, reptiles, and amphibians can transport hazards in three roles: they can be infected
 15 hosts, they can be contaminated with disease agents and serve as fomites, or they can serve as hosts to
 16 tick vectors of disease agents. Table A6-13 lists hazards that are associated with these animals through
 17 these three roles, including hazards for which these animals may serve as dead-end hosts or play a
 18 minor or theoretical role in transmission.

19 **Table A6-13: Hazards Associated with the Other Animals Pathway (Small Mammals,**

4 **A6.3.3.5.2 Release Assessment: Other Animals Pathway**

5 **Likelihood of Hazard Association**

6 Small mammals, reptiles, and amphibians can carry a variety of disease agents, either mechanically, as in
7 the case of rodents spreading African swine fever, classical swine fever, or foot and mouth disease virus
8 (CFSPH 2007e, 2009d, 2010a), or as biological hosts. All mammals are susceptible to screwworm
9 infestation and rabies virus infection (CFSPH 2007l, 2009m). Rodents are intermediate hosts of
10 *Echinococcus* species, and are reservoir hosts of Venezuelan equine encephalomyelitis virus (CFSPH
11 2008a; OIE 2008e). HPAI virus, Salmonella Pullorum, WNV, and JEV infections occur primarily in avian
12 species but can also occur in rodents (CFSPH 2007h; Cardona et al. 2009; CFSPH 2009j, q; USGS 2010).
13 The etiologic agents of surra and African animal trypanosomiasis have a wide host range that includes
14 most domesticated mammals and some wild species, including rodents (CFSPH 2009n, a). Vesicular
15 stomatitis affects primarily livestock, although evidence of infection has been detected in rodents
16 (CFSPH 2008g). Although birds are the main reservoir hosts of Eastern and Western equine
17 encephalomyelitis viruses, other animals including reptiles and amphibians can be infected with these
18 viruses (CFSPH 2008a). JEV infections have also been reported to occur in reptiles and amphibians
19 (CFSPH 2007h).

20 The increased international movement of reptiles for the pet trade has been cited as a high risk pathway
21 for introduction of exotic ticks and pathogens to new geographic locations (Burrige and Simmons
22 2003). Members of the genera *Amblyomma*, *Dermacentor*, *Haemaphysalis*, *Hyalomma*, and
23 *Ornithodoros* frequently parasitize reptiles, particularly terrestrial chelonians, snakes, and lizards, in
24 tropical regions (Pietzsch et al. 2006). Numerous ticks, primarily exotic species of *Amblyomma* and
25 *Hyalomma*, have been found on reptiles imported to the United States, sometimes after the animals had

1 reached their destinations within the country (Burridge and Simmons 2003; USDA-APHIS-VS CEAH 2006).
2 There is evidence that exotic ticks introduced with imported reptiles could be infected with organisms
3 pathogenic to domestic livestock populations (Pietzsch et al. 2006). For example, *E. ruminantium*, the
4 causative agent of heartwater, was detected in *Amblyomma sparsum* ticks collected from tortoises
5 imported to the United States (Burridge et al. 2000).

6 ***Traffic Volume and Origin***

7 The largest group of mammals imported to the United States from 2004 to 2008 was rodents, and the
8 number of rodents imported during those years steadily increased from nearly 40,000 animals in 2004
9 to more than 240,000 in 2007 alone (USFWS 2009a). These imported rodents, which include popular
10 pets such as rats, mice, hamsters, and gerbils, were almost exclusively bred and raised in captivity
11 (USDA-APHIS-VS CEAH 2010). Lagomorphs (rabbits and hares) were also among the top four most
12 frequently imported groups of animals from 2004 to 2008, although the total number of imported
13 lagomorphs declined during that period of time (USFWS 2009a; USDA-APHIS-VS CEAH 2010). Imported
14 rabbits and hares, like rodents, were almost exclusively bred and raised in captivity, and were imported
15 for commercial purposes or as personal pets.

16 The international trade in reptiles and amphibians has grown dramatically in the last decade, and the
17 U.S. pet trade is recognized as a major consumer of live reptiles and amphibians (Burridge and Simmons
18 2003). LEMIS records show that the United States imported an average of 1.5 million reptiles and
19 amphibians in more than 8,000 shipments per year during 2004 to 2008 (USFWS 2009a). In contrast to
20 the small mammal trade, most shipments of reptiles and amphibians imported to the United States
21 include specimens captured from the wild (USFWS 2009a).

22 Data are unavailable to quantify the number of small mammals, reptiles, and amphibians imported to
23 Guam or the Micronesia Region, although there is evidence that importation of these animals occurs,
24 through both legal and illegal means. Pet stores exist in Guam, CNMI, and FSM, where small mammals,
25 reptiles, and amphibians may be purchased (Vice 2010a). Several species of exotic snakes and turtles
26 have been discovered in the Micronesia Region in recent years; their presence has been attributed to
27 release by visitors on fishing vessels or by citizens returning from foreign travel (Buden et al. 2001, Vice
28 2010a).

29 As a result of USFWS requirements for most imported wildlife traffic to pass through designated ports
30 on the mainland United States or Hawai'i, most small animals, reptiles, and amphibians shipped to
31 Guam for the legal pet trade likely originate in or transit through the continental United States or
32 Hawai'i (Wyler and Sheikh 2009). LEMIS records show that the Port of Guam received no direct
33 shipments of live small mammals, reptiles, or amphibians from non-U.S. sources from 2006 to 2008,
34 with the exception of one shipment of turtles originating in Hong Kong, which was refused entry (USFWS
35 2009a). Countries in Africa and southeast Asia represent the top ten most commonly declared countries
36 of origin for reptile and amphibian shipments to the United States (USFWS 2009a). Illegal trade in
37 wildlife is identified as an economically significant activity in southeast Asia (TRAFFIC 2008).

1 **Mitigations**

2 Importation of wild mammals, reptiles, and amphibians into the United States is regulated by the
3 USFWS, whose major concern is compliance with the CITES agreement, which is intended to ensure that
4 international trade in animals does not threaten the survival of endangered species. Beyond CITES
5 regulations, no governmental agency in the United States has complete jurisdiction or comprehensive
6 import regulations for wild mammals, reptiles, or amphibians. According to USFWS regulations,
7 importers must declare animal shipments to USFWS inspectors at the port of entry and make the
8 animals available for visual inspection prior to removing them from the port. The USFWS reportedly
9 inspects approximately 25% of declared wildlife shipments at the U.S. border (Wyler and Sheikh 2009).

10 Other federal agencies regulate imports of certain wild animal species through a patchwork of controls.
11 Importation of African rodents into the United States is prohibited by Centers for Disease Control and
12 Prevention restrictions intended to prevent the spread of monkeypox (CDC 2003). The Department of
13 Health and Human Services regulates importation and sale of small freshwater turtles to prevent the
14 spread of Salmonella bacteria to humans (21 CFR § 1240.62) (CDC 2007c). Since 1991, federal
15 regulations intended to prevent the spread of foot and mouth disease have restricted the importation of
16 hedgehogs (all members of the family Erinaceidae) (9 CFR § 93.700-707). Importation of leopard
17 tortoises (*Geochelone pardalis*), African spurred tortoises (*Geochelone sulcata*), and Bell's hingeback
18 tortoises (*Kinixys belliana*) into the United States is prohibited and interstate movement of these three
19 species is restricted to prevent the spread of exotic ticks (9 CFR § 93.701 and 9 CFR § 74.1) (USDA-APHIS
20 2001).

21 Live animals entering the territory of Guam must be accompanied by an import permit and an official
22 health certificate approved by the chief livestock sanitary officer, or a state or federal veterinarian.
23 Animals imported to Guam are subject to inspection and quarantine, and any animal found to be
24 clinically affected or recently exposed to any infectious, contagious, or communicable disease or
25 infested with ectoparasites shall be returned to its point of origin or destroyed (9 GARR 1, Division 1,
26 Chapter 1). It is unclear to what extent these regulations are enforced for small mammals, reptiles, or
27 amphibians legally imported to Guam for the pet trade.

28 **Summary**

29 The larger human population resulting from the military relocation will likely increase demand for exotic
30 pets and for traditional foods and medicines, and therefore, we expect a slight increase in pathway
31 traffic volume in small mammals and reptiles.

32 Caged, captive-bred small mammals are unlikely to encounter livestock or poultry pathogens or host
33 ticks of importance to livestock. Although the role of small mammals in the introduction of hazards
34 listed in Table A6-13 to new regions is theoretically possible, we found no documentation of release of
35 hazards through importation of captive-bred rodents or lagomorphs. The Centers for Disease Control
36 and Prevention ban on importation of African rodents indirectly reduces the risk of introduction of
37 livestock diseases endemic in Africa, such African swine fever, foot and mouth disease, and
38 trypanosomiasis, through the small mammal pathway.

1 The United States is a major importer of reptiles and amphibians, and import records show that many of
2 these animals are captured from the wild in African countries. The primary hazards of concern
3 associated with reptiles or amphibians are tick vectors of several livestock pathogens, including the
4 etiologic agent of heartwater, which is endemic to regions of Africa. Reptiles are frequently parasitized
5 by several species of hazard ticks exotic to the Micronesia Region, and current mitigations are not
6 sufficient to prevent importation of tick-infested reptiles to the United States (Burridge and Simmons
7 2003). Illegal introductions of reptiles into the Micronesia Region have been reported (Buden et al.
8 2001; Vice 2010a).

9 ***Other Animals Pathway Release Assessment***

10 The increased risk of release of hazards into the Micronesia Region due to the military relocation
11 through intentional movement of reptiles (legal or illegal) is low.

12 The increased risk of release of hazards into the Micronesia Region due to the military relocation
13 through intentional movement of non-domesticated mammals and amphibians is negligible.

14 **A6.3.3.5.3 Exposure Assessment: Other Animals Pathway**

15 ***Biological Factors***

16 Amblyomma ticks known to be capable of transmitting heartwater are generally hardy, long-lived
17 species that attach to their reptile hosts for prolonged periods of time, possibly weeks to months
18 (Petney et al. 1987). The etiologic agent of heartwater, *E. ruminantium*, has been shown to persist in
19 these ticks for up to 15 months (Ilemobade 1976). These characteristics are favorable for both tick and
20 pathogen to survive transit with their imported reptile host to a new environment where susceptible
21 hosts may be present.

22 Populations of exotic ticks, including heartwater vectors, have become established in Florida, after
23 introduction via imported tick-infested reptiles (Burridge et al. 2000). After arrival in Florida, the ticks
24 apparently were disseminated from reptile importers to breeders, zoos, wildlife theme parks, pet stores,
25 and private hobbyists. Intentional release and subsequent establishment of exotic reptiles in the United
26 States has been documented, providing evidence of another plausible route for introduction and
27 establishment of exotic tick species (Brown et al. 1995).

28 ***Regional Factors***

29 There are several examples of exotic ticks successfully invading tropical island ecosystems. Originating in
30 Southeast Asia, the cattle fever tick *R. (B). microplus* has spread throughout the tropics, including islands
31 such as Guam, the Mariana Islands, Puerto Rico, and the U.S. Virgin Islands (Jongejan and Uilenberg
32 2004). The tropical bont tick *Amblyomma variegatum*, along with heartwater, has become established in
33 several Caribbean islands, presumably following introduction with imported cattle from West Africa in
34 the 18th or 19th century (Jongejan and Uilenberg 2004).

35 The presence of suitable habitat for tick survival in the Micronesia Region strongly influences the
36 likelihood that an introduced exotic tick species will become established and therefore, the likelihood

1 that a domesticated animal will be exposed to an exotic tick or tick-borne disease. Two essential factors
2 that control habitat suitability for ticks are the presence of hosts and a favorable environment (Keirans
3 and Durden 2001).

4 Among the most significant tick pests of livestock, ticks of the genera *Amblyomma*, *Hyalomma*, and
5 *Rhipicephalus*, in general, are well-adapted to tropical environments (Rajput et al. 2006). More specific
6 statements about candidates for establishment in the Micronesia Region, based upon habitat suitability,
7 cannot be made with certainty, because there is limited data on tick distributions throughout the
8 tropics, and much of the information about tick distributions in the Micronesia Region is anecdotal or
9 outdated.

10 Maintenance of water balance is essential to tick survival. In tropical environments, ticks seek sheltered,
11 humid microenvironments, generally woodlands and grasslands, to avoid desiccation (Sonenshine and
12 Mather 1994). Human alteration of natural communities and ecological changes at a local level are
13 factors that contribute to movement or emergence of tick populations and tick-borne disease (Korch Jr.
14 1994). When human pressures on the local environment are relaxed to allow lush growth of vegetation,
15 such as through reforestation or allowing cultivated fields to lie fallow, expansions of tick populations
16 have occurred (Sonenshine and Mather 1994). Conversely, habitat modification by destroying
17 vegetation through mowing or burning is a proven method of reducing tick populations (Piesman and
18 Gray 1994).

19 The military relocation in Guam is likely to reduce favorable tick habitat by altering vegetation on the
20 island. Construction activities associated with the military relocation are expected to result in loss of
21 woodlands and grasslands in Guam. For example, in Guam, construction could result in clearing of more
22 than 600 hectares of limestone forest, approximately 3.5% of existing limestone forest (U.S. Navy 2009f,
23 i). Estimates of potential impact also include clearing of almost 200 hectares of scrub, shrub, and
24 tangantangan forest; and approximately 8 hectares of savanna (U.S. Navy 2009i).

25 A tick requires a suitable host as a blood source which is needed for development and reproduction.
26 Host availability may be more important than climate in determining tick abundance (Estrada-Peña
27 2008, Randolph 2008). Introduced predators and land use changes in Guam limit the populations of
28 small mammals, birds, and large hoofed mammals, three important groups of vertebrate hosts for ticks.
29 Due to the presence of BTS, there are areas in Guam that lack all native vertebrates except for a few
30 species of small lizards (Rodda and Savidge 2007). Most species of birds have been extirpated from
31 Guam as a result of BTS predation, and small mammals are less numerous than before the arrival of the
32 snake (Rodda and Savidge 2007). The USDA Census of Agriculture documents the decline of livestock
33 farming in Guam; both the number of farms and the numbers of cattle, carabaos (*Bubalus bubalis*),
34 goats, and swine have decreased in Guam over the past decade (USDA-NASS 2009a).

35 Although Guam's populations of farmed hoofed mammals are in decline, wild hoofed mammals are
36 thriving and serve as hosts for introduced ticks. Feral populations of carabaos, Philippine deer (*Cervus*
37 *marianus*), and swine are present and increasing in Guam (Specht 2003; Wiles 2005). In Guam,

1 carabaos and deer are frequently infested by R. (B.) microplus ticks (Kohls 1953). Bovids and cervids, in
2 general, are preferred as hosts for numerous species of ticks (Kolonin 2009).

3 Because Guam serves as a distribution point for the rest of the Micronesia Region, exotic ticks
4 introduced to Guam could be disseminated elsewhere in the Region. The distribution of suitable
5 vertebrate hosts for ticks, particularly birds and small mammals, differs on other islands of the
6 Micronesia Region from that in Guam, and other islands may provide more suitable habitat for
7 introduced ticks than Guam.

8 **Summary**

9 Given the opportunity through introduction, exotic tick species currently existing in tropical areas may
10 extend their distributions to the Micronesia Region. In Guam, availability of vertebrate hosts and
11 suitable microclimate environments are limiting factors to the likelihood of establishment of exotic tick
12 species. The low density of some groups of vertebrate hosts for ticks may reduce the likelihood that
13 some exotic tick species, if introduced, will find suitable hosts and establish a population in Guam. The
14 military relocation is predicted to result in development in some woodlands and grasslands in Guam,
15 and therefore, remove some habitat suitable for ticks and their vertebrate hosts. There is no indication
16 that the military relocation will create a more favorable environment for tick establishment, and
17 therefore, the military relocation is unlikely to increase the risk of exposure of domesticated animals to
18 exotic ticks or tick-borne disease.

19 **Other Animals Pathway Exposure Assessment**

20 The risk of exposure of livestock or poultry to hazards released into the Micronesia Region through the
21 intentional movement of reptiles is low.

22 **A6.3.3.5.4 Consequence Assessment: Other Animals Pathway**

23 The two potential adverse events caused by the introduction of tick-infested reptiles are introduction of
24 an exotic tick-borne disease carried by an exotic tick, or establishment of an exotic tick species that
25 serves as a more effective vector of endemic disease, or causes more severe physical damage to hosts
26 than endemic ticks. *Ehrlichia ruminantium*, the etiologic agent of heartwater, a tick-borne disease of
27 ruminants, is a hazard of high consequence associated with imported reptiles; therefore, this agent is
28 the focus of the consequence assessment for this pathway.

29 **Biological Consequences**

30 Mortality due to infection with *E. ruminantium* in naive populations of ruminants may be high; mortality
31 rates of 40, 60, and 90% have been observed in calves, adult cattle, and goats, respectively (Kasari et al.
32 2010). *Ehrlichia ruminantium* is not thought to be zoonotic (CFSPH 2007g). Heartwater is readily
33 introduced into new regions in infected animals or ticks, and therefore, the presence of heartwater in
34 Guam would increase the risk of introducing this disease into the rest of the Micronesia Region, Hawai'i,
35 or the continental United States (CFSPH 2007g). If heartwater is introduced into the continental United
36 States, critical factors of tick vectors, suitable environment, and susceptible hosts are present to support
37 establishment of the disease (Kasari et al. 2010).

1 The direct effects of tick infestation of livestock, such as dermatitis, anemia, and loss of condition, due
2 to new tick/host interactions, are difficult to predict. Parasitism of cattle by the heartwater vector
3 *Amblyomma variegatum* is associated with bovine dermatophilosis, a severe skin disease with
4 significant impact on tropical animal health and production (Morrow et al. 1996).

5 ***Environmental Consequences***

6 Chemical control using acaricides continues to be the primary means of tick control and eradication
7 (Kunz and Kemp 1994). Intensive use of these products on livestock has led to resistance in ticks to
8 several classes of pesticides. Environmental concerns, particularly the persistence of pesticide residues
9 in the environment and their effects on non-target species, have been raised regarding the use of
10 pesticides on livestock. The environmental costs of area-wide or large-scale host applications of
11 acaricides may be unacceptable (Kunz and Kemp 1994).

12 Fatal heartwater infections have been reported in water buffalo and several species of deer and
13 antelope (Peter et al. 2002). Presumably, Philippine deer and feral carabaos on Guam would be
14 susceptible to infection, suffer high mortality, and serve as reservoirs, but confirmation is lacking.

15 ***Economic Consequences***

16 Historically, the United States has responded to the establishment of exotic tick species by mounting
17 eradication campaigns. These programs are expensive and require long-standing efforts, exemplified by
18 ongoing attempts to eradicate *Amblyomma variegatum* from the Caribbean. To date, control efforts
19 have reduced the numbers of ticks on some islands and eradicated them from others, but complete
20 eradication throughout the Caribbean remains elusive (CFSPH 2007g). Creating and executing a
21 successful tick eradication program in the present era is a difficult, if not impossible, task due to several
22 challenges: acaricide resistance, the abundance of white-tailed deer and other wildlife hosts, restrictions
23 on the use of pesticides, cost, and public attitudes (George et al. 2002).

24 Heartwater is a serious constraint to livestock production in areas of the world where it is endemic
25 (CFSPH 2007g). The greatest direct economic losses due to heartwater in endemic areas are attributable
26 to tick control costs, milk revenue loss, and livestock treatment costs (Mukhebi et al. 1999). In 1993,
27 USDA estimated that, if heartwater became established in the United States, the value of potential
28 livestock losses could total \$494 million over five years (USDA-APHIS 1993). In addition to direct losses,
29 introduction of heartwater into the continental United States would likely result in severe indirect
30 economic effects due to trade restrictions. In the event of a heartwater disease outbreak on U.S. island
31 territories, such as Guam or CNMI, countries would likely use a regionalization approach, imposing
32 restrictions on ruminants from the affected area only. The effect of regionalization would most likely
33 reduce the trade consequences at the national level. The local effect of trade restrictions for live
34 ruminants is not likely to be significant to Guam or the rest of the Micronesia Region, where no
35 commercial ruminant export trade occurs.

1 **Summary**

2 Importation of reptiles is a recognized pathway for introduction and establishment of exotic ticks and
3 exotic tick-borne diseases of livestock, such as heartwater. Establishment of exotic tick species or
4 introduction of heartwater in Guam, the rest of the Micronesia Region, or the rest of the United States
5 poses a significant threat in terms of biological, environmental, and economic consequences.

6 **Other Animals Pathway Consequence Assessment**

7 The significance of the consequences to Guam of livestock or poultry exposure to hazards released into
8 the Micronesia Region through intentional movement of reptiles is very low.

9 The significance of the consequences to the rest of the Micronesia Region of livestock or poultry
10 exposure to hazards released into the Micronesia Region through intentional movement of reptiles is
11 very low.

12 The significance of the consequences to the rest of the United States of livestock or poultry exposure to
13 hazards released into the Micronesia Region through the intentional movement of reptiles is medium.

14 **Other Animals Pathway Risk Estimation**
